Step 6: Define a threshold value *a*. Matrix *T* shows information on how one attribute influences another, it thus becomes required for the decision makers to define a threshold value *a* for elucidating the structural relation among attributes while simultaneously keeping the intricacy of the entire system to a convenient level. An influence relationship between two attributes is excluded from the evaluation if their correlation value in matrix *T* is smaller than *a* and only the effects greater than the set *a* value are chosen and shown in the digraph. In this work, the threshold value *a* is determined from the average of the values in matrix *T* using Eq. (6), where *N* is the total number of values in matrix *T*.

$$a = \frac{\sum\limits_{i\in n}\sum\limits_{j\in n} t_{ij}}{N} \tag{6}$$

Step 7: Build the relationship table by summing *D* and *R* and subtracting *D* from *R* in which *D*+*R* vector reveals how much importance the criterion has. The *D*-*R* vector divide the attribute into the causal and effect groups. Generally, a positive value of *D*-*R* refers to the attributes that belongs to the causal group and if the *a* negative value *D*-*R* refers to the attributes that belongs to the effect group.

Step 8: Use Eq. (7) to determine the importance weight for each attribute by normalizing the *D*+*R* vector in which the sum of normalized weights equals to 1.

$$w_i = \frac{\left(D+R\right)_i}{\left(\sum\limits_{i\in n}\left(D+R\right)_i\right)}; i = 1,2,...,n \tag{7}$$

Ranking vendors : ELimination Et Choix Traduisant la REalité (ELECTRE)

Bernard Roy developed ELECTRE algorithm at SEMA Consultancy Company to rank several alternatives. It is a Multi Criteria Decision Making (MCDM) algorithm used to evaluate and rank a number of alternatives from the best to the worst. ELECTRE applies a pairwise comparison among alternatives with respect to the required criteria' weights aiming to calculate the concordance and discordance sets. In this algorithm, different types of matrices are constructed based on the concordance and discordance sets and then uses the threshold values to filter the less favorable alternatives and select the better ones (Figueira et al., 2005). So far, ELECTRE is one of the most important evaluation MCDM algorithms employed for applications in real life MCDM problems, since it is based on the construction and exploitation of a valued "outranking relation" (Hwang and Yoon, 1981). The main procedures to apply ELECTRE for the evaluation and ranking of vendors can be described as follows:

1. Table 2 presents the linguistic variables and the correspondent numbers that were used to evaluate vendors' performance towards each criterion. This evaluation is based decision makers' expert since they need to give their opinions about the performance of each supplier with respect to **trasilience** criteria.
2. Construct the basics decision matrix A_{ij} as the number of matrix rows (i) and matrix columns (j) refer to the alternatives and the criteria respectively.

$$A_{ij} = \begin{bmatrix} r_{11} & r_{12} & r_{1j} \\ r_{21} & r_{22} & r_{2j} \\ . & . & . \\ . & . & . \\ r_{i1} & r_{i2} & r_{ij} \end{bmatrix}$$

3. Normalize the decision matrix as follows:

$$v_{ij} = \frac{r_{ij}}{\left(\sqrt{\sum_i r_{ij}^2}\right)} \tag{8}$$

Where the normalized decision matrix V_{ij} is presented as follows:

$$V_{ij} = \begin{bmatrix} v_{11} & v_{12} & v_{1j} \\ v_{21} & v_{22} & v_{2j} \\ . & . & . \\ . & . & . \\ v_{i1} & v_{i2} & v_{ij} \end{bmatrix}$$

4. Constructed the normalized weighted decision matrix W_{ij} by multiplying the normalized decision matrix by the criteria weight (w_i) revealed via DEMATEL.

$$W_{ij} = V_{ij} x\ w_j \tag{9}$$

5. Apply Eqs. 10 and 11 to determine the concordance and discordance sets, respectively. Concordance matrix is constructed by adding the values of weights of Concordance set elements. Discordance matrix is constructed by dividing discordance set members values to total value of whole set.

$$C_{lm} = \sum_{j^*} w_{j^*} \tag{10}$$

$$D_{ab} = \frac{\left(\sum \left| W_{aj^*} - W_{bj^*} \right| \right)}{\left(\sum \left| W_{aj} - W_{bj} \right| \right)} \tag{11}$$

where, $C(a,b) = \left\{ j,\ W_{aj} \geq W_{bj} \right\}$ and $D(a,b) = \left\{ j,\ W_{aj} < W_{bj} \right\}$.

6. Constructs the binary concordance and discordance matrices based on the obtained the sets obtained in step 5.
7. Rank the alternative by constructing the aggregated binary concordance and discordance matrices by the binary multiplication of the concordance and discordance matrices.

Research Methodology

This research aims to develop a user-friendly decision making tool as an aid to decision makers at an institution to select the best tender out of 7 proposed to implement an RFID-based passport tracking system considering traditional criteria and resilience criteria. Objectives of this work are as follows:

1) To develop a unified trasilience framework for the evaluation criteria categorized into two sections which include traditional criteria and resilience criteria.

2) To use the linguistic evaluation of decision makers to determine the qualitative importance of criteria and sub-criteria using the evaluation scale presented in Table 1. Tables 3 and 4 show the potential decision matrix to be given to decision makers.
3) To use the DEMATEL algorithm to determine the quantitative importance of criteria and sub-criteria.
4) To use the linguistic evaluation of decision makers to determine the qualitative importance of vendors towards the identified criteria using the evaluation scale presented in Table 2. Table 5 shows the evaluation table to be given to decision makers.
5) To use the ELECTRE algorithm to determine the quantitative importance and ranking of vendors based on their trasilience performance.
6) To validate the developed decision making tool based on a real case study.

Main research findings

In this study, we end up with a user-friendly decision making tool that identifies the main trasilience criteria as shown in Figure 1 and then quantifying them using the DEMATEL algorithm. Finally, the ELECTRE algorithm is to be used to evaluate and rank the performance of 7 vendors to implement the RFID-based passport tracking system.

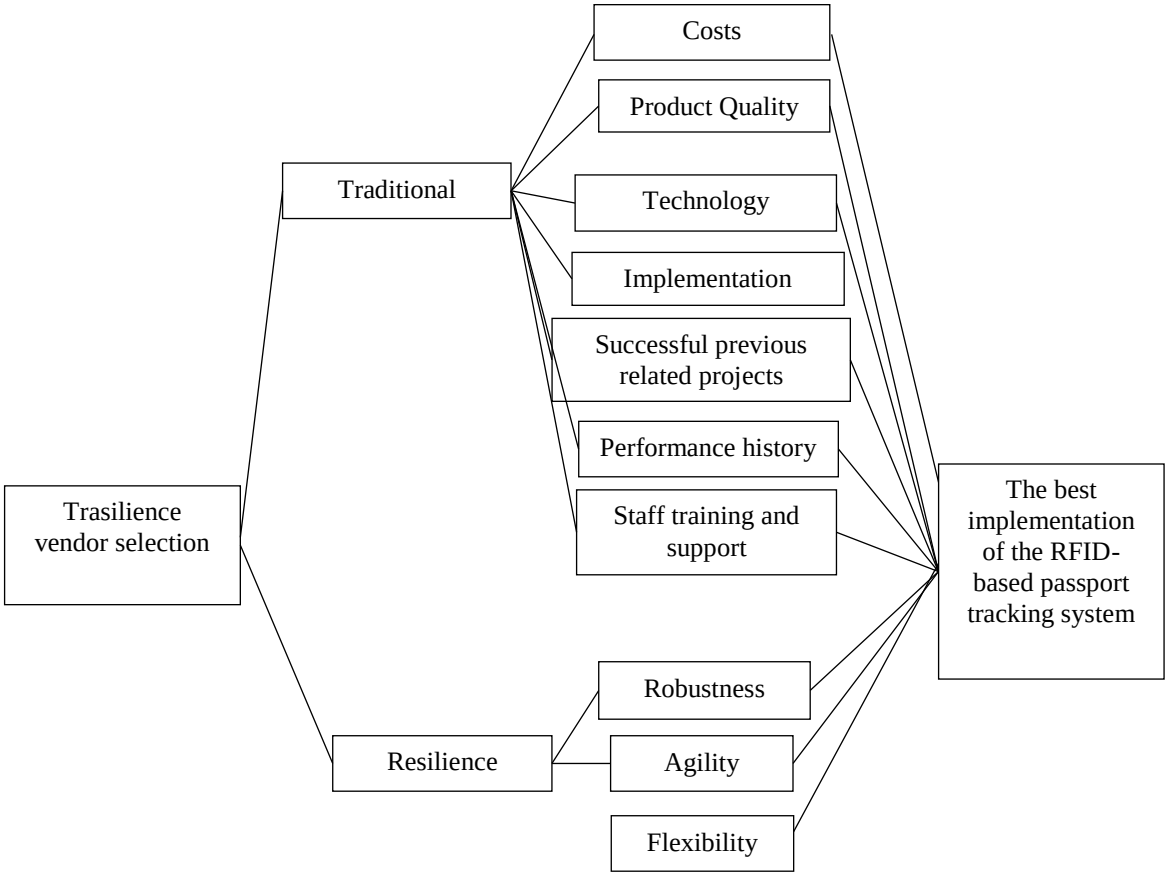

Figure 1. A hierarchal framework for the Trasilient vendor selection.

Conclusions

Vendor selection is one of the strategic decision in enterprises that should carefully considered as impropriate vendor may financially compromise the enterprise status and results in a bad project implementation which leads to an improper service level. Vendor selection problem has been studied extensively using MCDM algorithms. However, the performance of potential vendors is evaluated against multiple traditional criteria such as cost and quality lacking behind the importance resilience criteria which help in sustaining long-term service performance.

This study solves a real industry vendor selection problem using MCDM algorithm considering traditional and resilience criteria and sub-criteria. The potential research outcomes would identify the main trasilient sub-criteria in a unified framework. It is expected to determine the performance of each vendor towards the defined criteria and sub-criteria aiming to rank them from 1 to 7. Subsequently, decision makers will easily determine the best proposed tender to implement the RFID-based passport tracking system. Finally, the proposed tool would has a potential trend to solve similar supplier or vendor selection problems.

Abstract

This paper presents an approach to solve a supplier selection and order allocation problem considering traditional, green and resilience (TGR) characteristics. A set of criteria were identified within a unified framework and their relative importance weighted using the AHP algorithm. In addition, the suppliers were evaluated and ranked based on their performance towards the identified TGR criteria using the FTOPSIS algorithm. The obtained weights from are then to be integrated into a multi-objective programming model to be developed to obtain an order allocation plan towards the minimization of total cost and CO_2 emissions and maximization of TGR purchasing value.

Keywords: Supplier selection; Green development; Supply chain resilience.

Submission category: working paper

Introduction

The supplier selection and order allocation decision-making process represents a key activity in supply chain management since purchasing expenses exceed fifty percent of all firms' costs. Despite the importance of price, other evaluation criteria should be considered such as reliable delivery, which will ultimately effect productivity and efficiency within a production environment and therefore overall costs.

Presently, there are ever increasing responsibilities placed on companies to consider the environmental impact of their supply chain activities (Mohammed et al., 2017). Green supply chain management is the activity of purchasing, producing, marketing and performing various packaging and logistical activities that takes into account environmental implications (Sarkis, 1999). Kuo and Lin (2011) proposed an integrated approach using ANP and DEA for green

supplier evaluation. Akman (2015) suggested a two-step supplier-assessment framework to evaluate green suppliers. Purchasing managers may consider traditional and more recently green criteria when assessing suppliers while neglecting resilience. Resilience is the capability of the system to efficiently adapt an expected disruptions and back to its normal process, is a vital aspect of any supply chain management (Torabi et al., 2015). Recently, hurricane Sandy led to massive disruptions in US supply chains (Torabi et al., 2015; Burnson, 30 Oct 2012). To protect their business, purchasing managers should include resilience in to their decision-making criteria (Torabi et al., 2015). Pramanik et al. (2016) presented a fuzzy MCDM approach as an aid to developing a resilient supplier selection activity. Sawik (2013) designed a mixed-integer programming model to solve a supplier selection problem in a supply chain under disruption risks.

Since additional criteria, such as environmental sustainability and resilience are paramount to building a successful and competitive supply chain, supplier selection complexity has increased. A new approach is required, which incorporates three main criteria: traditional business, green and resilience. Despite the significant quantity of research already conducted around these topics, the vast majority of current literature considers the green and resilience aspects of supplier selection and order allocation independently.

This paper presents an approach for evaluating and ranking suppliers with respect to their traditional, green and resilience (TGR) characteristics and then order the right quantity of products from the right supplier. A set of criteria/sub-criteria were identified within a unified framework and their relative importance weighted using the analytical hierarchy process (AHP) algorithm. In addition, the suppliers were evaluated and ranked based on their performance towards the identified TGR criteria using the fuzzy technique for order of preference by similarity to ideal solution (FTOPSIS) algorithm. The obtained weights from AHPA and FTOPSIS are then to be integrated into a multi-objective programming model to be developed to obtain an order allocation plan that can help decision makers to order the optimal quantity of material from suppliers towards the minimization of total cost and CO2 emissions and maximization of TGR purchasing value. The applicability and effectiveness of the proposed approach is proved through a real case study by revealing a comparatively meaningful ranking of suppliers. The study provides a noteworthy aid to management who understand the necessity of building supply chain resilience while concurrently pursuing ‘go green’ responsibilities.

The supplier selection and order allocation approach

A laboratory instrumentation Original Equipment Manufacturer wants to develop a resilient supplier selection approach for evaluating their current suppliers in order to plan for unexpected events. Additionally, the company is keen to take ownership of their environmental responsibilities. This research supports the company's requirements through development of a supplier selection approach to facilitate evaluation and ranking of suppliers based on their performance with respect to traditional, green and resilience criteria. The traditional sub-criteria (TC1-TC7) include: cost, quality, delivery reliability, performance history, turnover, lead time, and operating capacity. The green sub-criteria (GC1-GC3) include: environmental management system, waste management and environment related certificate. The resilience sub-criteria (RC1-RC5) include: flexibility, leanness, agility, robustness and visibility (FLARV). AHP used linguistic expert assessment to determine the importance weight for each criteria and sub-criteria based on the evaluation scale presented in Table 1. FTOPSIS was then adapted towards evaluating suppliers based on their performance towards the criteria shown in Figure 1 using the evaluation scale presented in Table 2. Subsequently, the ranking order of suppliers was determined based on evaluation derived from FTOPSIS.

AHP

AHP is a multi-criteria decision making algorithm developed for considering both qualitative and quantitative aspects of decisions (Saaty, 1977). It aims to analyse the complex decisions to a series of pairwise comparisons and then reveals the final weight. In this work, AHP was applied to determine the importance weight for each TGR criteria and sub-criteria and Table 2 shows the evaluation scale in terms of linguistic variables that were used to perform pairwise comparisons. Decision makers need to give their opinion regarding the importance of each criteria / sub-criteria with respect to the others. In this work, AHP was implemented as follows:

1. Use decision makers' preferences to build a pair-wise comparison matrix (A) using the evaluation scale shown in Table 2:

$$A = \begin{bmatrix} 1 & a_{1,2} & a_{1,j} \\ a_{2,1} & 1 & a_{2,j} \\ \dots & \dots & \dots \\ a_{i,1} & a_{i,2} & 1 \end{bmatrix}; \; i = 1, 2, 3, \dots, I; \; j = 1, 2, 3, \dots, J$$

where I and J refers to the criteria.

2. Sum each column of A as follows:

$$Column\ S_i = \sum_{j \in J} a_{ij}, \tag{1}$$

3. Build the normalised decision matrix (R) by dividing each value in matrix A by the sum of its column:

$$R = \frac{A}{Column\ \mathrm{S}_i} \tag{2}$$

4. Determine the weight w_j of each criterion by calculating the average of its weight with respect to other criteria:

$$w_i = \frac{\sum_{i=1}^{I} rowS_i}{J} \tag{3}$$

Table 1. Evaluation scale of criteria in linguistic variables

Scale	Linguistic Variable
1	Equally important (EI)
3	Weakly important (WI)
5	Strongly more important (SMI)
7	Very strongly important (VSI)
9	Extremely important (EI)

TOPSIS

Hwang and Yoon (1981) developed TOPSIS to select an alternative based on its distance to the ideal solution and the negative ideal solution. In this work, TOPSIS was applied to evaluate and rank suppliers with respect to their TGR performance. The linguistic variables previously presented in Table 3 were used to evaluate suppliers towards each criterion. Decision makers need to give their opinions about the performance of every supplier based on their TGR performance. TOPSIS was implemented as follows:

Eq. (8) is used to normalise the decision matrix to get the normalised decision matrix (R):

$$R = \left[r_{ij} \right]_{nxm} \tag{4}$$

where

$$r_{ij} = \left(\frac{a_{ij}}{\sqrt{\sum_i a_{ij}^2}} \right) \tag{5}$$

The weight of criteria (w_j) obtained from the AHP approach should be multiplied by the elements of the normalised decision matrix (R) to form the weighted normalised decision matrix (V).

$$V = \left[v_{ij} \right]_{i*j} \tag{6}$$

where v_{ij} is obtained using the following equation:

$$v_{ij} = r_{ij} \; x \; w_j \tag{7}$$

The positive and negative ideal solutions are determined using Eqs. 11 and 12, respectively (Roy et al., 2004).

$$A^{+} = \left\{ v_1^{+}, v_2^{+}, \ldots, v_n^{+} \right\} \tag{8}$$

$$A^{-} = \left\{ v_1^{-}, v_2^{-}, \ldots, v_n^{-} \right\} \tag{9}$$

The distance of supplier 'I' from the positive ideal solution (d_i^+) and the negative ideal solution (d_i^-) are calculated as follows:

$$d_i^+ = \sum_{j \in n} d_v \left(v_{ij}, v_j^+ \right); \; d_i^- = \sum_{j \in n} d_v \left(v_{ij}, v_j^- \right); \tag{10}$$

where v_j^+ and v_j^- are positive and negative ideal points for criterion 'j', respectively.

Based on d_i^+ and d_i^-, the closeness coefficient (CC) for each supplier is then determined using Eq. 14. The supplier with the highest CC (varies between 0 and 1) is selected as the best green and resilient supplier.

$$CC = \frac{d_i^-}{d_i^+ + d_i^-} \tag{11}$$

Table 2. Linguistic variables and their TFN used for evaluating suppliers

Linguistic variable	Triangular fuzzy number
Very low (VL)	(1, 1, 3)
Low (L)	(1, 3, 5)
Medium (M)	(3, 5, 7)
High (H)	(5, 7, 9)
Very high (VH)	(7, 9, 9)

The multi-objective model

A new multi-objective programming model to be developed to solve the order allocation problem. It is used to support decision makers to order the optimal quantity of products from suppliers considering TGR aspects. Three objective functions were formulated: minimization of related costs (RC), environmental impact and maximization of resilience purchasing.

Application: a real case study

To validate the applicability and effectiveness of the developed methodology, it was applied with a manufacturing company (Company A, henceforth) that design and produce thermal desorption and time-of-flight mass spectrometry instrumentation in the UK.

The purchasing manager (PM) was invited to select a number of suppliers to validate the proposed approach in evaluating their performance towards the identified criteria illustrated in Figure 1. The PM has more than 18 years procurement experience. Two deep discussions (each about 2 hours) were held to explain, discuss and evaluate the TGR criteria, sub criteria and five suppliers' (S) performance.

Weighting TGR criteria

In this step, AHP was implemented to determine the importance weight for each TGR criteria and sub-criteria. Thus, the PM was invited to perform a pairwise comparison among TGC criteria and sub-criteria using the linguistic variables presented in Table 1. AHP is applied to determine the importance weights of each criteria and sub-criteria which are presented in Table 3. According to the calculations shown in Table 4, the weight of traditional criteria is 0.263293; the weight of green criteria is 0.051821; and the weight of resilience criteria is 0.684886. The resilience criteria obtained the highest weight followed by the traditional and then green pillar.

Thus, the resilience criteria are deemed to be the most important compared with the other traditional and green criteria. The PM confirmed that the company's current strategy was to build a resilient supply chain rather than selecting suppliers according to performance towards traditional criteria such as costs and quality.

Table 3. Weights of TGR criteria and sub-criteria obtained by AHP

Criteria	IW	Ranking	Sub-criteria	IW	Ranking

			RC5	0.251476	2

Ranking suppliers

After determining the importance for each TGR criterion, fuzzy TOPSIS was implemented to obtain the ranking order of suppliers based on their TGR performance. The PM was invited for another interview to evaluate the performance of selected suppliers with respect to each sub-criterion using the evaluation scale presented in Table 1. Table 4 shows the performance evaluation and rank of suppliers with respect to each TGR criterion. According to the obtained results, S_2 revealed the highest TGR performance with a closeness coefficient of 0.89373.

Comparing with the other suppliers the closeness coefficient of S_4 (0.733641), S_2 (0.489352), S_5 (0.432518) and S_3 (0.117511) were respectively in rank after S_1.

Table 4. Closeness coefficient and distances from the positive ideal/negative ideal solutions related to suppliers

	S_1	S_2	S_3	S_4	S_5
D_i^+	0.008212	0.008212	0.068047	0.023736	0.042167

rank	1	3	5	2	4

The Order allocation plan

In this section, we expect to end up with an optimal order allocation of products among the five suppliers according to (1) their performance and (2) a number of objectives (i.e., minimum total cost and CO2 emissions and maximum TGR purchasing value).

Conclusions

This work presents a unified traditional business, green and resilient supplier selection and order allocation approach. The framework was developed by identifying traditional, green and resilience criteria and sub-criteria. Two steps were followed to evaluate and rank suppliers. Firstly, AHP was applied to determine the importance weight of each criterion and sub-criterion based on the linguistic evaluation of a purchasing manager. The AHP results indicate that the resilience criteria are deemed the most important for company A, followed by traditional and green, respectively. Secondly, fuzzy TOPSIS was applied to reveal the order ranking of suppliers based on their TGR performance with respect to the importance weight of each criterion and sub-criterion. Currently, a multi-objective programming model is being developed to solve the order allocation problem incorporating weights of TGR criteria and suppliers obtained from AHP and FTOPSIS respectively. Based on the obtained suppliers' performance, we recommended that company A works with some of their suppliers (e.g. S_3 and S_5) to improve their resilience. The results demonstrate the applicability of the novel approach in assisting the purchasing manager at company A to produce a green and resilient purchasing strategy through supplier evaluation.

The dynamics of reshoring decision-making initiatives: which role for the purchasing department?

Antonella Moretto
School of Management, Politecnico di Milano, Via Lambruschini 4/B, Milan, Italy
Andrea Patrucco
Penn State University, Department of Business, PA, USA

Abstract
Literature is rich in the identification of different meanings and decisions about reshoring as well as in listing the main drivers for reshoring. Few contributions try to make a link between these two areas, identifying drivers for specific reshoring decisions. Literature highlights the importance to investigate the decision-making process and in this vein procurement department is mentioned as a key actor to involve in the process. Nevertheless, the involvement of purchasing along reshoring processes is still unexplored. Through 25 case studies, the link between reshoring decisions and drivers was hint and four patterns of involvement of procurement along the decision-making process identified.

Keywords: Reshoring decisions; reshoring drivers; procurement

Research background and motivations
Production offshoring has been one of the most diffused and effective strategies pursued by international companies in the last twenty years (Ferdows, 1997; Kedia and Mukherjee, 2009; Silveira, 2014). Even though a trend still present today, it cannot be neglected that firms devoted to this practice have start experiencing, during the years, some drawback of these decisions, like changes in the conditions of the local environment (e.g. higher costs, regulation evolution, undesired political issues), supply chain disruptions, and supplier and/or human resources quality problems (Dou and Sarkis, 2010). For these reasons, many organizations are now undertaking an opposite path, by deciding to relocate their facilities in other locations, often near their home country (Fratocchi et al., 2014), realizing the so – called "reshoring" phenomenon, which has caught the attention of many scholars and practitioners in the supply chain field.
Reshoring literature struggles in providing the main definitions of what a reshoring decision actually is. A reshoring initiative is quite simple in its meaning, as it can be interpreted as a location decision (Ellram, 2013; Gray et al., 2013) with the aim to revise a previous offshoring choice, by relocating a part of the production network back to the company's home country ("back-reshoring") or home region ("near-reshoring"), in order to seek new competitive advantages (Fratocchi et al., 2014). In this sense, reshoring can be defined as "*the relocation of value creation tasks from offshore locations to geographically closer locations such as domestic or nearshore countries*" (Foerst et al., 2016, p. 495). This definition entails several basic concepts of a reshoring initiative. First of all, it entails that a reshoring initiative is recognized as a reverse decision of a previous decision to offshore (Tate, 2014); secondly, it can refer to the relocation of all the activities as well as a part of those (Bals et al., 2013); finally, it entails to the possibility to move towards domestic or nearshore countries (i.e. backshoring vs nearshoring; Kinkel and Maloca, 2009). During last years, different interpretation of this have been provided, with some authors arguing reshoring in light of economic variables (such as the reduction

in labor cost differentials between low-cost and western countries and escalating logistics costs; Kinkel, 2014; Tate, 2014), others addressing supply chain issues (such the indirect drawbacks of offshoring: higher risks exposure, higher delivery time, and loss of flexibility; Ellram et al., 2013), and other ones pointing out asset considerations (e.g. intellectual property protection, product quality, brand image; Simchi-Levi et al., 2012; Dachs and Kinkel, 2015). Despite this, while offshoring dynamics have been extensively addressed, a clear definition and view about what is happening when firms decide to reshore, is still missing, despite recent studies have tried to shed more light on the decision-making process (e.g. Tate et al., 2014; Stentoft et al. 2015; Bals et al., 2016).
In this scenario, a problem which still remains crucial is how to manage the supply base location. With the offshoring trend in place, most domestic supply networks evaporated or followed their customers in the new country (Fel and Griette, 2017) - even though with a delay of a few years; similarly, if companies want to return their production facilities back home, they have to consider they will have to rely on a supply base still located in other geographical areas, at least until the economics for the supplier will also drive them to follow the company to the home country (Kinkel and Maloca, 2009).
This has an evident impact on the purchasing strategy decisions, thus making the involvement and the role of the purchasing department in the process crucial. If we look at what has been discussed so far, the contribution of purchasing in this type of company decisions has been addressed with mixed evidence (e.g., Foerst et al., 2016).

Research questions and framework

On these premises, there is space to enlarge contributions, to both theory and practice, in two ways. On one side, it may be interesting to shed more light on the dynamics of the reshoring decision – making process, by defining a comprehensive taxonomy including both reshoring options and drivers. On the other, it is interesting to characterize more in detail the role and contribution of the purchasing department, by analyzing the degree of involvement in this process and the type of expected contribution.

The reshoring decision: drivers and antecedents

If we look at the reshoring literature, we can actually identify two big research areas.
On one side, reshoring drivers have been one of the most recently debated topic. As a matter of fact, several authors have focused their attention on possible classification frameworks of these elements (e.g., Ancarani et al., 2015; Fratocchi et al., 2016).
On the other hand, several authors have tried to design some possible taxonomies to classify the company reshoring decisions (e.g., Bals et al., 2016; Foerst et al., 2016).
However, despite the richness of literature in these two areas, they have always been addressed separately, and a clear link about how to link reshoring options to reshoring motivations is missing (while present for offshoring decisions; e.g. Patrucco et al., 2016).
In light of this identified gap, the first aim of this paper is trying to understand whether some specific reshoring decisions can be driven and explained through specific drivers. Thereby, the first research question is the following:

RQ1: How can reshoring drivers be connected with specific reshoring decisions?

Being drivers the point of start, we have first tried to integrate the different contributions found in the literature; as a reference point, we consider the review made by Di Mauro et al. (2017), which distinguishes drivers in different categories, and provides a univocal definition. In defining the reshoring taxonomy instead, we decide to adopt a specific framework, that proposed by Foerst et al., 2016 (in turn, adapted from Contractor et al., 2010; Jahns et al., 2016), which discriminates reshoring decisions in light of two

dimensions: location (i.e. if the company is bringing operations back to the home country or near the home country) and ownership (i.e. if the company is changing the way these operations are controlled) of the activities. In light of these two variables, authors distinguish reshoring typology being: mono-dimensional driven, if the company is modifying the ownership (i.e., domestic insourcing, nearshore insourcing, offshore insourcing) or the location (i.e., outsourced backshoring, outsourced nearshoring, in-house nearshoring, in-house backshoring); bi-dimensional driven if the company is modifying both the ownership and the location (i.e., nearshore insourcing, backshore insourcing).

The role of purchasing

According to Bals et al. (2016), when managing the reshoring decision-making process, managers pass through three sequential stages: 1) ex ante activities, which involve evaluation of the feasibility of the decision; 2) activities to take the reshoring decisions, which involve the design of the reshoring decision (i.e. information gathering on alternatives; data analysis; development of the solution; selection of the sourcing option); 3) implementation activities, which involve the practical realization of the reshoring decision. In the past, scholars have discussed several contingent variables that can impact the dynamics of this decision-making process - e.g., country level factors (e.g., Dunning, 2000; Ellram et al., 2013); firm – specific factors (e.g., Sun et al., 2012; Macchion et al., 2015); decision impact factors (e.g., Kinkel, 2014); surprisingly, even though reshoring decisions imply reconfiguration of the supply chain and, in particular, of the supply network (Van den Bossche et al., 2014), a focus on the role the purchasing department should play in this process is missing. The strategic role of the purchasing in companies has been promoted so far (Spekman, 1988; Ellram and Carr, 1994; Brandon-Jones and Knoppen, 2017). As a strategic function, purchasing can actually play a proactive role in pursuing firm's goals with a long-term focus (Carr and Pearson, 1999; Carr and Pearson, 2002; Tchokogué et al., 2017), as well as when involved in strategic decision-making processes, such as the reshoring one (Gonzalez-Benito, 2007).

The second objective of the paper is thus to explore, more in detail, which are the conditions that lead to purchasing involvement, and the contribution purchasing can give to the reshoring dilemma when timely involved. Thereby, the second research question is the following:

RQ2: When is the procurement department involved in the reshoring decision-making process?

As a matter of fact, the involvement of procurement within strategic decisions is more likely to happen when purchasing is promoted as a strategic function in the organization (Ates et al., 2018). In order to discriminate the different levels of purchasing strategic relevance of procurement for a company, the model proposed by Paulraj et al. (2006) was adopted, which measures these aspects across three dimensions: 1) strategic focus, i.e. extent to which purchasing objectives are focused on long-term opportunities; 2) strategic involvement, i.e. extent to which purchasing people and activities are connected to company strategic planning processes; 3) purchasing recognition, i.e. extent to which purchasing people and competences are perceived as value – adding by top management and other departments.

Research methodology

As presented, the study is exploratory in its nature; for this reason, a multiple case study approach was selected, also because often used for analyzing offshoring and reshoring dynamics (e.g. Mudambi and Venzin, 2010; Di Mauro et al., 2017; Johansson and Olhager, 2018). This method is appropriate as a way to describe phenomena in real context (Voss et al., 2002) being able to provide in-depth comprehension of the unit of analysis, although limited in terms of standardization and generalization of results (Larsson and Lubatkin 2001). To define the sample, we first scout secondary sources (Cowton, 1998), and identify more than 100 companies mentioned in news as having performed reshoring initiatives in the last years; we then analyze in-depth information available about each initiative, in order to understand if this would have been useful for the purpose. If this was not evident from secondary sources, preliminary calls were performed to understand more in detail the main features of the initiative and to understand if the company was potentially valuable to be involved in the research.

This screening process lead to the identification of 25 suitable reshoring initiatives, referring to 18 different companies. On one side, these 18 companies can be considered useful for the purposes, being heterogeneous per country of origin, industry, and turnover; on the other hand, the 25 reshoring initiatives are homogeneous for focus on the reshoring initiatives. Being the research questions project – specific, our unit of analysis has been the reshoring initiative, so we can represent our sample as described in *Table 1*.

Table 1. Sample of analysis

Case	Industry	Turnover 2016	Employees 2016	Home country
Tractor	Automotive	390 Million €	1.234	Italy
Child 1	Pharmaceuticals	581 Million €	1.700	Italy
Child 2				
Shirt	Apparel	9 Million €	77	Italy
Travel luggage	Leather goods	39 Million €	112	Italy
Automotive	Automotive	113 Billion €	230.000	Italy
Work luggage	Leather goods	60 Million €	267	Italy
Knitwear 1	Apparel	73 Million €	379	Italy
Knitwear 2				
Trousers	Apparel	7 Million €	13	Italy
Elevators	Transport systems	9 Billion €	50.000	US
Sport shoes 1	Sportswear	74 Million €	173	Italy
Sport shoes 2				
Sport shoes 3				
Sport shoes 4				
Casual shoes	Apparel	39 Million €	n.a.	US
Sitting room	Furniture	437 Million €	2.232	Italy
Home appliances	Home appliance	5 Million €	38	Italy
Jackets 1	Apparel	47 Million €	125	Italy
Jackets 2				
Jackets 3				
Ski pole	Ski pole	1 Million €	5	US
Electric bikes	Bicycle	23 Million €	n.a.	Italy
Washing machine	Home appliance	5 Billion €	100.000	US
Formal suit	Apparel	1.3 Billion €	7.000	Italy

For each initiative, data were collected during 2016 and 2017 through direct interviews (from a minimum of 2 to a maximum of 5 for each project). Interviews were realized face-to-face (when possible) or through virtual meetings; each one involved at least two

researchers, in order to compare perceptions and avoid bias. Managers interviewed were Chief Purchasing Officer (CPO), Chief Executive Officer (CEO), Supply Chain Manager, Vice President, Production Managers, General Managers, etc. To avoid information loss, notes taken by researchers and interview recording (upon permission) were used. moreover, researchers take notes during the interviews.

Interviews were carried on following a semi-structured interview protocol. After the interviews, data were coded and shared with the company, to cross check everything was properly understood; in case something needed to be change, or missing information, e-mail or virtual meeting follow – up were used.

More, data collected through the interviews were always triangulated with other secondary sources - newspapers, websites, additional documents provided by the companies, presentation of the reshoring initiative in conferences or workshop. In some cases, interviews with trade associations (e.g., Assocalzaturifici – Italian association of shoe manufacturers; Sistema Moda Italia – Italian association of fashion companies; Founder of the Reshoring Initiative; Unindustria Como – Italian association of companies in the area of Como) were also performed to double check information.

Results and case discussion

The link between drivers and reshoring initiatives

The cross-case analysis on reshoring decision – making variables (i.e. direction of change, reshoring scope and type, driver typology) first shows that, for all the driver categories included in the framework, there is a correspondence in our sample, thus confirming that existing theoretical classification are consistent with the main motivations driving companies towards reshoring. We can observer that, among the different drivers, operational reasons and brand reputation aspects are the most claimed according to our sample; this result is consistent empirical evidence provided by other authors (e.g. Frattocchi et al., 2016), but may be strongly related to sample features. As a matter of fact, most of the reshoring initiatives involves moving from East or far East countries to Italy, with the main motivations to partially recover partial the Italian "made in effect", or to a stem increase of the overall costs, which are reducing the economic advantage bringing companies to offshore in the past. Another key factor is represented by the need to move operations close home country-based R&D activities: consistently with what promoted in the innovation field (e.g. Carrincazeaux, 2001), a strong proximity between innovation activities and operations department is fundamental to improve innovation performance and to reduce the overall time-to-market. So, the shorter the lifecycle of products (in combination with previous drivers), the higher is the need to accelerate product launch on the market, which has pushed companies to revise previous offshoring decisions (and less geographical distance).

Immediately after this, the risk reduction represents another relevant motivational factor for reshoring initiatives: several companies are either worried about fluctuation in currency exchange, or about specific supply chain risk (e.g. supply interruption or quality risk). Thereby, the choice to relocate their activities in the home country (or in a closer one) are linked to the broader supply chain strategy to reduce risk; this result, as well, is consistent with that part of literature demonstrating how global supply chains have more risk sources to deal with (e.g. Manuj and Mentzer, 2008).

Just a few companies mentioned instead organizational or government policy drivers.

Organizational factors have been mentioned essentially referring to the search for availability of qualified workers, who have demonstrated to be not as skilled as expected in the offshored countries, thus created technical and qualitative issues for companies.

Government factors are essentially embedded in tax incentives to rebuild local supply chains; this driver was particularly mentioned by companies headquartered in US and Switzerland, where tax incentives may give massive advantages when promoted by governments (Tate, 2014).

Each case was also analyzed in light of the reshoring scope, in order to understand whether the reshoring decision implied a bi or mono – dimensional change: as a matter of fact, for our sample, besides two cases (tractor and home appliances), only partial reshoring initiatives were involved. The fact that companies usually focus either on the location or the ownership can be interpreted in two ways.

On one hand, given that reshoring decisions already have a significant magnitude, companies try to smooth the risk associated to the initiative and by acting just on one of the reshoring dimension. In particular, in our sample, most of the companies tend to focus first on the dynamics of changing the location, despite revolutionizing the ownership too. At this regard, the Procurement Manager in the Tractor case said: *"In our company, we tend to separate reshoring decisions in terms of location change, and aspects linked to the ownership (…) We change make-or-buy choices too, but these usually don't strictly depend on the location where these activities are performed. (…) When we decided to bring production back from France to Italy, we did it because we feel we were losing the "Made in Italy" effect which has a value also for our industry (…) why we still rely on suppliers rather than managing activities internally is a totally different issue"*. This result is not completely aligned with existing literature (e.g. Bals et al., 2015; Foerst et al., 2016), which instead used to promote these choices as in synergy.

On the other side, if we look at the six cases that performed a bi-dimensional change (e.g. Child for both the reshoring initiatives), they all involve a change from outsourcing to insourcing of operations driven by the need to increase the level of control on these activities. As a matter of fact, companies discovered that outsourcing of production to a third part was not the best make-or-buy decision, and so take the opportunity of the relocation to reverse this choice. In the Child case, the CPO affirms: *"In the past, we decided to move our production activities to China mainly for cost reasons. After a while, not only labor cost in China started increasing, but we also started facing several unexpected challenges, such as the inability to be flexible to customer requirements, to quickly react to market request keeping lead time short, to limit the risk of suppliers start copying our products (…) Having plants with production capacity available, that's why we decided to take back those activities, in-housing them partially in Italy and partially in Romania"*. This is aligned with previous results, discussing on insourcing as being driven mainly by need of higher control and risk reduction factors (e.g. Hartman et al., 2017; Hartman and Ogden, 2017).

Finally, cross – case analysis allows us to understand if it is possible to identify some recurring patterns between drivers and reshoring decisions. *Table 2* reports main results.

Table 2. Link between drivers and reshoring initiatives

Reshoring scope	Reshoring type	Driver classification	Cases
Bi-dimensional change	• Backshore insourcing • Nearshore insourcing	• Operational drivers (operational flexibility) • Organizational drivers (availability of qualified workers) • Brand reputation (Made in effect)	Child 1 Child 2 Travel luggage Trousers Home appliances Electric bikes
Mono-dimensional change	• In-house nearshoring	• Cost drivers (labour cost; logistics cost) • Risk (currency exchange)	Work luggage Knitwear 1 Sport shoes 1

	• Outsourced nearshoring		Jackets 2
Mono-dimensional change	• Outsourced backshoring	• Operational drivers (lead time reduction; operational flexibility) • Brand reputation (Romania and Turkey)	Shirt Knitwear 2 Sport shoes 2 Sport shoes 3 Sport shoes 4 Casual shoes Jackets 1 Jackets 3 Ski pole
Mono-dimensional change	• In-house backshoring	• Brand reputation (Made in effect) • Operational (Proximity to the home base R&D) • Governmental (Tax incentives)	Tractor Automotive Elevators Sitting room Washing machine Formal suit

We are able to identify four main recurring patterns linking reshoring decisions driven and drivers. The first one involves bi-dimensional change reshoring: for all the six cases (although limited in number) drivers are quite similar, with most relevant motivations represented by the desire to regain control along the chain, to improve brand reputation as well as to improve operational flexibility. Also, the possibility to rely on their own qualified workers in the local area (compared to lower competences available in the offshore location) pushed companies to the decision of insourcing activities either in their home country or at least in nearest one. As cases reported, this choice is often perceived away to revert a previous choice, once realized desired results were not achieved. Of course, these results need to be interpreted also in light of some sample-specific factors, like the fact the cases in this group all refer to companies located in Italy and realizing a product were the "Made in Italy" factor is crucial (e.g., home appliances, clothes, etc.), making drivers and the possible need to reverse previous radical supply chain decisions in line with these characteristics. The situation is instead more complex if we analyse mono-dimensional change reshoring.

A second pattern can be identified for nearshoring initiative (either insourced or outsourced). In our sample, four initiatives decided to adopt this strategy, mainly with the aim to reduce either costs or risks. For the former, labour cost, logistic cost (e.g. from Romania) and quality control efforts were the main factors mentioned to push companies to relocate production activities closer. For the latter, several cases highlighted the impact that currency exchange volatility can have on economic performance, thus driving the need to move activities in countries with the same currency (e.g., euros). All those companies operate in labour intensive industries, where labour costs have a relevant incidence, and mainly realize functional products (i.e., work luggage, sport shoes, jackets), for which quality is relevant, but also cost remains a key parameter, and the "Made in" effect is not so impacting.

The third pattern refers to outsourced backshoring. This is the most diffused archetype, mainly driven by lead time reduction and need for stronger flexibility. It involves company operating in very volatile industries (e.g., fashion), where the ability to respond quickly and reactively to market request is crucial, thus justifying the outsourcing option. However, the brand reputation effect is fundamental as well, especially in case operations are backshored from countries closed to Italy (e.g., Romania and Turkey). In these cases, the cases mentioned explicitly as driver the importance to recover the Made in Effect.

Finally, the fourth pattern refers to companies realizing in-house backshoring. Consistently with literature ownership and location as both key variables to be considered

in reshoring decision making (e.g. Van den Bossche et al., 2014; Foerstl et al., 2016), this archetype presents different drivers if compared to previous ones. Although brand reputation is still present, it now has more widespread features: companies can use the reshoring initiative as an advertising element to promote their local image, presenting this choice as a byword for quality as well. Operational drivers are relevant as well, but they mainly relate to the need of increasing R&D proximity to operations, thus fostering collaborations and sharing of ideas (Carrincazeaux et al., 2001). Finally, it is only for this case that governmental policy driver seems to be key element: as a matter of fact, governments provide tax provisions only if companies directly control the operational activities, and so keeping control of operations in-house is a key choice.

The role of procurement department in decision-making process

Cross-case analysis (see *Table 3*) highlights that most of the companies are involving procurement department in the feasibility phase, although with different responsibilities (e.g., verifying cost and time constraints; evaluating broader perspectives for the supply base; measuring potential advantages). Several companies are also involving the procurement department in the implementation phase, especially when reshape of the supply base is necessary; in this case as well, the involvement may occur at different levels (e.g., redesigning the supply base; managing critical supplier relationships; participating to complex negotiation activities; renewing the relationships with suppliers, etc.). On the contrary, most of the companies are actually not involving procurement department as fare as reshoring planning activities are involved: just the Child and Trousers cases actively involved procurement department in data analysis and decision, while the Automotive company consulted procurement department before finalizing the reshoring configuration. Through the cross-case analysis, four types of involvement of procurement department in the reshoring initiative have been identified (*Table 4*).

Table 3. Patterns of involvement of procurement department in decision-making process

	Involvement in feasibility	**Involvement in decision plan**	**Involvement in the implementation**	**Companies**
No involvement	Not involved	Not involved	Not involved	Sport shoes Formal suit
Operational involvement	Not involved	Not involved	Redesign the supply base; Managing relationships with suppliers	Tractor Shirt Travel luggage Work luggage Knitwear Ski pol Electric bikes
Early involvement	Verifying cost and time constraints; Evaluating impacts on the supply base	Not involved	Redesign the supply base; Managing relationships with suppliers	Automotive Elevators Casual shoes Sitting room Home appliances Jackets Washing machine
Strategic involvement	Verifying cost and time constraints; Evaluating implications on the supply base	Data analysis and reshoring type decision	Redesign the supply base; Managing relationships with suppliers	Child Trousers

The four options differ in terms of phases in which procurement department is involved. We step from no involvement at all in the decision – making, passing through an operational involvement (just limited to implementation activities), an early involvement (when consultation occurs in the feasibility phase), to arrive to a full strategic involvement, where purchasing can act as real promoter of the reshoring decision.

These four involvement options can be read in light of the strategic relevance of the department within the company (*Table 4*).

Table 4. Patterns of involvement of purchasing department on the basis of strategic relevance of procurement

	Strategic involvement in company planning processes	***Strategic focus***	***Recognition within top management***
No involvement	Not involved	Short term	Low recognition
Operational involvement	Not involved	Short term	Low/good recognition
Early involvement	Involved	Long term	Low/Good recognition
Strategic involvement	Involved	Long term	Low/Good recognition

Empirical evidence show that recognition is apparently not a key variable to discriminate among the four types of involvement as, the three models giving purchasing a role in the reshoring decision-making see a balance between cases with low and good level of recognition. This is not surprising as, in many company, purchasing departments are still struggling in being recognized as equal partners by the organization, without this meaning they cannot have a role in strategic decisions (Luzzini and Ronchi, 2016).

Beyond that, both strategic involvement and strategic focus appears potentially valuable, consistently with existing literature (Paulraj et al., 2006).

On the other hand, case studies address that strategic relevance of procurement (measured in terms of strategic involvement, strategic focus and recognition within top management) is just partially discriminating among different levels of procurement in decision-making process, not differentiating all the four archetypes. In case the strategic relevance of procurement is low (i.e., low strategic involvement and low strategic focus), the two models either without any involvement of procurement or procurement with a mere operational role is pursuable; on the contrary, in case of a high strategic relevance of procurement (i.e., high strategic involvement and high strategic focus), the company can select between an involvement in data analysis as well as operational support or along all the process. This result is quite aligned with existing literature about strategic relevance of procurement: it is definitively necessary to assure the recognition within the company and by other departments of the strategic importance of procurement to assure an in-depth involvement in strategic decisions (Luzzini et al., 2014). On the other hand, this result extends existing literature about strategic relevance of procurement, demonstrating that is going beyond the implementation of strategic practices but also entails the involvement in key decision-making processes.

Conclusions and future developments

Being reshoring a phenomenon which is characterizing companies in different industries, this paper aims to address this trend in two ways. On one side, literature has deeply investigated which are main drivers for reshoring initiatives (Fratocchi et al., 2014; 2016), together with the definition of taxonomies for different typologies of reshoring initiatives (Foerstl et al., 2016); whereas, the link between these two streams is missing, thus representing a first open issue to be explored. Secondly, previous research addressed

the importance to look at reshoring as a process (Bals et al., 2013) thus making the organizational perspective an interesting area of investigation. In this vein, a relevant perspective is that of the purchasing department, consistently with the fact that supply base location is a key aspect of offshoring/reshoring (Van den Bossche, 2014), and with the consolidated debate about the strategic relevance of purchasing for company success. In this perspective, it seems interesting to investigate the involvement of purchasing along the reshoring decision-making process, and the strategic contribution these professional can give. To tackle these research goals, a case-based methodology was selected, through the conduction of multiple interviews in 18 companies, for the analysis of 25 different reshoring initiatives. From this empirical evidence, we are able to identify a link between specific reshoring drivers and four possible reshoring patterns (distinguished by changes in location, ownership or both of them); within this, we also define four type of purchasing involvement in the decision-making process (no involvement, operational involvement, early involvement, strategic involvement), which can be related to the strategic relevance purchasing has for the company. These results provide a contribution for both literature and for practice. From a theoretical perspective, this paper first enlarges reshoring literature by adding strong empirical-based evidence to the current most conceptual – based research (Foerst et al., 2016), which can indirectly be strengthen. Moreover, the paper links together drivers and reshoring initiative typologies, an area which is currently under-investigated. Finally, the paper shed light on the role that purchasing can have in this type of decision, thus contributing to bot reshoring and purchasing literature: This last contribution enlarges both research in reshoring and procurement area: for the former, we discuss the organizational impact and the potential contribution that a new department (not considered in previous literature) can give to the reshoring decision-making process; for the latter, the paper defines a new area where purchasing can demonstrate its strategic relevance for companies.

From a practical perspective, the paper provides some contribution as well. As a matter of fact, reshoring is a hot topic for managers, on top of the supply chain management agenda; managers can first use the drivers – reshoring framework to evaluate which reshoring decisions is most suitable for their companies when certain conditions are present. Then, they can rely on an appropriate model to evaluate the importance to involve purchasing in different phases of the decision-making process. As a matter of fact, this paper also has some limitations, representing further opportunities for future research. First, patterns identified are based on a qualitative sample, thus limiting the level of generalizability of results; further research might validate identified patterns through a statistical sample. Secondly, data were collected in 2016/2017, quite close to the period of implementation of the reshoring initiative. For this reason, quantify performance obtained from the reshoring initiative was not possible: adopting a longitudinal perspective, further research might define specific performance metrics to be evaluated for the company during years, in order to discriminate patterns also on the results side.

Abstract

Defence budgets tend to decline, thus reforming procurement processes to become apparent in order to maintain efficiency in high levels and Security of Supply (defined in the European Directive 2009/81). The purpose of this article is to suggest a holistic supplier selection approach that combines Five Factor Model (FFM) for Personality traits, with statistical methods under the concept of Civil Military Integration (CMI). It endeavours to provide a flexible and cost-effective approach for supplier selection by adopting a dipole process that addresses to the potential suppliers and in parallel to the team that will perform the section. It may be useful to public procurement managers, but also to private ones, as it combines characteristics from both procurement areas.

Keywords
Five Factor Model, Civil Military Integration, Supplier Selection

Introduction

The economic crisis in Greece led suppliers to exist in a complex and competitive environment mostly due to the fact that a lot of businesses operating in Greece focus on cutting cost, reducing capacities and consolidating suppliers. Those businesses, thriving to stay alive, try to adopt innovative approaches to safe their internal and external procedures of supply chains. Therefore, there is a great need to follow a strong and effective approach that may provide better performance and effectiveness. The defence area could not be an exception of that as it is stated that Military Logistics include,

among others, aspects of military operations that deal with the acquisition of parts, materials and services (DoD 4140.1, 2003; Apte, Rendon and Salmeron, 2011).
The objective of this paper is to present a methodology that is able to identify a supplier by using a tool for explaining personality (FFM) in a frame (CMI) that offers chances of reducing costs. Thus, statistical techniques are used to confront the subjectivity of human thoughts and expressions, factors that stem from our personality. It is applied on FFM, which seems to be a not widely used tool in the supplier selection area (Degraeve, Labro and Roodhooft, 2000; Kannan and Tan, 2002; Hsu, Kannan, Leong and Tan, 2006; Ho, Xu and Dey, 2010; Ware, Singh and Banwet, 2012). For the purpose of this paper, real data were collected through questionnaires of professionals of the private and public sector in Defence and in Health services, services that may be characterized as vital for a state/country/society. The questionnaires were based on the FFM personality trait. To these data, we applied statistical analysis in order to define the characteristics of the desired supplier and of the selection team in a CMI environment.

The paper also demonstrates the fact that FFM, a tool widely used for explaining personality (Schmitt, Allik, McCrae and Benet-Martinez, 2007), may assist in the supplier selection area whereas it turns the interest to a non-greatly lighted area, when examined in parallel with the supplier selection issue, that of the personality characteristics that a supplier selection team should have. It is hoped that the current study will enrich the defence literature by exploring and applying scientific and systematic theories of group decision support and personality theories in the supplier selection problem of the defence area. It combines well-structured and widely used methods with data in a professional area where, to the best of our knowledge, there is still work to be done. To support even better its contribution in the supplier selection area, Table 1 presents the results of a research/review of that area for unrestricted documents, where no combined use of FFM and Regression analysis seems to appear. The paper is organized as follows: In the next section, parts of relevant literature are reviewed and the areas of CMI and FFM are introduced. Then, the phases that comprise the evaluation procedure based on real data are described, and results, conclusions, limitations and directions for future research are discussed.

Literature Review

In this section the results of the relevant literature review are presented. Supplier selection is a Multi Criteria Decision Making (MCDM) issue and it may become the most important decision in procurement. In the literature of procurement, the need for methods/ways to resolve procurement issues has been highlighted (Institute for Security Studies, 2005; Tadelis, 2012). Efficient supplier selection reduces the purchasing costs and improves corporate competitiveness (Ghodsypour and O'Brien, 2001). The relevant literature generally discusses the ways to reach the optimal supplier, the qualitative and quantitative criteria and the trade-offs among them (Degraeve et al., 2000; de Boer, Labro and Morlacchi, 2001; Cheraghi, Dadashzadeh and Subramanian, 2004; Ho et al., 2010; Ware et al., 2012). That literature also demonstrated that no single appropriate approach exists for each supplier selection case, supply managers usually deal with uncertainty and adopt different selection criteria, and there is no statistical analysis regarding the application of a hybrid FFM model in an CMI frame (Degraeve et al., 2000; Lee, Sungo and Kim, 2001; Ho et al., 2010). The supplier selection approaches

mentioned in Table 1 can assist readers who would like to deepen their knowledge in the supplier selection issue.

Five Factor Model Short Overview

Supplier selection may be naturally considered as a decision making process and as such it is affected by aspects of human personality (Dewberry, Juanchich and Narendran, 2013). Jung's typology/Myers-Briggs type indicator has been widely used for investigating personality but it seems to have been criticized over its empirical character, not being tested enough scientifically. Several psychologists are convinced that an accurate representation of trait structure is provided by the FFM and that FFM is the most popular, reliable, and theoretically sound theory of personality due to the fact that it is at the periphery of the public administration literature (Cooper, Knotts, McCord and Johnson, 2013).

FFM is presented as an empirically verified, theoretically sound framework that is widely accepted within the field of psychology and applied by public managers as a tool to assess personalities, while at the same time it is widely accepted for its efficacy (Cooper et al., 2013). In a general frame, FFM is an hierarchical model that explains personality using five broad traits (openness, conscientiousness, extraversion, agreeableness and neuroticism) (Filiz and Battaglio, 2017). These traits are conceptualized as continuous variables with a normal distribution in a population, thus big samples are required to better approach normality hypothesis (Koutrouvelis, 2000). The following table depicts an overview of the five personality traits of the model.

Domain	Definition	Adjective Check List Marker Items
Extraversion/Surgency	The degree to which a person needs attention and social interaction	Quiet, Reserved, Shy vs. Talkative, Assertive, Active
Agreeableness	The degree to which a person needs pleasant and harmonious relations with others	Fault-Finding, Cold, Unfriendly vs. Sympathetic, Kind, Friendly
Conscientiousness	The degree to which a person is willing to comply with conventional rules, norms, and standards	Careless, Disorderly, Frivolous vs. Organized, Thorough, Precise
Neuroticism/Emotional Stability	The degree to which a person experiences the world as threatening and beyond his/her control.	Tense, Anxious, Nervous vs. Stable, Calm, Contented
Intelect/ Openness to Experience	The degree to which a person needs intellectual stimulation, change, and variety.	Commonplace, Narrow-Interest, Simple vs. Wide-Interest, Imaginative, Intelligent

Table 2. The Domains of the Five-Factor Model of Personality

Civil Military Integration Short Overview

CMI is both a driving force in acquisition reform and a product of acquisition reform. It is a concept that advocates bringing together the commercial and military sectors of industry, so both commercial and military work can be performed in a common facility using commercial processes and practices (Acquisition Review Quarterly, 1999). US Government officials and private sector executives have advocated the integration of the defense and commercial sectors (often termed civil-military integration or CMI). The claimed benefits of CMI include cost savings, increased technology transfer, and an increase in the number of potential defense suppliers (US Congress, Office of Technology Assessment, 1994).

A CMI strategy demands extensive modification of acquisition laws and regulations, if not already planned, and concerns over potential costs and risks of such modifications (US Office of Technology Assessment, 1994; Acquisition Review Quarterly, 1999). No ‘’silver bullet’’ policies seem to easily achieve CMI goals and barriers exist that demand a comprehensive (and complex) set of policies. CMI also allows companies to bring together companywide assets and resources that otherwise would be separated by type of work. The resulting efficiencies reduce operating costs and overhead and, in addition, there is an ability to provide the best solutions for commercial and government customers alike.

The Development of the Approach

Theoretical Frame- Restrictions-Assumptions

The number of the questionnaires used as our sample size was 30 (N=30) and constituted the basis for our analysis. That number draws its applicability from the Central Limit Theorem (CLT). CLT synoptically denotes that the sample mean of a large random sample of random variables with mean μ and finite variance σ^2 has

approximately the normal distribution with mean μ and variance σ^2/n (de Groot and Schervish, 2002). A sample may be considered large if $n \geq 30$ (Koutrouvelis, 2000) and consequently the sample size in this study covers the basic prerequisites for CLT to apply statistical analysis.

In our approach, descriptive statistics, regression analysis and correlation coefficient were applied. Regression analysis was used to analyze its importance and the variability of the data of several predictors (independent variables). Regression analysis and its derivatives, regression standards, create quantitative relationships between variables by associating the random observation of dependent variables with given observations of the dependent variable and random errors (Koutras and Euaggelaras, 2010). Also, it showed the determination of the regression accuracy (fit) of the regression model resulting from this process and the possibility of predicting the dependent variable value for known values of the independent variables.

R^2 is the symbol of the coefficient of determination indicating how much variation in the response is explained by the model. The higher the R^2 the better the model fits the data. It takes values between 0 and 1 and expresses the percentage of the total dispersion (the values of the dependent variable) which is explained by the independent variable through the regression line. As a satisfactory standard, it was considered to be with rates of R^2 above 60%, considering that there are several cases in several academic areas where rates of around 50% were considered satisfactory (WWW.BANKOFGREECE.GR, 2011; Mpalopitou and Xatzibaggeli, 2012).

MINITAB statistical software calculates the correlation coefficient for every possible pair and displays p-values for the hypothesis test of the correlation coefficient being zero. The linear correlation coefficient ρ measures the degree of the dependence of 2 variables, i.e. the intensity of the affinity, whether the variables are quantitative or qualitative (Kioxos, 1993). It is noted that correlation generally means that variables are linked to a relationship, but do not necessarily cause causality. In cases where the use of the linear correlation coefficient ρ was necessary, we assumed that, according to Kioxos (1993), although the values of ρ for which the correlation is possible depend on the number of observations, the following indicative values may apply:

a) If $|\rho| \leq 0.3$ then no correlation exists and if $0.3 \leq |\rho| \leq 0.5$ a weak correlation exists.
b) If $0.5 \leq |\rho| \leq 0.7$ an average correlation exists and if $0.7 \leq |\rho| \leq 0.8$ a strong one occurs.
c) $|\rho| \geq 0.8$ equals to a very strong correlation.
d) In addition, the Variance Inflation Factor (VIF) was used for quantifying the severity of multicollinearity and, according to Koutras and Euaggelaras (2010), the following rules are usually applied:
e) if VIF≤10, then the corresponding dependent variable does not have a multicollinearity problem.
f) If VIF> 10 then the corresponding dependent variable has a multicollinearity problem.

Analysis of the Approach

The real data collected were analyzed in order to provide a simple and clear statistical view. Descriptive statistics describe quantitatively the main features of a collection of data and MINITAB produces such descriptive statistics. Table 1 of the

questionnaire (Annex A) presents the ratings, on a Likert 5-scale of importance, of all the desired characteristics that a CMI supplier/manufacturer should have as these have been retrieved from the relevant literature.

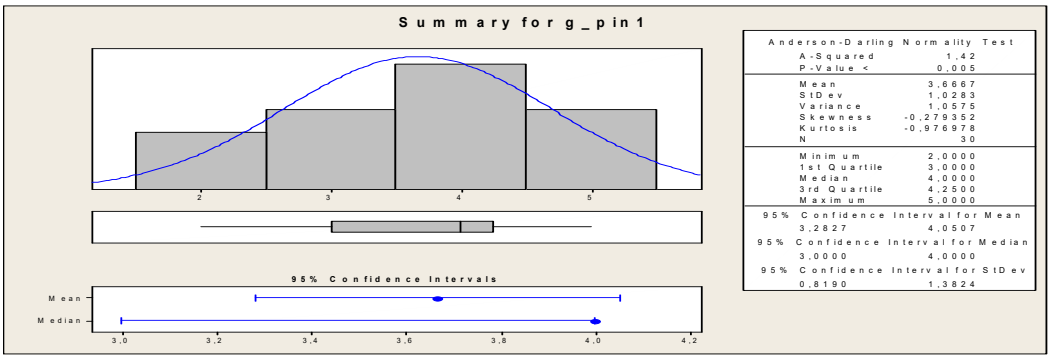

Figure 1.1. Descriptive Statistics for g_pin1

An example to a randomly selected variable of Table 1 (in Annex A) is provided in Figure 1.1. Skewness value of -0.279 indicates that in that distribution the tail on the left side of the probability density function is longer than the right side and the majority of the values lie to the right of the mean. Kurtosis value of -0.97 indicates a platykurtic distribution. 95% Confidence Interval (CI) for sample mean may be used for the calculation of the 95% CI of mean for the g_pin1 variable population (Koutrouvelis, 2000). Comparing the means and its respective CI for Table 1, we reached to the observation that variables d_pin1 (provision of long service commitment) and h_pin1 (ability to adopt commercial best practices) show the highest values. Below-mentioned correlation matrix (Figure 1.2.) describes the MINITAB Pearson Correlation results of Table 1 (in Annex A) where the notable correlations, at a significance level of 0.1, were highlighted.

Figure 1.2. Pearson Correlation Results for Table 1 of Annex A

Lizarraga, Baquedano, Oliver and Closas (2009) provided the 'Decision-Making Questionnaire' (DMQ) examining the factors that have the most influence on

professional decisions. This questionnaire could guide adolescents in a vocational decision process by calculating the internal consistency of each of the factors using Cronbach alpha coefficient. We selected 6 of these factors that presented the highest score to be evaluated as the desirable features of vendor selection team members in a CMI environment (how important it is for a team member to have this feature). The results of the descriptive statistics showed that the factor "Self-Regulation" had the highest 95% CI for Mean, while on the contrary ''Social Pressure' 'had the lowest respective value for the contrary. Correlation matrix for these 6 factors is depicted in Figure 1.3. where the notable correlations were highlighted.

Figure 1.3. Pearson Correlation Results for Parts 4 to 9 of Table 3 in Annex A

Tables 1 and 2, retrieved from the questionnaire shown in Annex A, depict the frame and provide the raw data where the regression analysis was performed for each one of the Big Five Traits. The persons that filled the questionnaire were asked to rate, on a Likert scale, all the desired characteristics that, according to the relevant literature, a CMI supplier/manufacturer should have. These ratings were linked with the Big Five Traits (BFT) in an attempt to depict the degree of their contribution in the existence of the specific trait to the profile of a CMI supplier. Figure 1.4. shows the results of our interest for a regression analysis performed with the CMI desired characteristics as predictors and the ratings of the BFT as the response.

Figure 1.4. BFT Regression Analysis

Discussion and Managerial Implications

Descriptive statistics of Figure 1.2. revealed that provision of long service commitment and the ability to adopt commercial best practices were the most highly rated, regardless of the nature of the work of people that rated them (public or private sector in Defense and in Health services). This leads us to the conclusion that the uncertain economic environment is now a factor that is often and seriously taken into account and created the need for stability in all kinds of co-operation, supply chain management issues included, and that there may be a common belief that the public sector could adopt practices mostly seen in the private sector and mostly commercially motivated. In addition, the overwhelming majority of the women that answered the questionnaire also highly rated the provision of long service commitment, i.e. expressed their preference in a form of stability. This fact comes in line with Gill, Stockard, Johnson and Williams (1987) who stated that women are more likely to be affected by the environment and they seek more information and more time to decide.

The correlation matrix in Figure 1.2. revealed some interesting observations. All correlations are at an average point. The factor ‘’flexible and agile manufacturing’’ is negatively correlated (-0.578) with a CMI supplier being commercially strong and agile manufacturing is found to be negatively associated with a cost-leadership strategy. These two statements seem to introduce a view that this kind of strategy is considered to be very important and that it leads to a supplier/manufacturer being commercially strong while the agile manufacturing increases the risk of financial implications.

This view deviates from prior studies in the supplier selection area where delivery and quality are the most important criteria for strategy and decision-making (Degraeve at al., 2000; Hsu et al., 2006; Ho et al., 2010). Another consequence is the positive average correlation (0.467) of ‘’applying best practices’’ and ‘’develop and diffuse technology’’ since the second one appears to be the step for implementing best practices. The ‘’adoption of commercial buying practices through a restructuring of the relevant frame’’ is positively correlated (0.460) to ’flexible and agile manufacturing’’. This fact depicts the need to allow restructuring of the law and institutional frame for buying practices towards a more flexible and lead us to argue that the persons who filled

in the questionnaires may think that commercial buying practices are more efficient than the public ones in a CMI frame.

Descriptive statistics in Figure 1.3. demonstrated that ‘’Self-Regulation’’ and ‘’Social Pressure’’ were the most important and the less important characteristic, respectively, for a vendor selection team members in a CMI environment. “Self-regulation’’, a characteristic stemming from subject demands that associate with a decision maker’s internal factors, refers to the planning execution and evaluation of a decision on efficient, well-established criteria. This shows that people at key positions in a CMI environment, being responsible for important decisions, deviate from sociable and optimistic decisional tendencies and prefer a more mature and cautious procedure focused more on targets and long-term consequences. Another conclusion would be that, since maturity distinguishes the afore-mentioned procedure (for deciding), it is logical to assume people of a certain age (e.g. above 40) hold positions of power [competence is normally acquired with age (Lizarraga et al., 2009)].

Regarding ‘’Social Pressure’’, we may assume that it does not affect a decision, or the decisions seem to be taken without any external pressure or under the influence of emotions. CMI functions in a demanding frame and the scaling conclusions for ‘’Self-Regulation’’ and ‘’Social Pressure’’ exactly justify its nature. The executive members prefer experience and competence rather than external influences and socially acceptable decisions. According to Figure 1.3., there is a strong negative correlation (-0.640) for these 2 factors. In addition, the matrix shows a weak positive correlation for the factors ‘’Work Pressure’’ and ‘’Social Pressure’’ It can be explained if we take into account that both characteristics have aspects orientated to the compliance of rules, being socially likable by avoiding conflicts, and establish good relationship by favoring the employees/workers.

The regression analysis performed to the BFTs and the significance test of the main effects of the 5 BFTs was implemented at a 10% significance level, for the following hypothesis for each factor of the question:

$H_0 : a_i = 0$ for each i = 0,1,2…5 and α = 1st variable (Desired CMI characteristics) up to 8

$H_A : a_i \neq 0$ for at least one in order to decide whether each factor affects the response variables.

After the data entry, MINITAB produces outputs that reveal the following findings:

- The fit of a regression equation of the factor ‘’Conscientiousness’’ is statistically significant (P value = 0.005) and can interpret 60.6% of its data.
- The fit of a regression equation of the factor ‘’Agreeableness’’ is statistically significant (P value = 0.001) and can interpret 92.6% of its data.
- The fit of a regression equation of the factor ‘’Extraversion’’ is statistically significant (P value = 0.07) and can eventually interpret 84% of its data.
- The fit of a regression equation of the factor ‘’Openness’’ is statistically significant (P value=0.001) and can eventually interpret 72.2% of its data.
- The fit of a regression equation of the factor ‘’Neuroticism’’ is statistically significant (P value=0.001) and can eventually interpret 92.8% of its data.

The predictors/variables that affect the responses at a 10% significance level (p-value=0.1 equals to the observed level of significance) are the following:

- For Conscientiousness are (e) and (g), (i.e. the use of best practices and the mentality to develop and diffuse technology).
- For Agreeableness are (a), (c), (d), (f) and (h).
- For Extraversion are (c), (d), and (g).
- For Openness are (c), (d), (f), and (g).
- For Neuroticism (a), (c), (d), (e).

We also observed that predictors (c) and (d) are the predictors that appear the most, a fact that demonstrates the ongoing importance of the financial crisis in the CMI environment. In addition, a CMI environment is a demanding environment for a supplier as he/she is asked to operate in a ‘’two-mode’’ function and for that the necessary fiscal power should exist in order to be able, for example, to provide long service support for the civilian ‘mode’’ as well as for the military one.

Additionally, the above results show that:

- CMI desired characteristics affect different traits of personality and financially based issues with aspects of moral behavior ability affect mostly traits of their character, i.e. the BFTs.
- The potential high number and/or complexity of the materials may create different characteristics in each procurement attempt since different aspects of personalities are influenced, thus affecting the management's view of the problems inherent to them and requires experienced supply chain management.
- In descriptive statistics, the predictor (h) shows the highest value of the CI mean while in régression analysis it is the predictor with the minimum appearances as a statistically significant factor, i.e it affects the specific response with intensity.

The approach of this paper may be practicable in several real world applications of non-defensive areas as well. It provides objectivity as it combines well established statistical tools with a popular process that benefits from the experience of the persons that answered the questionnaire. It attempts to weld theory with practice under a common denominator, the requirement for a solid and cost-effective supplier selection tool. The overall usefulness of this model could be, besides its applicability in the defence public procurement area by its innovative character, the fact that it provided a guiding tool about which CMI desired characteristics severely influence personality traits. By that, supplier selection procedures may become more customized to the desired profile of the potential supplier through a process that will receive data from these characteristics and will try to enhance the traits that correspond more accurately to the nature of the supplying case at issue. FFM in a CMI environment has proven to be capable of providing an avenue of understanding which aspects of a personality are influenced, and how, by CMI characteristics. Moreover it gave us the opportunity to assess the desired traits a supplier selection team should have, which is an innovation, as most supplier selection paper turn their interest to the potential supplier and not to the team that selects him. Managerial implications of this model lie on its actual results. Managers can conclude that it would only be effective in real world-applications, which are affected by the vagueness of the human thought. Moreover, the model may reduce time for decision-making by simplifying and visualizing information for complex factors like personality factors.

Limitations and Future Research Directions

While this study has provided the frame for the identification of an effective supplier, by no means has it answered all questions concerning this issue and all its sources/references are available unrestricted. An additional limitation for this approach is that it was designed on a statically credible but small sample. Possible future inquiry would be to develop a fuzzy approach and import Multivariate Statistical Analysis Methods, such a Principal Components Analysis to further reduce the predictors under evaluation.

Civilian Military Integration (CMI)

It is defined as the integration process of the defense technology and the industrial base of the private sector in one technological and industrial base. Common technologies, capital, labor force and infrastructure can be used to satisfy defense and commercial needs. In this framework, the questionnaire investigates the desirable characteristics of:

a. A supplier/manufacturer in order to provide items to an organization which is going to operate in a CMI environment.

b. A vendor selection team.

TABLE 1					
A. Evaluate all the desirable characteristics of a CMI supplier/manufacturer	1	2	3	4	5
a. Receptive in on site investigation					
b. Flexible and agile supplying/manufacturing					
c. Financially healthy					
d. Long service commitment					
e. Application of “best practices” of his sector					
f. Bridging of military standards with commercial practices					
g. Develop and diffuse technology					
h. Adoption of commercial buying practices through the reform of legal and statutory frame (different from e.)					

Five Factor Model (FFM)

It is a hierarchical model of personality analysis using five widely-described characteristics. The following table presents a brief analysis of these characteristics:

TABLE 2

Big Five Trait	Characteristics	General Description
Conscientiousness	Being dependable, carefully, thorough responsible, organized, planful, hardworking, achievement oriented and persevering	Inclination to achievement orientation (hardworking and persistent), dependability (responsible and careful), and orderliness (planful and organized)
Extraversion	Being sociable, gregarious, assertive, active, powerful and talkative	Propensity for social orientation (outgoing and gregarious), to be surgent (dominant and ambitious) and active (adventuresome and assertive)
Agreeableness	Being courteous, flexible, trusting, good-natured, cooperative, forgiving, soft hearted and tolerant	Propensity to be cooperative (trusting of others and caring) as well as likeable (good natured, cheerful and gentle)
Openess	Being imaginative, cultured, curious, original, broad-minded, intelligent and artistically sensitive	Disposition to intellectance (philosophical and intellectual) and unconventionality (imaginative, autonomous and nonconforming).
Neuroticism	Being anxious, depressed, angry, embarrassed, emotional, worried and	Tendency to render a lack of positive psychological adjustment

	unsecured	and emotional stability
Source: Wifling and al.,2011		

The following table tries to quantify the five personality characteristics on the basis of the desirable characteristics of a CMI supplier (**a to h in Table 1**) and the Table 2. Based on the above description, fill-in Table 3 using a scale of 1 to 5 (**decimal numbers acceptable**).

TABLE 3	Number in this field indicates the weighting on the profile of the CMI supplier	**a to h are the elements of Table 1:** Put number from 1 to 5 in **all** fields and then put **one number** from 1 to 5 in Big Five trait on the basis of the numbers in the specific elements**.**							
Big Five trait		a.	b.	c.	d.	e.	f.	g.	h.
Conscientiousness									
Extraversion									
Agreeableness

Neuroticism									

In the table in the next page, we want your opinion regarding the desirable characteristics of the members of the vendor selection team in a CMI environment.

4. : Desirable characteristics of the vendor selection team in a CMI environment (How much important is for a member of the team to has this characteristic)	1	2	3	4	5
Time/Money Pressure – TMP (Explained as follows)					
I. Evaluate the available time in which to make my decision					
II. Organize the actions depending on the time.					
III. Act quickly and precisely					
IV. Make sure the established times are respected.					
V. Determine whether costs match the money available.					
VI. Imagine economical options.					
VII. Compare results with time employed.					
VIII. Compare results with money spent					
5. : Desirable characteristics of the vendor selection team in a CMI environment (How much important is for a member of the team to has this characteristic)	1	2	3	4	5
Information and Goals – IG (Explained as follows)					
IX. Study the degree of difficulty of the decision.					
X. Organize the action sequence if the decision is complex.					
XI. Gather as much information as possible about the decision.					
XII. Discover the key information about the decision.					
XIII. Realize which information is lacking.					
XIV. Define the desired goals.					
XV. Analyze whether the goals interfere with each other.					
XVI. Choose the appropriate actions for the decision					
6. : Desirable characteristics of the vendor selection team in a CMI environment (How much important is for a member of the team to has this characteristic)	1	2	3	4	5
Self-Regulation – SR (Explained as follows)					
XVII. Know where I'd like to get to.					
XVIII. Trust my own personal experience					
XIX. Trust my personal capacity to overcome the difficulties					
XX. Plan the actions to be performed					
XXI. Use the strategies that seem the most efficient					
XXII. Monitor all the phases of the decision process					
XXIII. Appraise the achievements gained by the decision					
XXIV. Identify the errors committed in the choice.					
7. : Desirable characteristics of the vendor selection team in a CMI environment (How much important is for a member of the team to has this characteristic)	1	2	3	4	5
Cognition - COG (Explained as follows)					
XXV. Process the information about the issue to be decided					
XXVI. Reflect on the need to make the decision					
XVII. Identify the factors that affect the decision					
XVIII. Recall previously employed decision strategies					
XIX. Solve the problems that arise					
XXX. Relate the highest number of aspects of the decision.					
8 : Desirable characteristics of the vendor selection team in a CMI environment (How much important is for a member of the team to has this characteristic)	1	2	3	4	5
Social Pressure – SCP (Explained as follows)					
XXI. Avoid any conflict with others					
XXII. Make decisions without external pressure					
XIII. Adapt to the pace required by the environment					
XIV. Listen to other people's opinions about the decision					
XXV. Determine whether the consequences of the decision are socially acceptable					
XVI. Determine whether the decision respects social rules					
XVII. Examine whether socio/political ideas affect the decision.					
9. : Desirable characteristics of the vendor selection team in a CMI environment (How much important is for a member of the team to has this characteristic)	1	2	3	4	5
Work Pressure – WKP (Explained as follows)					
XVIII. Discover the relation between work rules and personal interests					
XIX. Follow work rules					
XL. Comply with the demands of the law					
XLI. Take the goals of the business into account					
XLII. Favour the workers					

THANK YOU VERY MUCH FOR YOUR TIME

The Achilles' Heel: Can compliance become the performance lever that developing country public procurement systems need?

Godfrey Mugurusi[§]

Public Procurement and Disposal of Public Assets (PPDA), Uganda

Alex Nduhura
Uganda Management Institute, Uganda

Abstract
Developing country public procurement systems depend significantly on the inherent legal frameworks to assure regulatory compliance. Public procurement compliance mechanisms have a significant effect on procurement performance of most public organizations, yet the practice of assuring public procurement compliance is not the most efficient and effective. Thus, does enforcing compliance in public procurement drive procurement performance or is this a not-worthy activity in developing public procurement systems?
To answer this question, we carried out a mini-survey within the two (2) biggest spend public organizations in Uganda, i.e. the Uganda National Roads Authority and Kampala Capital City Authority. In particular, four (4) susceptible non-compliance areas in the procurement process are studied: - procurement planning, contract management and record keeping and reporting. In addition, the study draws on documentary data from the Public Procurement and Disposal of Public Assets Authority (PPDA) as the regulatory compliance enforcer of the public procurement system in Uganda.
The findings suggest that not all compliance checks conducted into the studied processes, activities, documents etc of public organizations ensure better procurement performance among these organizations. In fact, compliance to procurement planning and contract management regulatory demands had strong implications for procurement performance as compared to record keeping and reporting in the procurement process. These findings infer that although process wide public procurement compliance does not necessarily safeguard better performance, targeted activities in the procurement process can guarantee efficient and effective procurement performance. We conclude that procurement compliance could be the "other" unfamiliar procurement performance that most public procurement systems need for effective service delivery.

Key words: *Public Procurement; Compliance; Procurement performance; Developing Countries*

Introduction
Compliance has traditionally been understood as conformity or obedience to regulations and legislation (Snell, 2004: Gelderman, Ghijsen, & Brugman, 2006: Eyaa & Oluka, 2011), yet like Brandon-Jones (2009) observes: "compliance is notoriously hard to force – individuals invariably find a way round things they dislike": hence an "Achilles heel" for most procurement systems. From a public procurement performance perspective, compliance is very critical as public procurement processes depend on adherence to proper processes and procedures. Surprisingly

[§] Corresponding Author: godfrey.mugurusi@ntnu.no : (47) 91271022

research has paid little attention to the issue of public procurement compliance, despite some academics (e.g. Arrowsmith & Anderson, 2011: Eyaa and Oluka, 2011) suggesting that performance of public procurement organizations significantly depends on how best they comply to procurement controls in place such as regulatory adherence, process requirements and contract audits in line with the legal frameworks in which they function. This therefore begs the question: *To what extent does procurement compliance contribute better procurement performance? Does enforcing compliance in public procurement compel better procurement performance, or is this worthy activity in developing country public procurement systems?* In answering these questions, we hope to contribute by providing an in-depth assessment of the precise effect of public procurement compliance has on performance of public organizations, which for a longtime has been associated with how efficient these organizations are in delivering public services (Agaba and Shipman, 2007)

This paper is organized as follows. We begin with the background, anchoring the problem as one faced by most developing countries. Next, we review the literature about compliance and procurement performance, with particular emphasis on: planning, contract management and record keeping and reporting. Thereafter we present the methods used for data collection and the results. Finally, we discuss and conclude on the results. We briefly present some managerial implications of this paper at the end.

Background – the problem of interest

For most developing countries, the strengthening of public procurement systems has been one of the key reforms prioritized by these governments. In Uganda for example, the Public Procurement and Disposal of Public Assets Act (a piece of legislation which governs the entire public procurement system) specifically emphasizes compliance reporting as a legal obligation for all organizations that procure public goods. The continuous increase in corruption cases and embezzlement of public funds in public agencies is attributed to non-adherence to procurement set laws, rules, guidelines and standards. This according to Mahmood (2010) and Agaba and Shipman, (2007) are typical signs of non-compliance and manipulation of the procurement procedures: the most affected areas in a typical public procurement process are at planning, management and administration of contracts, and record keeping. In Uganda specifically, the reviewed PPDA audit reports from the period 2010 to 2015 show that the high performing public organizations score highly in overall reporting, effective record keeping, procurement planning and contracts management. However, the PPDA compliance report (2015), the IGG Report (2014) and OAG Report (2013) suggest that these high performing organizations conversely scored poorly in procurement performance owing partly to non-compliance to procurement regulations. Essentially suggesting that non-compliance in procurement has a less significant effect on organizational performance, but from an institutional theory perspective (Rowan,1982: Scott 2004), functional performance cannot be detached from organizational performance.

Theoretically we draw on the institutional theory (Scott 2004: Zsidisin, Melnyk, & Ragatz, 2005: Meehan, Ludbrook, & Mason, 2016) partly because the institutional theory highlights the tensions between compliance and achieving efficiency and effectiveness, but mainly we posit that institutional demands for convergent business practices undermine the capacity for specific institutions to be more efficient which in turn affects functional performance.

Compliance in Public procurement and Procurement performance

Compliance is the degree to which an agent adheres to principal's directives, policies and procedures. The Oxford Dictionary (2015) defines "compliance" as the state or fact of according with or meeting rules or standards. Payan and McFarland (2005) referred to compliance as to a

target acting in accordance with an influence attempt from the source. From a public procurement perspective, Gelderman, Ghijsen and Brugman (2006) look at compliance with the procurement rules as a dichotomous variable that is, either one complies or one does not. Abebe (2012) measured the level of compliance by the Best Efficiency Accountability and Transparency Model, which indicates three highly interrelated principles thus, efficiency, accountability and transparency as essential ingredients in procurement compliance.
It is no coincidence therefore that effectiveness and efficiency are central concepts that link compliance and procurement performance. Van Weele (2006) revealed that procurement performance is considered the result of two elements: purchasing effectiveness and purchasing efficiency. Specifically, public organizations know that effectiveness of the use of public funds, including development assistance requires the existence of an adequate national procurement system that meets international standards and that operates not only to deliver public goods/services but also ensures value for money (Asare & Prempeh, 2016). This means that purchasing performance is not an end in itself but a means to effective and efficient control and monitoring of the purchasing function (Lardenoije, Van Raaij, and Van Weele, 2005).

Broadly, procurement looks at obtaining from external sources all goods and services which are necessary for running, maintaining and managing the organization's primary and support activities at the most favorable conditions (Van Weele, 2006). Within this process, Rendon (2008) summarizes the key procurement sub-processes as those to include: procurement planning, solicitation planning, solicitation, source selection, contract administration and contract closeout. Among these, and as earlier mentioned, the most susceptible to non-compliance include: record keeping, procurement planning, procurement reporting and contract management.

Planning is a process that consists of many steps and the bottom line is that planning is not concerned with future decisions but rather with the future impact of decisions made today (Thai, 2004: Robbins, 2001). From a procurement perspective, procurement planning is the primary function that sets the stage for subsequent procurement activities; it fuels and then ignites the engine of the procurement process (Basheka, 2008). It is very critical since non-compliance in procurement planning has wide implications for both functional and organizational governance. Thai (2004) notes that procurement planning enables the identification of major investment expenditures, which in turn facilitates budgetary decision-making.

Like planning, effective contract administration cannot be underestimated (Nullmeier, Wynstra, & van Raaij, 2016). Known also as contract management, this is a continuous process, starting with analysis and evaluation of the customer's inquiry, until contract closure, upon fulfillment of all contractual obligations (Brown & Potoski, 2003). The criticality of this step is how the contractual relationship is documented in the contract, not just the mechanics of administering the contract (Mendoza, 2007). Agreements, models and processes form a useful starting point for assessing whether the contract is underperforming, but communication, trust, flexibility and diplomacy are the key means through which it can be brought back on course.

Finally, procurement records and reporting working in tandem with procurement planning and contract management sub-processes. According to an ARMA International report (2005), organizational records facilitate how employees perform daily transactions. A record is a piece of information created by or received by an organization or business that gives evidence of a business decision or transaction and should be prescribed (Stewart, 2002). As such, the integrity of those records, facilities business continuity and compliance with legislative and regulatory requirements as well as manage risks. The loss of control of records has consequences for not

just employees and but the public since inadequate information systems affect the delivery of public goods.
The same can be said about procurement reporting. Typically, procurement reporting is a mechanism for information exchange between management, purchasers, and internal and external teams about the current procurement situation in the organization (Hunja, 2003). In this respect, suitable key procurement performance indicators as well as appropriate information and recommendations are compiled in a report for each recipient group either monthly/quarterly or spontaneously (Gunasekaran, Patel, & Tirtiroglu, 2001). According to the PPDA Act 2003, the PPDA checks that the method is appropriate to the amount and enters all details into a database. At central government level, the average delay in reporting is 8 months and some organizations fail to report altogether. False reporting maybe detected by field audit. There is a major improvement over the past years but still inadequate to deter concealment of noncompliance or splitting of contracts to put them below the respective thresholds.

We therefore summarily hypothesize that: *compliance to procurement planning positively contributes to better procurement performance (H1), just like compliance to contract management requirements positively contributes to better procurement performance (H2). Because of the link among the two key process activities (planning and contract management), we expect that the compliance to the record keeping and compliance to the procurement reporting requirements positively affects procurement performance (H3 and H4 respectively).*

The correlational research design – a mini survey
According to Sekaran (2004) correlational research is predominately a quantitative method of research that seeks to determine if there is a relationship between the two variables. It typically seeks to identify predictive relationships by using correlations or more sophisticated statistical techniques (Thompson, Diamond, McWilliam, Snyder, & Snyder, 2005). In this case, the two variables understudy is procurement compliance and procurement performance.
The interest of the study are the selected two highest spend and top ranked public sector organizations by performance in Uganda according to the PPDA compliance report (2015). The two are Uganda National Roads Authority (UNRA) and Kampala Capital City Authority (KCCA). Confirmatory documentary data is further collected from PPDA, the procurement regulatory body in Uganda.
The Uganda National Road Authority, UNRA is a public agency in Uganda with 956 employees, and whose mandate is to develop and maintain the national roads network, advise government on general roads policy and contribute to addressing transport concerns, among others. The UNRA budget for construction, maintenance and management of the country's national road network for the financial year 2016/2017 was US$494m (1.8trilion Uganda Shillings) (Uganda's 2016/2017 budget report). KCCA on the other hand, Kampala Capital City Authority (KCCA) is the government agency responsible for governance of the Capital City Kampala on behalf of the central government. As of 2016, KCCA had 1300 employees. The Authority, whose budget for the financial year 2016/2017 was US$154 million (561 Billion Uganda Shillings) (Uganda's 2016/2017 budget report), is mandated to provide public services following the public procurement guidelines.
The procurement activities of the above 2 organizations are governed under the PPDA Act of 2003 and amended in 2014: the same law that establishes the Public Procurement and Disposal of Public Assets Authority – the PPDA. The PPDA is the procurement regulatory body in Uganda, whose many roles is to among the many roles is to monitor compliance of procurement and disposal organizations that are publically funded.

The targeted study population was employees involved in the procurement function in the 2 organizations, who included the procurement department staff, administrative and technical staff, and accounting and finance staff who in total are involved in a typical procurement process (Table I). The survey also targeted key decision makers from PPDAs compliance department for confirmatory data.

Using both simple random and purposive sampling techniques, the sample for the study was 104 respondents. We draw on predominately on a mini-survey between the two organizations (UNRA and KCCA) and supplement this with selected interviews and documentary data from PPDA.

The mini-survey containing a set of questions on defined variables under study was administrated on a self-administered basis. The target of 96 respondents, only 65 respondents returned the questionnaires representing 68% response rate. This is an acceptable response rate for social science research according to Nulty (2008). In order to overcome the challenges of questionnaire surveys, we also considered secondary documentary data to (dis)confirm the quantitative data. Accordingly to Trautrims, Grant, Cunliffe & Wong (2012), data triangulation is important not just to give more insights into the phenomenon, but also ensures that inconsistencies in data sets are more easily identified and aligned.

Table I: Summary of Sample size and Sampling Techniques

Category	**UNRA**	**KCCA**	**Targeted population**	**Sample Size**	**Sampling Techniques**
Procurement department	11	14	25	24	Simple random**
Accounting & finance dept.	14	10	24	23	
Administrators/Technical staff	27	28	55	49	
Total			***104***	***96***	
PPDA Compliance Department			10	8	Purposive
Total			***114***	***104***	

** 5% sampling error, and 95% confidence level

The Results – Quantitative Data

The questionnaire asked respondents to rank their responses to a series of statements in the mini-survey along a 5– point Likert scale ranging from 5 – strongly agree; 4 – agree; 3 – neutral, 2-disagree; and 1 – strongly disagree. The statements asked around the four (4) susceptible non-compliance areas in the procurement process are studied, namely procurement planning, contract management and record keeping and reporting in relation to procurement performance of public organization. The descriptive results have not been included, but hereafter the results of the correlation analysis and are regression analysis descriptively presented.

Table II: Correlation Analysis: Compliance to procurement planning requirements and procurement performance

We assessed the procurement planning practices of the sampled organizations in relation to their overall procurement performance (H1). The coefficient result in Table II below suggests that the correlation between compliance to procurement planning requirements and procurement performance is a statistically significant positive correlation (Pearson correlation r=0.642, p-value<0.01). This therefore implies that the sampled public organizations procurement planning practices significantly influence their overall procurement performance.

		Procurement Planning	**Procurement Performance**
Procurement Planning	Pearson Correlation	1	.642**
	Sig. (2-tailed)		.000

	N	62	62
Procurement Performance	Pearson Correlation	.642**	1
	Sig. (2-tailed)	.000	
	N	62	62

**. Correlation is significant at the 0.01 level (2-tailed).

The regression analysis model between compliance to procurement planning and performance

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.642[a]	.412	.401	.56536	.412	39.899	1	57	.000

a. Predictors: (Constant), Procurement Planning

The regression analysis model above confirms the findings in Table II on the effect compliance to procurement planning has on procurement performance but yet that effect on procurement performance can only be explained by compliance to procurement planning requirements for up to 41 % (R square of 0.412).

Table III: Correlation Analysis: compliance to contract management requirements and procurement performance

We assessed the contract management practices of the sampled organizations in relation to their overall procurement performance (H2). The coefficient result in Table III below suggests that the correlation between compliance to contract management requirements and procurement performance is a statistically significant positive correlation (Pearson correlation r=0.629, p-value<0.01). This therefore implies that the sampled public organizations contract management contract significantly influence their overall procurement performance.

		Contract management	**Procurement Performance**
Contract management	Pearson Correlation	1	.629**
	Sig. (2-tailed)		.000
	N	59	59
Procurement Performance	Pearson Correlation	.629**	1
	Sig. (2-tailed)	.000	
	N	59	59

**. Correlation is significant at the 0.01 level (2-tailed).

The regression analysis model between compliance to contract management requirements and procurement performance

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.629[a]	.495	.385	.57327	.395	37.243	1	57	.000

a. Predictors: (Constant), Contract management

The regression analysis model above confirms the effect compliance to contract management requirements has on procurement performance but that effect on procurement performance can

only be explained by compliance to procurement reporting requirements for up to 50% (R square of .495).

Table IV: Correlation Analysis: compliance to record keeping requirements and procurement performance

We assessed the record keeping behavior of the sampled organizations in relation to their overall procurement performance (H3). The coefficient result in Table IV below suggests that the correlation between record keeping requirements and procurement performance is not statistically significant (p-value>0.01). This therefore implies that the sampled public organizations record keeping behavior does not significantly influence their overall procurement performance.

		Record Keeping	**Procurement Performance**
Record Keeping	Pearson Correlation	1	.207**
	Sig. (2-tailed)		.115
	N	62	62
Procurement Performance	Pearson Correlation	.207**	1
	Sig. (2-tailed)	.115	
	N	62	62

**. Correlation is significant at the 0.01 level (2-tailed).

Table V: Correlation Analysis: compliance to procurement reporting requirements and procurement performance

We assessed the procurement reporting behavior of the sampled organizations in relation to their overall procurement performance (H4). The coefficient result in Table V below suggests that the correlation between compliance to procurement reporting requirements and procurement performance is a statistically moderate correlation (Pearson correlation r=0.473, p-value<0.01). This therefore implies that the sampled public organizations procurement reporting behavior has little influence over their overall procurement performance.

		Procurement Reporting	Procurement Performance
Procurement Reporting	Pearson Correlation	1	.473**
	Sig. (2-tailed)		.000
	N	62	62
Procurement Performance	Pearson Correlation	.473**	1
	Sig. (2-tailed)	.000	
	N	62	62

**. Correlation is significant at the 0.01 level (2-tailed).

The regression analysis model between compliance to procurement reporting and procurement performance

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.473[a]	.224	.210	.64948	.224	16.422	1	57	.000

a. Predictors: (Constant), Reporting

The regression analysis model above confirms low effect compliance to procurement reporting has on procurement performance but yet that effect on procurement performance can only be explained by compliance to procurement reporting requirements for up to 22% (R square of 0.224).

Results – the Secondary sources

This section presents results from the review of several documents from the PPDA predominantly guided by the research questions of the study.

Table VI: Document Review Analysis

No.	Document	Compliance to:			
		Procurement Planning Requirements and Procurement Performance	**Contract Management Requirements and Procurement Performance**	**Procurement Reporting Requirements and Procurement Performance**	**Record Keeping Requirements and Procurement Performance**
1.	KCCA Audit and performance Report FY 2015/16	There were delays in confirmation of availability of funds for two procurements. 18% of the total contracts were not implemented according to market price which implies a gap in estimation at the time of procurement planning	65% of the procurements sampled were conducted in accordance with the planned timelines. The Entity completed 75% of the sampled procurements within the contractual completion time. 85% were awarded within the cost estimate in the procurement plan	The procurement plan and 100% of the monthly reports were submitted to the Authority.	The Procurement and Disposal Unit maintained records pertaining to pre-contract; however, contracts pertaining to post contract management were not always availed to the PDU to maintain on the respective procurement action file.
2.	UNRA Audit Report FY 2015/16	The Entity conducted procurements outside the Procurement Plan There were variances in estimates between the approved estimates in the Procurement Plan and the estimates indicated on the requisition. There were variances between the estimated and final contract prices Delays at initiation that lead to delays in the procurement process and delayed service delivery The Entity implemented 51.4% of its procurement budget, which implies that the Entity did not fully implement its procurement plan.	The audit revealed unjustified delays at the contracting and contract management stage Laxity by the contract managers to invoke the penalties on delays provided in the Special Conditions of Contract. 8% of the total contracts were not implemented according to market price which implies a gap in estimation at the time of procurement planning	The procurement plan and 100% of the monthly reports were submitted to the Authority Failure to report procurement data into the performance system makes it difficult for the entity to assess their individual performance and for the Authority to identify and recommend targeted actions towards the key performance areas under PPMS that are weak and require additional support. .	Lack of records for some procurements evidencing payment to the PDU from the Finance department for maintaining on file.

3.	PPDA Annual progress report. FY 2015/16	6% of the PDEs conducted procurements outside the procurement plan 25% of the Organizations did not follow the schedules set out in their procurement plans which leads to late initiation of procurements or emergency/direct procurements There was increase in unimplemented planning recommendations mainly related to poor estimation of Procurement requirements. Poor absorption of procurement budgets due to poor level of planning by Organizations as well as late initiation of procurements	Delays in completion of contracts lead to delays in service delivery. The Authority observed that delays in evaluation of progress reports and payment result in delayed contractor performance as providers end up with insufficient funds to implement projects. The Authority also noted that Organizations are not implementing recommendations related to contract award and implementation, which include poor contract monitoring, appointment of contract managers, delayed payment of providers and preparation of the contract management reports.	76% of organizations submitted procurement reports.90% submitted procurement plans The non-compliance to submission of procurement plans is partly as a result of some new PDEs in the that did not have their procurement structures fully filled. 52% of the PDEs did not submit their reports on time leading to omnibus submissions 15% of the PDEs submitted incomplete procurement plans Submission of procurement plans and reports should improve with the roll out of the Government Procurement Portal as it creates a platform for PDEs to post their Procurement plans online.	9% of the unimplemented audit recommendations were related to record keeping especially contract management records and payment records.

Source: *Secondary data*

Discussion and Conclusion

The results reveal a rather interesting dimension which forms our discussion going forward. That, not all procurement process activities are integral to procurement performance. However, some of these activities enable of the process deliver efficient outcomes. We know from a Harland, Telgen, & Callender, (2013) and Brandmeier & Rupp (2010) that by leveraging key process activities, procurement can achieve its performance related goals, which in the public setting include: value for money, managing cost and risk, meeting socioeconomic targets etc.

We purposively studied and tested 4 key process levers that included planning, contracts management, record keeping and reporting, which according to Thai (2001) and Amemba, Nyaboke, Osoro, & Mburu (2013) should are integral process activities that have an impact on value for money.

Table VII: Hypothesis testing summary

Hypothesis		**Result**
H1	Procurement planning → (+) procurement performance	Supported
H2	Contract management →(+) procurement performance	Supported
H3	Record keeping→ (+) procurement performance	Not supported
H4	Procurement reporting→ (+) procurement performance	Not supported

As the results suggest in Table VII, public entity's compliance to record keeping and reporting requirements has little effect on the performance of the procuring organizations. This however should not suggest that record keeping and reporting are any less significantly important compared to other sub-processes included in the survey. The lack of action procurement action files has significant impact on how a procurement entity is rated. Incomplete records affects the audit trail making it difficult for oversight institutions for example the PPDA to assess the Entity's performance. The study revealed that lack of reporting on procurement information affects the entity's ability to monitor their individual performance. Without reports, the Entity and regulatory body cannot identify and recommend targeted actions towards improving the key performance areas that are weak and require additional support. Poor record keeping affects the ability by the user departments of the PDUs to carry out effective contract monitoring (Amemba et al 2013: Manavazhi & Adhikari, 2002.).

The results confirm that both planning and contract management are central aspects in public procurement performance. Basheka (2008) concurs that procurement planning is the primary function that sets the stage for subsequent procurement activities According to Bonser & Wu (2001) planning is an essential aspect of public procurement performance allows procurement organizations prioritize resources for effective service delivery. Basheka (2008) suggests that through planning, the procurement function is able to manage time effectively by estimate the time required to complete the procurement process and award contract for each requirement. This can be a basis for combining or dividing procurement requirements into different contract packages to allow effective contract administration (Brown & Potoski, 2003).

In addition, the PPDA Act (2003) provides that prior to the commencement of a procurement process an Accounting Officer should undertake an assessment of the market price of the supplies, services or of the unit costs of the works in respect of which the procurement is to be made. Such controls, including one that authorizes an Accounting Officer not sign a contract,

where the price quoted by the bidder is higher than the market price established by the Accounting Officer, suggest the important this sub process has on the entire procurement cycle. Therefore, compliance to such provisions tends to lead to improved procurement performance in terms of procurements conducted within the planned budgets and timelines and contracts implemented under clearly approved terms.

In addition, the role of effective contracts management cannot be underestimated. The correlation between compliance to contract management requirements and procurement performance was positive. The regression analysis indicates procurement performance is explained by compliance to procurement planning up to 50%. According to Mendoza (2007), the overriding rather fundamental aim of contract administration is to ensure the delivery of cost effective and reliable service at an agreed price and standard. The study revealed that the major challenge in the area of contract management is unjustified delays at the contracting and contract management stage that in the long run leads to delays in service delivery. The findings further reveal that the poor performance of appointed contract managers leads to poor quality of the conducted procurements.

So, as we demonstrate using a mini survey carried out in Uganda, compliance to key procurement sub-processes can provide for better procurement performance in most developing country procurement systems. But to what extent can procurement compliance be considered as "another lever" for procurement performance in a public sector performance?

Bedi (2017) suggested that levers are "a set of actions that enable procurement to achieve its goals". Using supply related concepts, Bedi (2017) further suggested that procurement levers are mainly 4: price-based levers, total cost levers, demand management levers and supply base levers. In public sector procurement setting, these levers are embedded activities in the procurement process (Thai, 2001: Hunja, 2003).

We argued earlier and as shown by the results, that compliance to procurement process requirements can be leveraged for better performance. This evidently suggested that compliance is public procurement performance lever. Tukamuhabwa (2012) and Gesuka & Namusonge (2013) show that the impact of non-compliance has significant impact on the entire procurement system in terms of poor service delivery to tax payers and no value for money in public projects.

The evidence presented in the paper, although not thoroughly conclusive, it appears to suggest that procurement compliance is a fundamental lever to ensure the efficient and effective execution of the procurement process and as such better procurement performance in the long-term.

Implications for managerial practice

Despite its methodical and structural challenges, this paper highlights a number of implications which public procurement organizations could consider going forward. Evidence has shown limited interest in procurement compliance, which is currently at the periphery of most developing world public procurement systems. Here, we demonstrate that compliance is key to better performance: in particular compliance within planning and contracts management.

As part of the efforts to plan for institutional procurement needs, most countries have resorted to using their annual procurement plans as a possible way of managing few resources. Yet these are not effectively monitored to ensure compliance (Mahmood, 2010). The reforms towards

electronic information systems should reduce the amount of manual records required and improve on the monitoring of the procurements. Moreover, such electronic management information systems would help public organizations to improve contract management, the reporting and monitoring of procurement activities.

STUDENTS' PERCEPTIONS OF THE SUPPLY CHAIN STUDENT ASSOCIATION AT THE UNIVERSITY OF KWA-ZULU-NATAL

Micheline Naude and Nomalizo Dyili

University of KwaZulu-Natal, South Africa

Summary

This paper uses exploratory and descriptive research approaches to provide insight into an initiative, introduced by two third year supply chain management students at the University of KwaZulu-Natal to enhance their supply chain learning.

South Africa experiences various skills shortages. Suitably skilled staff in Supply Chain Management is recognised as a scarce skill in the National Scarce Skills List. Even though the number of students enrolling for supply chain management modules is increasing, more is needed to close this skills gap.

The purpose of this paper is to provide insight into students' perceptions of the Supply Chain Student Association at UKZN. Data was gathered through a structured questionnaire administered to students who are members of the Supply Chain Student Association.

The findings reveal that the main factors contributing to the success of the association, include seminars, the creation of interaction and site visits. The main factors limiting the success and effectiveness of the association, include lack of communication and financing.

Key Words: Supply Chain Student Association; Supply Chain Management; supply chain learning initiatives.

Submission category: Educational Paper

Introduction

Supply chains are growing in significance as businesses realise that supply chains are important change agents of the future. While both Dell and Wall-Mart have become successful because of their business model the increasing effective use of the supply chain has been the enabler to allow for this (Fawcett, Ellram and Ogden, 2014). Major trends in Supply Chain Management include: increased global competition, more demanding customers, changing customer demands, high-quality innovative products, and globalisation (Bozarth and Handfield, 2013; Fawcett et al, 2014; Sanders, 2012). This has increased the complexity of supply chains which, in turn, has increased the need for skilled staff in the field of Supply Chain Management.

In the South African publication *National Scarce Skills List: Top 100 Occupations in Demand*, suitably skilled staff in Supply Chain Management at operational and management level are listed (Government Gazette 380: 2014). The increasing demand and lagging supply is considered to be a challenge for stakeholders in the business environment. The identification of current and future skills gaps are necessary as this informs tertiary and training institutions as to what education and training should be provided to meet the needs of society and the economy.

Gattorna (2006) notes "*It is people who drive the supply chain, both inside and outside your business, not hard assets or technology. You can't do **anything** without the right people*". Mangan, Lalwani, Butcher and Javadpour (2012) define these "right people" as those with the right skills and knowledge to ensure that supply chain strategies will be carried out effectively and efficiently. Thus suitably educated, skilled and trained supply chain practitioners are required for businesses to succeed with functional knowledge being a base requirement for these supply chain managers of the future.

In 2014, two third year supply chain students at the University of KwaZulu-Natal, Westville Campus, noted that students at other higher learning institutions in South Africa had created students associations. These were based on the premise of their being a gap between a students' academic knowledge and the requisite industry knowledge. They identified a similar gap in their own institution and wanted to explore the opportunities. As a result the Supply Chain Student Association (SCSA) was founded.

The mission of the SCSA is to garner knowledge through research into industry-specific issues to improve students' practical knowledge of supply chain management. In order to achieve this, the SCSA holds two workshops per semester, two seminars per semester, monthly general meetings and organises two factory visits per year.

Within this context, the research question of this study is:

> *Does the Supply Chain Student Association, at UKZN, benefit students and what are the benefits and limiting factors of this Association?*

Against this background, the aim of this study is to provide an overview of the association, determine the benefits and limiting factors of this association, and whether it has been successful in attracting students.

This paper consists of a brief background of the UKZN, insight into Supply Chain Management modules offered at second, third and fourth year level, the research methods used for this research, the findings and concludes with recommendations for further study.

Background of the University of KwaZulu-Natal

The University of KwaZulu-Natal was formed on 1 January 2004 as a result of the merger between the University of Durban-Westville and the University of Natal. The University of KwaZulu-Natal has five campuses. Three of the campuses are based in Durban and these are: Westville Campus (which houses the office of the Vice-Chancellor, the offices of Executive members and University-wide administrative divisions); Howard College; and the Medical School. The other two campuses are Edgewood Campus (based in Pinetown) and Pietermaritzburg Campus (based in Pietermaritzburg). Supply Chain modules are offered at Westville and Pietermaritzburg Campuses only.

The study that forms the basis of this document took place in the School of Management, Information Technology and Governance at Westville campus during the 2016 academic year.

Supply Chain Management Majors at UKZN

One of the primary goals of the Higher Education Qualifications Framework (HEQF) in South Africa is to "facilitate the education of graduates who will contribute to the social, cultural and economic development of the country and participate successfully in the global economy and knowledge society" (Republic of South Africa, 2007). In this context, Supply Chain Management education needs to develop professionals that can apply their skills in industry. Therefore, industry needs have to be determined as starting point to develop curriculums.

UKZN offers four supply chain major modules at third year level as part of a Bachelor of Commerce Degree, for students who intend to major in Supply Chain Management. These major modules are: Purchasing Management; Operations Management; Logistics Management; and Special Topics in Supply Chain Management. In order to register for these modules, the prerequisite module is the Introduction to Operations Management, offered at second year level.

UKZN also offers a fourth year degree, namely the Bachelor of Commerce Honours Degree, a research Masters Degree and a PHD in Supply Chain management. Table 1, provides the students numbers at the two campuses at UKZN registered for supply chain management at Undergraduate and Honours level between 2014 and 2017.

Table 1 refers - of note, in 2015, is the decrease in the numbers for the third year classes at the Westville Campus. This had an effect on the honours class intake in 2016. Besides that, the student numbers between 2015, 2016 and 2017 have shown an overall increase.

Table 1: Student numbers Pietermaritzburg and Westwille Campuses

Research Project	12	12	11		101	104	58	102

* This module will no longer be offered in 2018.

**This module is currently only offered on the Westville campus, as there is no capacity to offer it on the PMB campus.

Research Methods

A qualitative methodological approach was followed. This study is exploratory and data was collected through administering a questionnaire to the 106 members of the SCSA The questionnaire consisted of open-ended questions. The purpose of the questionnaire was to identify the benefits and limiting factors of this Association and whether it has been successful in attracting students to its ranks. Prior to empirical data collection, a letter of introduction was sent to the students asking them to participate in this study. Respondents were made aware of the purpose of the research and assured of their anonymity with participation in the study being voluntary. The response rate was 35.85% (38 out of 106 questionnaires). NVivo was used to analyse the qualitative data. The findings of the study are explained next.

Findings of the Study

Profile of the respondents (N=38)

- The respondents ranged between the ages of 18 and 25. The average age of respondents was 22 years.
- Thirty-one of the respondents were female and seven were male.
- The demographic representation consisted of 28 African, 9 Indian and 1 Coloured respondents.
- The respondents indicated that IsiZulu (25), English (3), Xhosa (2), IsiKhosa (1), IsiXhosa (1), Saiswati (1), Xitsonga (1) is their home language.
- Of the third year respondents 17 were registered for the Bachelor of Commerce degree, 1 for the Bachelor of Business Science degree and 6 for other degrees. Of the fourth year

respondents, 10 were registered for the Bachelor of Commerce degree and 1 for the Business Science degree.

Overview and motivation for setting up the Supply Chain Student Association (SCSA)

The SCSA was founded in 2014. It was an initiative by two third year students, who identified a gap between students' academic knowledge and broader industry knowledge. The founders' initial aim was to endeavour to bridge this gap by having two seminars per semester and inviting business representatives and past UKZN students working in the field of supply chain management to provide guest lectures.

The SCSA has a working committee that consists of six members, and 106 student members. Members include second year, third year and fourth year students registered for Supply Chain Management. This is an indicator of how receptive students are to this initiative and that the SCSA may well continue in the long term.

Does the SCSA benefit students?

Of the respondents (N=38), 36 indicated that the SCSA benefits them whereas 2 indicated that it does benefit them at all.

Main factors contributing to the success of the SCSA

Figure 1 presents the main factors that make the SCSA successful. It consists of eight nodes, of which seminars, site visits and creating interaction are the largest nodes.

Figure 1: Main Success Factors

Seminars

The findings reveal that 'seminars' is the **most important** category that contributes to the SCSA. The following are selected comments pertaining to seminars made by respondents:

"Seminars held by SCSA allow us to meet and network with people/mentors that have extensive knowledge."

"It creates an awareness about difficulties and opportunities by doing fieldtrips and seminars that create interaction between students and companies."

"Seminars that are regularly held, are most important because we can learn how SC is applied in the workplace."

"Their seminars and workshops are very informative. They are challenging and intellectually stimulating."

"It deals with issues that students (3rd year) are able to relate to and information gained at seminars and workshops helps with material from the classroom."

Create interaction

The findings reveal that 'create interaction' is the **second most important** category that contributes to the SCSA. The following are comments pertaining to seminars made by respondents:

"They engage with the industry that they will work at in the future merging reality and theory."

"It is engaging and informative."

"They help students engage in practical activities."

"It engages with students and helps prepare them for the job market by helping them with practical aspect of the operations field."

"The working together of the different sub committees in the association."

"It is interactive and encourages students to join and become a part of merging theory with reality. This makes supply chain more interesting and broaden views and understanding of supply chain."

Site visits

The findings reveal that 'site visits' is the **third most important** category that contributes to the SCSA.

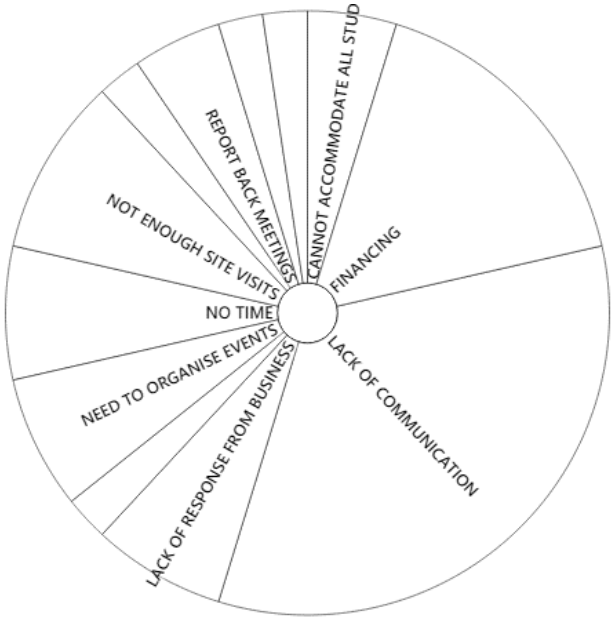
Figure 2 is a word cloud output on the various comments made by respondents on the main success factors of the SCSA. The larger terms/words are the most frequently mentioned.

Figure 2: Word Cloud output of various comments – main success factors of the SCSA

Main factors that limit the success of the SCSA

Figure 3 presents the main factors that limit the success of SCSA. It consists of twelve nodes, of which lack of communication and financing are the largest nodes.

Figure 3: Main limiting factors



Communication

The findings reveal that 'communication' is the most prominent limiting factor - the largest node. Some pertinent comments made by respondents pertaining to communication include:

> *"Lack of communication."*
>
> *"They need to make more students aware so that it can continue in the coming years."*
>
> *"Availability of information about itself."*
>
> *"Not enough people know about it."*
>
> *"They have low exposure."*
>
> *"It would have been more helpful to receive notification via emails sooner."*
>
> *"It is not marketed well in our camps."*
>
> *"Not many people know about the association."*
>
> *"The 2nd years are not exposed to the organisation. They know about its existence but not what it is all about."*

Financing

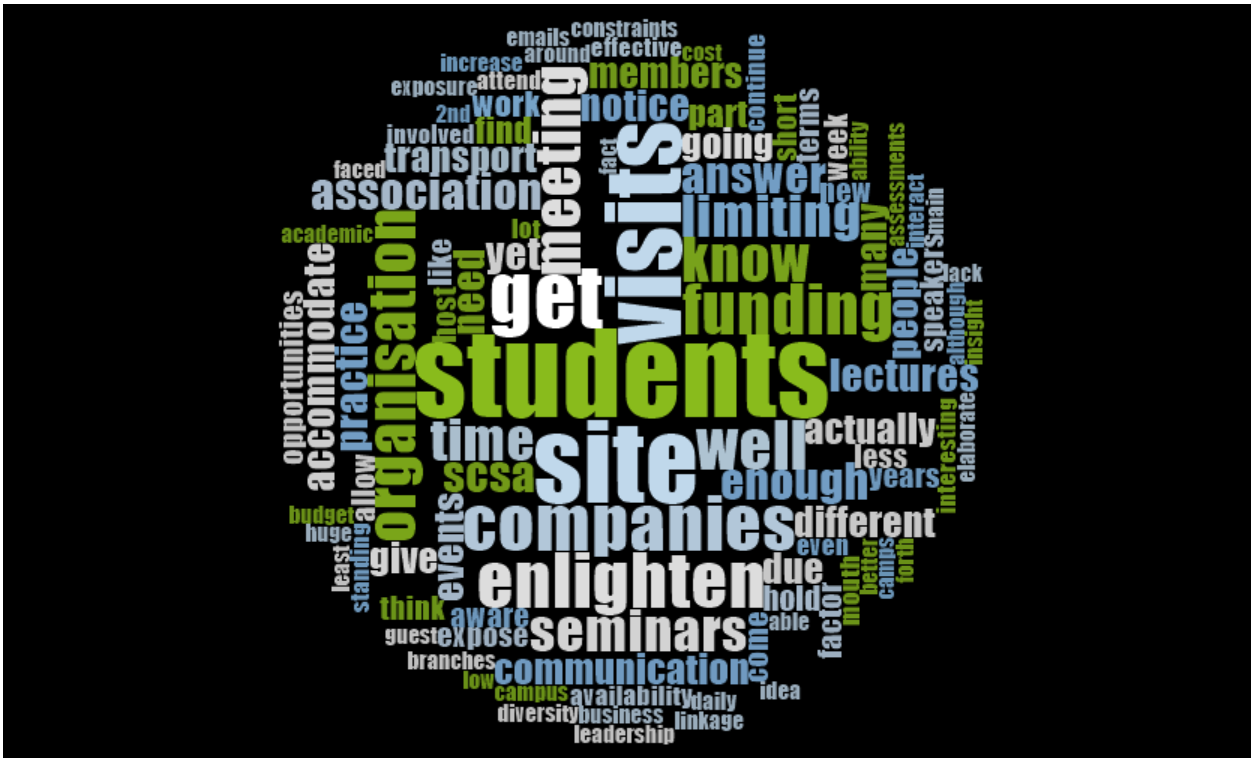
The findings reveal that 'financing' is the second most prominent limiting factor – the second largest node.

Some pertinent statements relevant to finance made by respondents are as follows:

> *"Less recognition by the finance department limits site visits for students."*
>
> *"They should get more funding to be able to hold more seminars and site visits as well as increase their communication and get more companies involved as guest speakers to enlighten us."*
>
> *"Not having enough funding to host as many seminars as possible to enlighten us and give insight from different companies to students."*

Figure 4 is a word cloud output on the various comments made by respondents on the main factors that limit the success of the SCSA. The larger terms/words are the most frequently mentioned.

Figure 4: Word Clout output of various comments – main factors that limit the success of the SCSA



Conclusion

The aim of this study was to provide an overview of the supply chain student association, and provide insight into the benefits and limiting factors of this association from the student's perspective and whether it has been successful in attracting students. However, the insights of the study should be viewed in terms of the limitations discussed.

The findings reveal that the main factors contributing to the success of the association, include seminars, the creation of interaction and site visits. The main factors limiting the success and effectiveness of the association, include lack of communication and financing.

It is anticipated that this paper will encourage the sharing of information about and of possible networking opportunities of other initiatives by students in the field of Supply Chain Management at tertiary level. This paper lays the foundation of a longitudinal study to determine the value added by the SCSA and the benefits and limiting factors thereof for the members going forward into the future. The SCSA is in its initial stages, having been founded in 2014, and its future sustainability will be monitored as well as the achievement of the objectives set by its founding members. It is also recommended that the establishment of a similar association be initiated on the Pietermaritzburg campus.

Closing the circle: On the impact of intrapreneurship on circular purchasing

Petra Neessen[a], Marjolein Caniëls[a], Bart Vos[b], Jeroen de Jong[a]

Summary
The role of purchasers is changing in face of the challenge to adjust circular practices in the broader context of a transition towards a circular economy. Their role is changing towards a more strategic role in which purchasers should behave as intrapreneurs. Although the literature on intrapreneurship shows a relationship between intrapreneurial behavior and the development of innovations, the effect on circular purchasing has not been investigated. This survey research aims to clarify the relationship between intrapreneurship of purchasers and circular purchasing. In addition, we examine how this relationship is influenced by organizational citizenship behavior and level of function.

Keywords: intrapreneurship, circular purchasing, Organisational citizenship behaviour towards the environment (OCBE)
Submission category: working paper

Introduction

The transition towards a more circular economy is becoming relevant for an increasing group of organisations. Circular economy is defined as 'an industrial system that is restorative or regenerative by intention and design' (World economic Forum, 2015, p.15). The idea behind this is that linear systems are not sustainable. However, this transition is by no means an easy one. Not only is it often unclear what circular economy and circular purchasing entails, but moving away from existing structures is a difficult undertaking which requires an approach that differs from current practice (Ghisellini, Cialani and Ulgiati, 2016). Purchasers can play a major role in this trajectory, but in doing so purchasers need to have a more strategic focus instead of an operational focus (Crespin-Mazet and Dontenwill, 2012; Giunipero, Denslow & El Tantawy, 2005)

In literature, intrapreneurship is linked to innovative, proactive and risk-taking behaviour of individual employees that result in new products, processes and ventures (Antoncic and Hirsch 2003; Rigtering, 2013). It is referred to as entrepreneurship within an existing organisation (Antoncic and Hirsch, 2003). Based on findings from a literature review (Neessen, Caniëls, Vos & De Jong, 2017), a definition of intrapreneurship is proposed that includes the behavioural aspects of intrapreneurial employees and emphasises the multilevel nature of intrapreneurship: "Intrapreneurship is a process whereby employee(s) recognize and exploit opportunities by being innovative, proactive and by taking risks, in order for the organisation to create new products, processes and services, initiate self-renewal or venture new businesses to enhance competitiveness and performance of the organisation."

Intrapreneurship is a construct that connects the actions of an individual to positives outcomes for the individual, team and organisation. Intrapreneurship is a concept that directly links the

employee with the organisation and is therefore distinct from entrepreneurship (Neessen et al., 2017). The employee always acts within the structure of an existing organisation. Neessen et al. (2017) argue that the most commonly used combination of intrapreneurial behaviours, e.g. innovativeness, proactiveness and risk-taking, should be complemented with the constructs of internal and external networking and opportunity recognition.

Becoming more intrapreneurial is expected to increase the impact of purchasers on the level of circular purchasing within their organisation. However, it is not clear to what extent purchasers show intrapreneurial behaviour, because their role within organisations is changing. Furthermore, in the literature intrapreneurship has been linked to developing new products, services and ventures, but not specifically to conducting circular purchasing (Ağca, Topal and Kaya, 2012; Rigtering 2013). Therefore, this study aims to examine the relationship between the level of intrapreneurship of purchasers and the level of circular purchasing.

Circular economy and circular purchasing

Circular economy is a model that is an alternative to the make-take-waste model. The later model has several negative effects on sustainability of the natural system and therefor the sustainability of the economic model (Ghisellini et al., 2016). Circular economy strives to close the circle of materials and goods and eliminate waste as much as possible (Murray, Skene and Haynes, 2017). Still, it should be noted that designing and purchasing in a circular economy requires more than just waste management. A broader system perspective encompasses the entire life cycle of products and processes and its interaction with the environment and the economy. Circular economy is concerned with the creation of self-sustaining production systems (Genovese, Acquaye, Figueroa and Koh, 2017; Ghisellini et al., 2016). Ghisellini et al. (2016) reviewed the literature on circular economy and they found the following seven principles of circular economy, each with its specific challenges: Design, reduction, reuse, recycle, reclassification of materials and nutrients so that materials are designed to be reused at the end of the cycle or safely returned to the ecosystem, and renewable energy as the energy source. When designing products and its purchasing processes, innovative concepts alone are not enough. Actors involved should also be innovative in their work, whether these are purchasing professionals, R&D professionals or sales persons (Ghisellini et al., 2016). For example, purchasing professionals and supply chain managers need to work together with suppliers to gain access to the right materials and with end-users to ensure that the products or services can be reused or recycled (Genovese et al., 2017).

Purchasing professionals increasingly have a strategic position within the organisation to contribute to the bottom-up transition towards a more circular economy (Genovese et al., 2017). However, there has not been a lot of literature connecting circular economy with the role of purchasers, whereas, as mentioned before, the circular economy concept entails a new way of looking at products and requires a different design in which the principle of reuse, recycle and reduction are included (Ghisellini et al., 2016). New product development (NPD) might be essential in the transition towards a circular economy. Research shows that including purchasing professionals in the new product development results in a higher NPD performance (Nijssen, Biemans, de Kort, 2002). Hence, we focus on the purchasers and their (changing) role towards a more circular way of purchasing (Crespin-Mazet and Dontenwill, 2012; Giunipero et al., 2005).

Intrapreneurship and circular purchasing

The transition toward circular purchasing and the strategic role of purchasers within this transition require different behaviour from purchasers. They need to be innovative in the design of the product (in collaboration with R&D) and they need to be able to network with the

different actors involved, both inside and outside the organisation. This transition also involves some risks and not everyone in the market will be willing to changes. This implies that risk-taking and pro-activeness are behaviour needed for purchasers. These types of behaviour are all dimensions of intrapreneurship. In general, intrapreneurship is found to be positively related to performance (Baggen, Lans, Biemans, Kampen and Mulder, 2016). More specifically, intrapreneurship of purchasers is also positively related to the relationship quality between internal consumers and suppliers (Steward, Wu and Hartley, 2010). We thus expect that intrapreneurial purchasers will be able to contribute to the transition towards a circular economy, resulting in our first hypothesis:

> *Hypothesis 1: A higher level of intrapreneurship of the purchaser results in a higher level of circular purchasing*

Green behaviour, intrapreneurship and circular purchasing

Since intrapreneurship is linked to innovation, but not necessary green innovation, we expect that green behaviour of the purchaser also influences the percentage of circular purchasing. Organisational citizenship behaviour towards the environment (OCBE) is a type of green behaviour that is related to behaviour at work. OCBE is defined as voluntary and unrewarded environmental actions that go above and beyond the job requirements in an organisational setting (Temminck, Mearns and Fruhen, 2015). We hypothesize that purchasers with a high level of OCBE also have a higher percentage of circular purchasing (hypothesis 2).

In addition, some researchers point out that organisations need champions or 'green intrapreneurs' to increase their environmental performance and to assure that green initiatives create actual change in a product or a process (Andersson and Bateman 2000; Boiral and Paillé, 2012). In that line of thought, we expect that that intrapreneurship mediates the relationship between OCBE and circular purchasing (hypothesis 3).

> *Hypothesis 2: A higher level of OCBE of the purchaser results in a higher level or circular purchasing.*

> *Hypothesis 3: The level of intrapreneurship mediates the relationship between OCBE and circular purchasing.*

Methodology

An electronic survey was sent to purchasers in the Netherlands and Flanders (Belgium). Purchasers were contacted by a mailing through the Dutch and Belgian Purchasing Associations and via a message on a Dutch forum for purchasing professionals. In addition, the members of a Dutch group of purchasers of large companies were asked to promote this survey amongst their purchasing professionals. In total we received 124 usable responses, 27.4% from Flanders and the rest were Dutch. Also, 67.7% of them were male. The majority indicated that they worked in a strategical (44.4%) or tactical purchasing function (30.6%). Also 65.8% of the participants worked for a profit organisation in comparison to 34.2% that worked for a non-profit or governmental organisation (Table 1). We put several measures in place to increase the number of responses, such as a small financial reward if appreciated. After a couple of weeks, we also send out a reminder of the survey. The data was analysed anonymously.

Table 1 Sample characteristics

Characteristics of the respondents (n=124)	% of the sample
Nationality (n = 124)	
Dutch	72.6
Belgium	27.4
Gender (n = 124)	
Male	67,7
Female	32,3
Age in years (n=109)	
Younger than 30 years	4.6
31-39 years	21.1
40-49 years	34.9
50-59 years	35.8
60 years and older	3.7
Type of organisation (n=111)	
Non-profit	34.2
Profit	65.8
Level of function (n=124)	
Operational purchasing	6.5
Tactical purchasing	30.6
Strategic purchasing	44.4
Manager	13.7
Director	4.8
Educational level (n=122)	
Secondary general education	7.4
Secondary vocational education	12.3
Higher education	43.4
Scientific education	36.9

Questionnaire

The survey consisted of a number of questions related to the behaviour of purchasers and their level of circular purchasing. Based on a literature review of Neessen et al. (2017) we used the constructs opportunity recognition, internal and external networking as well as the constructs of innovativeness, pro-activeness and risk taking to measure intrapreneurship of purchasers. We combined several scales measuring these concepts to construct a more complete measure of intrapreneurship. For innovativeness, proactiveness and risk-taking we used a scale adapted by Fellnhofer, Puumalainen and Sjogren (2016) (Bolton, 2012; Langkamp, Bolton and Lane, 2012), for opportunity recognition we used a scale of Wang et al (2013) and the scale of Chen et al (2015) was used to measure networking. The combination of these scales resulted in 24 items measuring the sub concepts of intrapreneurship. A confirmatory factor analysis showed a good fit and legitimised the use of this combined measure for intrapreneurship, with the exception of pro-activeness and one item of opportunity recognition which had a low reliability

score. Organisational citizenship behaviour towards the environment (OCBE) was measured using a scale of Temminck et al. (2015) consisting of 7 items. The scales of intrapreneurship and OCBE were indicated with a 5-point Likert scale.
The dependent variable was the percentage of circular purchasing. The participants were asked to indicate what percentage of their purchasing was purchased in a circular manner. Before we asked this question, we explained the construct of circular economy, which we described as: 'a system in which the circle of products and materials is closed and that waste is minimized'. We also asked for a number of control factors, such as type of function, type of organization, age, gender and educational level.

Analysis
The data was analysed with a mediation analysis using the process template of A. Hayes in SPSS (Hayes, 2013), in which intrapreneurship was the mediation variable, circular purchasing the dependent and OCBE the independent variable.

Results
Reliability analysis show a low reliability of the subscale pro-activeness (α=.337). The opportunity recognition scale also had a low reliability, but after excluding item 3 the reliability increased to an acceptable alpha ((α=.642). The other scales innovativeness (α=.789), risk taking (α=.664), internal networking (α=.869), external networking (α=.714) and OCBE (α=.893) were also reliable. A confirmatory factor analysis showed a good fit (RSMEA = .056; CFI = .922; TLI=.908) and legitimised the use of this combined measure for intrapreneurship, with the exception of pro-activeness and one item of opportunity recognition which were deleted from analysis due to the low reliability score (Schreiber, Nora, Stage, Barlow, and King, 2006).

Circular purchasing
The respondents were asked to indicate the level of circular purchasing, operationalized as the percentage of their purchasing budget used for circular purchasing. The results show that the level of circular purchasing is quite modest. The average percentage of circular purchasing in comparison to the total purchasing budget available per participant was just over 15% and around 26% of the respondents said that they had (nearly) zero percent circular purchasing (Figure 2). This implies that there is still a long way to go in order for all purchasing activities to become circular.

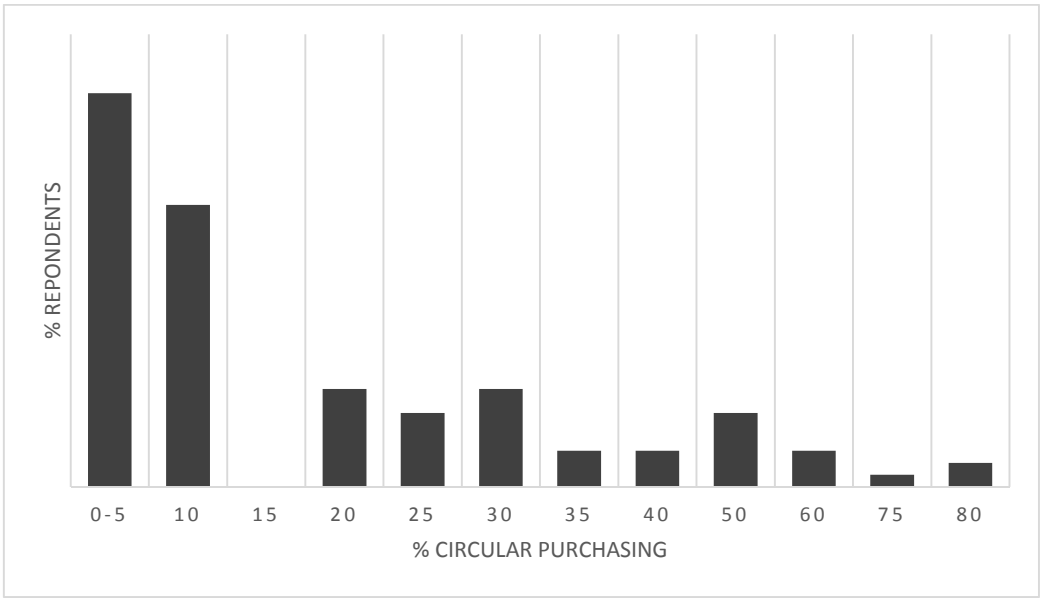

Figure 2. The level of circular purchasing (n=123)

Relationship between intrapreneurship, OCBE and circular purchasing

The correlation analysis (see Table 2) reveals that OCBE and intrapreneurship were correlated, but there was no indication of multicollinearity. Moreover, we did find that the control variables 'type of organization', age, gender and educational level were not correlated with the three main variables (OCBE, intrapreneurship and circular purchasing), except for the level of function. The dummy variable level of function was positively and significant related with intrapreneurship. Therefor we included this variable as a possible moderator in our further analysis.

Table 2 Correlation matrix

	Variables	**Mean**	**s.d.**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
1	Intrapreneurship	3.91	.38							
2	OCBE	3.32	.68	.31**						
3	% circular purchasing	15.74	18.25	-.10	.04					
4	Type of organisation (non-profit 1; profit 2)	1,66	.48	-.03	-.11	.19				
5	Level of function (high 1; low 0)	.63	.48	.23*	.04	-.11	.09			
6	Age group (5 groups)	3.13	.94	.02	.02	-.16	-.01	.10		
7	Gender (male 0; female 1)	.32	.469	-.02	-.06	.03	-.25**	-0.11	-.14	
8	Education level (5 groups)	4.06	.10	.07	-.02	-.14	-.07	.28**	.05	-.02

Notes: n = 124. * $p < .05$, ** $p < .01$

The results of the regression analyses are shown in table 3. We did find a positive relationship between OCBE and intrapreneurship (b = .184; p < .05), but no effect of intrapreneurship on the percentage of circular purchasing. The direct effects of OCBE and level of function were negatively significant (respectively b = -9.303; b = -56.579). However we found that these variables interacted with each other (b=16.022; p<.01).

Table 3 results of the regression analysis.

	Model 1 (dependent variable: percentage of circular purchasing)
Independent variables	
Direct effects	
Intrapreneurship	-5.503
OCBE	**-9.303***
Level of function	**-56.578****
Interactions	
OCBE x Level of function	**16.022****
Conditional indirect effects	
Low level function	**-9,304***
High level function	**6,719***
R^2	.099
F-Value	3.206
N	124

Notes. * p < .05, ** p < .01.

When examining this interaction effect, we found a conditional direct effect of level of function on the relationship between OCBE and the percentage of circular purchasing. Purchasers in a higher function (e.g. strategic, manger or director) showed a positive relation between OCBE and circular purchasing and purchasers in a lower level function (e.g. operational and tactical) a negative relationship (see Figure 2). Further research is needed to analyze why purchasers in a lower level function and with a low OCBE score appear to purchase more in a circular manner.

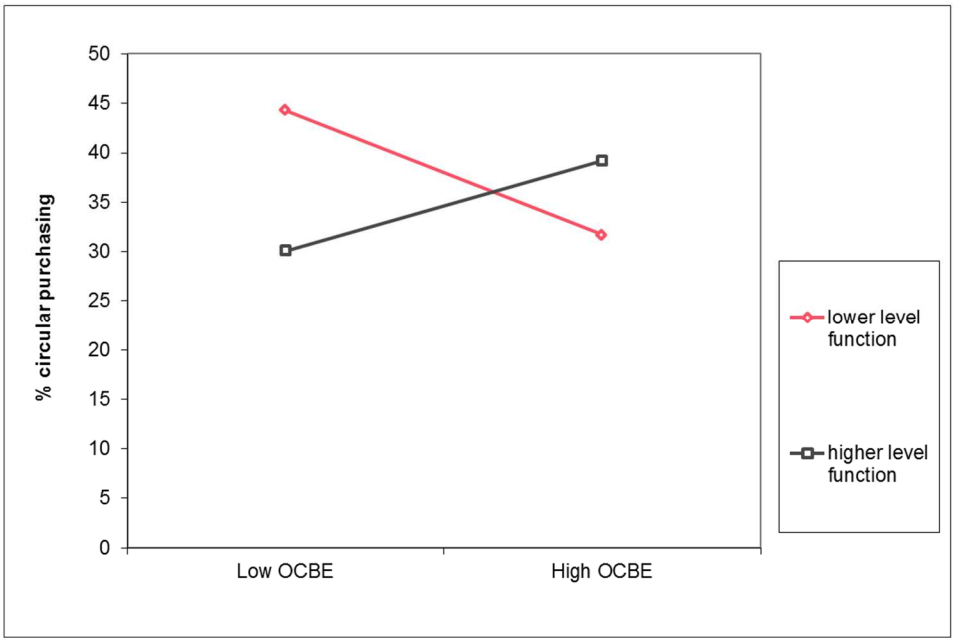

Figure 2. Conditional effects of level of function and OCBE on the percentage of circular purchasing.

Discussion, limitations and conclusions

Our results show that we need more research into the (intrapreneurial) behavior of purchasers leading towards more circular purchasing and how different personal and organizational factors could influence this relationship. Our study did yield some initial results on this relationship.

Firstly, the level of circular purchasing by the purchasers in our survey was low. This could indicate that circular purchasing and also circular economy is still a concept that is used in the communication of the organization and not (yet) find its way into the processes of the organization. More specifically, the views and goals of the organization communicated towards the outside market are not in alignment with the inner organization. Previous research indicates that the alignment of the processes with the top-management strategy is positively related to the effectiveness of sustainability incentives and as an indirect result sustainable performance (Parisi, 2013). Another explanation for this low level of circular purchasing could be that the concept of circular purchasing is still difficult to interpret. Even though we did state in the question that we define circular purchasing as purchasing based on the principle of circular economy which is a system in which the circle of products and materials is closed and that waste is minimized, the actual practicality of this system might still not be entirely clear. Circular economy entails much more than just purchasing sustainable products. It also means that the purchasers have to be aware what happens with the product or material after the product has been used. This aspect of circularity entails a much more intensive role of the purchasers that has to work with suppliers, logistics, recovery specialist and the end users to complete or ensure the life circle of the product or material. In order to do that, it must me clear for all parties involved what circular economy is and how it could be brought into practice. Based on our results, we think that the 'vagueness' of the concept results in a high perceived risk factor and uncertainty for the actors involved. Subsequently, the step to actually purchasing in a circular manner is too high, even for the intrapreneurial purchasers who might accept a higher risk and uncertainty of projects. This might also explain the lack of results regarding the relationship between intrapreneurship and circular purchasing. Future research could test what the barriers are when implementing circular purchasing. Does the alignment of the organization and the inner processes play a role, or is the risk factor and the uncertainty that the concept of circular economy entails too high for the actors involved?

Second, we find a positive relationship between OCBE and intrapreneurship. This was expected because OCBE entails behavioural actions that go above and beyond the job requirements (Temminck et al., 2015). Going above and beyond your job requirements entails some risks and extra work that would also be behavioural dimensions of intrapreneurship. It could be concluded that purchasers that show a high level of OCBE and thus go the extra mile for environmental friendly actions, are also more intrapreneurial. The results regarding the relationship between OCBE and circular purchasing are more difficult to explain. As hypothesized we find a positive relationship between OCBE and circularity, but only for the purchasers in a higher level function. For the purchasers in a lower level function, we find the opposite effect. Hence, this effect of function type is an interesting future research direction. One explanation could be that the level of support by the management perceived by the purchasers of a lower function might be different from the purchasers in higher level functions. Management support is an organisational factor that enables employees to behave in a more sustainable way (Brinkhurst, Rose, Maurice and Ackerman, 2011). Another study showed that the status of the purchasers influences the level of sustainable purchasing (Luzzini and Ronchi, 2016). Purchasers in a lower level function may have a lower status within the organisation,

which may explain that regardless of their own level of OCBE, they perceive they cannot enhance the level of circular purchasing.

There are some limitations to this study. We contacted a high number of purchasers via several routes. Unfortunately these routes were mostly indirect via networks or via purchasing associations. This might be the reason the total number of usable responses was low. We advertised the survey by addressing the changing role of purchasers. We specifically withheld from mentioning circular purchasing in the opening statement of the survey. This was done to assure that purchasers who work in organisations that are not really 'sustainability minded' also felt inclined to participate. Still, this decision did not appear to increase the response rate. We also included both profit and non-profit organisations in our research sample. Although we did not find any effect of type of organisation on the results, we realise that the purchasing process of purchasers working in a non-profit environment is different from the processes of purchasers working in a profit organisation.

In conclusion, we found that the level of circular purchasing is much lower than expected. This might be the reason why we did not find a significant relation between intrapreneurship and circular purchasing. However we did find a positive relationship between OCBE and intrapreneurship and a positive relationship between OCBE and circular purchasing amongst purchasers in a strategic, manager or director function and surprisingly a negative relationship between OCBE and circular purchasing amongst purchasers working in a lower function (operational and tactical function). This study could be the basis for future research towards circular purchasing and the role of the purchasers.

CONTRACTING STRATEGIES IN CAPITAL CONSTRUCTION PROJECTS
(A structured literature review)

Anna Nikulina (nikulina@rsm.nl), Finn Wynstra (fwynstra@rsm.nl)
Rotterdam School of Management

Summary: Capital construction projects are characterized by high levels of outsourcing, as project owners rarely have resources to complete the design and manage/perform the construction process. Thus, a choice of a project delivery and contracting strategies (i.e. scope of work, payment type and risk allocation) is a crucial task for the sector. Recognizing its importance, academics have investigated project delivery and contracting approaches over the years; however, no systematic existing research review on the topic has yet been completed. The present article reports on the first literature review effort and identifies opportunities for the future research.

Key words: contracting strategy, risk allocation, construction

Introduction

Capital construction projects are characterized with high levels of outsourcing, as project owners rarely have all necessary resources to complete the design and manage/perform the construction process. Thus, the influence that suppliers and contractors have on the outcome of construction projects is very significant (de Araújo, Alencar, & de Miranda Mota, 2017); the choice of an effective project delivery approach and contracting strategy is key for the project owners.

Oyetunji and Anderson (2001) define the project delivery and contracting strategy (PDCS) as follows: "The way the … tasks in a particular project are packaged for execution, and the types of services that the owner retains for the execution of those tasks define the delivery system ... Complimentary to the delivery system is the contract strategy … <that> defines how the owner pays for the services rendered by service providers ... This implicitly defines the allocation of financial risks between the owner and the service providers" (p.1). PDCS choice is contingent on various circumstances such as project product/process uncertainty, desired risk allocation, owner's characteristics and capabilities, as well as market conditions (Liu, Huo, Shen, and Yang, 2015; Suprapto, Bakker, Mooi, and Hertogh, 2016).

Recognizing the importance and relevance of PDCS, researchers have studied various aspects this complex phenomenon. Just to name a few studies, a comparison of project delivery approaches was completed by Liu et al. (2015); Ward and Chapman (1994) conceptualized pricing mechanisms; partnering approach was examined by Eriksson (2015); Iossa and Martimort (2012) investigated risk allocation in PPPs. The existing research is mainly concentrated in the engineering & construction management (ECM) and project management (PM) literature; and to a lesser extent in the operations and supply chain management (OSCM) research, that has typically focused on series manufacturing context, with some exceptions (e.g. a 2010 special issue of Journal of Purchasing and Supply Management devoted to the construction industry studies).

Despite the obvious interest of scholars in the PDCS topic and its high relevance, there has been no previous attempt to review and systemize the academic research related to it. Thus, we may lack a clear view which important questions have been under-investigated. E.g., application of incentive or risk allocation seem to have attracted attention of many scholars; other questions, such as comparison of single- versus multi-contracting approach, have been studied to a very limited extent (with exceptions such as Rojas (2008), or Mogre, Talluri and D'Amico (2016). There

is also an issue of multiple definitions developed over time and in different countries: e.g., "project delivery approach" can be named "procurement route" or "contract strategy", "contract pricing" means the same as "payment type" or "contractor compensation scheme", "risk allocation" can be "risk apportionment" etc.). Finally, we perceive that the existing literature, although extensive, is rather fragmented: e.g. construction management scholars do not necessarily draw from OSCM sources (based on citations), and vice versa.

Thus, we believe it will be valuable to undertake an effort to systemize the existing literature about PDCS by combining strands of the construction, project management and OSCM research (and potentially identifying other fields that have interest in this question). We aim to uncover main topics, trends, and future research needs; as well as provide a critical review of the current state of the PDCS studies (De Araújo, et al., 2017).

Classification of studies related to PDCS

Based on our familiarity with the topic and the initial literature investigation, we divided studies of the PDCS phenomenon into three parts (See Figure 1 below).

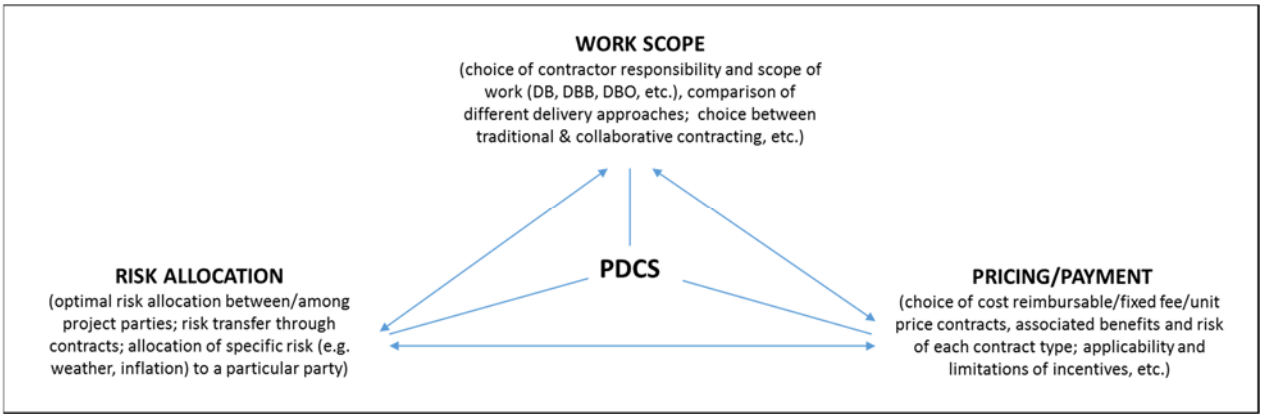

Figure 1: PDCS components and associated research topics

The first part (and related studies) covers questions about how the project work scope is allocated among the parties over the project phases (design, engineering, procurement, construction). These questions relate to the part of PDCS commonly called "***project delivery***".

We chose to split the second part, traditionally referred to as "***contracting strategy***", into two separate topics: pricing/payment and risk allocation. Although the definition of PDCS above states that these questions are inherently connected, there are two distinct groups of studies related to them. Enquiries related to the problem of how contractor(s) should be paid often discuss the allocation of risk, however, in such studies risk is understood at a very high level, mostly as general risk of financial losses resulting from the project schedule/budget overrun (Ward and Chapman, 1994; Turner, 2004; Turner and Simister, 2001). At the same time, the problem of project risk allocation is also investigated at a more granular level in a separate group of studies; general "project" risk is broken down into particular categories, such as weather, government, raw material price fluctuations, etc. (typology varies depending on the author approach). Such studies are not necessarily connected to the question of type of pricing/payment in the contract, but focus particularly on which type of risk should be allocated to a certain project party for the overall minimization of risk (and thus cost/schedule) of the project.

Our ultimate objective is to provide a systematic review of the studies that relate to PDCS research. However, given the complexity of the task and a large body of literature (our search identified ~400 articles that need to be fully read and coded), this working paper reports on the first

part of the project and covers studies related to contracting strategies: pricing/payment and risk allocation questions. Following the approach suggested by Cooper (1998), Seuring and Muller (2008), Fink (2013), we organize the rest of the paper in the following way: fist, we describe the approach and the process of material collection; next, we offer a descriptive analysis of the articles. Finally, we perform evaluation of the collected material and present our interpretation and findings.

Method

Coding sheet, approach and classification categories

Cooper (1998) recommends developing the coding sheet prior to search and analysis of the literature begins, as it helps to identify how the search should be designed and which information needs to be retrieved from the collected material. The initial draft of the coding sheet was developed by the first author; it was discussed and by both authors and refined; after test-coding of 20 articles it was revised again, and additional fields were added (e.g. owner/contractor view, project ownership type, etc.). The full list of applied classification categories is in the Table 1 below.

Table 1. Classification categories used in the coding sheet (final version)

Classification categories	
Basic categories	Title, authors, publication year, journal, abstract, RQ/intended contribution, findings
Relevance	Yes, no, partial (partial if the question of risk allocation or contract payment/pricing is not the only one discussed in the article, but still substantial enough to include it in the review)
First and second level codes	First level (scope, pricing, risk, combined, other-specify); second level (open list to allow for the broad list of included subtopics, e.g. particular contract payment type, etc.)
Project ownership	Ownership type (public, PPP, private, not specified)
Project delivery type	DB, DBB, DBO, DBOT, EPC, EPCm, Turnkey, alliance, relational, cooperative, other-specify, not specified
Payment/pricing type	Fixed price, cost plus, incentive, unit price, other – specify, not specified
Publication type	Non-empirical conceptual (NEC), non-empirical modelling (NEM), empirical, mixed
Research strategy	Literature review, case study, survey, secondary data analysis, interviews, experiment, mathematical modelling (MM), mixed, not available (N/A), not applicable (N/A)
Data analysis method	Quantitative, qualitative, mixed
Intended contribution type	Theory building, testing, exploratory, prescriptive, mathematical modelling, N/A; contribution explicit/implicit (implicit – if not discussed, but identifiable from the text)
Theoretical lens	Open coding (name of theory that is mentioned or used; none; N/A)

Main definitions and search keywords for the literature search

According to Ward and Chapman (1994), main types of contracts applied in construction are fixed-price, cost plus fixed fee, incentive. Carty (1995) classifies contracts into lump sum (fixed price), unit price, guaranteed maximum price, and cost reimbursable. Turner and Simister (2001) differentiate between fixed price, remeasurement and cost-plus agreements; Van der Puil and Van Weele (2013) use the list of fixed-price, cost-reimbursable (including target cost and incentive) and unit-price, but call this classification pricing mechanism rather than payment type. "Risk allocation" can also be "worded" in a several ways, e.g. . it can be named "risk sharing" (Carpintero and Petersen, 2015), or "risk transfer" (Bayley, 2003; Burke and Demirag, 2017) – depending on the specifics of the research question and exact focus/topic.

Based on the identified terminology, our initial list of search terms/keywords was as follows: "fixed price contract*", "lump sum contract*", "incentiv* contract*", "unit price contract*", "cost reimbursable contract*", "cost plus contract*", "remeasurement contract*", "target cost contract*","guaranteed maximum price contract*", "contractor* payment*",

"construction contract* pric*", "project risk*", "construction risk*", "risk allocation", "risk sharing", "risk transfer", "risk apportionment".

Information sources and material collection

As there are no prior systematic reviews about the topic of interest, our aim was to cover as large a time interval as possible: we searched for the academic literature from 1975 to 2017. We settled on the year 1975 as search in Web of Science (WoS), the main citation database that we used, goes back to 1975. We chose WoS, as it covers a wide range of journals across the disciplines of our interest (Rashman, Withers, and Hartley, 2009). To ensure consistent quality and possibility for an adequate analysis of the literature, we decided to include in our search only original academic publications from peer reviewed academic journals published in English. Although our primary goal was to include the research in ECM, PM and OSCM strands, we did not limit search to the journals in these categories; understanding what other fields/disciplines are interested in this topics and what is their contribution, is necessary for a systematic literature review.

We undertook three steps to identify relevant publications in the WoS search results. First, we read all titles and their sources, and excluded clearly irrelevant articles. Next, we read all abstracts and further refined our list. Finally, we excluded some more articles after examining the full text (during the coding process). While doing the screening of WoS search results, we found some more relevant keywords, and performed additional searches, e.g. on "incentive/disincentive contract*", or "risk/reward". Our WoS search resulted in 122 relevant original research articles included in the review (56 related to payment/pricing, 66 to risk).

Given a very broad terminology in the topic and a risk to miss relevant publications, we additionally examined all article titles in all volumes/issues of six key journals in the area of interest, as recommended by Rashman et al. (2009). Five key journals in the field of project and construction management were searched (Naoum and Ebgu, 2016): International Journal of Project Management; Journal of Construction Engineering and Management; Engineering, Construction and Architectural management; Journal of Management in Engineering; Construction management and Economics. We added Journal of Purchasing and Supply management to the list as the leading journal in the PSM field. This search added 13 articles to our list (8 related to payment, 5 to risk).

Finally, we checked references of the articles found through the WoS and key journal search. We also came across two publications that contained comprehensive lists of literature related to contract (payment/pricing) types - Antoniou, Aretoulis, Konstantinidis, and Kalfakakou, (2013) and incentive contracts - Kerkhove and Vanhoucke (2016). The reference search approach added 23 more articles to our list (19 for payment/pricing, 4 to risk).

The present article contains analysis of 158 publications (83 – related to payment/pricing, 75 to risk). A full search protocol and list of references can be obtained from the first author.

Descriptive statistics

Although our literature search started from 1975, we were not able to identify any relevant publications prior to 1980; since then, we see a continuous growth in the interest to topic, as the number of publications related to contracting strategies has been increasing (see Figure 2 below).

We split all the identified journals into four categories based on Nauom and Egbu (2016) and our own approach. The largets share of the articles (62%) is concentrated in the journals that publish research in the ECM field, as can be seen in Figure 3 below. Substantial number of publications was found in PM literature (22%), while interest of OSCM to the studies of construction contracts is limited (only 5%). The final 13% of articles related to the topic were found in the journals that we classified in "Other" category, as they do not belong to any of the three research strands mentioned above.

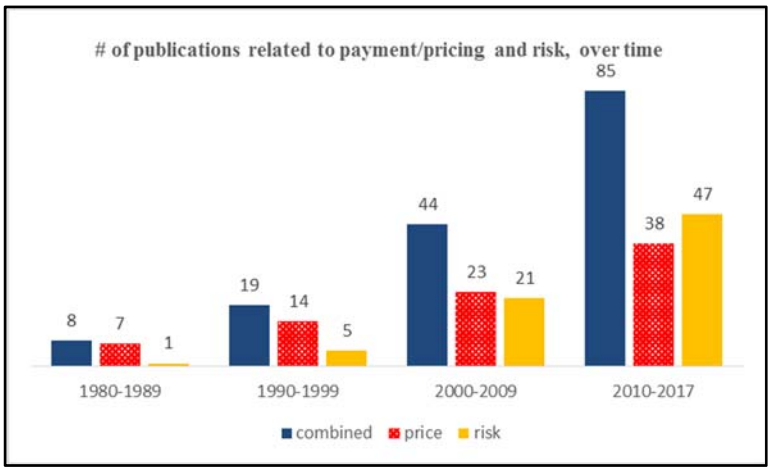

Figure 2. Number of publications related to the payment/pricing and risk components of contracting strategy

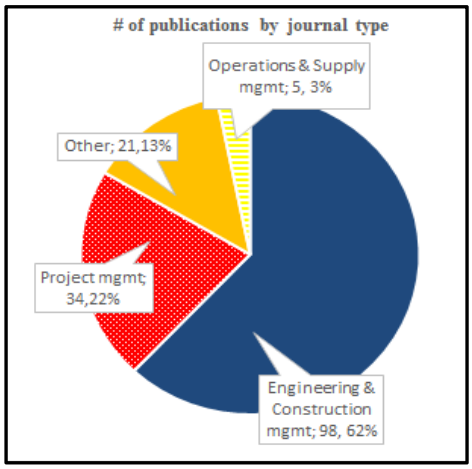

Figure 3. Number of publications by journal field

Out of 158 publications 58 (37%) are non-empirical (39 conceptual and 19 mathematical modelling studies), 12 (7%) were classified as mixed; 88 (56%) apply empirical methods. Trends over time can be seen in Figure 4 below. A total of 96 (61%) papers apply quantitative data analysis methods; 18 (11%) articles combine quantitative and qualitative approach, and 43 (28%) are qualitative. Survey is a preferred research strategy (46 papers, 29%), however, in many cases the collected data analysis is limited to descriptive statistics. Surveys are followed by the mathematical modelling (41, 26%) and case studies (23, 15%). In ~ 30% of cases researchers applied more than one method of scientific enquiry. See Table 2 below for more details.

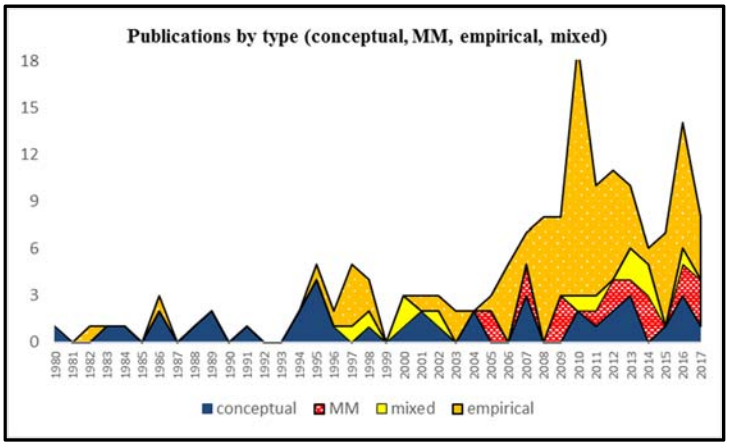

Figure 4. Number of conceptual, mixed and empirical papers on contracting strategies, over time

Table 2. Applied research strategies

survey	46	29%
mathematical modelling (MM)	41	26%
case study	23	15%
N/A	15	9%
survey + MM	8	5%
case study + survey	5	3%
secondary data analysis (SDA)	5	3%
interviews + survey	3	2%
case study + MM	2	1%
interviews	2	1%
literature review (LR)	2	1%
case study + SDA	1	1%
interviews + SDA	1	1%
interviews + case study	1	1%
interviews + MM	2	1%
systematic LR + survey	1	1%

Out of 88 empirical papers 32 (38%) collected (or used secondary) data from Asia, 27 (30%) from Europe, 12 (14%) from Australia, 11 (13%) – Americas, 5 (5%) from Middle East, and 1 (1%) – Africa. Empirical researchers investigate different types of projects in terms of ownership: 39 (25%) papers focus on PPP, 18 (11%) study public procurement, 4 (2%) combine data from public and private projects; however, many articles do not specify ownership type, or

data potentially comes from various types of projects in case of survey methods applied. Only 34 papers clearly reported in which construction sub-sector data was collected, and in 29 cases it comes from the infrastructure sector (water, rail, roads).

We faced a challenge in determining the theoretical contribution of many papers; only in 18 articles (11%) the authors explicitly attempted to build new or test an existing theory. We classified the rest of papers based on our understanding of their purpose/contribution. We divided the remaining 140 papers into the following categories: theory building (31, 20%), testing (24, 15%), modelling (33, 21%), exploratory (45, 29%) and prescriptive (7, 4%).

We found that research on the topic of contracting strategies is highly under-theorized: 116 papers out of 158 (73%) do not use or even mention any theoretical lens. In 33 cases authors clearly used at least one theory, and in 9 it is possible to identify it implicitly. Agency theory was explicitly mentioned in 17 publications, Transaction cost economics – in 12. Other applied theories include Contract theory, Utilities theory, Game theory, Price options theory, Resource-based view. However, even in those papers that used a theoretical background, in quite some cases it is limited to borrowing certain underlying assumptions or concepts (e.g. "bounded rationality" from TCE, "moral hazard" or "adverse selection" from Agency theory), rather than fully investigating a research question from a certain theoretical perspective.

Literature analysis – main topics

As we initially separated research related to payment/pricing and risk allocation questions (see above), we will present analysis of the literature separately: first for 83 papers related to payment/pricing, then for 75 publications focused on risk allocation problems.

Contract payment/pricing - conceptualization

Several "classic" articles conceptualize the choice of contract payment/pricing type. Veld and Peeters (1989) offer a decision framework for the contract types (fixed price, cost-reimbursable or incentives) based on several factors that include cost, schedule, technical uncertainty, etc., and include the contractor view in their decision framework. Ward and Chapman, 1994; Chapman and Ward, 1994 also discuss fixed price, cost reimbursable and incentive contracts; the choice of the contract payment type, according to them, should be based on the owner's desired risk allocation. Turner and Simister, 2001; Turner, 2004 add the re-measurement and alliance contracts to the list, and claim that the contract should be chosen to align interests of client and contractor. An attempt to optimize the choice of payment mechanisms using modelling was undertaken by Motawa and Kaka in 2009.

Particular contract types: fixed price, cost-reimbursable, convertible, incentive.

Griffis and Butler, 1988 conceptually argue for the advantages of cost-plus contracting; Smith, 1997 discusses positive implementation results of cost-plus contracts based on case studies in Canada; Rosenfeld and Geltner, 1991 offer conceptual arguments of disadvantages of cost plus and incentive contracts. However, in the later literature the focus largely shifts to studies of incentive contracting (see below). There is one conceptual publication (Carmichael, Karantonis, 2015) devoted to convertible contracts that allow for changing the payment type over the contract duration. We have not identified empirical studies related to this contract type.

Studies of incentive contracts constitute the largest share of articles in pricing/payment literature; this is why we chose to further divide it into two sub-topics. First, there are papers that study application of incentive mechanisms in construction contracts in general. Stukhart (1984), Herten and Peeters (1986), Bajari and Tadelis (2001), Bower et al. (2002) conceptualized the applicability of incentives and incentive contracts in the construction contracts, and discussed their benefits and limitations. Empirical research by Meng and Gallaher (2012), Bubshait (2001),

Bogus et al (2010), Suprapto at all (2016) focused on finding the effect of financial incentives and incentive contracts on the project results. Rose and Manley (2010) investigated the success drivers of financial incentives' implementation, and the effect of incentives on contractor's motivation, as well as its limitations. Hosseinian and Carmichael (2013) attempted to design an optimal incentive contract for the cases of risk-neutral contractor; another attempt to model the optimal incentive contract design was undertaken by Kerkhove and Vanhoucke in 2016.

The second group of articles focuses on a certain type of incentive contract: guaranteed maximum price/target cost (GMP), incentive/disincentive (typically schedule-oriented), and cost-plus-incentive-fee (CPIF) agreements. GMP contracts in particular are well covered in conceptual (Perry and Barnes, 2000; Lahdenperä, 2010, 2016 a,b) and empirical research. Risk ranking and allocation in these contracts, as well as benefits of GMP contracts were empirically studied by Chan et al. (2010, 2011, 2012) and Laryea (2016); sharing ratios discussed by Broome and Perry (2002), and Badenfelt (2008). CPIF contracts were both conceptualized and empirically studied by Berends (2000, 2006, 2007) and Al-Subhi Al Harbi (1998). A separate body of literature developed around a specific type of contracts applied in the road construction –incentive/disincentive (I/D) contracts. Some authors focused on analysis of the success factors of such contracts and developing guidelines for their application: Jaraiedi at al, 1995; Bayraktar and Hastak (2009), Choi and Kwak (2012) attempted to build a decision support model for incentive/disincentive contracts. Design of incentive provisions in I/D contracts was empirically studied by Arditi et al., 1997 and Ardity and Yasamis, 1998, Shr and Chen, 2004.

Connection of payment/pricing to the work scope/project delivery method

A limited number of papers investigates payment types in connection to a certain project delivery/work scope type. Bresnen and Marshall, 2000, Ling et al. 2006 focus on incentives in the alliance contracts. Cheng et al., 2016 study the appropriate payment types in design-build contracts, Love et al (2011) focus on suitable payment mechanisms for alliances; Berends (2006) discusses applicability of CPIF contracts in Engineering, Procurement, Construction management (EPCM) project delivery. We expect to discover more studies on this question in the second part of our project , when analyzing literature that we classified as "project delivery".

Publications focused on risk allocation

Overall this literature is dominated by the topic of optimization – either in an attempt to find opinions on the optimal risk allocation from various project parties, or to build mathematical models to reach best possible project risk allocation. Conceptual qualitative papers are rather an exception, e.g Barnes (1983), where a qualitative algorithm for risk allocation is offered. The majority of risk-related papers are quantitative, even if they are aimed at theoretical questions such as critique of agency-based principal-agent approach in risk allocation (Chang, 2014).

Risk identification, assessment and allocation preferences

A large share of papers (22 out of 75) focuses on identifying preferred risk allocation among project parties in PPPs. Such studies have been conducted in China (Chang et al (2011); Xu et al. (2011)) Indonesia (Wisbowo and Mohamed (2010), UAE (Sayegh and Mansour (2015)), Taiwan (Wang and Chou (2003)), Australia (Loosemore and McCarthy (2008); Perez et al. (2017)), and also Iran, Hong Kong, Singapore, Malaysia, Greece, etc. These studies use similar design: literature review and preliminary expert interviews to develop a list of relative risks for the questionnaire, then survey pilot testing with a group of experts, its refinement and finally the survey. They also typically report on opinions of clients, contractors and sometimes consultants and subcontractors, investigating their risk assessment and allocation preferences, and differences

in opinions among the groups of respondents. Sometimes a comparison of actual and desired risk allocation is added to the scope.

Modelling optimal risk allocation

The second dominant type of papers (17 out of 75) uses mathematical modelling methods to offer a methodology for optimal risk allocation: Lam et al., (2007); Jin and Zhang (2011); Nasirzadeh et al. (2016); Li et al. (2017). There are several attempts to translate the qualitative risk assessments into mathematical methods through fuzzification of qualitative inputs, such as Xu et al. (2010); Khazaeni et al. (2012); Nasirzadeh et al. (2014), Valipour et al. (2016).

There is not any other dominant topic in the risk allocation papers. Several publications discuss the cooperative (or joint) approach to risk allocation and management, and are connected to alliance contracting: e.g. Rahman and Kumaraswamy (2002); Witt and Liias (2010); Hanna et al. (2013); Osipova (2015). Some papers study the question of risk allocation in the contract texts/clauses (William and Ashley (1986); Hartman and Snelgrove (1996); Hartman et al. (1997)). Two recent articles address a question of how risk allocation affects relationship among project parties, and thus build a bridge into topic of interplay of contractual and relational governance (Burke and Demirag (2017); Zhan et al. (2016)).

Conclusions and suggestions for further research

Theoretical limitations and suggestions

As descriptive statistics shows, the research on contract payment/pricing and risk allocation is heavily under-theorized. While literature from OSCM field consistently applies theories, and in some cases so do PM publications, almost all ECM research lacks in this aspect. Absence of a theoretical lens, or its implicit/fragmented application limits theoretical contribution and value of the research. There is further room for application and elaboration of well-established agency theory, TCE, utilities theory, game theory. There could be also further suggestions in studying incentive contracts in particular with application of property rights theory (Selviaridis and Wynstra, 2015), or further application of real options theory in studying convertible or target cost contracts.

We also see some room for improvement in terms of rigor of wording the intended contribution and results. A clear explicit statement of research question and intended contribution in terms of exploration, theory building, testing or elaboration, and discussion of results connected to it would help in proper positioning the papers in the existing body of the research, and would help future authors to identify the filled and existing gaps in the knowledge base.

Empirical limitations and suggestions

While there have been attempts to answer many important questions in the topic of choosing the best contractor payment type, one (and probably the most important) question is still open: the role of, or the effect of the contract payment/pricing in the project results (that also can be understood quite broadly – in terms of cost, quality, schedule, but also safety, customer satisfaction, etc.). It is a question of high importance: if we do not understand which role the contract type plays in the project, we cannot ultimately properly evaluate and argue about its effectiveness. It is a very challenging problem, as many other factors except the contract type affect the project outcomes, and it is not possible to control for all of them. However, there is a need to continue searching for the answer, possibly in moderating of mediating relationships, continuing work of Rose and Manley (who attempted to find the effect of incentives in the project results) and Suprapto et al. (investigation of different contract types' influence on the project outcomes).

A lot of attention has been devoted to incentive contracts that are complex to design and manage, but at the same time have a unique potential to balance risk between the project parties (and thus overcome the problem of "extreme" risk allocation that both fixed price and cost

reimbursable contracts have). While incentive contracts seem to have been investigated quite well, there are still questions that are open for research: e.g., there is no investigation about design and effect of behavioral, or input, incentives that are applied in practice, sometimes in combination with such traditional ones as cost and/or schedule.

Among contract payment/pricing types, the convertible contract has received the least attention from scholars so far. It still needs to find its place in the range of contracts; we need to understand better its potential for balancing risk allocation between the contract parties and overall applicability. It may be less complex to design and implement than incentive contracts, but it may be able to link the risk allocation to the level of project risk and uncertainty. However, these are still open questions that await the investigation.

Risk-related literature is strongly focused on the problem of optimization of risk allocation, understood as overall minimization of the project risk. While numerous original models for optimal risk allocation have been created, there is limited information about their actual practical applicability and use; they need to be further tested in practice, as their ultimate goal is to offer a suitable tool for practitioners. We also lack information in general about the need (for more) of such models in practice. There is room for more studies about what various types of organizations (owners, contractors, consultants, etc.) actually do when they face the task to allocate project risks: what methods and tools they apply, and what is the actual work process they follow. These studies call for qualitative methods, in order to ensure deep understanding of the context and processes.

Numerous survey studies have investigated risk allocation preferences of different project participants. However, most publications are exploratory and do not attempt to identify any relations between/among variables and test theory. In addition, they have primarily studied PPPs; their findings are limited to the desired allocation of risk to either public or private project participants, but do not go to a more granular level. Finally, many surveys have developed original risk registers, but the fact that they differ makes comparison of these studies a challenging task. There is room for more theory testing, based on solid theoretical background. We also do not have sufficient understanding about risk allocation in the private construction (as generalizability of the studies focused on PPPs may be limited): what are the preferences of project participants, what factors enhance and hinder optimal risk allocation, etc.

Finally, we would like to point several more research opportunities that apply to both pricing/payment- and risk-related studies. First, all papers in our review are examples of "variance" research; as scientists, we still know little about the process of developing decisions about contractor payments and risk allocation; such questions call for longitudinal studies and especially process research. Second, the reviewed publications address the problem of payment and risk allocation on organizational or inter-organizational level; no studies that look inside the organizations, e.g. how different project functions (e.g. procurement, legal, project and risk management, etc.) view optimal risk allocation or contract types, or what are their roles in development of the contracting strategies. Third, while a construction project is a one-time undertaking, the same parties can work together in several projects (simultaneously or over time). How and if repeated interaction affects the choice and the process of risk allocation and contract payment type has not yet been investigated. Finally, we have noticed that many empirical studies turn to the infrastructure sector for the data collection. While infrastructure projects are complex and expensive, and give a lot of ground for thought and investigation, we suggest that the research diversifies into other types of construction, or attempts to compare construction sectors to understand their differences, similarities and potential generalizability of existing studies' results.

This working paper reports on the first part (contracting strategies) of our systematic literature review. While rich and varying literature has been uncovered, there is still need and room for future investigations. We also expect that our findings will be enriched (and potentially altered) after the completion of the second part of the study related to the project delivery approaches.

Abstract
Since companies increasingly leverage external resources, supply market intelligence (SMI) has become firms' key capability. This is challenging as supplier and supply market data derive from various sources. This study examines creating business value from applying big data analytics (BDA) in SMI. To achieve this objective, qualitative data is gathered from focus group discussions of 40 purchasing professionals and BDA experts, and semi-structured interviews of 22 purchasing professionals and BDA experts. The findings indicate that BDA can create competitive advantage through SMI by integrating external data into companies' context and providing value through actions, especially related to supply risk management.

Keywords: Big Data Analytics, Business Value, Supply Market Intelligence

Introduction

In today's complex and dynamic business environment, supply management researchers and practitioners are searching for new ways to increase supplier visibility (Li et al., 2017). Development of technologies legitimate the next level of maturity in procurement, which can be referred to as procurement (and supply management) 4.0. This progress stands for the digitalization and automation of the function within its company and supplier environment, in which the degree of integration and change in supplier relationships has an important role (Glas & Kleemann, 2016). Thus, special capabilities, such as big data analytics (BDA), are needed for the procurement function.

In procurement 4.0, companies need strategies for integrating established technologies available on the supply markets (Glas & Kleemann, 2016). Responsiveness to market change determines a firm's effectiveness, and effective incorporation of market knowledge reduces unexpected surprises, resulting in enhanced dynamic capability (Sher & Lee, 2004). In the context of procurement 4.0, this capability refers to supply management alignment, empowering the linking of internal and external parties (Handfield et al., 2015). The supply management alignment requires creation of supply market intelligence (SMI), which can be defined as "the ability to develop deep insights into key supplier market characteristics, including emerging technologies, price and cost trends, mergers and acquisitions (M&A), capacity requirements, quality and delivery performance, and other key supplier capabilities that form the basis for sound strategic sourcing" (Handfield et al., 2009, p. 103). Even though the importance of SMI is recognized as a central factor of supply management, BDA in the context of SMI is a topic that has been only rarely researched.

The scope of this study is BDA in SMI, focusing on the strategic importance of investing in insight-based decision-making and value co-creation. In order to study BDA in SMI, the paper answers the research question: *What is needed in order to achieve business value from big data-driven supply market intelligence?*
As the theoretical background of this study, existing literature focusing on BDA in supply management is reviewed. The research is conducted via qualitative methodology of different data collection methods. Empirical data is gathered from BDA experts and purchasing professionals using focus group discussions and semi-structured interviews. The findings and analysis of the results are presented in the form of four propositions, followed by conclusions and discussion.

Literature Review of Big Data Analytics in Supply Management
As the strategic importance of supply management has increased (Ahtonen & Virolainen, 2009), supply management professionals need to generate and disseminate large amounts of information, develop a shared knowledge of the information, and filter the shared understanding into potential value, as well as store and share valuable intelligence within the organization (Handfield et al., 2015). In the literature (Handfield et al., 2015; van Weele & van Raaij, 2014), the importance of supply management in combining internal stakeholder needs and suppliers' resources is recognized. Supply management professionals need to develop their ability to better contribute in supporting corporate improvement targets and creating organizational competitive advantage (Tchokogué et al., 2017).

Creating SMI for forming the sourcing strategies has an effect on many value adding business areas, such as product innovation, technology development, knowledge sharing, new process capability development and multi-tier supplier integration (Handfield et al., 2015). The ability to scan the business environment for breakthrough innovations and new product development is increasingly essential for the success of companies (Cousins et al., 2011). According to Song & Thieme (2009), supplier involvement in market intelligence gathering activities has a consistent, positive impact, especially on the success of incremental innovations across predesign and commercialization activities. In terms of radical innovations, building a knowledge base through internal knowledge sharing and market knowledge acquisition contributes to the knowledge management activities (Zhou & Li 2012). Relevant SMI consists of insights about suppliers of products and services, including their capabilities, past performance and strategic initiatives, in addition to information about technology, industry trends, networks, capacity, inventory levels, as well as transportation and storage options (Esper et al., 2010).

The acquisition and transfer of knowledge between suppliers and a focal company characterize a fundamental driver of innovation, allowing managing and discovering new solutions to technical and commercial challenges in the marketplace (Cousins et al., 2011). New technologies may need new supply markets for products and services that build, operate and maintain innovative technology (Knight et al., 2015). Supply management professionals need to ensure that essential supply market information is acquired, shared, interpreted and exploited in a manner that creates competitive advantage (Zsidisin et al., 2015). Big data technologies enable the decision makers to create real-time intelligence from high volumes, varieties and velocities of data (Gandomi & Murtaza, 2015). Big data can be defined as "high-volume, high-velocity and/or high-variety information assets that demand cost-effective, innovative forms of information processing that enable enhanced insight, decision making, and process automation" (Gartner, 2017). Big data is a combination of qualitative and quantitative data that depicts, among others, internal and external databases, social media, and the Internet.

The key in applying BDA in supply management is to apply big data tools for business decisions through an iterative process driven by business issues (Fig. 1). Gathered data from the supply base and markets need to be filtered and analyzed in the context of a specific business issue to meet data requirements and fulfil defined criteria (Handfield et al., 2009). Through this manner, BDA can identify and qualify new suppliers, map probable reactions to business events and highlight new trends in the industry, in addition to facilitation in finding new markets (Markham et al., 2015).

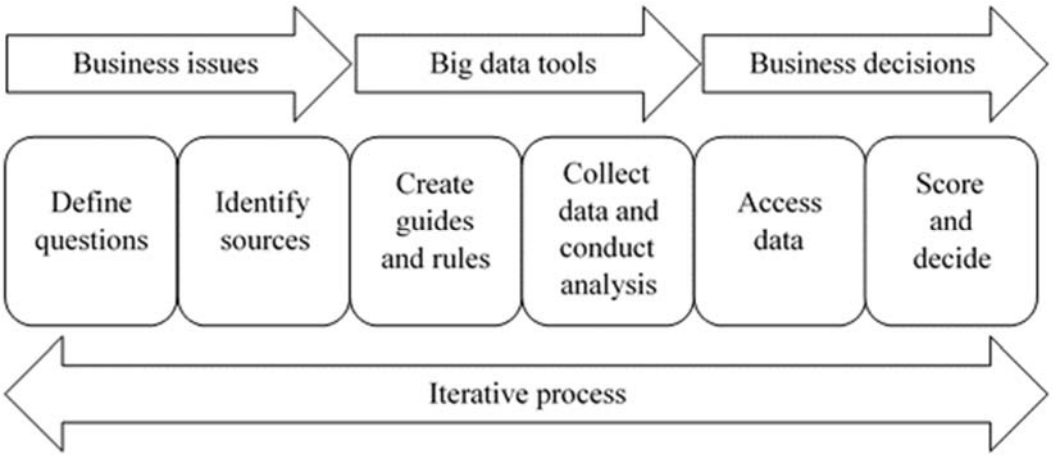

Figure 1. Process for big data-enabled decision-making (Markham et al., 2015).

Investments in information technology contribute the most when they enable dynamic collaboration capabilities in the supply chain (Fawcett et al., 2011). Regardless of the company's particular focus area, the fundamental objective is to accomplish alignment between the needs of the focal company and the capabilities of the suppliers from technical, cultural and behavioral perspectives (Petersen et al. 2005). BDA involves experimentation, which requires strong relationships and partnerships (Chen et al. 2012). Thus, it important to understand that BDA is a tool, not a direct answer (Markham et al. 2015).

Research Methods

Qualitative research is chosen as the methodology of this study due to the topic's novelty and continuous development, with only minor previous insights pertaining to the phenomenon under study. The choice of data collection methods was based on the type of objective of the study; to examine what is needed in order to achieve business value from BDA in supply management. Multiple methods of focus group discussions and semi-structured interviews were chosen in order to gather empirically relevant data from a large number of purchasing professionals and BDA experts.

Empirical data was gathered from two main areas: 1) focus group discussions of 40 purchasing professionals and BDA experts divided into six groups, and 2) 22 semi-structured interviews of seven BDA experts and 15 purchasing professionals from 11 companies (Table 1). Focus group discussions enable collective examination of the research topic through interactive discussion among the participants (Eriksson & Kovalainen, 2008). Additionally, semi-structured interviews allow gathering relevant and targeted information, via its customization to the study's research objectives (Lee & Lings, 2008).

Table 1. Overview of data collection

Objective	Method	Role of informants	Number of informants
To examine what is needed in order to achieve business value from big data-driven supply market intelligence	Focus group discussions	Purchasing professionals and BDA experts	40 (in six groups)
	Semi-structured interviews	Purchasing professionals and BDA experts	22 (15 purchasing professionals from 11 companies, 7 BDA experts)

Data analysis was conducted using NVivo qualitative data analysis software. The analysis was done via an inductive manner, due to the exploratory nature of the research. Following the characteristics of the inductive approach, the coding nodes were not predefined, but evolved during the coding process. The empirical data was analyzed from the point of view of answering the study objectives.

Triangulation of data is used to enhance validity of the study through collecting empirical data from different sources with various data collection methods. Triangulation refers to the use of different independent sources and data collection techniques within the study for certifying that the data is answering the objectives correctly (Lee & Lings, 2008). In this study, data triangulation is applied via sources of purchasing professionals and BDA experts. In addition, different views of analyzing the data by two researchers was applied.

The findings and analysis of the results are presented in the following chapter as aggregated answers of the respondents in tables, consisting of the unit of analysis, coded node and the reference. The amount of semi-structured interviews or focus groups in which the corresponding references were raised are presented in brackets after each topic.

Findings

In this chapter, findings from the empirical data of purchasing professionals and BDA experts are presented in the form of four main propositions. The first proposition states the importance of SMI in strategic supply management, the second proposition discusses the potential of BDA in creating systematic SMI, the third proposition states the significance of integrating internal and external data to create SMI, and the fourth proposition deliberates the realization of creating value from BDA. At the end of this chapter, a summary of BDA process for decision-making support in supply management is presented, followed by some of the main fundamentals for reaching the full potential of BDA in supply management, and future directions.

The focus group discussions provided insights into the strategic importance of SMI in supply management (Table 2). According to the purchasing professionals, SMI can facilitate negotiation of satisfactory price levels, conducting cost breakdown and accurate delivery forecasting, as well as minimizing unexpected and ambiguous price increases. When first segmenting the key suppliers, they can be further monitored through SMI in terms of growth, development, investments, strategic alignment and price fluctuations. Therefore, it is vital to have visibility into the company's spend costs and the supply market prior to negotiations.

The table below represents answers regarding the importance of SMI in the unit of analysis of strategic sourcing, as perceived from all the data collection methods. The amount of interviews / focus group discussions is presented in brackets after each reference.

Table 2. Importance of supply market intelligence in strategic sourcing

Unit of analysis	**Strategic sourcing**		
Coded node	**Spend analysis and opportunity assessment**	**Sourcing strategy**	**Category management**
Reference	- Category and supplier segmentation (10) - Market development / aftermarket opportunities (6) - Examination of the share of suppliers' revenue (3)	- Negotiating good contracts (12) - Defining strategic criteria and future vision (10) - Examining the focal company's attractiveness (5) - Supply base reduction (5)	- Categories based on components, technologies or suppliers (5) - Elimination of single sourcing (3) - Category strategy consists of regular scanning / value stream mapping (2)

Comprehensive SMI can facilitate ensuring better service with negotiations and contracts, especially when the focal company is a small buyer to the supplier and the purchase value is low. The attractiveness of the focal company is based on the share of revenue it provides to the supplier. The attractiveness can also increase by indicating growth potential for a particular project or product in contract negotiations. The purchasing professionals noted that required timespan for the supply market forecasts depends on the lead time and project-based orientation of the services and/or products in a particular category. Furthermore, start time of the negotiations has an impact on the negotiated prices depending on prevalent market prices. Thus, proposition 1 can be summarized in the following statement.

Proposition 1: Creating comprehensive SMI is important, especially in activities related to sourcing strategy such as establishing good contracts and achieving contract compliance with suppliers, based on knowledge and understanding of components' and products' market price levels and cost components.

In addition to sourcing and category strategies, SMI is needed for continuous risk and opportunity monitoring (Table 3). Supply risk management versus opportunity identification requires defining criteria for risks in the particular company and category. Different factors concerning supply risks, such as price compared to quality or amount of returns, can be evaluated via BDA.

Table 3. Creating continuous competitive advantage through supply management

Unit of analysis	Continuous improvement cycle of supply management	
Coded node	**Supply risk management**	**Driving innovation**
Reference	- Reliability of delivery and quality (6) - Alternative suppliers / materials (5) - Management of change / communication (5) - Financial situation of suppliers known (4) - Mapping country risks across borders (3) - Anticipating cost increases (3) - Proactive actions to new regulations (2) - Dependency / collaboration (2)	- Supplier technology roadmaps in collaboration with R&D and business (7) - Need derives from NPD processes (3) - Early supplier involvement (3) - Innovation execution / scouting disruptive innovations (3) - Utilizing partners' ecosystems (2) - Product upgrades require new requisites (2)

Supply risk management is different between categories as well as between strategic suppliers and tactic suppliers, and therefore requires different risk management platforms. Foremost, purchasing professionals considered it important to identify strategic suppliers, and form iterative risk evaluation, mitigation and contingency plans with them. Risk mitigation practices can consist of, for instance, recognizing new customer segments, technological developments and cooperation possibilities.

Further, visibility of emerging technologies and innovations, including digital transformation, was considered to be one of the most important aspects of SMI. Innovations need to provide new opportunities for value proposition synergies. Being able to absorb new technologies, the personnel need strategic and analytical competences. Driving innovation in the context of supply management includes conducting supplier technology roadmaps in collaboration with R&D and business. In addition, new product development processes require creating comprehensive SMI in order to find the best and most innovative suppliers. This leads to proposition 2 below.

Proposition 2: BDA has great potential in creating competitive advantage for companies in a continuous manner through actions related to supply risk management, such as availability of materials, and reliability of delivery and quality.

Even though there is additional hype associated with BDA, both the purchasing professionals and BDA experts considered BDA to have great potential in creating SMI. Based on the semi-structured interviews, some of the most important proactive actions that can be facilitated by BDA were perceived as forecasting customer needs and evaluating performance based on relevant measures, such as service level agreements or other quality measures. Furthermore, activating stakeholders and one's own business in development of strategies and processes in a proactive manner based on the analysis was considered important. According to the focus group discussions, ideal use of resources in SMI requires that everyone in the organization is involved in creating SMI and they must also understand the value of strategic decision-making.

In the semi-structured interviews of purchasing professionals, it was discovered that most of the interviewed companies gather external market data to support strategic decision-making. However, there is no systematic way to integrate the analyses into internal data and processes in-house. In many cases, external service providers and external sources such as consultant reports are utilized to create SMI. The need for applying an external solution provider for BDA depends on available resources and size of the company. Instead of focusing on the technical execution of the analysis, attention should be paid to integrating all necessary data into the analysis. *"In principle, any analyst can conduct the analysis, but incorporating the quiet information that is not written anywhere into the analytics delivers the real benefits. But it is not done a lot"* as identified by one of the BDA experts.
As perceived by the BDA experts, the source of value from BDA in supply management requires combining the company data and particular context with external data by utilizing analytical capabilities. One of the BDA experts stated from professional experience: *"Often companies start to resolve one issue, receiving some benefits, then resolving another issue and receiving new benefits, then conducting SMI and receiving some benefits, but really, the super value is in that you are able to do something in the intersection of the information clusters."*

There are various types of data from the supply markets, such as suppliers' financial performance and digital developments, which can contribute to creating deep insights in the suppliers' capabilities. One of the BDA experts stated: *"When it comes to big data, you can use any data, even that kind of data that would primarily seem irrelevant, but it can still make a difference."* Some of the most important data and information that is needed from the external supply markets allows examining and forecasting future market trends, innovations and technologies, suppliers' quality and delivery performance, existing suppliers' abilities, but also new suppliers and solutions, global price levels as well as product and service availability (Appendix 1). Once the size of the data increases, the data need to be stored on a cloud warehouse management system.

When integrating data from different sources to support decision-making, it is important to first gather and organize internal data from different databases and business units. After that, external data can be aggregated and integrated into the company's context. In order to integrate BDA into continuous decision-making support, internal data transfer and information retrieval first needs to be organized. One of the BDA experts advised as follows: *"This would be my best advice: don't think about the big thing and go into a project spending thousands or tens of thousands of euros and do the big thing, rather start small and do it in phases."* Therefore, proposition 3 can be stated as follows.

Proposition 3: Systematic and comprehensive SMI can be created by first organizing internal data, followed by integrating internal and external data from different sources and databases in order to implement BDA.

Based on the focus group discussions as well as the BDA interviews, existing suppliers' and different business units' data has to be first organized and integrated, in which communication and information sharing is important. Since the supply market consists of large amounts of data from different sources, it is not possible or even worthwhile to attempt to gather all feasible external data. Therefore, it is important to define what data is needed, why it is needed and how it is utilized to support the supply management processes. The BDA experts stressed that many companies still fail in aggregating internal data, such as purchase invoices, so integrating comprehensive external data to the unorganized internal data is a major challenge. Data aggregation of both internal and external data is a prerequisite for executing successful analysis.

According to the purchasing professionals, SMI can provide business value by building a system that gives alerts when actions need to be taken, such as a supplier has financial difficulties. As a solution, a BDA solution provider can code an external standardized signal that alerts and provides information when it encounters customized internal criteria related to changes in the supply base or market requiring actions. However, as one of the BDA experts specified*: "It is not enough that the system gives an alert, but it needs to justify why it was distributed and what should be done."* Instead, the alert should automatically be distributed to the correct person in charge of the particular field, and provide additional insights such as recommendations for further actions. In simple cases, issues can be automatically solved, since intelligent algorithms can learn from experience and past data input, enabling the proper handling of different situations.

Even though analytics and/or data aggregation could be outsourced to a solution provider, companies need internal capacities to absorb and distribute results of the analysis to support decision-making. If the extracted insights are not converted into intelligence across business units, value from the analysis will be unexploited. A gap may exist between analysts and business people, diminishing the potential value of BDA. As encapsulated by a BDA expert: *"A very critical part is that the one who is using the information understands what it is, and that is the biggest challenge."* Thus, proposition 4 can be summarized in the following statement.

Proposition 4: Value from BDA is realized only when the analysis is implemented into actions via more informed decision-making, derived from asking the right questions.

From the technical point of view, according to the BDA experts, BDA can create a competitive advantage for companies through SMI by integrating external data into a company's context via analytical capabilities and providing value through actions, especially related to supply risk management. In order to extract value from BDA, integrating internal and external data into a cloud warehouse management system is a prerequisite for transferring big data into the company's context. Different big data technologies can be used to conduct advanced analytics and interactive reporting for providing the end user a so-called *single point of truth user interface* for intelligent decision-making, which provides the analyses in one place in an understandable manner (Fig. 2).

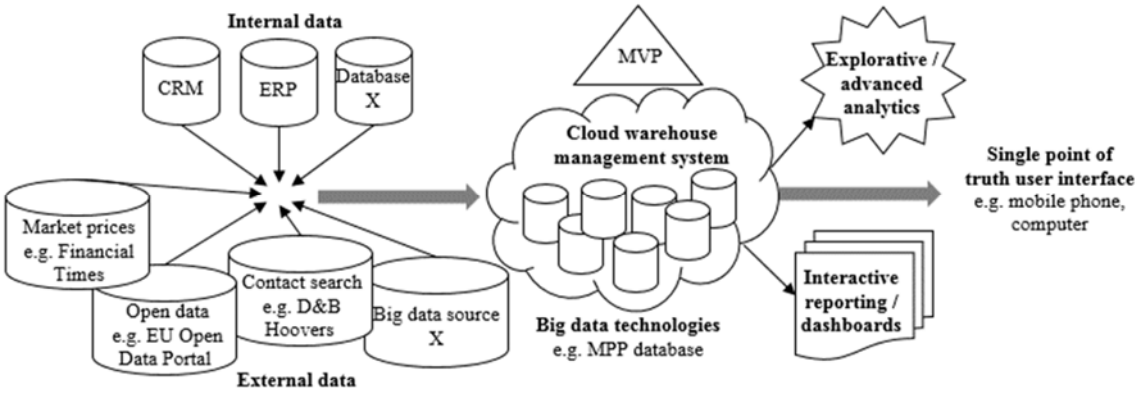

Figure 2. BDA process for decision-making support in supply management.

Ideally, the analyzed data can be accessed via interactive data exploration platforms and dashboards that enable zooming and mapping the needed knowledge. Most of the BDA service

providers execute a minimum viable product of the technical solution and leave room for developments according to customer preferences. A current technology innovation called a *massively parallel processing database* or other big data technologies can be used to provide real-time ad hoc analytics in addition to traditional reporting of the integrated data.

Some of the fundamentals for reaching this potential are that the analytics applications should be linked with the key performance indicators and aligned with strategy and business processes. Consequently, BDA implementation requires extensive background research and collaboration with the supply management professionals and analysts. The purchasing professionals do not need to conduct the technical analysis themselves, rather educate themselves about the analytical benefits in order to understand the analysis. Incorporating the analysis into actions enhances decision-making through improved forecasting.

Future directions of BDA in supply management were deliberated in the focus group discussions and semi-structured interviews. Firstly, in addition to integrating information within a company between departments and units, it will be integrated between different stakeholders. Integrating tasks with service providers will also increase, resulting in fading the interface between the focal company and suppliers. Suppliers can become more proactive, and the responsibilities for different areas can be shared when both parties have access to real-time information. Thus, easy-to-use and comprehensive information systems including global stakeholders will increase importance in gaining analytics visibility (e.g. spending and contract databases)

Conclusions and Discussion

In conclusion, it can be proposed that according to purchasing professionals, SMI is especially important in driving innovation by forming supplier technology roadmaps in collaboration with R&D and the overall business. The recognition that supply management can support the organizational competitive strategy (Tchokogué et al., 2017), is imperative for creating business value via SMI. Furthermore, SMI is vital for making good contracts with suppliers, consisting of negotiating desired terms. Knowledge of the predominant supply market conditions provides leverage in negotiating prices and deliveries. BDA can create competitive advantage for companies through SMI by integrating external data into company's context via analytical capabilities and providing value through actions, especially related to supply risk management.

Gaining visibility of market developments to influence the structure and evolution of the supply market in an attempt to ensure a sustainable and competitive supply market (Knight et al. 2015), can be facilitated by BDA. Analytics visibility through integrated information systems will become a requisite in global supplier relationships, in order to manage the external resources based on analyzed data. Understanding between business people and the analysts increases importance when implementing analysis into processes. Partnerships between supply management professionals and BDA experts are therefore vital in generating business value from big data.

In mature procurement 4.0, which is facilitated by development of technologies, companies need new capabilities to manage the suppliers' resources (Glas & Kleemann, 2016). Thus, companies need new strategies for integrating established technologies available on the supply markets. According to the empirical data, purchasing professionals and BDA experts consider BDA to have great potential in creating SMI. BDA enables the deployment of automated solutions. Routine functions and processes that are too easy or too complex to conduct by humans are automated ever more, leaving more time for strategic and meaningful tasks.

However, other digital technologies, such as blockchain technology, need to be considered in future research in order to study the potential ways of contributing to the overall competitive position of the focal firm (Foerstl et al., 2017). External solution providers can conduct analyses and assist in the technological implementation in collaboration with the focal company. Nevertheless, internal analytical mindset and understanding of the analyses are important for creating business value through new technologies.

Limitations of this study constitute of concentrating on the scope of supply management, and more specific area of SMI, instead of other theoretical perspectives, such as knowledge management. Future research could be conducted from the point of view of other theoretical lenses such as dynamic capabilities theory, as well as a wider range of technologies included in digitalization. This study is a first step for an important phase of unveiling the full potential of creating business value from applying BDA in SMI.

		M&A and labor turnover	
		Rules and regulations	

The value of vendor rating for public institutions: the impact of supplier measurement systems on Italian public works performance

Abstract

In the private context, the vendor rating process represents an important lever for both strengthening the relationships with suppliers and the improvement their performance. When dealing with the public sectors, dynamics of this process presents substantial differences, mainly as the result of the stringent regulation which grounds on open competition, transparency and equality principles. Such characteristics make supplier performance measurement complicated, as they bind both the public institutions and the suppliers in a short – term view of the relationships, thus discouraging investment on this process. With this work, we aim to investigate the advantages that structuring the phases of vendor rating process (i.e. qualification, selection, ongoing assessment) may bring to institutions in terms of performance obtained from suppliers. In doing this, we consider as unit of analysis a specific type of contract – public works, and we adopt the perspective of the suppliers, testing this relationship on data about 205 public works projects executed in Italy in the last three years. Results show that, the higher the attention paid to the design of the qualification and ongoing assessment step, the better are the project performance (i.e. time, cost quality), while no significant benefit results from a structured selection procedure.

Theoretical background

Public Procurement is the process used by public sector organizations to obtain goods and services from a third party by mean of contract (e.g. Loader, 2015). Despite its traditional operational perception, this government function is today gaining even more and more relevance for public institutions at all levels, for two main reasons.

On one side, given that public spending dedicated to purchasing of goods and services impacts, on average, 29% of OECD countries' total government expenditure (OECD, 2015), this has become the first area where institutions look at when they are in search for efficiency and budget cut, in time of tight economic conditions. On the other, it is evident how, most of the goods and services are directly brought and used for citizens operations, thus affecting the level of service offered by national, regional and local government (Flynn and Davis, 2016; Loader, 2013; Pickernell et al., 2011; Uyarra and Flanagan, 2010).

These aspects are even more amplified if we consider a particular type of government procurement – the sub-contracting of public works. Public works are defined as the physical structures and facilities developed or acquired by public agencies to house governmental functions and provide water, waste disposal, power, transportation and similar services to facilitate the achievement of common social and economic objectives (Nash et al., 1977). The definition already gives a clear idea of the magnitude of spending that government invest in this category, up to 30% of Italian public procurement expenditure in 2016 (ANAC, 2017), and 27% on average at European level.

Public works represent a critical cornerstone for public procurement management, as they suffer from long durations (Gori et al., 2017) and a high degree of complexity from a financial, technical and legal point of view (Lenferink et al., 2013). Public works often relies on contracts that are subject to information asymmetries and contractual incompleteness, which often bring to renegotiations, cost

overruns or delays (e.g. Saussier and Tirole, 2015), and both cost and time escalations are likely to imply higher social costs and/or lower social benefits (Lewis and Bajari, 2011).

All these factors imply several problems when it comes to the work execution, by translating into performance, in terms of cost, time and quality (Chan and Chan, 2004), that are not optimal or in line with what expected (Wegelius-Lehtonen, 2001; Flyvbjerg et al., 2002; Ahadzi and Bowles, 2004; Cûlfik et al., 2014).

To explain the ex-post performance of public works, the previous literature has mostly looked at pre-execution stages, focusing either on the effectiveness of auction formats in limiting renegotiations or on the factors that prevent the contracting authority from accurately predicting the work's time schedule. Some others, instead, have addressed the shade relates to the influence that a number of relevant buyers' characteristics may play on procurement performance (e.g. Ambrosanio et al., 2016; Brown and Potoski, 2003; Guccio et al., 2014).

With the present paper, we want to add a new perspective on this, by considering in this problem the role played by performance management systems (PMS).

The government need of measuring performances management comes directly from the spread of the New Public Management (NPM) discipline (e.g. Verbeeten, 2008), promoting that the focus on the design of sound PMS represent a necessary condition to improve performance in public sector organizations (O'Flynn, 2007). Of course, this affects every government functions, including public procurement (Flynn and Davis, 2016).

Performance management for public procurement can be differentiated at two levels - internal (i.e. the execution of the public procurement process) and external (i.e. at a contract level, intending the results obtained from active suppliers), even though the maturity on institution on this is still under – developed, especially referring to the assessment at contract level (Patrucco et al., 2016).

If we look at private purchasing and supply management literature, the so called "vendor rating" process – defined as the set of metrics that, at different levels, are used to quantify both the efficiency and effectiveness of suppliers' actions (Caniato et al., 2014) - has received a lot of attention. The implementation of these systems, in fact, has demonstrated to be very effective when applied in a structured way, as they allow for a structured selection and evaluation of suppliers (Kannan and Tan, 2002) which, in turn, translates into cost savings (Ittner et al., 1999; Carter et al., 2010), improvement of business performance (Dumond, 1991; Kannan and Tan, 2006; Luzzini et al., 2014) and high-quality relationships (Carr and Pearson, 1999).

On the contrary, despite the large body of literature about public management PMS (e.g. Boland and Fowler, 2000), the topic of supplier evaluation seems not to be extensively addressed in both theory and practice (e.g. Ancarani, 2009). This is not so much surprising; public procurement is regulated by specific norms and regulation – promoting transparency, equality, fairness and open competition principles (Erridge and McIlroy, 2002; Raymond, 2008; Thai, 2009) – which don't make feasible establishment of long-term buyer-supplier relationships (Erridge and Greer, 2002) and, most importantly, don't allow inclusion of previous suppliers' performance into suppliers' tender (Sánchez Graells, 2015).

Although, it is evident that, as for the private sector, structured vendor rating systems represent the first driver for performance improvement, and attention on this variable cannot be neglected just for regulation motivations. These is even more critical for particular categories – like public works – where supplier improvement and good performance can be of benefits of both citizens and local

economy (Huang and Keskar, 2007). Hence, within the context of public procurement, they seem to be an interesting unit of analysis to spread awareness of vendor rating role and relevance for public administrations.

According to these premises, this work wants to study the application and consequences of supplier evaluation practices in the public context, using, as unit of analysis, procurement of public works projects.

Exploring vendor rating role in public procurement: a research framework

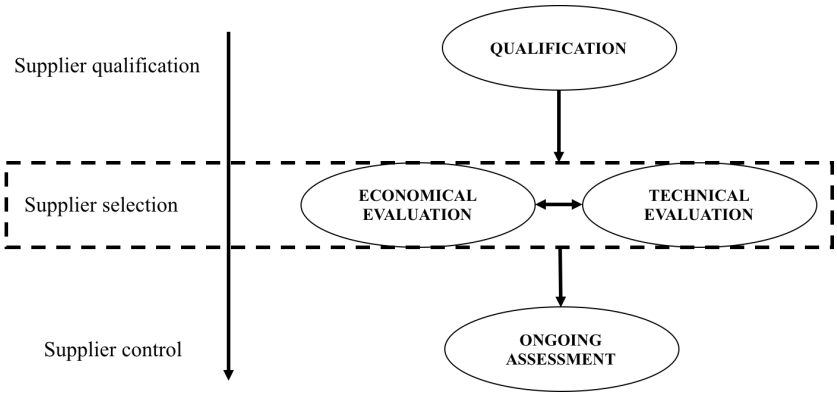
What emerges from the previous overview, is that, despite the relevance of performance measurement promoted by NPM for all government functions, this aspect is not so much diffused and addressed for what concern public procurement, for both regulation (there are some constrains limiting the degree of freedom of PMS design) and status (public procurement has been generally perceived as an administrative function) reasons (Rendon, 2008; Murray, 2009); this is even more true if we consider the contract level (i.e. supplier performance evaluation at contract level). However, these don't represent fair motivation, given the continuous improvement push that these systems can give, from which huge spending category (like public works) can benefit (Gori et al., 2017).
Sound supplier PMS, by enabling a structured selection and evaluation process (Kannan and Tan, 2002), generate advantages in terms of cost (Ittner et al., 1999; Carter et al., 2010), overall performance (Dumond, 1991; Kannan and Tan, 2006; Luzzini et al., 2014) and relationship (Carr and Pearson, 1999) improvement.
So, starting from this, the first aim of this research is trying to shed more light on the steps that public institutions should follow to design a structured supplier PMS, and the value they can get from this investment.

Since studies on public procurement in the public management field do not provide comprehensive contribution about on the design supplier PMS systems, in order to build our research framework, we start from the literature of the private context, trying to extract the design characteristics that better fit the public procurement process; from this, the model has been shaped according to the regulatory framework public procurement must respect.
Finally, the model is then specified for a particular procurement category – public works.

The supplier evaluation process in the public sector: research framework and motivations
As already discussed, in the private context, Caniato et al. (2014) identify three key choices in the designing a supplier PMS – strategic alignment, process configuration, execution; these three levels can be considered relevant also in the public sector, even though adapted to the public procurement environment.
In particular, given that the concept of "strategic alignment" can be hardly conceptualized for public authorities – where the "strategy" of government function is given and driven by broader policy objectives (Schapper et al., 2006), and that the decisions related of vendor rating execution (i.e. tools to support diffusion of the systems, control of measures and responsibilities) have similar implications that in the private context (e.g. Croom and Brandon-Jones, 2007), our attention is first on the process configuration choices, where the public procurement system seems to have higher impact.
First, we consider that, given the three typical phases of the measurement process – supplier qualification, supplier selection and supplier performance control, they are all relevant for the public domain, even though the public procurement regulation imposes some constraints at the different steps. So, if we want to suggest a reference framework for evaluating supplier performance, we still need to include and differentiate these three components, each one representing a different phase of measurement. Of course, the intensity of measurement in any of this stage will depend on both the

importance given by the procurement department to that specific stage, and the extent to which this concurs to strategic alignment and execution efforts (Flynn and Davis, 2016).
Considering the single step, the main conceptual difference between public and private context is in the case of supplier selection. In the case of public procurement, supplier selection can be managed according to two different options: lowest price or MEAT. Nevertheless, whatever the awarding criterion, the price always reveals to play an important role, being assigned a considerable weight (Roodhooft and Van den Abbeele, 2006).
This means that, according to the different situations, the selection criteria could include just economic aspects, or both economic and technical aspects, weighted differently.
For qualification and control, the regulation does not impose specific approach, neither a mandatory implementation. However, in line with the transparency principle, when present, qualification criteria and information gathered during contract execution (and results) need to evident and communicated to suppliers (Prahinski and Fan, 2007), thus indirect affecting the potential contract performance (Cûlfik et al., 2014; Gori et al., 2017). Finally, the discretional mechanisms based on the use of supplier performance in past relationships, which have proved to be very effective in the private context (Spagnolo, 2012) and in the U.S. public sector (Snider and Walkner, 2009), are not allowed to EU public institutions (Sánchez Graells, 2015). Past performance can although be included in an indirect way and only at supplier qualification level: at this step, contracting authorities may decide to ask the list of other authorities and industrial customers with which suppliers did business in previous years, thus being able to certify the overall performance of the vendor.

This discussion leads to the following framework (*Figure 1*):



As anticipated, in exploring the role that supplier PMS can have in the public context, we decide to use, as unit of analysis, a particular purchasing category – public works.
These types of projects are indeed characterised by some aspects making their execution worthy of attention such as high cost (Larson, 1995; Flyvbjerg et al., 2002; Wegelius-Lehtonen, 2001, Jacobson and Ok Choi, 2008), long durations (Ahadzi and Bowles, 2004; Chan and Chan, 2004; Cûlfik et al., 2014; Gori et al., 2017) and significant complexity (Takim and Akintoye, 2002; Lenferink et al., 2013). Furthermore, another important aspect highlighting the final performance of public works is the impact they have upon society (Lemer, 1999).
Thus, improving the performance of public works (in terms of cost, time and quality; Chan and Chan, 2004) is crucial interest for public administration at all levels, and a sound supplier qualification, selection and control process can definitely support this objective. Despite this, the regulatory framework characterizing public procurement seems to prevent the implementation of effective supplier PMS, so further analysis on the motivations that may force institutions to focus on this aspect can be considered value adding.

The supplier evaluation process in the public sector: hypothesis and research model

The previous discussion gives the possibility to state some more specific hypothesis on the role that the vendor rating process has for public institutions and, in particular, on the execution of public work projects.

First, it is reasonable to assume that a well-structured qualification may lead to the inclusion the "best suppliers" in the supply base. Some studies show how rigorous qualification requirements make the contracting authority capable to forecast whether the supplier is able to meet the specifications (Edler 2005) and to avoid misapplications of the procurement procedures (Jones, 2007). Special attention must be paid to this phase in the case of construction works, since a non-structured qualification leads to a wrong vendor selection, affecting the overall success of the work (Benaitiene and Banaitis, 2006). This leads to the formulation of the following hypothesis:

H1. A greater attention paid to the qualification stage may have a positive impact on work performance.

Then, we discuss that, regardless the selection criteria used, price always plays an important role in supplier selection (Roodhooft and Van den Abbeele, 2006). This is also true for public work, where the economic proposal evaluation is usually differentiated from the technical proposal evaluation (Gori et al., 2017). So, public institutions need to pay attention to the design of structured approaches for managing both types of evaluation, in order to arrive to the most suitable supplier choice.
On one side, selecting a supplier offering a reasonable bid from an economic point of view is crucial when dealing with expensive purchases as public works are (Huang and Keskar, 2007); on the other, identify the best economic offer is not enough, given the multi-dimensional complexity of public works (Lenferink et al., 2013), and also non-price attributes become important in the bids evaluation process. It is the combination of the two that may bring to the selection of the best suppliers, thus driving (indirectly) better work performance. This leads to the formulation of the following hypothesis:

H2. A greater attention paid to the economic evaluation of supplier proposal may have a positive impact on work performance.
H3. A greater attention paid to the technical evaluation of supplier proposal may have a positive impact on work performance.

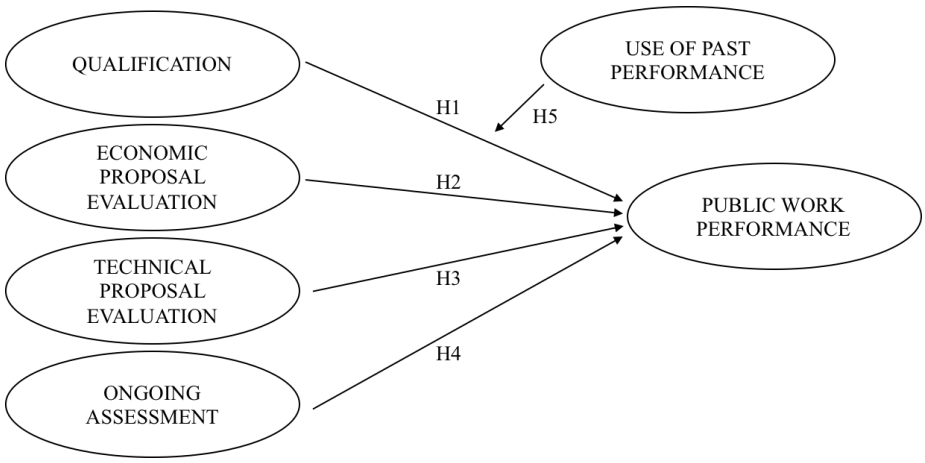
Differently to what happens for other purchasing categories, public works are characterised by long contract durations and activity execution (Ahadzi and Bowles, 2004; Lenferink et al., 2013), generating the need of measuring supplier performance during an extended period of time (Shenhar et al., 1997; Atkinson, 1999; Chan and Chan, 2004). Although measuring ongoing performance is complex and time-consuming, it is the point of starts for the identification of operational improvements, as well as for reducing project costs and duration (Wegelius-Lethonen, 2001).
This leads to the formulation of the following hypothesis:

H5. A greater attention paid to the measurement of ongoing supplier performance may have a positive impact on work performance.

Finally, even though with a limited incidence, we also include the role of supplier's past experience. As discussed, this role is weak if compared to the private sector, and it is allowed by the regulation only in the qualification stage. However, we cannot neglect that, when past experience and performance are included, the qualification stage can benefit of a more comprehensive view of suppliers. This leads to the formulation of the following hypothesis:

H5. The inclusion of past supplier performance in the qualification stage mediates the effect that intensity of qualification has on work performance.

The previous discussed hypothesis can be conceptualized in the following research model (*Figure 2*):



Research methodology: data collection and sample characteristics

Structure of the questionnaire

In order to test the model, we used data collected between September 2016 and March 2017 via online survey questionnaire, which was specifically designed for the purpose of this study. The ideal target respondent was construction company recently been involved in a public work contract.

The final version of the questionnaire uses, as a unit of analysis, a specific public work project (chosen by the respondent) executed within the last 3 years, and it is composed by 26 questions (most of them adopting a 1 – 4 Likert scale), divided into 4 sections: 1) Introduction (where general data about the company, the project and the public institution involved were collected); 2) Qualification (where information about the qualification criteria and approach used by the institution were collected); 3) Economical and technical proposal evaluation (where information about the selection criteria and approach used by the institution were collected); 4) Ongoing assessment (where information about the performance measured approach used by the institution during project execution were collected); 5) Results of the work (where information about overall project performance were collected)

Data collection

Our initial idea was to collect information using public administration as target respondents, but we realized that this type of data would hardly be collected because public managers initially addressed found difficult to identify the suitable person able to answer the questions or were not open to share this information for research purposes.

So, we decide to change the perspective, and consider, as target respondent, the suppliers.

To build our sample we start from the public available list of suppliers of the Italian public sector during the last 2 years. From the initial 83.000 company names on this list, we identify 6.013 references which actually were active construction companies in the recent past.

Before administering the survey, the questionnaire was first tested by selecting some of these companies (where contacts were already in place), to check the clarity of the questions.

Then, the questionnaire has been sent by mean of certified e-mail, asking the recipient to identify the most suitable person in the company to answer the questions. All the respondents are actually senior

and highly qualified project manager or construction manager, which were involved in first person in the project considerer as a unit of analysis. The final sample is composed of 205 responses (3,4% response rate).

The procedure of the study was a first way to control common method bias (Podsakoff et al., 2003). First, even though the research project was labelled as a comprehensive study to understand how public institutions manage the vendor rating process for public work projects, no reference to the model in *Figure 2* was provided, so that respondents' attention was not drawn to the relationships being targeted in this study. Moreover, questions were organized in an order that separated project characteristics from different vendor rating phases as well as from performance, to prevent respondents from developing their own theories about possible cause-effect relationships.
Finally, we immediately realized that a great bias in the data could have been asking the suppliers about the overall project performance (i.e. how much cost, quality and time of public work execution were under, over or in line with the contract target); however, once collected, the data about the projects were triangulated with information from Italian public administrations (public work reports over a certain threshold must be available to the public, upon justified request); in some cases, they were already present on the website; in others, follow – up calls and emails were necessary.

Sample descriptives

Table 1, 2 and 3 summarize characteristics of the respondents.

Geographical Area	Small	Medium	Large	Total
Northern Italy	22	56	14	92
Central Italy	6	39	6	51
Southern Italy	5	52	5	62
Total per area	**33**	**147**	**25**	**205**

UNSPSC	Meaning	Frequency	Freq. (%)
72102801	Renovation of buildings or landmarks or monuments	30	14,63
72102802	Restoration of buildings or landmarks or monuments	28	13,66
72131701	Highway or road paving or surfacing	28	13,66
72102902	Landscaping services	20	9,76
72103300	Infrastructure maintenance and repair services	13	6,34
Total answers		**205**	

Geographical Area	Regional	Local	Total
Northern Italy	12	92	**104**
Central Italy	3	54	**57**
Southern Italy	7	37	**44**
Total per area	**22**	**183**	**205**

Measures

The five constructs included in the model are summarized in *Table 4* and *Table 5*, in light of existent literature.

Table 4 summarizes the characteristics of the construct related to the vendor rating process, in light with the overall rationale of this process (Luzzini et al., 2014; Caniato et al., 2014).

Construct	Item	Sub-item	Variable	References
Qualification	Consider the qualification stage for the work you describe before. Please indicate to what extent the following aspects have been evaluated by the contracting authority (on a 1-4 scale)	Professional competence	Qualification 1	Shahadat (2003) Caldwell et al. (2005) Hackney et al. (2007) Raymond (2008)
		Financial capabilities	Qualification 2	
		Technical capabilities	Qualification 3	
	Consider the qualification stage for the work you describe before. Please evaluate the transparency shown by the contracting authority during the process (on a 1-4 scale)	-	Qualification 4	McCue and Gianakis (2001) Caldwell et al. (2012)
Economic Proposal Evaluation	Consider the selection stage for the work you describe before. Please indicate to what extent the following aspects have been evaluated by the contracting authority (on a 1-4 scale)	Economic proposal	Economic ev.1	Roodhooft and Van den Abbeele (2006) Huang and Keskar (2007)
	Consider the selection stage for the work you describe before. Please indicate the tendering tool used by the contracting authority	-	Economic ev.2	Croom and Brandon-Jones (2007) Gardenal (2009)
	Consider the selection stage for the work you describe before. Please evaluate the transparency shown by the contracting authority during the process (on a 1-4 scale)	-	Economic ev.3	Costa and Tavares, (2013) Spagnolo (2012) Costantino et al. (2011)
Technical Proposal Evaluation	Consider the selection stage for the work you describe before. Please indicate to what extent the following aspects have been evaluated by the contracting authority (on a 1-4 scale)	Project organization and duration	Technical ev.1	Chan and Chan (2004) Cûlfik et al. (2014) Gori et al. (2017)
		Quality of the work	Technical ev.2	
Ongoing Assessment	Consider the evaluation of performance during the execution of the work. Please indicate to what extent the following aspects have been evaluated by the contracting authority (on a 1-4 scale)	Financial capabilities	Ongoing 1	Takim and Akintoye, (2002) Chester and Hendrickson (2005) Shenhar et al. (1997) Wegelius-Lethonen (2001)
		Technical capabilities	Ongoing 2	
		Cost of the work	Ongoing 3	
		Schedule of the work	Ongoing 4	
		Quality of the work	Ongoing 5	
	Consider the evaluation of performance during the execution of the work. Please evaluate the frequency used by the contracting authority to communicate to your organization about the collected performance (on a 1-4 scale)	-	Ongoing 6	Prahinski and Fan (2007)

Table 5 shows instead the face validity for the dependent construct "Performance", which was assessed according to the cost, time and quality dimension (Chan and Chan, 2004). In order to obtain the performance indicators, starting from the data collected, we used the project variance approach for cost overruns, delays and activity scope (Flyvbjerg et al., 2002; Hsieh et al., 2004; Cûlfik et al.,

2014; Gori et al., 2017), by calculating the percentage of changes between what established at a contract level and what performed during the execution.

Variable	Item	Sub - item	Indicator	References
Cost	Consider the evaluation of performance during the execution of the work. Please indicate the cost (in €) established in the contract.	Cost.1	$\frac{Cost.2 - Cost.1}{Cost.1}$	Shenhar et al. (1997) Atkinson (1999) Wegelius-Lehtonen (2001) Chan and Chan (2004)
	Consider the evaluation of performance during the execution of the work. Please indicate the actual cost (in €) performed.	Cost.2		
Time	Consider the evaluation of performance during the execution of the work. Please indicate the execution time (in days) established in the contract.	Time.1	$\frac{Time.2 - Time.1}{Time.1}$	
	Consider the evaluation of performance during the execution of the work. Please indicate the actual execution time (in days) performed.	Time.2		
Quality	Consider the evaluation of performance during the execution of the work. Please indicate how much activities were executed in line with the project scope document	Qual.1		

According to these definitions, we try to operationalize the constructs on the data by running a factor analysis, with indictors on factors loading and Cronbach Alpha detailed in *Table 6*.

Variable/Factor	A	B	C	D	E
Qualification 1		0,970			
Qualification 2		0,877			
Qualification 3		0,939			
Qualification 4		0,965			
Economic ev. 1			0,679		
Economic ev. 2			0,901		
Economic ev. 3			0,871		
Technical ev. 1				0,858	
Technical ev. 2				0,823	
Ongoing 1	0,921				
Ongoing 2	0,971				
Ongoing 3	0,962				
Ongoing 4	0,961				
Ongoing 5	0,955				
Ongoing 6	0,882				
Cost					0,603
Time					0,918
Quality					0,638

Cronbach	*0,939*	*0,969*	*0,765*	*0,917*	*0,701*
Total variance explained = 72.322% Extraction Method: Principal Component Analysis, 5 factors imposed, Cases excluded pairwise. Rotation Method: Varimax with Kaiser Normalization. Factor loadings under .45 are not shown.					

As the value of Cronbach alpha are all higher than 0.7, we can consider the constructs acceptable.

5. Data analysis

In order to analyse data and test the model, we first performed some tests to assess common method bias. Given that we relied on a single respondent design, we controlled for common method bias in two ways: through the procedure of the study and through statistical control (Podsakoff et al., 2003). We already discuss the procedure of the study (*section 4.2*); to check common method bias from a statistical perspective, we performed the common latent factor technique (Podsakoff et al., 2003). With this analysis, we found that the common latent variable has a linear estimate of .6352. This value, when squared, indicates a variance of .404 which is below the threshold of .50. Overall, this ensures data analysis is not excessively affected by common method bias.
The presented hypotheses were tested using Covariance-based Structural Equation modelling (CB-SEM), which is a common method employed for this type of research, together with Partial Least Square Structural Equation modelling (PLS-SEM; e.g. Perols et al., 2013). As objective of our research is theory testing and confirmation, we decide to adopt CB-SEM, being PLS-SEM more suitable when the research objective is prediction and theory development (Hair et al., 2011).
The model was tested using the maximum likelihood (ML) estimation method (Arbuckle, 2009), as ML compared to other methods (like Generalized Least Squares and Weighted Least Squares) is able to provide more realistic indexes of overall fit and less biased parameter values for paths that overlap with the true model (Olsson et al., 2000). ML estimation assumes that the variables in the model are (conditionally) multivariate normal, which is true for our dataset according to the Doornik – Hansen test ($p > \chi^2 = 0.000$).

The hypothesized model was tested statistically in a simultaneous analysis of the entire system of variables to determine the extent to which it is was consistent with the data. As long as the goodness-of-fit is adequate, the model argues for the plausibility of postulated relations among variables. The research model is analysed and interpreted sequentially in two stages: first the assessment of the reliability and validity of the measurement model and secondly the assessment of the structural model (Anderson and Gerbing, 1988; Hulland, 1999). Stata 14.0 was used to estimate both the measurement model and the structural model. The ML algorithm was used to obtain the paths, the loadings, the weights and the quality criteria.

Results

Measurement model

The measurement model fit indicators were found to be satisfactory (χ^2=202,823; χ^2/d.f.=1,673; RMSEA=.058; GFI=.907; AGFI=.869; IFI=.942; CFI=.980). The factors reliability, as measured by the Cronbach's alpha and Composite Reliability (Fornell and Larcker, 1981) was fully satisfactory (Nunnally, 1994). Additionally, convergent validity was assessed through significant loadings from all scale items on the hypothesized constructs, and through the Average Variance Extracted (AVE, Anderson and Gerbing 1988): AVE ranges between 52 and 78%.

Structural model

The postulated path model produced a sufficient fit to the data (χ^2=387,866; χ^2/d.f.=2.83; RMSEA=.095; GFI=.982; AGFI=.922; IFI=.926; CFI=.937). *Table 8* shows the results of the hypotheses testing. As we can see, standardized effects are positive and highly significant on work performance for Qualification and Ongoing Assessment influence (p-values < 0,05). By contrast, hypotheses H2 and H3 must be rejected.

Parameter estimates		**Std error**	**Z**	**p**
Qualification → Work performance	.94***	.023	3,997	.000
Economic proposal evaluation → Work performance	-.15 (ns)	.035	-0,417	.677
Technical proposal evaluation → Work performance	.022 (ns)	.028	0.802	.423
Ongoing assessment → Work performance	.121***	.038	3,215	.001
*Notes: *p<0.5; **p<0.01; ***p<0.001 (two tailed test)*				

We also test whether the use of reputational mechanisms based on supplier's past performance during qualification moderates the (statistical relevant) relationship between the work performance and the qualification itself.
The "use of past performance" has been measure in the questionnaire through a binary variable (1 if the institution has asked the supplier to provide references, 0 if not). *Table 9* show the results of the moderation analysis: the interaction hypothesis must be rejected because of a p-value equal to .7525, higher than the .05 threshold.

Model	**Coeff**	**Std error**	**t**	**p**
Constant	2.0046	.0502	39,9694	.000
Past performance	.2305	.06404	.3599	.7193
Qualification	.1179	.0234	5.0337	.000
Interaction	-.0551	.1746	-.3158	.7525

Discussion of results

The tested research model aims to study the influence that a structured vendor rating process may have on the performance obtained during the execution of a public work project.
Our results show that higher intensity in designing a sound qualification stage and structured measures for assessing supplier performance during the execution of the project has a positive impact in driving good project performance, while no evidence is found relating to the intensity of the economic and technical proposal evaluation. Also, past performance seems not to influence the relationship at the qualification stage (the only step, within the public vendor rating process, where they can be integrated).
The positive relationship between the design of a proper qualification for public work suppliers, and the performance obtained from those suppliers (once the contract has been activated) are in line with what theoretically affirmed by some scholars in the past. In the private sector, the importance of qualification has been extensively analyzed, demonstrating that this step, if properly executed, can have a positive impact upon the overall performance of the buying company (Carter et al., 1998; Sánchez-Rodríguez et al., 2005). This is not so different if we look at the public sector; qualification should be the first evaluation step also for public institution, independently from the procedure (open or restricted; Erridge and McIlroy, 2002; Bovis, 2005; Patrucco et al., 2017).
In this stage, the contracting authority excludes all those potential suppliers who do not meet the minimum requirements to carry out the supply (Wong et al., 2001; Arrowsmith, 2009); so, rigorous qualification requirements might enable a contracting authority to forecast whether potential supplier will be able to meet the required specifications successfully (e.g. Edler 2005).

Of course, qualification parameters in the public context are limited by the regulation (e.g. on-site visits are not allowed for a matter of transparency and equality; McCue and Gianakis, 2001), but this does not mean that this stage should be neglected. The EU Directives encourage supplier evaluation in terms of professional competences, financial capabilities and technical capabilities, despite this not being mandatory.
This is even more critical if we consider purchases with high cost relevance and long duration (like public works), since a non-structured qualification may lead to a wrong vendor selection, affecting the overall success of the contract (Benaitiene and Banaitis, 2006).
So, by demonstrating and empirical and positive relationship between the intensity of the qualification, and the performance obtained from the suppliers, we are able to push institution attention toward this (often) neglected step. Public administration should invest time and resources in designing a good qualification system, because this pays back in terms of work activities execution, brining better results in terms of cost, time and quality. From a broader perspective, a strong screening of the supply base, aligned to public procurement principles, assures that only the suitable suppliers will have access the selection phase.

The positive relationship between the ongoing assessment of suppliers performance during work execution and project performance, drives instead the attention toward another long – standing problem of the public sector: the contract approach to performance measurement. Public institutions tend to limit the definition (and control) of performance to what agreed at contract level; if this could be enough for simple purchases, this may become critical for complex ones, like public works, which are characterised by long durations and capital investment (Ahadzi and Bowles, 2004; Lenferink et al., 2013), thus generating the need of measuring work performance during the execution itself and using different metrics (Shenhar et al., 1997; Atkinson, 1999), in order to understand how suppliers are performing.
Supplier performance assessment should not be limited to verify that the supplier is accomplishing what has been established in the contract (normative approach), but it should be the point of start to collect information for identifying potential areas of improvement and understand how to improve future selection processes. Even though the formal inclusion of past performance is not allowed in public procedures, this does not mean that institutions should forget to monitor such performance (Erridge and Greer, 2002; Spagnolo, 2012; Sánchez Graells, 2015). Nevertheless, when information is gathered during the work's execution and the results are communicated to suppliers ongoing (Prahinski and Fan, 2007), there is a probability that the suppliers will try to improve or keep performance at good level, thus positively affected the final performance of the project (Cûlfik et al., 2014; Gori et al., 2017) and this aspect should not be underestimated, given the characteristics of public works, in terms of cost (Larson, 1995; Flyvbjerg et al., 2002), duration (Shenhar et al., 1997; Atkinson, 1999; Ahadzi and Bowles, 2004; Cûlfik et al., 2014; Gori et al., 2017), and complexity (Lenferink et al., 2013).

It is also reasonable that data don't show statistical relevance on the relationship between technical and economical evaluation and project performance.
For what concerns the hypothesis H2, which assumes an impact between the intensity of measurement in a usual selection process based on price criteria and the success of the work, it has been said so far that, supplier selection in the public sector is generally driven by price (Roodhooft and Van den Abbeele, 2006). The economic proposal evaluation is already a standard and a consolidated practice in the public procurement process, so higher intensity or a better structuring does not drive strong push on supplier performance. Similar consideration can be made on H3, as our data does not support the linkage between the intensity of public organisation in structuring the evaluation of technical aspects of supplier proposal during the selection and the result obtained with the work. It is thus clear that selecting suppliers by giving high relevance to what their bid proposes in terms of duration and

quality is not enough to understand the reasonability of such offers so as to prevent delays and low-quality executions.
Finally, some fundamental considerations can be made. Coming back to the steps of supplier evaluation in public procurement and their connection to the regulatory framework, it is possible to highlight how the qualification stage is carried out in some specific circumstances, depending on the awarding procedure used for the specific procurement process. The implementation of the Ongoing Assessment is instead left to the discretion of the public institution. By contrast, supplier selection must be carried out by resorting to open tendering procedures (Falagario et al., 2012; Patrucco, 2014). In such processes, the price is always assessed (Roodhooft and Van den Abbeele, 2006; Costantino et al., 2011; Patrucco, 2014) while the evaluation of the technical aspects is done when the awarding criterion used is the MEAT. In such a context, differently from what happens with Qualification and Ongoing Assessment, the supplier selection through tender is always carried out, regardless the characteristics of the specific project. Thus, a non-differential process among the different observations, is definetely not the driver of superior results.

The main findings and implications are summarized in *Table 10:*

Finding	**Implications**
Investing in designing a structured supplier qualification system and performance evaluation during the work execution pushes superior project work performance. Therefore, despite the binding regulation surrounding public procurement, the benefits provided by the vendor rating systems in the private sector can be transferred to the context of public works when the process focuses on these two phases.	1) Qualification is a supplier evaluation stage whose implementation is allowed independently from the awarding procedure. Public administrations should invest in designing their qualification stage, as this increase information collected on their suppliers 2) Ongoing performance assessment is an arbitrary phase of measurement. Public administrations should invest in designing their supplier ongoing performance assessment because it is the main lever to obtain superior performance, independently from what agree at contract level
The effort on evaluating supplier bids, from both economic and technical perspective, does not impact directly performance obtained from the suppliers	Supplier selection approaches are constrained and should be mandatory executed according to specific rules and circumstances. Public administrations should assure compliance to this regulation, but not invest additional resources on their design because, besides accomplishing public procurement principles, they are not a predictor of the work success.

Abstract

More and more, academics and practitioners are urging organizations to adopt systems, techniques, or methods to use big data (BD) in their procurement practices to remain competitive. A major existing gap is the lack of understanding on how to generate value from the large amounts of varied data in procurement practices. Thus, with this study, we aim to increase the understanding of possible application areas of BD in procurement. By conducting a systematic literature review on the topic, we generate five procurement related research avenues for future studies, and thus develop a research agenda.

Keywords: Big data; procurement; predictive analysis

Introduction

Big data analytics (BDA) offers organizations powerful means to obtain value from the increasing amounts of data created internally and externally. Procurement, or in other words, the practices related to the inflow of supply including activities from strategizing for supply to the selection of suppliers, management of supplier relationships, and ordering and expedition, has claimed having a huge potential, but being lagging behind in benefiting from BDA (Schoenherr & Speier-Pero, 2015). In this area, knowledge generation has been suggested to happen by, e.g., using BDA to evaluate different supply risk scenarios (Schoenherr and Speier-Pero, 2015), improve data-driven projections on demand to plan purchases (Sanders, 2014), or aligning better internal and external supplier goals and processes to improve supply flows (Wang, et al. 2016). The purpose of this paper is to map current understanding about application areas of BDA in procurement through conducting a systematic literature review.

Big data (BD) is about large amounts of observational data that can support different decisions at different time frames (Bag, 2016). One existing issue is the understanding of how to utilize the data for business purposes. Stentoft et al. (2016) suggest that most companies don't yet know how to generate value from BD or a large amount of varied data. We aim to advance the field by studying how BDA literature has handled procurement, and how research could proceed to support procurement managers in their attempts to benefiting from BDA. Our research questions (RQ) are:

RQ1: How does extant research about BDA address and support procurement related decision-making?

RQ2: What are the future research opportunities for advancing knowledge generation through BDA in the area of procurement?

Method

For this study, we employed a systematic literature review approach to map the state of knowledge on BDA in procurement. We followed the process suggested by Rousseau et al. (2008), with the aim to answer our RQs. The following steps were taken to identify, extract and synthesize the findings.

Comprehensive identification of relevant research

Five stages of search and selection were performed to identify the relevant research. A keyword search was conducted in Google Scholar (in the article titles and keywords), and further validated by a search in Scopus and Web of Science (in the abstracts and keywords). No additional articles were found in the validating round. The keywords used for the search were originally based on an exploratory literature review using the phrase 'big data in procurement', and then through a discussion between all three authors a broader range of terms synonymous to big data and procurement were added. Two groups of keywords were defined, one indicating the definition of procurement (i.e. procurement, purchasing, supply, sourcing, supplier, negotiation), and those covering BD (i.e. big data, data analytics, data sciences, predictive analysis, data-based decision making, intelligence), and one keyword from both groups were required to appear in the articles (the logical operator 'AND' was used). The three authors jointly decided on the initial cleaning criteria and on the focus, which was to include all available articles that were accessible including journal, conference, and practitioner articles. One of the researchers went through the hits and based on these criteria, and deleting double hits, ended with 214 initial articles.

These articles were divided between the three authors so that at least 2 authors reviewed each paper. The inclusion and exclusion criteria were jointly decided by the three authors. Each of the researchers, color coded the articles according to red (excluded), yellow (uncertain), or green (included). By comparing the color codes, each pair of researchers disagreed or were uncertain about 20-25 articles (i.e. those coded as red-green, red-yellow, yellow-green, yellow-yellow), which they read again and held joint discussions until consensus was reached. The 76 articles identified in this round, were then divided between the authors for a more in-depth review by reading the whole article. Before data extraction, each article was again reviewed to ensure that it both had findings related to procurement or supply management, and that it was on BD. The excluded articles were then read by another author, and in case of difference of opinion they were discussed in the group until consensus was reached. Finally, articles mentioned in the literature reviews on BD in procurement were identified and reviewed according to our criteria (ended up in 3 additional papers). This comprehensive process resulted in 52 articles which were reviewed and coded.

Organizing and interpreting

For data extraction, following the Rousseau et al. (2008) suggestions, we first developed codes jointly among all authors, based on the exploratory round and previous literature. Codes for the procurement decisions were adapted from Van Weele (2010) strategic, tactical, and operational parts of the purchasing process (additional codes were added if procurement decisions not included in the framework were discussed in the papers). The codes were tested for four articles and adjusted accordingly. The articles were divided between the three authors for coding. To reduce mistakes and avoid omission of relevant material, the researchers met frequently during the coding process to discuss uncertainties and coding procedures. Next, the overall coding tables were combined, and reviewed by one of the researchers, and data was organized, probed, and sifted. Different themes

and topics of analysis were identified and divided between the authors (i.e. see next section of the paper). If necessary, data was again organized, probed, coded, aggregated, and cross-tabulated in different excel sheets for synthesis.

Synthesis

The themes, issues, and gaps surfaced in the process and based on the data were summarized in graphs and tables, and reviewed in the team by all authors. Inconsistencies (e.g. whether the paper was in fact discussing BD, or if the method was relevant) were also discussed in the team until consensus was reached. The results of this process are summarized in the next section of the paper.

Results

Over half of the articles were from academic journals, 32% of the articles were from conference proceedings (i.e. 17 articles), and 1 article was from a practitioner based journal of *Procurement Executive Insights*. From the 34 academic journal articles, two were from the *Journal of Computers & Operations Research*; all the other journals had one article each. From this list, there was one procurement based journal (*International Journal of Procurement Management*), three logistics and SCM journals (*International Journal of Logistics: Research and Application, International Journal of Physical Distribution and Logistics Management,* and *Journal of Business Logistics*), and an additional two operations management journals (i.e. *International Journal of Production Economics,* and *International Journal of Operations and Production Management*).

Development of the research throughout the years

As shown in Figure 1, the topic has gained attention only in the recent years with the first articles on the topic being published in 2008 and it is only gaining momentum from 2014 onwards (with 7, 6, 14, and 18 articles each year until 2017). The analysis about the focus areas of the articles (Figure 1), revealed that the articles with SCM as their main topic dominate the sample (29 articles/55%). Around one third of the articles (16 articles/30%) was discussing procurement as their main topic. Articles from other topics with findings related to the application of BDA in procurement were from supply chain (SC) risk management, supply market intelligence (SMI), new product development (NPD), and e-commerce (i.e. 3, 2, 1, and 1 articles, respectively). As visible in Figure 1, SCM and procurement are the two topics that have published articles on the application of BDA in procurement for the longest time (i.e. since 2008); SC risk management's first article on the topic was in 2013, SMI's in 2014, and NPD and e-commerce's in 2016.

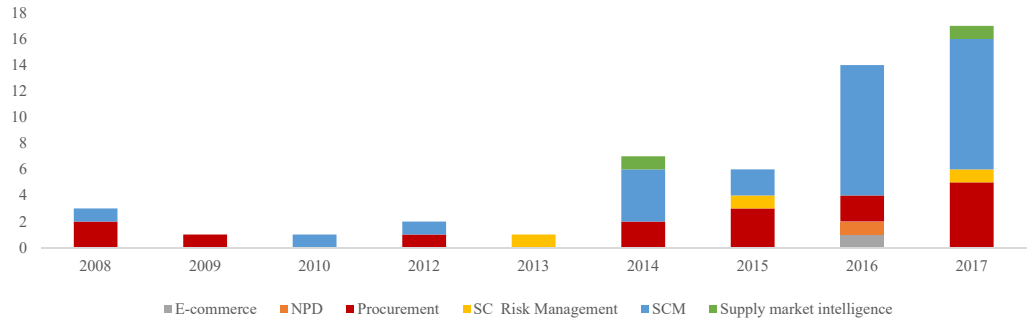

Figure 1 Number of articles with focus on different topics throughout the years (from 52 articles)

Methodology used in the articles

The majority of the articles, as shown in Figure 2, are either conceptual (i.e. 16 articles), or use modelling methods (i.e. 13 articles). This is followed by literature reviews and articles employing mixed methods (i.e. with 8 and 7 articles each). From the mixed method articles, 2 use focus groups and interviews, 2 use a combination of modelling and conceptual development, 1 uses modelling and a single case to illustrate its application, 1 uses modelling and empirical experiments for validation, and 2 use a combination of surveys and interviews, from which one also included a multiple case study. Additionally, there are 2 articles using a Delphi methodology and 2 using surveys. There is only one pure case study paper, and two articles using methods borrowed from other disciplines: sentiment analysis and native category approach. The practitioner based journal article, had not specified the method used behind its analysis.

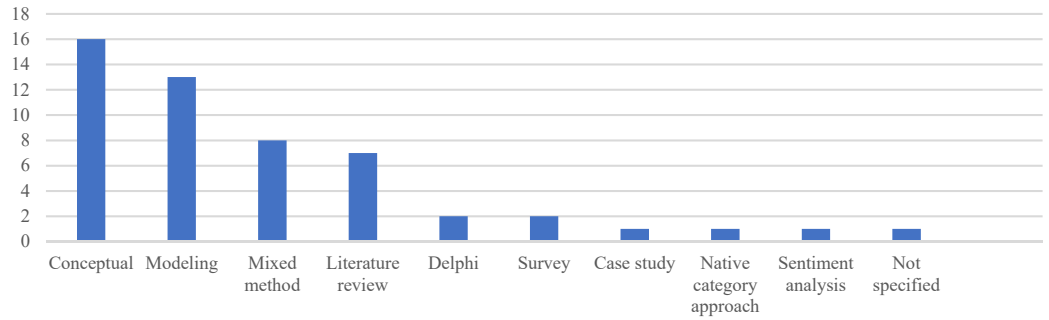

Figure 2 Distribution of articles based on method employed (from 52 articles)

From a total of 16 articles that used empirics to reach their conclusions, 46% used qualitative data, 27% used quantitative data, and another 28% used a mix of both quantitative and qualitative data. More details of these empirical papers are discussed under application avenues of BDA in procurement.

Scope of procurement related big data

The majority of the articles (i.e. 37) use the term BD, followed by other terms such as supplier intelligence (Jeeva and Dickie, 2012), supply market intelligence (Handfield, 2014), or word of mouth data (WOM) (Swain and Cao, 2017). Others refer to the concept using phrases such as '*huge amount of information regarding SC members*' (Rubio et al., 2016), or '*vast amount of data in various forms*' (Sahay and Ranjan, 2008), without using the actual term big data. While these articles used different characterization for BD, the majority referred to the 3Vs, describing Volume (beyond traditional data management capabilities), Variety (in different formats and form different sources) and Velocity (created in higher speed than ever) (e.g. Rozados and Tjahjono, 2014). Some of the articles had attempted to discuss BD in the procurement context, or what we will call procurement big data (PBD). Summarizing these discussions within the 3Vs, PBD was characterized to be in large volumes compared to traditional data, be of high variety in terms of sources (i.e. internal firm sources, external sources, private and public sources, open source, and the internet), as well as in terms formats (i.e. structured and unstructured, traditional and new, historical, etc.), and to be dynamic, and capture the real-time situation.

In terms of variety, a multitude of different sources and formats was suggested in the articles, reflecting on the seeable and unseeable potentials for PBD, which can be classified based on the internal and external source of data. From an external perspective, data from different social media sources, different data from or on the supply market (e.g. electronic market places, market indices,

market journals, etc.), data gathered from different media forms, and risk related data (such as indices, reports, critical commodity or supplier lists, weather report, natural disasters, etc.) were stressed the most. Among internal data types, spend data, purchasing data (e.g. product, ID, date, time, etc.), supplier data (e.g. qualification or performance profiles), and transactional data were the most highlighted.

Application avenues of BDA in procurement

The use of higher-level theories is almost absent in the articles in our sample. The only exception is the article by Liang et al. (2016) that applied social network theory to the context of procurement fraud detection. The article uses big data to quantify intimacy between buyers and suppliers and abnormal interactions, commodity prices and supplier credits.

We also summarized what procurement decisions (i.e. strategic, tactical, and operational) could benefit from BDA (Table 1). From the complete sample of 52 articles, supply risk management and supplier selection were the two procurement decisions that were mentioned the most. Strategic procurement decisions ranging from supply risk management and sourcing to sourcing innovation and category management in general had been mentioned more than others. On the other hand, operational decisions had received little attention.

Table 1 Suggested procurement decisions that can be supported by BDA

	Procurement decision	References	No

Total number of articles		52

Looking closer at the finding of articles that used empirics, as listed in Table 2, we can classify them as those suggesting how companies can be more successful in application of PBD analytics, those describing the status of PBD in the industry, and those discussing the potential benefits that BDA can have for procurement decisions. In terms of success factors for PBD analytics, aside from the required PBD analyst skills (Bag, 2016; Handfield, 2014), it is suggested that organizations need to first internally integrate their information systems and then reach external integration before applying BDA, include suppliers in the decision making, know how or why they can use the BDA results, and, develop performance measurements for PBD analytics. The studies looking at the status of PBD in practice, suggest the area to be of growing importance (Sanders, 2016; Schoenherr and Speier-Pero, 2015), and that several companies are outsourcing parts or all of the analytical process to third parties (Sanders, 2016; Handfield, 2014). The articles on benefits of PBD either introduce an applicable model, map the opinion of experts/practitioners, or investigate the link between big data and procurement outcomes by regression path analysis (see Table 2 for details).

Table 2 Findings of the empirical articles

Nature of findings	Finding	Method and data	Reference
Success factors PBD application	For application of BDA, orgs first need internal integration, then external collaboration	2 focus groups with 75 purchasing professionals + 6 semi-structured interviews	Paajanen et al. 2017
	Supplier inclusions in decision making can assist BDA application	Survey of 481 responses	Banerjee and Mishra, 2016
	Skills of a Procurement BD analyst	Multi-criteria model based on evaluation of three candidates for a position by three decision makers based on eight skill sets	Bag, 2016
Success factors PBD application, & Status of PBD in practice	Sourcing is a growing area in terms of BDA; need to know how to use BDA results; Orgs are outsourcing BDA	52 open ended interviews + 102 survey responses + 4 cases	Sanders, 2016
	Orgs need to develop capabilities; Orgs are outsourcing BDA; need for performance measure for BDA	9 interviews and a survey of 89 companies	Handfield, 2014
Status of PBD in practice	45% of their sample had some sort of PBD initiative and another 18% had future plans to incorporate	Survey of 531 SCM experts (6.2% purchasing)	Schoenherr and Speier-Pero, 2015
Potential benefits of PBD	BDA can improve sourcing (supplier selection, evaluation, and price negotiation)	Modelling based on 1 manufacturer, 18 suppliers, 5 criteria	Deswal and Garg, 2015
	BDA can improve sourcing (supplier selection, evaluation, and price negotiation)	Delphi study with 24 individuals	Brinch et al. 2017
	BDA can improve strategic and tactical sourcing	4 focus groups with 15 procurement experts + non-specified number of interviews at the cases	Moretto et al. 2017
	BDA can improve procurement visibility and thus, sourcing	Modelling based on procurement transactions of one company between 2011 and 2014	Tan and Lee, 2015
	AHP and PCA both have shortcomings in handling BD for supplier selection	Survey from 235 suppliers on 21 criteria	Matta and Tayal, 2017
	BDA can improve sourcing (supplier selection, evaluation, and price negotiation), collaboration, visibility, and risk management	27 interviews in 27companies in 6 countries	Richey et al. 2016
	BDA can improve collaboration, visibility, and risk management	Delphi study with 20 individuals	Kache and Seuring, 2017
	Social media can improve collaboration, visibility, risk management, and supplier selection	Regression analysis of unstructured social media data from 600 companies	Swain and Cao, 2017

	BDA can improve procurement fraud detection	Modelling based on 100s of fraud cases and used in 65000+ vendors in 150 countries over 12 months	Dhurandhar et al. 2015
Total number of articles			**15**

Going deeper into the articles that suggest an actual application solution for BDA in procurement, we identify a number of common themes (see Table 3) with the two major ones being models to use BDA for supplier selection and better manage supply risk (e.g. detection of fraud, abnormalities, anomalies, unusual behavior). The other articles were grouped into those suggesting frameworks or models that can improve procurement visibility (i.e. visualization tools, RFID tracking, pattern identification), and frameworks or models related to how to use BDA to more generally support procurement decision making.

Among these suggested models and frameworks, less than a handful are based on empirical data and are worth highlighting. Tan and Lee (2015) introduce an analytical model to use BDA to improve decision making regarding internal demand aggregation and better coordinate procurement. They use an online analytical processing (OLAP) concept that includes drilling, pivoting, dicing and aggregating of data. Dhurandhar et al. (2015) suggest a model to identify procurement related fraud/risk using public and private sources of data ranging from transactional data, private sources (e.g. vendor master files, RFXs, risky vendor list, vendor bank account numbers, vendor-employee bank account matches, risky commodity list, global clip levels, company risk reports, financial indices, social networking data), to public data sources (e.g. government listed forbidden parties, country perception indices, tax haven locations, advance search engine searches, DUNS numbers). Finally, Mori et al. (2012), Deswal and Garg (2015) and Matta and Tayal (2017) apply analytical models (fuzzy logic, AHP, and PCA) to use BDA to select suppliers; all three articles either base their models on, or validate by, empirical data.

Table 3 Findings of the articles suggesting an application solution for BDA in procurement

Theme	Application solution	Method	Reference
Supplier selection	Shows application of AHP and PCA for handling BD for supplier selection	Model based on a survey from 235 suppliers on 21 criteria	Matta and Tayal, 2017
	A model using fuzzy logic approach and using MATLAB they show a supplier selection case	Model based on 1 manufacturer, 18 suppliers, 15 criteria	Deswal and Garg, 2015
	An AI model to match plausible partners	Validated by experiments on 30660 mans	Mori et al. 2012
	An analytical model using Fuzzy cognitive mapping to use BD for better sourcing of IT services	Modelling (No data)	Choi et al. 2016
	An analytical model to use BD for better and sustainable supplier selection and order allocation	Modelling (No data)	Kaur and Singh, 2017
Supply risk	A conceptual framework and simulation for using BDA for supply risk management	Conceptual	He et al. 2014
	Automated screening to identify deception instances	Modelling (No data)	Zage et al. 2013
	A robust tool to identify procurement related fraud/risk using public and private sources	Model based on 100s of fraud cases. Used on 65000+ vendors	Dhurandhar et al. 2015
	Procurement fraud detection system using data crawling in social networks, company profiles, and the internet	Modelling (No data)	Liang et al. 2016
Visibility	Application of data visualization for quick identification of issues, and access to e.g. supplier, model, part info.	Conceptual	Tan et al. 2016
	Cloud based system that tracks using RFID tags	Conceptual	Chircu et al. 2014
	An analytical system that uses open government budget requests and procurement records to identify spend patterns	Modelling (No data)	Surasvadi et al. 2017
Decision making support	A SCA architecture to use SC BD including supplier data to support decision making	Conceptual	Biswas and Sen, 2016
	An eProcurement system based on agent technology and OLAP to better co-ordination supply and demand	Modelling (No data)	Shaoling and Yan, 2008
	A framework for application of advanced analytics throughout the procurement process	Modelling (No data)	Lee et al. 2009

	An analytical model to use BD to improve decision making regarding internal demand aggregation and coordination	Model based on procurement transactions of one company between 2011 and 2014	Tan and Lee, 2015
	A simulation model using BD on capacity distributions to make dual versus single sourcing decisions	Modelling (No data)	Ivanov, 2017
Total number of articles			**17**

Discussion and further research

Our literature review contributes with a state-of-the-art description of the documented knowledge in the field of PBD. The findings add to our general understanding of how BDA can be utilized for procurement practice and paint a better picture of the current understanding of the matter. These findings also shed lights on possible and needed further research. We find that the number of publications on PBD is increasing but the total body of literature is still quite small. Big data's usefulness for procurement has mainly been studied as part of the wider SCM area, while there are very few papers with a specific focus on big data in procurement. These studies are too limited in number, data points, and findings, to make general conclusions and there is a need for more studies to develop such understandings. We identify five general areas of future research: conceptualizing and theorizing PBD, PBD capabilities, PBD application areas, PBD practices and trends, PBD interventions and design.

We found that the literature identifies many different data sources and formats of potential relevance for PBD. However, no conceptualization or categorization of data sources and data types has been presented from a procurement process perspective, and data sources and types have not been related to specific procurement applications. The review mainly shows that a wide spread of data sources and formats could be relevant for many different types of procurement decisions. Clearly defined and commonly used definitions and concepts are necessary for theoretical grounding and allowing for cumulative knowledge generation in the field. Consequently, future research should *establish common definitions and constructs of big data sources and formats of relevance for procurement decision making*.

Second, we only identified one paper on PBD capabilities, which is arguably an important topic in this field; i.e. the 'competence to provide business insights using data management, infrastructure and talent capacity to transform business into a competitive force' (Akter and Wamba, 2016). The lack of studies on capabilities is not surprising; it is hard to study without primary access to practices. Future research on *how capabilities moderate the PBD link to functional and firm level performance* is important for understanding the potential of PBD in strategy formation. Such studies should explore how management, technology and talent related big data capabilities contribute to achieving this. Such studies would require access to primary empirical data, but should also build on findings on BDA capability studies in other domains. Several companies are exploring and experimenting how they could benefit from BDA, so very soon we should have a much better understanding of what and how to benefit from BDA in procurement. No reviewed study uses an existing theoretical model on such a topic. In general, there is a weak theoretical underpinning among the reviewed studies. Future capability studies could, for example, build on resource-based view or dynamic capability models. So, a question for future research is *how existing operations management/organizational theories could help to better understand or predict application of BDA in the procurement area*.

Thirdly, Table 1 contributes with a preliminary conceptualization of application areas of PBD, and Tables 2 and 3 contribute with summaries of detailed findings on PBD application. The literature identifies many possible procurement application areas of BDA, with the majority of studies related

to supply risk management and supplier selection, and where future research should build on the existing findings. Supplier risk management is the most developed area, with at least three models showing the possibility of prescriptive and predictive models to use different data (structured and unstructured) from internal and external, and public and private source to better detect and thus manage disruptions (Zage et al. 2013; Dhurandhar et al. 2015; Liang et al. 2016). Future research should study the question w*hat are the topics and areas in supply risk management that BDA can better solve.* Supplier selection is another area, which had received attention by suggesting different BDA models for this area. However, there is still scarcity of studies, and *more studies are called for to test and validate a variety of different BDA models for supplier selection.* The PBD application topics have mainly been studied with modelling approaches using predictive and prescriptive analytics. The primary focus has not been the big data, but rather the analytics. In correspondence with the conclusions of Wang et al.'s (2016) review of big data in logistics and SCM, we identify very few studies exploring the use of descriptive analytics. Future studies on *using descriptive analytics in PBDA* would be relevant.

Fourthly, there are a handful of studies attempting to capture current practices and industry trends related to BDA in procurement. The findings range from the need to better define the reason for BDA in procurement, the identification of the potentials in BDA for procurement (without being specific), the interest in companies, or the need for integrated internal and external data systems, and that some companies have been outsourcing the analytics. None of the studies captures application possibilities or analyzes actual needs of the companies or industries. Most studies are using on conceptual, modelling and literature review methods. We identified one case study, the other empirical papers are based on focus groups, surveys, expert interviews, and Delphi studies. The lack of case study based papers is not surprising, as few PBD application practices exist to study. However, future studies on various aspects of PBD practices are needed in order to further the knowledge in the field. We see a future research need of *describing the level and patterns of implemented PBD applications in practice*, *understanding types and ways of using BDA in procurement*, and *perceptions and projections about future trends* of PBD. We found no study on *challenges, costs,* or *failures* of PBD. Such future studies would be very beneficial for developing practical and relevant knowledge about PBD.

Fifth, PBD, its application and analytics, is quite a new field of study with limited implementations in practice. Thus, there is a need for future studies *proposing how to use data sources and data types in procurement, and what outcome to expect*. Such studies could benefit from collaboration between researchers and practitioners, and the application of design science approaches where new interventions are developed, designs proposed and tested in practice.

Abstract

With this study, we aim to increase our understanding of trust when selecting suppliers. Entering a relationship with a supplier for an extended period of time requires a certain level of trust on different facets (e.g. the interpersonal relationships, continuous supply, compatibilities, etc.). The question raised is how this trust is actually defined and used during sourcing, when the buyer decides on entering a relationship with a supplier. The phenomenon is studied in the automobile industry, which is experiencing a higher level of dependency on suppliers for sensitive and at times strategic components. A single case of a major Auto manufacturer is studied using 29 interviews. Our findings show that sourcing trust is a multi-leveled concept ranging from inter-personal to the network level.

Keywords: Supplier selection, Sourcing trust, Automobile industry

Introduction

The automotive industry is typically looked upon as being old and traditional, however, products and manufacturing processes are increasingly influenced and based on new technologies that are at times offered by consolidated supply markets (Kompalla et al., 2016). The electrification of vehicles is spanning from the removal of fossil fuels to integrating cars to both the infrastructure and other cars (Gao et al., 2016). Such changes lead to an increased use of software which is permeating the whole value chain. To be able to keep up with the rapid changes and technical improvements, an increased degree of collaboration between OEMs and their suppliers is required. Example of this can be seen in the partnerships in pursuit of developing autonomous cars. As a result, automakers, increasingly, need to rely on their suppliers (Henry, 2015; Holweg, 2008), being exposed to the supply risks including partner opportunism (Williamson, 1973); and thus, much care is required in the selection of suppliers.

The process of selecting suppliers is extensive and of great importance (Van Weele, 2014). There are a number of aspects to consider both commercially and technically, such as suppliers' operational capabilities, technological capabilities, organizational capabilities, quality, logistic consideration and delivery, and of course cost. In addition to traditional economic criteria, more contemporary requirements have surfaced including intangible attributes like honesty and reputation (Yadav and Sharma, 2016). Trust is one of the important drivers of the behavior-based attractiveness of strategic partners (Tanskanen and Aminoff, 2015). During initiation of a buyer-supplier relationship, trust, reputation, and mutual goals are considered to be more important than investments and commitment (Valtakoski, 2015; Dyer, 1996). However, purchasing managers do not typically consider these aspects, especially trust, in their decisions (Smeltzer, 1997).

The supplier selection process for auto manufacturers is affected by its supply chain structure where high dependencies between components, modules, and systems exist. This makes the process more complicated, hence it is of increased importance that the suppliers have competencies beyond development and production. This means, for example, competencies in module assemblies and the procurement of non-core components (Behncke et al., 2011). It is, actually, found that in the automotive industry a company's trustworthiness and its' market-share performance correlate (Dyer and Chu, 2011). Thus, it can be argued that suppliers need to be to some extent trusted or evaluated prior to selection to ensure they will remain trustworthy during the course of the relationship. Theoretically, trust in suppliers has been a recurrent subject of research during the last two decades (see e.g. Doney and Cannon, 1997; Villena et al., 2016; Zaheer et al., 1998; Agndal and Nilsson, 2008; Akrout, 2015; Dyer and Chu, 2011).

Studies are generally testing theoretically deduced hypotheses on what supplier trust is, the impact of contextual attributes, or how it is valued both positively (Valtakoski, 2015; Zaheer et al., 1998; Johnson and Grayson, 2005) and negatively (Villena et al., 2016) and mainly using survey data. Inter-organizational trust between existing partners has been studied the most in existing literature. While no direct link has been found between the duration of a relationship and amount of trust (Ganesan, 1994; Kumar et al., 1995), many contend that trust is developed as a result of relational aspect and during one (Dyer and Chu, 2011). However, trust can and arguably should develop prior to entering a relationship. Few studies have attempted to explain how this trust is understood or explained (Ekici and Sohi, 2000), calling for more exploratory studies to gain a deeper understanding of the topic. While some studies have suggested measures of trust in suppliers (see e.g. Seppänen et al., 2007), their findings are usually related to the ongoing relationships in a given context. Additionally, as these aspects often are investigated using quantitative methods and

thereby limited by the researcher's own understanding of the concept, a qualitative method can result in different conclusions regarding how trust for selecting suppliers is understood. We aim to contribute to these studies by studying how trust is understood and used to select a supplier partner (i.e. sourcing trust) by conducting in-depth interviews within an automobile manufacturer.
On the other hand, inter-organizational connections are dependent on the ties in between individuals, but also organizations and even the networks within which they operate (see e.g. Berends et al., 2011; Gulati and Sytch, 2008) and where trust is also suggested to manifest (Zaheer et al., 1998). We also add to this stream of literature by bringing empirical evidence (i.e. which has been scant) showing that sourcing trust manifests on four distinct levels of interpersonal, organizational, inter-organizational, and network (compared to previous studies discussing mainly inter-personal and inter-organizational levels).

Theory

Defining buyer-supplier trust

In business literature, trust has been defined quite varyingly and broadly discussing it in many different contexts, on different layers and levels, with no universal agreement on one definition, but, it is generally accepted that it is multidimensional and a critical factor in developing an inter-organizational relationship (Zaheer et al., 1998; Zhang et al., 2011). Yet, many scholars have conceptualized trust by the confidence (see e.g. Morgan and Hunt, 1994), and belief (see e.g. Kumar et al., 1995) in a partner's credibility and benevolence (see e.g. Doney and Cannon, 1997). For instance, Mayer et al. (1995) contend that benevolence together with ability and integrity capture the major portion of a partner's trustworthiness; ability relates to the partner firm's skills and competencies, while integrity relates to the trust in their use of a set of certain acceptable principles. In another example, Pirson and Malhotra (2011) suggest that in addition to integrity and benevolence, organizational trustworthiness is also based on the managerial and technical competence, identification and transparency. Sako (1992) distinguishes between three types of trust, contractual trust, competence trust and goodwill trust. Often in business relationships, however, credibility and benevolence are quite intertwined and impossible to operationally separate (Doney and Cannon, 1997; Zhang et al., 2011). In this study, we understand trust in a similar manner and as the buyer's confidence and belief in the credibility and goodwill of the potential supplier.

Credibility is based on a firm's belief that a vendor's capabilities and expertise can lead to the effective and reliable performance of the required tasks (Ganesan, 1994). Valtakoski (2015) studies the initiation of buyer-seller relationships and identifies that trust has a cognitive dimension, characterized by attributes representing credible demonstrations of success in implementing past solutions and the presence of formal education to demonstrate expertise related to the offerings. The findings from Stuart et al. (2012) suggest that trust in a supplier from a buyer's perspective is mainly defined by delivery reliability, quality conformance and general expectations of what constitutes "good supply".

In addition to credibility and goodwill/benevolence, we can also identify other attributes for buyer-supplier trust. The possibility to identify with another organization based on *matching goals*, interests, or values is one underlying attribute for trust. Existing of mutual goals and interests are the foundations required for trust to flourish on. Akrout (2015: 29) suggests that it is "paramount to pave a way for the emergence of trust" that companies create a fertile ground that encourages "mutual interest- seeking, needs and expectations management". In a similar manner, Hardin

(2002) claims that trust is mere the encapsulation of interest. And he argues that the trustee takes the trustor's interest into consideration only because they value the continuation of the relationship.

Valtakoski (2015) also identifies *willingness*, or interest in the relationship, such as the other firm's brand, sacrifices made to participate in meetings abroad, resources allocated, and the knowledge of local competition, as one dimension of trust when initiating a relationship (i.e. what he terms an affective dimension). Pirson and Malhotra (2011: 1090) suggest that the "understanding and internalization of the interests and intentions of the other party, based on shared values and commitment" is an important part of trust.
Transparency has also been mentioned as a prerequisite for trust (Agndal and Nilsson, 2008). Pirson and Malhotra (2011) define transparency as the degree to which an organization is willing to explain its decisions, openly share relevant information, or says if something goes wrong. For example, having an open-book policy and be transparent in the way they charge for a product or service can show trust and openness (Agndal and Nilsson, 2008). Sources influencing the assessments should be evaluated to ensure its validity (Doney and Cannon, 1997).

Finally, *Honesty*, defined as the fairness of partners, their motivation to lie, or their history or possibility of making false claims is also connected to trust. Honesty has been suggested by many authors including Jones et al. (2010), Whipple et al. (2013), Svensson (2001), and Swan et al. (1985). With this study, we aim to better understand which of these attributes, and potentially what other, manifest in the sourcing phase.

Multiple levels of inter-organizational trust

As organizations enter exchange relationships with others, they engage in different levels of connectedness. An organization's existing ties, past experiences and relationships, and expectations and position within a network creates opportunities for, and impacts its, future ties (Uzzi, 1997). But ties between organizations is also dependent on the connection between individuals across organizations (Berends et al., 2011; Gulati and Sytch, 2008). In addition to this inter-personal (between individuals) and inter-organization level (between organizations), Whipple et al. (2013) argue that trust in between organizations also manifest on two other levels of organizational (between individuals and an organization) and inter-organizational network-level (between one and many organizations). It is important for buyers to differ between the inter-organizational trust established with the seller organization and the interpersonal trust with the individuals representing that organization the interpersonal trust (Doney and Cannon, 1997).

One question arising is that at the pre-relationship phase (i.e. prior to selecting a supplier), on which of these levels does trust manifest. The first three levels can be conceptually argued for: the trust of the individual(s) at the buyer organization selecting the suppliers in the individual(s) at the selling side of the potential supplier; the trust of the individual(s) at the buyer organization selecting the suppliers in the potential supplier organization; and, the trust of the buyer organization in the supplier in the potential supplier organization. With this study, we explore to better understand how trust manifests on these levels and whether and how it shows itself on the network levels.

Svensson (2001) finds that trust is understood and used quite differently by the automakers towards their suppliers. It has been suggested that, at least in the automotive industry, interpersonal trust does not necessarily translate into inter-organizational trust. Instead, inter-organizational trust is highly based on processes on which the business is built upon, or "process- based trust" (Dyer and Chu, 2011). Impersonal processes and routines develop a solid context for exchange, which allows

individuals within the organization to come and go without affecting the organizational trust. Similarly, in their study on trust in buyer-supplier relationships in North America, Stuart et al. (2012) find that interpersonal communication between the buyer's and supplier's employees did not have any significant impact on trust. Managers saw trust as consistent with terms such as dependability and reliability; trust seemed to be synonymous with meeting expectations of the customer. Additionally, a trusting stance towards business partners seems to be somewhat connected to the company/business culture, since it appears that companies that highly trust their suppliers also trust their customers (Svensson, 2001). We aim to explore if existing supplier selection processes, in fact, reduce the significance of interpersonal trust and/or a strong trusting culture can impact the four levels.

Method

As recommended by authors such as Yin (2009) and Ellram (1996), studying a contemporary and dynamic phenomenon with limited previous knowledge, is best done in its real-life context. Since, the aim of this study was to answer questions about trust in terms of "how" it is understood by purchasers, we opted to study a single case, to gain in-depth knowledge. An established automaker in Sweden was selected as a representative of an organization facing the contemporary challenge to include trust as a parameter when selecting suppliers while having an established supplier selection process, and being a proponent of trust in business relationships. Additionally, as trust is a concept that requires a high level of communication with respondents to gain a deep level of understanding, semi-structured interviews were designed (as suggested by e.g. Easton, 2010).

Data were collected during Fall of 2015 and Spring of 2017. Data on the purchasing process, the organization, and the nature of the phenomenon was collected by one of the senior researchers by interviewing three persons on top of the purchasing department. After the 3 initial interviews, 26 other employees were interviewed, on the research questions, during a master thesis project by two of the authors (see Andersson and Tharing, 2017), and closely controlled by another of the authors acting as the supervisor during weekly meetings during Spring 2017. The interviewees were selected to cover the different aspects considered when assessing supplier trust; to represent a spread of scope of the performed tasks (i.e. operational to more strategic level); represent work with different types of suppliers in terms of size and commodity complexity; and, the inclusion of internal supplier selection stakeholders i.e. purchasing, Supplier Quality Management (SQM) and Research & Development (R&D). Selection of the supplier types was done together with the senior employee at the purchasing department of the company. Then, the operational buyers were identified and contacted through the corresponding responsible for each supplier category. Finally, responsible internal supplier-handler from the SQM and R&D were contacted as well (see Appendix).

Each interview lasted between 40-50 minutes. During the interviews, a set of questions were asked concerning the different aspects of trust in a supplier selection process. The questions were open-ended and designed to give the interviewee new perspectives to reflect on, by asking for concrete examples based on their experience. Prior to the interviews, each subject received an explanation of the research and the questions. All the interviews were recorded and transcribed.

Later, the raw data (transcripts) were translated and analyzed by the two senior authors in the Winter of 2017. Since every individual interview followed a slightly different route, each transcript was analyzed and the answers were sorted by the corresponding question. Then the organized answers were coded using an open coding technique (as defined by Yin, 2009). The answers of

each interviewee were assessed and grouped if showing similar traits, without the ambition of assigning any particular label to the group itself. The derived groups were assessed iteratively, where the number of repetitions varied between the groups. These were created based on either recurrent words or the nature of the content. Finally, the group was given suitable category name, where the traits for each category was compared with denominations from literature in order to potentially clarify the content with the use of common terminology. The processing of qualitative data concluded with a discussion regarding the potential gaps and similarities between the collected data and the theory identified during the literature review.

The case of supplier selection at an automobile manufacturer in Sweden

Supplier selection strategies, organization, and vision

Purchasing within the case company is a well-recognized and long-established function. The purchasing function is included in the production process and, from a development point of view, in top management of the business in general. For the case company supplier management, along with cost and quality are key factors. At the case company around 70 percent of the vehicle production costs come from external suppliers. Purchasing for the manufacturing of vehicles is done in the Car Purchasing unit and includes all the components, raw materials, and activities for the car itself. The annual turnover of direct materials for vehicle manufacturing in this company is about 76 BSEKs with around 200 employees. The company has approximately 500 active suppliers for direct materials on around 1200 active sites. Indirect purchasing, such as buying of facilities, services, and maintenance, is done at the Powertrain and Indirect Purchasing unit.

There is no strategy or directive on using the existing supplier base at the company. The aim is mainly to create the most efficient optimal supplier base for each individual purchase. The company has been working with many of their suppliers for decades and the top 10-15 suppliers have been working with the company for an average of 20 years. In such relationships, if no party (the supplier or the company) cancels the purchase order by the end of the year, they continue the business relationship for another year. From a technical perspective, it is often easier to work with old and established suppliers since the organizations know each other, their respective capabilities and their people. This might, however, result in missing out on important innovations. In the last two years, they have tried to broaden their supply market knowledge. In the opinion of the chairman of the Car Purchasing unit, the biggest barriers are mindsets; "*such market scanning takes much resource and people would rather stick to the old ways*".

The supplier selection process

The main purchasing process at the company is called the "sourcing process", where a supplier is nominated for business. This process is triggered by the company's decision on a vehicle development. Such developments require new suppliers for certain new components or ideas. In regard to the vehicle development "sourcing process", needs arise in the engineering department. They first prepare a sourcing plan, mapping needs, required activities, timeframe, and suppliers to invite. Then they perform what they call a "sourcing approach", in which the internal buyer or buyer team (i.e. the individual or team responsible for the purchase) presets their strategy to top management.

The executives and CEOs of suppliers regularly meet with the company's top managers; they present their research and advanced engineering and together discuss what the suppliers can add to the company. Supplier relationships management is also a question of how incoming offers are

handled and how they are used within existing processes and designs; "*it's one thing to talk at an executive level, it's another thing to actually make something of it*", one of the company's Executives argues. Another challenge is how to trust the right supplier; "*it's both about supplier management and also about selecting the right one*".

In the development of a new car, they often award suppliers contracts with a length of several years. The supplier then typically takes part in both the development and production of a component. Before making such a supplier selection, suppliers, and particularly new suppliers, are extensively reviewed. Three functions partake in the review: purchasing, SQM and R&D. For new suppliers, purchasing makes an overall review of the company, involving aspects such as financial data, ownership structure, and sustainability profile. A visit to the supplier is often made to interview management and a set of questions is guided by the use of an evaluation sheet. Purchasing also ensures that the supplier follows production purchasing global terms and conditions (PPGTC) and follow up cost estimates and cost breakdowns of products.

The company's SQM is responsible for reviewing production and quality issues at the supplier. A manufacturing site assessment (MSA) is made by visiting factories, conducting interviews, as well as investigating processes, quality systems and how defects and complaints are handled. In addition, a desktop review is made as well as a quality review. The R&D department reviews how well the supplier will manage technically to develop and produce a specific item. The supplier's technologies, technical capabilities, knowledge in-house and their systems are reviewed. The outcome of the reviews made by purchasing, SQM and R&D is collected and the suppliers that pass all the reviews go through to the next stage in the selection process. Following, purchasing conducts negotiations with the suppliers to get the best price. A "business case" is built and often the supplier with the best price is selected.

The four levels of trust when selecting suppliers

We found that a clear understanding or guideline for trust toward a potential supplier was missing at the organization; "*When dealing with a completely new supplier, you somehow have to assume that you can trust them*" (P11). This can be seen in the responses that discussed the role of individuals at their organization as a source of developing organizational trust or distrust: "*an individual can demolish your view of a supplier, just as an individual can trick you into thinking that the supplier is trustworthy*" (P8). The sensitivity and role of individual opinions in the lack of a clear guideline for development of trust can be seen in conflicting statements by the following two purchasers: "*I also check with my colleagues when we have a new supplier, to see what their views and opinions are about the supplier representative and the supplier organization*" (P2), in contrast to "*trust is very personal. I don't think it is something that can be put into a system or making it a policy. Trust is personal, it's emotions. It does not matter how good someone else thinks a supplier is if they are not good from my point of view*" (P10).

It is difficult to capture how individuals perceive trust as they often have very different definitions of what it is. While many consider trust an underlying factor to enter a relationship with another organization, some consider it a secondary, or even irrelevant: *"when I look at our part in SQM, then there is no personal trust, our documents (processes) ensures that we focus on other factors. … the personal trust towards one or two individuals does not matter. If I look at how purchasing is working, with their evaluation criteria they are very fact driven"* (S6). However, by digging deeper into the interviews we can see (as summarized in Table 1) that trust does, in fact, manifest at all four levels of interpersonal, organizational, inter-organizational, and network (as defined in

the previous literature by e.g. Whipple et al., 2013) during the selection of suppliers. In Table 1, we have summarized the coded results from our interviews in terms of how trust was understood (i.e. Manifestation) and based on information from what sources (i.e. Source), at these four levels, by the individuals in the purchasing (Px), SQM (Sx), and R&D (Rx) departments. We will further elaborate these findings in the following sections.

Interpersonal - The interpersonal level of trust relates to trust between individuals (Whipple et al., 2013), which in our study manifests in trust between individual employees at the case company and the individual supplier representatives; "*often it is the representatives from the supplier that determines how you view the supplier*" (P1). The interviewees pointed towards the importance a representative can make in the development of trust towards a supplier: "*the personal relationship is very important. If you meet good representatives from a company that creates some kind of trust towards that company*" (P11) or that "*a good KAM usually has a good organization and company behind him*" (P11). Our study shows a number of manifestations of interpersonal trust, such as credibility, honesty, willingness, knowledge and competence and transparency (see Table 1).

Table 1 Manifestation and information sources of trust when selecting suppliers on different levels

Level of trust	**Manifestation** **(How is trust understood?)**	**Source** **(What is the understanding based on?)**
Interpersonal (person-person)	**Credibility** [P1, P2, P3, P7, P8, P11, P13, P14, P15, P16, P18, S1, S2, S3, S4, S5, R1] (*top management, representatives, contacts, etc. on e.g. decision making*) **Honesty** [P12, P14, P15, P16, R1] (*e.g. intentions*) **Willingness** [P6, P12] (*e.g. understand the company's needs*) **Knowledge & competence** [P2, P7, P12, P13, P16, P18, S2, S4] (*e.g. their own offering, processes, technology, cost structures; professionality*) **Transparency** [P2, P10, P12] (*e.g. admitting mistakes and informing about problems and failures*)	Interview management [P14, S1] Negotiation [P18] Through working and interactions [P1, P7, P16] Providing the information that we need [P2, P9, P13, P16] Open dialogue [P7] Fact-based information [P2, P3, P13] Sales representative fights for the company's internally to get resources [P6] Being proactive [P1] Providing good examples [S1]
Organizational (person-org)	**Matching goals and interests** [P14, S6] **Stability** [P1, P8, P9, P14, S4] (*e.g. top management changing often, financial, ownership*) **Knowledge & competence** [P8,P14,P15,S2,S6,R1] (*e.g. commercial & technical, development & production capacity, quality systems, routines & standards, certifications*) **Performance** [P2,P3,P4,P8,P9,P14,P15,P18,S2, S6] (*e.g. quality, logistics, delivery reliability, turnover*) **Technology** [P4, P7, P9, P14] (*e.g. IT, production*) **Transparency** [P3, P9, P12, P14, P17, S3, S4, S6, S5, R1] (*e.g. information, organization systems, processes and structures*)	Understand our needs [P12] Discussing processes [S3] Financial data [P1, P8, P14, P15] Reports [S3, S5] How well do they answer our questions [P16] Similar previous work [R1] SEM, MSA, reviews, visits, audits [P1, P9, P14, P17, S2, S3, S5, S6] Repeated defects [S2] Common procedures across sites [S5] Verifications, testing, and simulations [R1] Accurate estimates [P3] Improvement possibilities [P2] Teach their product and technology [P9] Sharing possible challenges [S4] Not trying to cheat in order to get advantages to win the deal [P2, P14] Providing ideas and suggestions [P12] Colleagues views on the supplier [P2, P3]
Inter-organizational (org-org)	**Matching values** [P6, P8, P17, S5] (*Business culture, code of conduct*) **Collaborative/long-term orientation** [P1, P7, P9, P15, P16, P17, R1] **Transparency** [P12, S3, S6, R1]	Joint idea discussions [P12, R1] Working according to our expectations [P13] Keeping promises e.g. delivering a quota on time [P2, P5, P12, P17] Sharing patents [R1]

	(*e.g. communication channels, complaints, etc.*) **Experience** [P4] (*e.g. history, business today*)	
Network (org-network)	**Global presence** [P14] (*e.g. to deliver to other factories globally*) **Network of suppliers** [P15, P16, S5] **Network of customers** [P12, P15, P16, S4, S5, S6]	References from e.g. other OEMs [P14] Track record e.g. projects and customers (supplier of premium brands e.g. BMW, Porsche, etc.) [P12, P15, P16, S4, S5]

We find that credibility for the interpersonal dimension is related to top management, supplier representatives and whether the speaking partner has mandate to make decisions. Similar to Pirson and Malhotra (2011), we find that credibility in top management is important for trust: *"We meet with top management, if they are good then the rest of the organization usually also is good"* (S1) and *"A company's attitude and culture is formed by its management"* (S2). Since many automotive suppliers are bigger companies than the case company, it is somewhat difficult to affect these suppliers' management, hence making credibility in top management more important in the supplier selection phase. In addition, to build credibility, the supplier representative needs to have mandate to make decisions: *"You lose trust in a person when you sign a deal and then it turns out that the management said no to the deal"* (P8).

In addition, the daily contacts in form of sales representatives and key account managers are important for forming trust on an individual level. Credibility is also related to expertise (Ganesan, 1994), where a more experienced representative can be viewed as more credible: *"Sometimes trust is related to the sales representatives, what knowledge they have, how long they have been doing this and their attitude"* (P13) and *"Companies lose in having bad sales representatives I would say. Because we work so much together that we need to have a good relationship"* (P13).

Honesty, which is often discussed in the literature (see e.g. Jones et al., 2010; Whipple et al., 2013) is related to intentions, where supplier representatives does not have the intention to lie or deceive: "*I trust in the people I work with, that they have honest intentions"* (P14). Similar views are expressed: *"Trust is very important. I don't want to invite a supplier that I don't trust to final negotiations. I want to be sure that they can do what they promise"* (P18) which can be compare with a more critical view on supplier representatives: *"I have learned that all suppliers lie to me all the time"* (P11). Willingness on an individual level is manifested in the suppliers' willingness to understand the company's needs for a specific component or technology. Also, the supplier representatives need to be willing to fight internally to get resources for the company, who often is competing with larger automotive customers such as Volkswagen or Toyota: *"The sales representatives need to fight for us internally at the supplier"* (P6).

On an individual level, knowledge and competence are important attributes for trust. The supplier representative needs to have knowledge and competence about their own offerings, their manufacturing processes, their technology, understand cost structures as well as behaving professionally. Finally, transparency, which has been described as sharing information as well as communicating failures (Pirson and Malhotra, 2011) is manifested as transparency in admitting mistakes and informing about problems and failures. By knowing these issues, the company has the possibility to help the supplier solve its problems to ensure that failure does not repeat.

Organizational - The majority of the individuals in our study also discussed several aspects that contributed to their trust towards the organization (c.f. Whipple et al., 2013) which could be selected as a supplier; "*somehow it's the person you work with on a daily basis that creates trust. But it is important to separate trust in individuals and the company*" (P16) or "*I would say that*

80% is the company and 20% is the representative" (P11). One person from the SQM department noted that people move within the organization and thus in addition to "*working with individuals*" you will also be "*working with the company*" (S3). Trust in the organization was expressed to be about being able to trust that their systems, individuals, functions, and the entirety of the organization would be able to deliver; "*I need to know that a whole organization can deliver. Both during the project and during production*" (P18) or "*if you don't trust your counterpart then you need to control and double check everything*" (P16). As explained by several of the purchasers, such a comprehensive trust towards another organization would not just *simply* be gained: "*with extremely few exceptions, I don't trust a single supplier. They do what they can to rob us of money. It's as simple as that*" (P4) or that "*there are not that many suppliers that I trust completely*" (P6).

These aspects contributing to developed trust at an organizational level can be summarized as the matching of the organization in question's goals and interests with that of the company's, the organization's stability (in terms of their ownership, changing of their top management, and financial situation), knowledge and competence capacities on different functions (e.g. commercial & technical, development & production capacity, quality systems, routines & standards, certifications), performance (e.g. quality, logistics, delivery reliability, turnover), owned technology (e.g. IT or production technology), and organizational transparency (e.g. information, organization systems, processes and structures). The latter and former aspects are very much in line with what has been previously discussed in the literature (e.g. Hardin 2002 on matching goals and Pirson and Malhotra, 2011 on Transparency). It was, especially, noted how it is important for the case company to develop trust in the supplier's technical and developmental capabilities; "*generally, you need to have some trust in the supplier, not just commercially but also technically, that they are able to deliver according to R&D's requirements*" (P7).

The information on these aspects can be gathered from several different sources ranging from discussions, to reports, visits, audits, and different information the organization shares. One of the purchasers noted: "*with a new supplier, the focus is more on systems, structures and other things that are visible. Things that you can try to find out during a visit*" (P17). In this regard, it was noted how visits and audits can develop trust on the specific capacities and capabilities of that specific site, but perhaps "*not so much on another site*" (S5); or that in situations that a supplier had a joint venture, it would be necessary to assess it in relation to e.g. "*the communication alignment of the two*" (S6).

Inter-organizational **-** In our study, the inter-organizational dimension of trust was manifested in matching values, collaborative/long-term orientation, communication channels and experience. Matching values and interests includes aspects such as the business culture (Svensson, 2001) and professional code of conduct: *"Trust in relation to companies is that you can trust in a professional collaboration"* (P16) and *"We have to trust in the supplier that we are collaborating with, it's about trust in many areas. We need to understand each other and not have any hidden agendas between us"* (R1). Hence, it is important to have an understanding between the firms and that there exists organizational trustworthiness (Pirson and Malhotra, 2011). In addition, matching values includes that the suppliers are working according to the firm's expectations, keeping promises and delivering on time: *"That they do what they promise to do, according to our contract and on time"* (P5).

Collaborative and long-term orientation suggests a more relational view of the exchange, where the suppliers takes part in development efforts by joining in idea discussions, problem solving and other development activities (see e.g. Rosell et al., 2017; Melander and Lakemond, 2015). In such

a relationship, sharing information and ideas are vital: *"What are they open about? What are they not open about? Do we feel that we have gotten 100% fact from them?"* (P3). Although many of the company's relationships with suppliers are of a collaborative and long-term nature, there is still the need to be open towards new suppliers, both for accessing new technologies and for getting a better price: *"Long-term relationships are important, but we need to be open and try new suppliers"* (P9). Although it may be comfortable to rely on a known supplier, the need for new suppliers is understood in the firm, even if it may require more resources, time and money: *"Sometimes it's worth taking in a new supplier and investing money in helping them"* (P7).

Trust between organizations was also understood through communication channels, where daily oral communication as well as sharing of documents, drawings, test results and similar information is included. For a new supplier, building infrastructure for communication usually takes some time: *"For new suppliers we have a learning period, how we should communicate and contacts. From oral communication to drawings, models and simulations. The communication between the firms needs to be built on all levels"* (R1).

Finally, trust between organizations is manifested through experience, where the history of the supplier as well as previous collaborations are included. Suppliers need to show that they have succeeded in the past with technological implementations as well as commercial success (Valtakoski, 2015). For new suppliers, reviews of the organization are an important source of information: *"We do a thorough investigation of our suppliers before they are selected. We look at financial data and make supplier evaluations. We build knowledge about a supplier if it is a new supplier for us"* (P1). Experience is also expressed through the business that the supplier has today, where being an automotive supplier is important, as it shows that the supplier has experience from delivering to other high demanding customers. Although trust is viewed as important on an organizational level, it seems that price is a more determining factor in the supplier selection process: *"Trust is important. We don't pay more to get it, but if the choice is between two equal suppliers, then we choose the one that we trust the most"* (P5).

Network **-** The respondents also mentioned many aspects related to how trust on the supplier's network impacts their trust in the organization in question. Here, trust manifests in the global presence of the supplier organization, their network of suppliers and customers.

Potential issues with second-tier suppliers in e.g. delivery can directly impact the company. One of the purchasers mentioned how they experienced supply delays from one of their suppliers that was related to one of their sub-suppliers and not that easily solved (P16). To combat this, they try to audit and gather information on the supplier network of potential suppliers as well: "*we visit our suppliers and when there is a need we would like to check their suppliers as well (2nd tier). We need to have trust in that their suppliers can deliver and have the right quality. It's also about how they handle the material, their processes and inspections. There is an automotive standard, so most suppliers have the same standards and ways of working, but we want to make sure that it works*" (S5). Many of the respondents mentioned the importance of the customer network of the supplier all mentioning that the reputation of the customers increased their trust in the supplier, or that the "*trust in a supplier is much about its track-record … being an automotive supplier of premium brands such as BMW, Audi, Porsche etc.*" (P12).

Discussions and conclusions

Findings from this study, add to the ongoing conversation on buyer-supplier trust (see e.g. Akrout, 2015; Zaheer et al., 1998) by conceptualizing sourcing trust, or the buyer trust towards potential suppliers during the supplier selection phase. We extend the four levels of trust in inter-organizational relationships that are suggested in the previous research (e.g. in Whipple et al., 2013) by applying it to the supplier selection context and find that trust manifests in different ways at all four levels of inter-personal, organizational, inter-organizational, and network. Our findings suggest that the inter-personal level of trust is very much characterized as described in the buyer-supplier literature (see e.g. Pirson and Malhotra, 2011), but at the inter-organizational and network level new labels are required. This is not surprising as most previous literature has focused on the two former levels (see e.g. Pirson and Malhotra, 2011; Valtakoski, 2015; Doney and Cannon, 1997), and very few have discussed the latter two (see e.g. Whipple et al., 2013). Based on our findings, we argue that while the knowledge and competence (at interpersonal and organizational level), stability, performance, technology (all at the organizational level), experience (at the inter-organizational level), and global presence (at the network level), can all be categorized as part of credibility towards the organization (c.f. Ganesan's, 1994 definition), they need independent labels to better characterize trust in the supplier selection context.

At the network level, specifically, previous literature has defined it as the trust between multiple organizations (c.f. Whipple, et al. 2013), but there is very limited understanding of what it actually means and/or how trust really manifests at this level (Schorsch et al., 2017). Our findings present a clearer understanding of trust at this level, defining it as the trust of the buying organization towards the network of the potential supplier (i.e. the supplier's suppliers and customers); this trust can be related to the supplier's credibility both in terms of e.g. having reputable customers or suppliers, but also the credibility of the extended partners not to disrupt future supply. Further in-depth research is required on the inter-organizational and network level of trust in buyer-supplier relationships to paint a clearer picture of its characteristics.

This study further extends the work on buyer-supplier trust, such as the work by Sako (1992), which distinguishes between contractual trust, competence trust and goodwill trust. We find that elements from the three types of trust by Sako (1992) can be found in each of our four levels of trust. However, as we have studied the supplier selection phase, we find more elements related to competence trust and goodwill trust than to contractual trust. This is natural, as our study does not include contracts per se, but of course the firm's previous experience of the suppliers' capability of carrying out previous contractual agreements is one part of trust during the supplier selection phase.

Our findings show that contrary to suggestions by e.g. Svensson (2001) and Dyer and Chu (2011) - suggesting buyer-supplier trust in the automobile industry to be more inter-organizational (or process based) than inter-personal – that, in fact, trust is quite complex, manifests at all different levels, and that the levels impact each other (e.g. inter-personal trust impacts inter-organizational trust). Finally, the presence of the different functions in the buyer-supplier relationship, makes the totality of trust in this context quite complex, and thus, we recommend more studies to understand how, and if, trust is understood differently among the different functions interacting between the buyer and supplier, and to shed light on the potential implications of this.

Appendix B Semi-structured interview guide

Finding	Question
How trust in supplier are understood in an automotive context	"What is your perspective on the word "trust" in the context of a supplier selection?" "How do you view the relationship between a company and its representatives?"
Which qualities that result in trust	"Which qualities/attributes do you think should be existent in order for a company to be considered trustworthy?" "How do you assess the trustworthiness of a supplier?"
What the effects of trust in suppliers are	"What is your perspective on the word "trust" in the context of supplier selection?" "How do you view the role of trust in comparison to other factors influencing the selection of a supplier?"

Adapting sourcing and supplier relationship management practices for discontinuous innovation through early purchasing involvement

Summary

The purpose of this paper is to investigate the research question of how Early Purchasing Involvement (EPI) in New Product Development (NPD) process can adapt existing sourcing and supplier relationship management practices for Discontinuous Innovations (DI). Based on an embedded case study approach, this paper explores four DI projects where the purchasing department was involved early in the NPD process. Data is gathered through interviewing managers and staff from the R&D, purchasing and marketing departments, and suppliers involved in the projects to capture their perceptions of early purchasing practices. The findings reveal interesting insights into how DI projects required a different approach to existing purchasing practices including a new role for the purchasing department and its relationship with other departments. Benefits and challenges associated with adapting existing purchasing practices through EPI are captured. Benefits include improvements in supplier research collaboration, the creation of recombinant innovations, and new supplier's technology advances for the focal company. Challenges include the promotion of new suppliers from distant technological domains. We derive propositions to guide further research into the role of EPI in DI. A framework of new and alternative sourcing and supplier relationship practices required for DI is also proposed.

Keywords: Early purchasing involvement, sourcing, supplier relationship and discontinuous innovation.

Competitive paper: 178

Introduction

Traditionally, discontinuous innovation has occurred throughout history such as the internet and mobile phone, but there is strong evidence that it is becoming increasingly more commonplace (Birkinshaw, 2007; Kortmann, 2014). For example, although smartphones incorporated existing digital camera technology, adapting this to mobile telephones, they were not responsible for developing new camera technology, but did profoundly alter the ways users used and bought photographic equipment. In 2017, Nestlé and Samsung announced a research collaboration to explore the potential of nutrition science and digital sensor technologies to provide new insights into healthy living (see nestle.com/media/news).

Although there is a body of research regarding purchasing involvement in New Product Development (NPD), a research gap exists in purchasing's role when companies embark on NPD under discontinuous innovation (DI) conditions. Managing DI from the standpoint of an organization requires new or at least significantly adapted approaches to their effective management (Bessant et al., 2010; Durisin & Todorova, 2012; Phillips et al. 2006). More specifically, previous research shows that practices that work well in the context of incremental innovation do not work in the context of DI (Bessant et al., 2010). Similar to Durisin and Todorova (2012) and, Kishna, Negro, Alkemade and Hekkert (2017), the term "discontinuous innovation" refers here not only to new product technology but extends also the exploration of new markets.

Applying the new regulations of the Energy Performance of Buildings Directive (EPBD) adopted in 2002 by the European Commission which imposes limiting the use of electricity has pushed HVAC companies to follow the development of renewable energies. It is in this context that the company we studied, which we call Anémos for reasons of confidentiality, has sought

to approach new renewable energy suppliers to develop its first DI project. Although the project seems to be controlled by the Anémos project team, issues related to the collaboration of new suppliers have emerged. In the period following this first project, Anémos decided to improve its supplier relationship and technology sourcing practices. Some of these improvements were related to involving the purchasing department at the early stages of NPD process.

Based on an embedded case study approach, we attempt to identify exploration practices such as sourcing for supplier ideas from unfamiliar domains (Phillips et al. 2006; Subramanian & Soh, 2017); scanning new technology (Rothaermel & Alexandre, 2009; Rohrbeck, 2010); and supplier "dalliances" relationships (Phillips et al. 2006) developed by the purchasing department early in the NPD for DI context. Two research questions are addressed: 1) how can purchasing (departments) involved early in NPD adapt existing sourcing practices for DI projects? 2) How can purchasing (departments) adapt existing supplier relationship practices for DI projects?

Our paper is organized as follows. After a literature review on discontinuous innovation and purchasing involvement in NPD, we present four case studies to illustrate how the purchasing department of Anémos pursues creative and alternative sourcing and supplier relationship practices in an attempt to respond actively to a DI environment. Then, we discuss our cross-case analysis and delineate further research by providing propositions. While four case studies may not be sufficient to construct far-reaching conclusions, our findings point to a need for a fresh look at the role of Early Purchasing Involvement (EPI) in DI. Furthermore, a framework of sourcing and supplier relationship practices in NPD under DI conditions is proposed.

Literature review on purchasing involvement in discontinuous innovation

Wynstra et al. (2003) argued that studies on supplier involvement in NPD need to be extended to purchasing involvement. The difference between purchasing involvement and supplier involvement in NPD is that supplier involvement does not focus on the function responsible whereas purchasing involvement specifically focuses on the purchasing's function role and responsibility on the collection and dissemination of information before or in parallel to the involvement of suppliers. According to Handfield et al. (1999), purchasing play an increasingly important role in involving suppliers in NPD as the level of knowledge regarding supplier capabilities is a critical success factor. Petersen et al. (2003) argue that supplier integration should require a detailed formal evaluation and selection of potential suppliers prior to consideration for involvement. In this case, McDermott and Handfield (2000) found that project managers must involve purchasing personnel early in the NPD process to help identifying potential suppliers with a demonstrated record that offer technological solutions to meet market needs.

An early contribution to research on early purchasing involvement in NPD under DI conditions was made by Burt and Soukup (1985), who identified six points in the design process at which purchasing should provide information and advice to engineering. These authors found that purchasing can act as a facilitator between NPD projects and suppliers' capabilities –especially when the product incorporates state of the art technology or combines technologies that have not been used together in the past. Under these conditions, purchasing can provide information about the costs, performance, availability, quality and reliability of various components. R&D or engineering teams would not normally have such information, which is necessary to avoid supply problems in the NPD process.

Appendix A presents an overview of literature on supplier involvement and purchasing's role in NPD under DI conditions. It includes information on study (authors and year), NPD under

DI conditions which entails technological change or "really new innovations" i.e. those requiring market discontinuities or technology discontinuities (according to Garcia and Calantone, 2012), method, focus, purchasing's role, findings and journal. The overview of literature shows that managing sourcing and supplier relationship in NPD under DI conditions becomes increasingly central to suggesting Early Purchasing Involvement (EPI). However, and similar to Johnsen's (2009) literature review, contradictory findings have been also noted regarding the adequate supplier relationship and the organization of purchasing to balance exploration / exploitation technology sourcing.

Technology sourcing or scanning methods

Anderson and Tushman (1990) identified that organizations should be able to combine technological capabilities with the ability to shape inter-organizational networks as technology cycles unfold in the course of their daily activities. Thereafter, Lambe and Spekman (1997) and Macher and Richman (2004) confirm that accessing external sources of information becomes more important the greater the time constraints; thus, successful firms in innovation-intensive industries are likely to institute organizational change or to promptly acquire technology knowledge from external sources of information.

Rothaermel and Alexandre (2009) suggest that technology knowledge searches can be either known or new to the organization based on the degree of uncertainty facing a firm in an innovation project. Thus, the firm's overall technology sourcing strategy might consist of simultaneously pursuing exploration by sourcing new technology and exploitation by sourcing known technology. In pursuing exploration, Rohrbeck (2010) argues that sourcing in DI requires technology scouting, which is a systematic approach by companies assigning part of their staff to gather information in the field of sciences and technology. Neither study, however, mentions how this affects purchasing managers or purchasing professionals.

Based on consortium benchmarking of six firms, Schiele (2010) explores the question of how to organize the purchasing department so that it can take a leading role in the sourcing of new technologies. He found that most of the firms had devised a separation into advanced sourcing and life-cycle sourcing. While an advanced sourcing took the lead for sourcing during the NPD process, a life-cycle sourcing took over once a product had entered production. His exploratory work, however did not investigate the implications of NPD under DI, although he suggests that some methods, such as purchasing scouts dedicated to scanning the supply market for new and unknown components, seem to be particularly relevant for this type of innovation.

Supplier alliances or "dalliances"

Supplier alliances have been found to be an important source of innovation to performance external technological knowledge into the process of innovation (Lambe & Spekman, 1997; Luzzini et al., 2015). Moreover, open communication with suppliers to understand their technology becomes more important in the presence of conditions of technology uncertainty (Ragatz et al., 2002). One explanation is that sourcing new technology from suppliers under DI is not sufficient; new technology also needs to be assimilated or internalized into the organization throughout supplier relational mechanisms (Knoppen et al., 2011; Melander & Lakemond, 2014). Another explanation is that alliance routines can improve mutual understanding and relative absorptive capacity with former suppliers, which is helpful in bridging diverse ideas across technological and organizational boundaries (Subramanian & Soh, 2017)

Bessant et al. (2005) argue that DI changes the "rules of the game" in managing supplier relationships, creating the need to look in strange "dark" areas and develop relationships with organizations from unfamiliar zones. Similarly, Phillips et al. (2006) propose that innovating firms seek to develop short-term "dalliances" with suppliers located on the periphery or even outside the firm's usual perceived supply chain boundary. Based on Phillips' et al. (2006) work, Noke et al. (2008) studied one supplier's strategic dalliance relationship in the oil and gas industry. They found that the strategic dalliance relationship was an effective enabler for DI projects by providing unlocking resources and novel information. In their study, a strategic "dalliance" was defined as a non-committal relationship that companies "dip in and out of" while simultaneously maintaining longer-term strategic partnerships with other suppliers.

Recently, Subramanian and Soh (2017) have demonstrated that a firm can benefit from having more explorative alliance experience with both former and unfamiliar partners. Despite these valuable insights, research on how the purchasing personnel manage explorative alliance relationships with their supply base or "dalliance" relationships with unfamiliar suppliers in DI projects remains rare.

Early purchasing involvement: organizational structure or parallel structures

There is a distinct lack of research on how to organize the purchasing department so that it can take a leading role in sourcing new technologies and supplier market spaces. As mentioned before, Schiele (2010) stressed the dual role of purchasing in NPD: supporting the process of innovation while at the same time maintaining cost and integration responsibility over the entire product life cycle. This duality suggests the presence of the classic exploration-exploitation "ambidexterity" paradox originally proposed by March (1991), who suggested that efforts to excel in exploration and exploitation naturally compete for scarce resources, such that they tend to crowd each other out.

Several studies on innovation have suggested that ambidextrous organization is a system that can handle both incremental and discontinuous innovations by exploration and exploitation activities. Based on this approach, Calvi (2000) demonstrated that many firms opt for a structural distinction between an "advanced (or forward) sourcing" department and a "strategic sourcing" department. The advanced sourcing team is integrated into all NPD projects, while the strategic sourcing team has a stronger commercial focus and is connected to internal customers. We can envision several different ambidexterity arrangements within the "advanced sourcing team" depending on the nature of innovation. The idea that DI requires a different organizational arrangement than that needed for incremental innovation is supported by Tushman and O'Reilly III (2006) and recently by Kortmann (2015), who suggest that the effectiveness of organization depends on the adaptability of oriented decisions and the nature of the innovation effort sustained by the exploration process.

An alternative approach to the challenge of ambidexterity for managing DI is offered by Bessant et al. (2010) Birkinshaw, Zimmermann, and Raisch (2016) and Gibson and Birkinshaw (2004). They suggest that ambidexterity should not be incorporated in the organizational structure as the deployment of both innovation practices for incremental and DI as it is likely to create tensions and conflicts inside the organization. Instead, organizations can develop organizational parallel structures. Recently, Gualandris et al. (2017) argued that purchasing functions will also need to establish these "parallel structures" to balance exploration and exploitation practices. Their analysis suggests that "purchasing functions may need to adjust their exploration-exploitation balance over time in order to match the dynamisms of their external environment" (p. 22).

In summary, although studies on technological discontinuity and organizational response have progressed and there has been a considerable amount of academic research done on the subject, since 2013 little empirical research has been done on purchasing practices developed by companies for managing DI projects. Traditionally, when purchasing becomes engaged in NPD projects, it is focused on continuous improvement. Yet, little is known about how the purchasing department involved in NPD projects under DI can adapt existing sourcing and supplier relationship practices to more exploration practices. Arguably, there are strong implications for purchasing departments, as the role of purchasing professionals in managing supplier research collaboration become more common and visible in a firm's innovation process (Luzzini et al, 2005; Pihlajamaa et al. 2017).

Research methodology

The HVAC industry –a discontinuous innovation context

The Heating, Ventilation, and Air Conditioning (HVAC) industry has seen a great deal of technological development in recent years due to the role of new regulations, i.e. the Energy Performance of Buildings Directive (EPBD) adopted in 2002 by the European Commission. The industry context has been extensively used in studies of DI (Durisin & Todorova, 2012). Therefore, we searched for an industry with a DI context known for its innovativeness.

Our focal company, which we here refer to as 'Anémos', has a strong manufacturing culture creating HVAC design and systems. Because of the ambition of companies to develop HVAC equipment with the objective of reducing energy consumption and a more sophisticated use of this equipment with appliances and electronics, it was important that Anémos search for external and alternative technological opportunities. By combining premium design, innovation and cutting-edge technology, Anémos has actively invested in renewable energy. 4% of turnover is invested in the company's R&D to provide a constant impetus for innovation. In 2006, it entered the renewable energy market, which in 2015 represented 12% of its turnover, and invested in a new state-of-the-art production line to improve its manufacturing process.

Hence, the HVAC industry context was suitable for this study because the four innovation projects selected for this research were regarded as attempts by Anémos to respond actively to increasing demands on a completely new market, technology, political regulations and customer expectations in the industry. According to Kishna et al., 2017; Phillips et al., 2006, these characteristics correspond to the sources of discontinuity.

Cases selection

R&D and purchasing managers actively participated in the case selection. Initially, there were discussions with them regarding suitable DI projects based on existing indicators that have already been used in a variety of empirical studies (e.g. Rice et al., 2002; Magnusson et al., 2003; Phillips et al., 2006b; Brentani and Reid, 2012; Bergek et al., 2013). The project selected had to respond positively to at least one of indicators e.g. *Is it an innovation project triggered by changes in the regulatory industry? Is it an innovation project that acts as a catalyst for the emergence of the new market? Does the innovation project require the application of new technology already in use elsewhere outside of the industry?? Does the innovation project require the intersection or combination of two technological domains?*

Four case studies were selected based on the logic of theoretical sampling (Eisenhardt, 1989). In contrast to the projects studied by Van Echtelt et al. (2008), which were based on NPD projects with different degrees of innovation, in this study theoretical sampling was designed

to enable one specific project: NPD under DI conditions. The projects defined and identified as DI projects by the purchasing and project managers were considered highly innovative projects involving new technological applications or solutions to challenging targets on environmental performance (similar to Magnusson et al., 2003 empirical work on DI). The four NPD projects often required technology that was not part of its firm's core competence (Golden, 1992) and posed significant challenges, such as the use of unfamiliar suppliers or new supplier collaboration (Bergek et 2013; Lambe and Spekman, 1997; Phillips et al., 2006). The list of projects and their descriptions are illustrated in Table 1.

Table 1 Summary of case descriptions

Project	**Discontinuous nature of project / salient details**	**Gate stage of project**	**Informants / Job titles**
Case A	The development of a new hybrid-heating system by the application of an alternative technology with the ambition to develop an HVAC product with high energy efficiency required with the objective of new regulations. Compared to a traditional heating system, this hybrid heating system can reduce CO2 emissions by more than 70%.	Commercialized (2009)	R&D heads of business unit and Purchasing heads of business unit and Purchasing director
Case B	The development of an innovative Triple Heating System by the application of a technology sensor connected to an electronic card that manages the maximum temperature in a regulating circuit. Traditional heating of towels operates with a mechanical system, which controls the safety temperature of the device by a circuit breaker.	Commercialized (2013)	R&D heads of business unit, Purchasing heads of business unit, Marketing heads of business unit, Purchasing director and Supplier (Thermo)
Case C	The development of an eco-design heater that is more aesthetically pleasing and slimmer than existing models. Idea fostered for the first time in collaboration with Purchasing and suppliers based on a potential new customer demand.	Product development (2015)	R&D heads of business unit, Project manager, Purchasing director, Purchasing heads of business unit, Buyer, and Marketing heads of business unit and Supplier (Sierra)
Case D	The development of compact radiators with the same objective of reducing energy consumption. Idea fostered for the first time in collaboration with the R&D and one supplier during innovative workshop meetings.	Concept planning (2015)	R&D heads of business unit, Project manager, Purchasing heads of business unit, Marketing heads of business unit, Buyer and Supplier (Sales and R&D manager from Ocean)

Data collection

Prior to conducting the main case studies, a pilot study involving eight face-to-face interviews in an automotive company was conducted. From the pilot study, we observed a structural distinction of the purchasing department into an advanced sourcing team integrated early in NPD projects and a life-cycle sourcing integrated later in the NPD, which has already been found in other studies on automotive companies (Schiele, 2010). This pilot study helped to refine research questions, the researchers' general understanding of purchasing involvement in DI and the accentuated need for more research on the organization of EPI in other sectors.

In our main case studies, purchasing representatives manage incremental and DI projects or advanced sourcing and life-cycle sourcing at the same time. Thus, our sampling perfectly fit with our research objectives of understanding how purchasing representatives adapt existing practices to exploration practices following prior theorizing that purchasing may need to adjust their exploration-exploitation balance in parallel in order to match the dynamisms of their

external environment e.g. DI conditions (Bessant et al., 2010; Gibson & Birkinshaw, 2016; Gualandris et al., 2017).

During the data collection, multiple sources of information were used: primary sources of information, such as interview transcriptions, factory visits, observations of business meeting events, and secondary sources of information, such as companies' websites, report and presentation materials provided by suppliers and Anémos enhancing the validity and reliability of the research. The use of multiple respondents in different projects allowed us to identify, to classify, and to compare purchasing practices and innovation results, although the focus was on a single company's strategy and organization (Dubois & Araujo, 2007).

In total, 30 face-to-face interviews across purchasing R&D and marketing departments and with suppliers involved in the four projects were conducted, each one typically lasted 2-3 hours. Interviewees were identified in consultation with Purchasing and R&D managers, following a "snowballing" approach, based on their project involvement. The interviews were semi-structured, aiming to capture the different perceptions of sourcing, supplier relationship and early purchasing involvement practices in the four projects. All interviews were recorded, transcribed, and sent to informants for verification, thereby increasing the confirmability of the case information (Lincoln & Guba, 2002). Recorded and verified data was all imported into and analyzed using NVivo 10 software.

Within case analysis

A thematic approach to data analysis within the case study was used to identify purchasing practices and emerging themes. The data analysis process consisted of labelling passages of the interviews according to the themes identified in the literature review and mentioned before: EPI, sourcing technology, scanning supplier market, purchasing communication, supplier dalliance, supplier alliance, and R&D and purchasing interaction (Miles, Huberman, & Saldaña, 2013). Then, the process was followed by data-driven codes or emerging codes (Strauss and Corbin's, 1998, Corbin and Strauss, 2008); meaningful emerging codes were: "advanced purchasing and marketing interaction", "purchasing challenges", "supplier day", "supplier research collaboration", "innovation purchasing strategy" and "recombinant innovations". From the initial thematic codes, emerging codes were aggregated into each main theme.

In order to analyses each case study as a stand-alone entity to conduct the comparisons between the four cases without losing important details, we adopted a within-case analysis (Yin, 2009). Thus, data was organized according to a time perspective by which the researcher tries to create a story from the different occurrences that are presented in the data. Each case was written by a chronological event-based account taking into consideration the main themes of the conceptual framework. During the event account when specific statements from interviews or conversations are used, a reference between brackets is made to the specific function that the persons fulfilled.

Case A: The hybrid-heating system

Since the R&D of Anémos did not yet have a lot of knowledge regarding renewable energy and involved technology in 2005, Anémos was forced to search for technology know-how outside of the company. To do this, a sourcing team of representatives from the Purchasing and the R&D departments had to work together to find suppliers with expertise in alternative technologies in the renewable energy market. Although a representative from the Purchasing department was involved in the sourcing process, this process was handled as usual: The R&D department gives primary specifications to suppliers, and Purchasing handles supplier selection

by their technological capability and cost price estimation. Then, the supplier selected becomes involved during the engineering phase of the NPD process.

The R&D representatives were confident about their technical knowledge on developing water heaters to carry out the project and to manage the supplier collaboration by themselves (ref: purchasing manager). Thus, the NPD project in case A started without active participation from the purchasing department. Although the NPD process appeared to be under the control of / controlled by the NPD project team, the project was operated by engineers who paid little attention to the relationship with this new supplier. In fact, the project was a very new technological solution for Anémos and the way to handle supplier relationships in this context was definitively also new (ref: purchasing director).

Consequently, uncertainties occurred with the planning and final cost of the product. As the project team did not know how to proceed with supplier collaboration, they contacted the purchasing director to help solve communication and organizational problems with the supplier. New agreements were arranged with this supplier for the final development, but after some time the supplier decided to terminate the collaboration with Anémos. However, in the period after this project was introduced onto the market, attempts were made to improve supplier collaboration in Anémos NPD projects. A key part of these improvements concerned how purchasing representatives could be earlier in NPD projects in order to enhance supplier collaboration. According to the purchasing manager and echoed by the R&D manager:

> *"The wrong choices or the bad decisions we did in this project related to supplier involvement and relationships [which meant] that we could not continue working jointly with the supplier in further innovations. If we had done the process of early purchasing involvement we're doing today, perhaps we would not be in a failure situation with this supplier" (Purchasing Manager)*
>
> *"Absolutely, and we could be bouncing on complementary innovations" (R&D Manager)*

Case B: The Triple Heating System

The purchasing department was not involved from the beginning of the NPD process in case B, but earlier than normal when it comes to identifying and engaging with new suppliers. R&D and Purchasing therefore worked together on searching and identifying suppliers by attending trade fairs and special events. The responsibility of the purchasing department was to select the appropriate supplier with the technical capabilities needed to develop this project but maintain the control of risk in the supplier selection (ref: purchasing manager).

After scanning the supplier market, Anémos had two suppliers who could support the project. One of these two suppliers was an unfamiliar supplier; that means this supplier had never worked for Anémos. This supplier was rich in experience in the application of this new technology. However, the purchasing manager decided to select Thermo. Thermo was a known supplier for the company, so the purchasing department did not need to ask them to participate in the supplier approval process. According to the purchasing manager:

> *"Anémos has not yet developed any strategy for unfamiliar suppliers. Therefore, it is difficult to take the risk, we do not trust suppliers before the supplier approval process, we are afraid that this supplier will take our know-how or technical expertise."*

During the project, Thermo worked closer than usual with Anémos to adapt this new generation of heaters to their business unit production. Anémos describes the relationship with Thermo as a good and close relationship based on open communication. Thermo in turn describes the relationship as a partnership, but in Anémos, the relationship with Thermo is not yet considered

a partnership, as a partnership agreement has not been signed. This partnership agreement, developed in 2014, consists of an engagement to share know-how, technical capabilities, and IP between buyer-supplier involving open communication with the goal to develop an innovative idea.

Although the new system had the potential for the company to not only capture market shares from current HVAC competitors, but also to substitute traditional heating of towels by combining the bathroom radiator and towel dryer, customers did not perceive a new value added from this technology (ref: marketing manager). In contrast to case A, this project created a sense in the company of a need to involve marketing function in the supplier involvement processes. One of the challenges learned from this project according to the marketing department is to share the expectations of Anémos customers with suppliers. That is, supplier integration in the innovation process needs to start by putting the customer needs in the central debate of an innovative idea.

Case C: The design-heaters

The design-heaters project does not only involve new technological processes, but a new organizational mode of Anémos' innovation process. In this case, the purchasing department was involved early in the NPD process and was thus a participant throughout the project. In fact, the idea to develop this NPD was fostered for the first time in the purchasing department.

The sourcing process for the design-heaters project in case C was very different from the traditional one (ref. purchasing and R&D managers). Instead of providing technical specifications to suppliers, the purchasing manager met suppliers to ask them if they were able to propose technical solutions to improve the aspect of the existing water-heater models. Since the request was neither precise nor clear, the purchasing department received many propositions that were difficult to coordinate. Therefore, the purchasing department decided to contact the marketing department in order to ask them what the important areas or themes to develop for product innovations were. The marketing department responded to the purchasing manager to work on two identified critical areas: comfort and eco-design.

The concept design and technical solutions were therefore provided by a number of suppliers. For the supplier selection process, purchasing organized a supplier day presentation. A supplier day consisted of presentations from suppliers to show what they had done to support the development of this project and propose different designs and solutions. From the Anémos side, there were representatives from the Marketing, R&D and Purchasing departments to listen to supplier propositions. Purchasing representatives, together with the representatives from the other departments, decided to select one supplier here referred to as "Sierra". Although Sierra was considered a new supplier for the R&D of Anémos, it was a known supplier for one of the purchasing managers.

> *"Sierra is a known supplier for me. I met this supplier from my prior experiences in other companies. Actually I've known Sierra very well for a long time.*" (the purchasing commodity manager).

Sierra demonstrated that they had processes and structures to handle a project with Anémos in a partnership relationship. Hence, they accepted to meet the CEO of Sierra group and Anémos' industrial director to show the importance of this project collaboration.

> *"We had not even started the project when the CEO of Sierra and our industrial director met and had already exchanged on their industrial vision and the vision of further business" (Anémos purchasing director).*

Anémos acknowledged that engaging in a co-innovation project at the early stage of NPD required a totally different interaction and communication pattern. To solve the technological system process issues of the first prototype, engineers from both firms worked together on a second prototype by visiting the supplier's production and vice-versa, engineers from Sierra visiting Anémos' production. The purchasing manager describes the relationship with Sierra as an engineer-to-engineer relationship, as engineers from Sierra and Anémos spent time together to test and find technical solutions. The R&D manager describes the relationship with Sierra as a good and close relationship based on well-defined agreements in terms of IP, royalties and responsibilities that protect both parties, resulting in transparency and mutual trust.

Case D: The design-heaters

Based on new internal processes for involving suppliers earlier into the NPD process set and formalized in Anémos in 2014, traditional organizational roles were reconsidered. The role of the purchasing director became a more strategic role in innovation, as he was now involved in the innovation committee with top management and strategy group directors' meetings to discuss HVAC industry trends. Consequently, one of the new responsibilities of the purchasing director was to provide advice to purchasing managers of different manufacturing sites about emerging innovation questions, new supplier collaboration modes, and research contracts with suppliers.

Moreover, the purchasing director set new objectives for the purchasing managers, such as identifying suppliers with strong technical capabilities and research expertise in NPD to sign a partnership agreement with them to develop new product ideas. Purchasing managers therefore had the responsibility to identify, to attract, and to motivate suppliers to work in a partnership relationship at the ideation stage of the NPD process. The marketing department in turn was now involved in the sourcing process by presenting the market context and customer expectations to the purchasing department.

The sourcing process in case D started by identifying innovative suppliers from the supply base and asking them to share know-how, technical capabilities, and research to develop a NPD project. The purchasing department elaborated, together with the R&D and Marketing departments, a Power Point presentation around Anémos' customer expectations and the HVAC technological trends to present to pre-selected suppliers. Then, the purchasing department coordinated and organized an innovation meeting with each supplier. The innovation meeting started with a brainstorming about the HVAC market and Anémos products followed by the historical buyer-supplier relationship between Anémos and the supplier selected. Anémos also invited suppliers to do the same presentation to start a mutual trust and transparency buyer-supplier relationship. This meeting finishes with the signature of a research contract and confidential agreements where suppliers accept to respect confidential issues and to be engaged in sharing of expertise, technical capabilities, and IP to reach the development of new product innovations.

After different innovation meetings with suppliers, representatives from the R&D department and Purchasing department selected one supplier, referred to here as Ocean. According to the purchasing department, Ocean was always suspicious of the way Anémos managed its co-development projects; therefore, it had been a long time since both companies had worked together on an innovation project.

The NPD team initially met to work on creativity workshops, which consist of discussion about potential product innovations, ideas, technological trends, and solutions (ref: R&D manager). Creativity meetings were run with different propositions to develop incremental and radical product innovations. The challenge of the design-heaters project is for Ocean to have a general

vision of the concept design of radiators. R&D from Anémos describes the relationship with Ocean as good and more open based on mutual trust and interest. Ocean in comparison describes that the buyer-supplier relationship in a NPD under DI can sound like an opportunistic strategy. According to representatives from Ocean*:*

> *"Maybe it is only sounds opportunistic. I think that in order to have suppliers participating in the same fruitful way customers need to be able to be quite open, to have a clear discussion, to communicate if customers want suppliers believe in their co-innovation projects and be engaged."*

Cross-case analysis and discussion

In this section, the cross-case analysis (table 2) is used to answer our two research questions into how the purchasing department involved in NPD projects can adapt existing practices as an attempt to respond actively to DI. These practices are discussed and propositions are developed in the following:

Discontinuous innovation

As can be seen in table 2, the majority of cases are characterized by technological discontinuities. Two of them, C and D, are characterized by creating distinctive product characteristics aimed at different market segments or potential customer needs. Case B is the only project characterized by creating value through a marketing or branding dimension; this implied that in this case no evidence of emerging purchasing practices was observed as un unexpected finding. Despite this, one similar pattern across case studies was found. This pattern was suggested by most respondents, the successful NPD projects under DI conditions often required the involvement of new actors in the NPD process (e.g. suppliers or customers), consequently different NPD organizational forms.

Technology Sourcing

The cross-case analysis identified an alternative sourcing process. In effect, sourcing practices in cases C and D were different from cases A and B. In cases C and D, sourcing new technology from suppliers without having any product specifications or a NPD project in mind required the use of different scanning methods. The "*reversed"* sourcing process, as the purchasing representatives call it, consists of using a variety of exploratory practices to scan the supplier market. For instance, in case C, an "idea competition" mechanism was deployed to scan the supplier market. In the open innovation literature, idea competition builds on the nature of competition as a means of encouraging users to participate in an open-source projects (Piller & Walcher, 2006; Von Hippel, 2007).

In this study, the idea competition began by sending out a bid invitation to suppliers that are believed to have the necessary technical competences to participate in this activity. This finding was similar to the case of Sjödin and Eriksson (2010), but in their case, the idea competition was performed by the R&D department. The management of product ideas and/or new technological solutions from different suppliers resulted in several challenges for the purchasing department to coordinate, filter, and evaluate them or, in purchasing terms, to select and evaluate suppliers. Surprisingly, the reversed sourcing process involved mainly interactions with external partners as well as different functional areas and hierarchical levels. According to Soukhoroukova, Spann and Skiera (2012), the involvement of several disciplines is the best way to filter and to evaluate new product ideas from an idea competition. Moreover, this finding

supports the important interaction of customer-facing marketing executives in a complex DI environment also found in Song and Di Benedetto's (2008) work. In cases C and D, customer expectations provided by the marketing department facilitated communication of supplier tasks required for evaluating the quality of product idea submissions.

Table 2 Cross-case analysis

Analytical dimensions	Case A	Case B	Case C	Case D
Discontinuous innovation	*"Really" new technological solution (Purchasing and R&D managers)*	*New marketing approach (Marketing manager)* *The concept of this heater application has already used in others industry applications, therefore, but I think for Anémos it was a kind of different marketing approach. (Supplier)*	*…a revolution in the world of water heaters (purchasing manager)* *Radical innovation with different technical solutions, adaptations, and architectures with major implication.* *(R&D manager)*	*A new product lines (Marketing manager)* *Potential discontinuous innovation (R&D manager)*
Early Purchasing Involvement	*We could not be analytical about what was written in the specifications stage because we lack of knowledge. We realized after when we had difficulties in the level of product quality and to get everyone's responsibility. (Purchasing manager)*	*Buyers of Anémos know well the technical of products. (Purchasing Director)* *We have buyers who have technical engineer background. (R&D manager)*	*Sierra is a known supplier for me, I met this supplier from my prior-experiences in NPD projects with other companies, and actually I know Sierra very well since long time (Buyer)*	*The role of EPI was to be contributor of product ideas and innovations and to be ground in the relationship of our suppliers in the case of this project.(Marketing manager)*
Sourcing technology	*We had no technical knowledge for the development of this project, so it was broadcast on an existing panel focused on Europe; we said we need someone local. (Purchasing manager)*	*The technology operates by suppliers must be close enough to our products* *(R & D manager)*	*In sourcing new technology or product ideas, we search for a supplier with a common interest. If we have not a common interest, there cannot be a deal.* *(R & D manager)*	*We are in search for suppliers who have a know-how, strong technical capabilities and motivation to be able to work in the mode of research collaborative projects (Purchasing Director)*
Scanning supplier market	*In this project, two trade fairs in Europe allowed us to have a maximum of suppliers (Purchasing manager)*	*We did not have the technical solution in the R&D to develop this project, so the purchasing and R&D departments go to trade fairs and conferences to identify potential suppliers (Purchasing manager)*	*We returned to our suppliers and we ask them not to work on everything, we said that we need ideas or technological solutions to improve the aesthetic of Anémos products and then we ask them to propose us something new. (Purchasing manager)*	*The purchasing department organized the meeting between the R&D department and the supplier for a period of brainstorming (Purchasing manager)*
Purchasing communication with suppliers	*We somewhere segregate a little the supplier relationship, saying to the supplier, we have a need*	*Anémos asked for specific technology application (Supplier)*	*The supplier asked me if they could propose something for the aesthetic of Anémos products, I said yes, you prepare a presentation, and I will*	*We had not even started the project when the CEO of the supplier and our industrial director met and have already exchange on*

	and you respond to the need (R&D manager)		*organize a meeting with the Purchasing and R&D directors (Buyer)* *Usually, the exploration or research phase is done with institutions, schools or research centers, sometimes with suppliers, but is rare. Often, when we start talking about a new product with suppliers is because the supplier has a new technology to sell. This project is the first case that we work with a supplier in the exploration phase in a free, open and unscheduled climate. (Project manager)*	*their vision and the vision of further business (Purchasing Manager of Heating)* *The research contract is a global contract where the objective is to start a relationship with the supplier in an open communication climate, technical sharing and transparency suitable for the development of product innovations (Purchasing manager)*
Purchasing interaction with other departments	*Clearly, it is the role of the purchasing department to ensure that suppliers have a place in the R&D activities, and to avoid the NIH syndrome, because we are talking about new ideas which come from suppliers, not from us. Purchasing should push for integrating supplier ideas and these ideas being well accepted. That is why, the people who go to visit supplier sites are the purchasing and the R&D department (Purchasing Director)*		*There were the Marketing, the R&D and other functional departments at the supplier presentations, so it is created exchange. It is part of the new EPI strategy. (Marketing manager)*	*The communication between purchasing, R&D and marketing is now part of the corporate strategy; This strategy allowed us to put the customer in the center of the supplier technological exchanges (R & D manager)*
Supplier technical exchange	*After these projects, we realized that we had suppliers that we work with for 15 years ago now, they did not even know our products, and they did not know what is going go in the HVAC industry. It is extraordinary, we must do something, we should get closer to them (Purchasing Director)*		*Engineers from Sierra come here (Anémos manufacturing site) to spend time testing the prototype, we also go its place to study the project. It happens by an engineer-engineer relationship. (Purchasing manager of Water Heating)* *It is a win-win project, we will be able to grow through innovation, and we will be able to bring him a technology or expertise that could not develop for himself. (Supplier)*	*Before, we had a product idea and we selected a partner to develop it. But in this approach we are not in a co-innovation. The co-innovation is the fact of getting together a product idea, thinking together this idea and shares our technology knowledge to develop a new product as in this case. (R&D manager)*
Supplier research collaboration	*The bad choices or the bad decisions that we have made on supplier research collaboration during this project result in a broken supplier relationship that we cannot continue to work jointly with the supplier (Purchasing manager)*	*N/A*	*It was about working on finding new solutions for Anémos products to fit better in the home, the purchasing department worked jointly with the supplier by asking to propose something new and it works well, confident enough to get two solutions until a prototype, so a ready-product (Marketing manager)*	*It seems that there were uncertainties in the organization how to handle a supplier, because before we worked a close and strong partner and then; the strategy was not being so open so during a year or two years it was not so clear how to be. Now since a couple years we are not back to the same partnership we will never be probably, but is open and a good relationship. There is a research contract, before there was not contract. The IP is clear (Supplier)*

Recombinant innovations	*N/A*	*N/A*	*It was about working on finding new solutions for Anémos products to fit better in the home, the purchasing department worked jointly with the supplier by asking to propose something new and it works well, confident enough to get two solutions until a prototype, so a ready-product (Marketing manager)*	*Suppliers before proposed existing technologies because they did not want to take risks sharing new trends, technologies, ideas and so on. With this new agreement supplier had more confidence to share them because IP and confidential issues are negotiated before the project. This is good for Anémos because it means that we are in advance regarding new technological knowledge and solutions from suppliers (R&D manager)*

Therefore, we develop the first proposition as the following:

P1 *Interactions between purchasing and marketing departments at the early stages of the NPD process can enhance exploratory sourcing practices required for DI.*

The purchasing manager in case D developed a similar reversed sourcing process pattern. An important observation was the differences in supplier involvement practices from the purchasing manager in case D. In case C, the purchasing manager invited different suppliers in the supplier market to participate in NPD ideas whereas the purchasing manager in case D pre-selected suppliers from the supplier base that could participate in NPD ideas. Although the scanning method of the purchasing manager in case D was limited to pre-selected suppliers and coordination of supplier technical exchange rather than exploring a large number of suppliers like the purchasing manager in case C, findings indicate that the scanning of the supplier base can also generate radical NPD ideas or architectural NPD. This is consistent with some studies, particularly Bozdogan et al. (1998) and Subramanian & Soh (2017) studies. This leads to our second proposition:

P2 *Scanning the supplier base through EPI can introduce discontinuity in the NPD process.*

Supplier relationship

The findings indicate that transparency, alignments and socialization were important mechanisms to successful supplier technical exchange early in the NPD process required under DI conditions. The findings also suggest that the occurrence of a number of supplier collaboration problems in case A can be partially attributed to the inefficiency or absence of these mechanisms.

As can be noted in table 2, efforts on supplier relationship were carried out for NPD projects in cases C and D. Firstly, two pro-active innovation meetings served to promote internal supplier technical exchange in Anémos. One meeting was initiated in case C and consisted of supplier presentations on product propositions to improve the aspect of heating-waters. This meeting was an opportunity to discover new suppliers that had been working for Anémos providing specific components, but they had never been involved in NPD projects. The same pattern was found in case D where a similar meeting convinced a historical supplier to work on a NPD project with Anémos. As mentioned before, informal innovation meetings were organized by the purchasing department with the objective to convince suppliers to participate in open discussions with the representatives of the R&D of Anémos to develop NPD ideas jointly.

Alignments in Anémos were developed through socialization practices which were similar to the Japanese practices, for example informal meetings to share cultural, technology and market goals for the development of potential innovation projects (Cousins et al., 2011; McDermott & Handfield, 2000). The purchasing department was responsible for assuring the alignment of suppliers with Anémos' innovation strategy by organizing informal and formal pro-active innovation meetings. Schiele (2010) defines these proactive "innovation meetings" as supporting tools used by the purchasing department to create technical ideas originating with suppliers and to support the firm's process of innovation.

P3*: Innovation meetings with suppliers organized by the purchasing department can enhance supplier technical exchanges early in NPD that in turn can facilitate the development of DI.*

However, the supplier in case D defined these proactive innovation meetings as an opportunistic strategy. It appeared that combination of a potential long-term relationship and a "dalliances"

short-term relationship (Phillips et al., 2006) is in fact hidden during these innovation meetings. For example, it was noted in case C that the NPD process was purely driven by supplier innovation. That is, the supplier developed the first prototype and it was responsible for the development of a second prototype. Anémos only provided the equipment and facilities to test the prototypes. If at the end of the testing stage, Anémos realized that the NPD would not be feasible because the prototypes were not working, Anémos had the right to stop the project, and the supplier had the right to offer or to sell the prototype to other customers. Therefore, a kind of dalliance supplier relationship at the ideation stage was identified.

> ***P4:*** *A combination of supplier dalliances and potential long-term relationships can help to convince suppliers to work in an exploratory NPD collaboration under DI.*

Early Purchasing Involvement

The findings from this study provide a distinct view of purchasing's importance in NPD under DI conditions based on the timing of purchasing involvement. That is, in contrast to prior research, which points out that the role of purchasing in NPD under DI conditions has limited influence (Melander and Lakemond, 2014), our findings demonstrate that purchasing's role and importance in NPD under DI conditions depends on the timing of purchasing involvement. More specifically, in cases C and D, the involvement of purchasing managers at the ideation stage of NPD contributed to a large number of new suppliers' product ideas and technological advances for NPD needed under DI conditions.

For Tushman and O'Reilly III (2006) and Kortmann (2015), the effectiveness of organization's DI capacity depends on the exploration process where DI requires a different organizational arrangement than incremental innovation. In this study, it was found that the organizational implementation of an Early Purchasing Involvement (EPI) supports the exploration of new product ideas or technology from suppliers required in the context of DI. Similar to Kortmann's (2015) work, which emphasizes the significant role of strategic leadership in implementing ambidexterity-oriented decisions for the development of DI, our study shows that the top management decision to implement EPI encourages purchasing representatives to adapt existing purchasing practices to more exploration practices into new technology or ideas from both former and new suppliers. Moreover, this study found that the implementation of EPI contributed to cross-functional team structures such as top management, marketing, R&D and purchasing interaction. This leads to the following proposition:

> ***P5:*** *The organizational implementation of EPI at the strategy level can encourage purchasing managers to adapt existing sourcing and supplier relationship management practices as required for DI.*

Moreover, the findings of this study show that although two different sourcing processes were found, there is no evidence of potential structural distinction of the purchasing department to pursue effective exploration practices (Schiele, 2010; Calvi, 2000). Actually, it appears that the *reversed* or alternative sourcing process was the result of the involvement of purchasing at the early stage of NPD rather than an official or well-documented process. Thus, it can be argued that explorative sourcing practices are developed in a "parallel" structure as suggested by Birkinshaw et al. (2016), Gibson and Birkinshaw (2004) and Gualandris et al. (2017).

Based on our case study findings and propositions, we develop a framework of early purchasing involvement practices for DI (Table 3). The framework sets out three purchasing themes,

comprising six purchasing practices and their definitions that could facilitate supplier research collaboration in NPD under DI conditions.

Table 3 A framework for purchasing involvement practices for NPD under DI conditions

Sourcing	
Scanning the supply base	Pre-selecting suppliers by technical capability, historical supplier relationship and R&D resources Communicating new market axes to supply base for future collaboration in innovation projects Coordinating pro-active innovation meetings with the supply base
Scanning the supply market	Establishing an "idea and/or design competition" activity by involving the supply market Asking suppliers to provide new product ideas or technological solutions based on potential customer expectations Organizing supplier day presentations
Supplier relationship management	
Collaborative "dalliance" relationship	Organizing face-to-face discussions with suppliers to work on further specifications Organizing innovation meetings to share and to align market, technology and business culture goals with suppliers Coordinating review meetings
Evaluating supplier collaboration at the ideation stage of NPD	Establishing and communicating confidentiality agreements to frame the openness and transparency for future collaboration in innovation projects Providing feedback to suppliers about their technological solutions offered that can be used for the development of new products
Early Purchasing Involvement	
Organizing advanced technology sourcing	Attending internal meetings focus on firm's innovation strategies Promoting supplier integration knowledge into firm's innovation process Outlining the objectives of all buyers regarding supplier innovations Establishing and communicating targets of product innovations with suppliers
Exchanging new STK information with Marketing, R&D and Top management	Gathering information on customer expectations from the marketing department Selecting suppliers by involving R&D and marketing Coordinating supplier's ideas and product planning propositions with R&D and Marketing Organizing innovation meeting between the Top management of both companies from buyer and supplier

In summary, the formal organization of EPI in NPD projects under DI conditions in Anémos assessed a purchasing department pro-active in the searching and integration of former and unfamiliar suppliers into the NPD process. The cases C and D are the outcome of this formal organization implemented in 2014. Both projects are ongoing, so while it is too soon for a final evaluation of the implementation of EPI in NPD performance (e.g. profitability goals), we can still analyses its achievement and shortcomings to estimate some benefits of this involvement. In table 2, we can observe an improved supplier collaboration, supplier technical knowledge exchange, and access to new supplier's knowledge and capabilities in both projects. The improvements can be associated with the result of significant learning experiences by adapting traditional purchasing practices to explorative purchasing practices. Similar to Subramanian and Soh (2017), the findings of our study further imply that a firm's potential absorptive capacity for exploring and integrating supplier ideas, knowledge and/or capabilities into the NPD process can be enhanced by prior purchasing experience on DI projects.

Conclusion

Previous studies suggest that managing NPD under the context of DI requires firms to learn and adapt new innovation practices (Anderson and Tushman, 1990; Bessant et al., 2010; Tushman and O'Reilly III, 2006). The purpose of this paper is to provide new insights into how purchasing involved in NPD projects can adapt new innovation practices as an attempt to respond actively to DI. Each project was able to capture new and alternative practices developed by purchasing representatives involved early in the NPD process under DI conditions. We seek to conceptually advance the role of EPI in NPD under DI conditions and we derive propositions.

Theoretical and managerial contributions

We contribute to recent research on purchasing involvement, ambidexterity and discontinuous innovation by providing empirical findings of how purchasing (departments) involved early in the NPD process adapt sourcing and supplier relationships practices for DI projects. Similar to Bessant et al. (2010) Birkinshaw et al. (2016) and Gualandris et al. (2017), we identified new purchasing practices for DI projects which are combined with existing purchasing practices as parallel structures. Thus, we suggest that the implementation of EPI organizational form at the strategy level can encourage purchasing managers to adjust their exploitative practices to explorative practices as required for DI.

We propose a framework of purchasing practices that can be used as an initial instrument by consultants, project managers, and purchasing managers for evaluating existing purchasing practices in NPD under DI; guiding the implementation of alternative or explorative purchasing practices. This framework may enable the purchasing department to differentiate between traditional purchasing practices for NPD projects and the use of explorative practices for NPD projects under DI conditions.

Limitations and future research

The case study method was appropriate since it allowed for flexibility as the scope and aim of the study were adjusted over time. However, a common critique to the method is its limitation in terms of generalisability. Another limitation was the number of respondents in each case. In case A, it was not possible to gain access to one of the supplier and marketing representatives. The relationship with the supplier involved in case A was broken after this project. The marketing manager involved in this case had left the company when the interviews were started.

An interesting area of investigation (only touched upon in this study and not investigated thoroughly) is with respect to the "dalliance" supplier relationship strategy, more investigation into how purchasing manages transparency, socialization and alignment within this strategy is needed. In addition, it would be of interest to examine the supplier perspective in a dalliance relationship. In this study, it was found that dalliance supplier relationships with an existing supplier created the feeling of "opportunistic behavior" from the supplier perspective. In contrast, it was found that dalliance supplier relationships with new suppliers created the feeling of "challenge and commitment" to participate in a NPD project with a potential customer.

Abstract

Innovation is a recognised source of competitive advantage for commercial organizations and is a cornerstone of European Union (EU) economic policy and business growth assistance programmes. Collaboration in turn is an essential enabler of innovation, particularly in a business to business context. This grounded theory study of collaborative social processes, highlights the importance of personal competences and social compatibility, above organisational compatibility, for new relationship development. The research has implications for new relationship formation in supply chains and peer alliances, especially in an innovation context where diverse experience and knowledge sources are required.

Keywords

Innovation, Collaboration, Social Capital.

Introduction

Innovation, particularly among SMEs, is a prominent feature of public policy for economic growth. This importance is illustrated in Europe by the current round of European Union investment. The European Commission (EC) and the European Investment Bank (EIB) are dedicating €33.5Bn of direct investment, as part of a €500Bn programme, designed to promote economic development, including help for an estimated 290,000 SMEs (European Commission, 2017). Eight billion euros will flow directly to SMEs that have an ambition to grow, irrespective of their research orientation (European Commission, 2016).

Collaboration provides the platform through which innovation relationships are formed and developed, and as such has been described as the *sine qua non* of innovation management (Dodgson, 2014). Collaborative relationships expose firms to diverse knowledge sources, new ideas and complementary resources through which radical and even market changing product and process developments occur (Berghman, Matthyssens, & Vandenbempt, 2012). Although the process may sometimes be unwieldy, under the right circumstances innovations can lead to significant improvements in business performance (Kanter, 2012).

The establishment of appropriate collaborative relationships is complicated in an innovation context, because countervailing forces act to narrow the range of appropriate partners. On the one hand the most radical, novel and potentially valuable ideas arise from distant, exploratory

relationships (March, 1991). On the other hand, an organization's ability to learn from, and use such knowledge, its absorption capacity, is related to what the organization already knows (Cohen & Levinthal, 1990). Therefore, there is an optimal point at which collaborators are sufficiently distant that novelty exists, but close enough such that the cognitive distance does not compromise the exploitation of an idea (Enkel & Heil, 2014; Nooteboom, Van Haverbeke, Duysters, Gilsing, & Van den Oord, 2007). The more that potential collaborators share in common, the more knowledge they can absorb.

Through social capital theory, we know that extensive networks increase the prospects of links being established with innovative sources (Burt, 1992), but less well established, especially in a business context, are the social processes through which ties are formed and developed into effective and productive collaborative relationships.

Much of the literature relating to innovation collaboration is based in University to Business (U2B), rather than Business to Business (B2B) studies, particularly in 'high velocity' sectors such as biotechnology, electronics and telecommunications (Eisner, Rahman, & Korn, 2009). Biotechnology is a particularly popular research context because of prevalence of researchable patents (Howard, Steensma, Lyles, & Dhanaraj, 2015). Much less is documented about how contacts across networks of B2B organisations can be better developed into productive relationships that in turn, will realise the outcomes envisaged by public policy makers.

Collaboration research is also typically undertaken at an organisational actor level, despite collaboration being fundamentally a social phenomenon, such that the role of individuals and social processes in collaboration has "largely escaped scholarly attention" (Schillebeeckx, Chaturvedi, George, & King, 2016, p. 1494). Collaborative relationships are not all equally effective (Al-Laham, Amburgey, & Baden-Fuller, 2010; Vlaisavljevic, Cabello-Medina, & Pérez-Luño, 2016) and an understanding of personal characteristics and social intricacies can provide insights into the reasons for those differences.

The underplayed role of individuals (Emberson & Storey, 2006; Gligor & Autry, 2012) assumes organisations are populated by a homogeneous, malleable and randomly distributed group of individuals (Schillebeeckx et al., 2016) that ignores individuals' characteristics and preferences. In order therefore, to increase the number of, and efficacy of collaborative B2B relationships, it is vital that knowledge relating to the social processes underpinning business collaboration is extended. The research therefore adopts a social perspective to address the question: how may we increase the number of business collaborations and the innovation potential of those relationships?

Literature Review

Innovation potential is recognised to be highest where individuals are exposed to new ways of thinking, and different experience (Corsaro, Carla Ramos, Henneberg, & Naudé, 2012) and diversity among its technical partners (Lucena & Roper, 2016). For firms, this means that contacts outside their normal sphere of collaborative relationships may have the greatest potential for inspiring product, process or technology related changes that may improve their competitive position.

Whilst, existing ideas can be incrementally *exploited* to realise their full innovation potential, the most radical, novel and valuable ideas arise from distant, exploratory relationships (March, 1991). The more distant the source of knowledge, the more innovation potential it may have, but also the more difficult it becomes to understand and to realise that potential. This distance has been termed the *cognitive distance*, exhibits an inverted 'u' shaped relationship with

organisational learning (Enkel & Heil, 2014). An organisation's ability to absorb knowledge is its absorption capacity, and is highest where that knowledge most closely relates to knowledge already absorbed by members of the organisation (Cohen & Levinthal, 1990). Inverted 'u' shaped results are also reported between innovation performance and innovation search strategy (Laursen & Salter, 2006), where again a point is reached, beyond which, it is more expensive to search for innovation potential that can be absorbed.

Absorptive Capacity

Given the potential inherent in distant contacts, even large organisations should no longer consider innovating alone (Pisano & Verganti, 2008). Organisations need to ensure that they seek ideas from broad enough sources, both internally and externally (Hansen & Birkinshaw, 2007), whilst also ensuring that they have an absorptive capacity appropriate to the complexity of knowledge being assimilated. The absorptive capacity needs to be sufficient not just to transfer the knowledge into the organisation, but also so translate this into tangible value, something which many companies do poorly (Hansen & Birkinshaw, 2007).

Absorptive capacity differs between firms and is enhanced by a firm's ambidexterity (Lucena & Roper, 2016) and the establishment of social capital. Vlaisavljevic et al. (2016) show, for instance, that relational social capital can extend an organisation's ability to absorb knowledge from diverse partners, where trust leads to a greater willingness to bridge cognitive gaps. Through direct and prolonged collaboration, groups not only establish trust, but also are able to exchange complex tacit knowledge based on "intensive, repeated interaction" (Molina-Morales & Martínez-Fernández, 2009, p. 1015). Rich social ties, in which individuals are connected through multiple routes, further enhance innovative knowledge transfer (Aalbers, Dolfsma, & Koppius, 2014). The dependency on close relationships also explains why firms that attempt to access technical innovation by buying-in technical resources, fail to develop an internal capability capable of accessing the critical tacit knowledge that is the basis for genuine competitive advantage (Al-Laham et al., 2010).

Whilst complex knowledge transfer depends on close inter-personal links, weak-ties are sufficient for the transfer of highly codified information, and indeed the sharing of innovative ideas is better facilitated through weak-tie networks (Hansen, 1999).

Social capital theory and innovation

The tension between location of innovation sources and the potential to absorb complex knowledge from those sources illustrates the two primary mechanisms underlying social capital theory. The first relates to weak-tie networks through which innovation sources may be located, whilst in the second, close inter-personal bonding capital provides the basis for complex knowledge exchange.

Social capital theory distinguishes the weak social links of acquaintances (weak-ties) from the close, social bonds of cohesive groups (strong-ties), and proposes that weak-ties provide superior access to new knowledge and contacts, where these links bridge previously disconnected groups (Granovetter, 1973). Members of closely knit groups share much of each other's knowledge, but weak-tie bridges give members of connected groups access to new contacts and information (Granovetter, 1973, 1983). These weak-ties are a source of informational power to the bridging individuals. Weak-ties require much less time to establish and to maintain than strong ties, so that considerably more ties may be maintained, as long as they remain weak (time spend developing those relationships will be at the expense of extending that person's weak-tie network). Individuals with many weak-ties are best placed to diffuse ideas quickly to the largest number of targets (Granovetter, 1973). Bridges are most

valuable when diffuse social networks contain structural holes that the weak-ties bridge (Burt, 2000).

Strong-tie group relationships also confer advantages on group members. Groups of closely linked individuals share information sources and develop social capital through shared meanings and normalised values (Coleman, 1988). This bonding form of social capital leads to the development of trust among group members that facilitates commitment and responsive action.

Effectiveness of the bridging and bonding forms of social capital

The relative merits of bonding versus bridging forms of social capital are widely discussed in the literature. From a contingency perspective, it has been suggested that each has merit depending on the nature and uncertainty of the task. Social closure (high bonding) is better suited to complex and uncertain problem solving, however, where tasks are more certain but information or resource access are concerns, then network bridges provide for a more cost-effective means of access to a wider range of resources (Adler & Kwon, 2002). In an inter-organisational context, the tie-strength between collaborating groups in each organisation is an important consideration. Whilst weak-ties are sufficient for the transfer of highly codified knowledge, strong-ties are needed to enable the transfer of complex and non-codified knowledge (Hansen, 1999). Rich-ties, in which multiple links are established between collaborating groups, have also been linked with enhanced transfer of complex knowledge (Aalbers et al., 2014).

Ultimately however, the effectiveness of social capital is contingent on factors beyond structural network conditions and tie-strength. The existence of a bridge across a structural hole is not in itself enough to generate social capital: "Brokerage opportunities do not by themselves turn into success, and people are not equally comfortable as brokers between groups" (Burt, 2000, p. 383). Actors must be willing to utilise their social capital; they must have the opportunity and capability (Adler & Kwon, 2002), and have an expectation of success (Nahapiet & Ghoshal, 1998). The establishment of social capital is therefore contingent on personal as well as network and task factors.

Social capital should not be regarded solely as a beneficial resource (Adler & Kwon, 2002; Nahapiet & Ghoshal, 1998), as forms useful for one purpose may be ineffective or detrimental to other purposes (Coleman, 1988). A preoccupation with contrasting the relative benefits of the bonding versus bridging perspectives has meant that negative facets of social capital are underplayed (Portes, 2000). Close bonding can lead to the exclusion of outsiders and isolation from outside information, whilst social norms can restrict initiative (Portes, 2000). These factors can stifle external collaboration and preserve the status-quo in businesses. It has also been suggested that close bonding leads to a convergence of ideas, beliefs and knowledge that stifles creativity.

Method

This research considers how the number of business collaborations may be increased, especially those featuring innovation, via a better understanding of the social processes through which such relationships are established. The context is provided by European Union strategic policy, in which innovation and collaboration involving SMEs is at the heart of plans for economic development.

This inductive, qualitative study explores inter-organisational collaborative practices across a broad range of contexts including: vertical supply-chains, horizontal peer-peer collaborations, and complex consortia featuring both vertical and horizontal relationships. A qualitative study is suitable to the exploration of complex social phenomena where even the more obvious behaviour may depend on intricate social organisation (Silverman, 2013). An emergent inductive design was chosen for its flexibility in exploring relevant but unexpected insights. Grounded theory was adopted because of its social process focus, sampling approach and theory generating capability. Established grounded theory recommended practices were adhered to throughout (Gephart, 2004; Kaufmann & Denk, 2011; Suddaby, 2006). Grounded theory is well suited to interactional research (Goulding, 2005) and for researching complex, dynamic social processes in a business context (Flint, Larsson, Gammelgaard, & Mentzer, 2005). The constructivist version of grounded theory was used because of its high relevance to collaboration contexts in which truth is highly subjective and socially constructed.

The context of the study includes but is not limited to SMEs. Selected organisations ranged from small companies to global corporations and regional, national and international collaborations were reviewed, to explore the social processes through which collaborative relationships are formed and developed.

The study was undertaken in two phases. In the preparation and scoping phase, field notes were compiled on collaboration issues observed during 990 hours of direct engagement with six SMEs, as part of a business collaboration and innovation programme, funded by the European Commission. In the second phase, data collection proceeded through open-ended, semi-structured interviews with twenty-nine senior managers/executives from twenty-seven different organisations. An active interview (Holstein & Gubrium, 1995) approach was adopted and open-ended questions were used to "encourage unanticipated statements and stories to emerge" (Charmaz, 2014, p. 65). Interviews typically lasted 1-1.5 hours, were digitally recorded, and fully transcribed to ensure that the respondent voice was accurately represented during initial coding. The interview protocol was revised as the study proceeded, in accordance with the method principles, to focus on emerging topics of interest and to explore categories in progressively greater depth as the analysis progressed through focused coding into theoretical coding (Saldanha, Mello, Knemeyer, & Vijayaraghavan, 2015). Data gathering continued until the properties and dimensions of the core categories were fully established and it was considered that further data gathering would be unlikely to add further insight (Kaufmann & Denk, 2011).

Data analysis

As transcripts and supplementary materials became available they were loaded into NVivo® 10 and coded. Coding and analysis processes followed three stages of coding: initial coding, focused coding and theoretical coding (Charmaz, 2014). Initial coding is a wholly inductive process allocating emergent codes as indicated by the data. In accordance with the study objectives, the focus during initial coding was on identifying action, actors and situations, rather than less insightful passive, descriptive codes (Saldana, 2016). In focused coding the enquiry is narrowed to focus on categories abstracted from the initial codes and it is from this stage that the first-order concepts were established. In the final (theoretical coding) stage the first-order concepts are examined in relation to each other and by a theoretical explanation of the phenomenon sought. Through this abductive process, the second-order concept (Saldana, 2016) of collaborative compatibility was established and presented as interpretive theory (Charmaz, 2014).

In the development of the process typology, reported as a first-order concept, action and process-related initial codes were collated into categories and elaborated during focused coding. Commonalities and differences in situations, activities and outputs were considered when selecting, structuring or reforming the categories. Codes that were not considered to represent social interaction were excluded, whilst duplicate codes were merged. Complex codes that covered more than one fundamental process were deconstructed. The structure and descriptions of sub-categories stabilised as the properties were elaborated during subsequent data gathering. The final structure of the social process category is presented in the findings as a typology, before the details of the second-order concept of collaboration compatibility are presented.

Research rigour was a priority and criteria appropriate to inductive research (Gioia, Corley, & Hamilton, 2013) were adopted to ensure that process validation was not subverted by positivist predilections (Johnson & Duberley, 2015).

Findings

From this study of the social processes underpinning collaboration, a set of eight fundamental categories of collaborative process are recognised that are used across three phases of a relationship. A set of situational and behavioural factors are also identified that moderate the effectiveness of collaboration processes. These elements are presented as first-order concepts (directly traceable into coded data) and depicted in Figure 1. The analysis of inter-relationships between process categories, and the factors that promote or inhibit them, also led to the definition of *collaborative compatibility* as a second order concept (Table 1).

Initial codes (examples)	**First-order concepts**	**Description (of 1st order concepts)**	**Second-order concept**
Allying Anonymising Anticipating Arbitrating Arguing Benchmarking Brokering Consulting Contributing Delivering … Valuing	*Process categories* • Contributing • Learning • Influencing • Problem solving • Exploiting • Socialising • Brokering • Allying	A typology of eight categories of social processes through which all encountered collaborative action can be described (see Table 2)	*Collaborative compatibility:* Personal competences • Skills • Willingness • Risk attitude • Knowledge & experience Social compatibility: • Identity proximity • Shared cognition • Trust Organisational suitability

Table 1 - Conceptual development

In the following sections the process categories are presented as a typology in Table 2, and the effect of the situational and behavioural factors is discussed. The second-order (abstract) concept of collaborative compatibility is subsequently presented. The higher explanatory power of second-order concepts is used to explain the preeminent importance of personal and social factors in widening business participation in collaborative relationships.

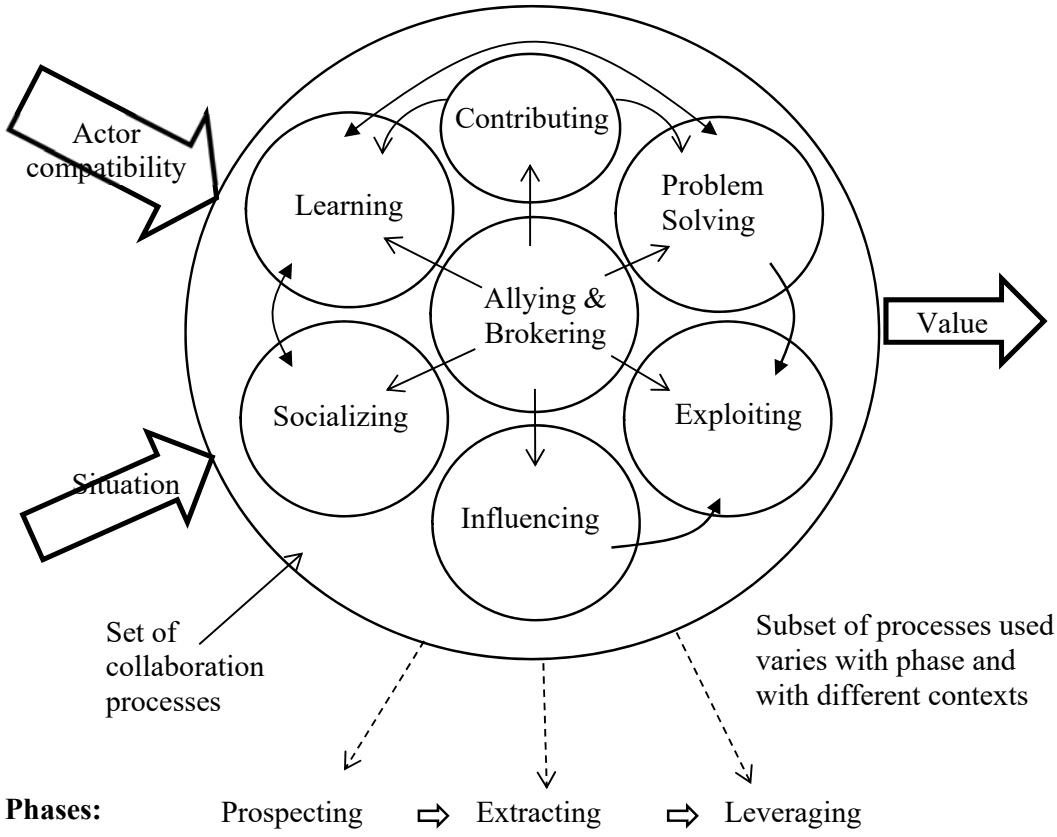

Figure 1: Collaborative social processes

Social processes

A typology of eight categories of collaboration processes (Figure 1) was identified through the analytical aggregation process described in the method. Many of these fundamental processes, described in Table 2, have implications in an innovation context.

Collaborative learning, a cornerstone of innovation, occurs in many forms, including: didactic forums; explicit knowledge media; discursive interaction; site visits; trade shows and during regular commercial interaction. Collaborative influencing bodies (e.g. trade associations) improve innovation potential through political lobbying to affect trading environments, as well as through intra-sector influence to establish and regulate industry specific standards. Problem solving processes are most relevant during the (value) extracting and leveraging phases of collaboration and depend on bonding social capital.

Socialisation processes either, may increase bonding capital associated with existing relationships, aiding knowledge transfer, or enable the development of weak-tie social capital. It is through weak-tie socialisation that firms are most likely to access new contacts and innovative ideas. Examples encountered in this study included the development of a new metal treatment process, arising indirectly from an earlier overseas engagement, and a new business line developed by a steel fabricator, in which a new composite material solution to an existing business problem was identified during a chance social interaction.

Collaboration process	**Description**	**Outputs (org. value and social & human capital)**	**Indicative quotes**
Contributing	Unusual form of collaboration in which one party is contributing knowledge, experience, time or other resources with no immediate expectation of gain. Motivation mainly seems to be repayment of a perceived social debt. Group affiliation may also increase an individual's feeling of indebtedness.	Increased reference value to the donor, with some increases in social capital but most benefits accrue to recipients.	UR "First time I went it was great ... It allowed me to develop a network that really helped me. 18 months later we were the ones presenting … it was a way of putting something back …" [GlobalCo Manager] UK "… I mean / any effective network or association can't just rely on taking out can it, so there has to be putting in …" [SME TD]
Learning	Collaborating with the purpose of acquiring new information, or new knowledge. Examples noted covered: Technical: knowledge of new technology, techniques or new application, acting as a source of innovation; Market: information about competitor proposition, competitive environment; Relational: contacts, access points and opportunities. *Learning* may be an active, purposive process, or passive as a by-product of other collaborative activities.	Individually centred human capital leading to organisational intellectual property when absorbed. Individual social capital also increased during learning.	MS "In the industry it's called stealing with pride … so we'll look at something and … look at introducing something like that in our line". [SME Works Manager] DG "you never know what you're going to pick up from when you walk around a company … you get best practice sharing … things that may spark off ideas for you". [Broker CEO]
Influencing (incl. lobbying & persuading)	*Lobbying* seeks to affect the macro-economic business environment for the benefit of a group. Changes in tax, regulation, investment policy are examples. Change is sought but not guaranteed. *Persuading* is the code used to distinguish collective collaborative effort designed to affect the micro-economic environment, such as through agreeing industry standards. Here influence is exerted on peers and the group potentially has power to effect change.	Vanguards increase social capital, power, reference, and human capital. Organisations benefit from reduced costs and increased market activity where action succeeds, but activists may incur higher costs, motivating others toward freeloading.	QA "the Chief Exec … we've kind of … targeted him to things like opening links with Government and … lobbying activists and things like this … LG "… we have agreed with the World Trade Organisation that when these issues are discussed … at governmental level that we should be involved … An import/export ban … those bans have been lifted quite quickly after we've complained". [Broker CEO]
Problem Solving	*Fixing*, *sourcing*, *solutioning*, exemplify a variety of codes covering design, resourcing and remedial activities that either enable new value streams or stem value losses. The mind-set of creative engineers was a recurrent theme in several interviews.	Group members increase human capital and bonding social capital. Organisations gain intellectual capital, but value timing is variable.	TA "there must be some new technologies that would help us … we would then go out to the market … to come up with ideas …" [UKGov Prog. Manager] QB "We've solved some of our customers' problems … This goes back to having an interest ... Solving problems is an interesting challenge. That's maybe why I do crosswords …" [SME MD]

Exploiting	Collaborative commercial exploitation of an opportunity. Accessing additional resources. Driving revenue and value. Once established, the interaction may persist for an extended period in this 'run' state. It is this state to which much existing literature limits its attention.	Organisationally centred, commercial value	DG "Yes, because it is all about commercialisation. So suddenly the challenge is … do you get others involved, how do we ensure that we're getting … money in to companies locally …" [Broker CEO] TA "You would then work with them … speak to relevant people … then take it to the next stage ..." [UKGov Prog. Manager]
Socialising (incl. Networking)	Social relationship development relating to formation or development of business relationships. Value objective & locus may be vague. Includes *networking*, the process of developing business contacts. *Socialising* is a more general interaction between business contacts in any setting, including private social settings.	Individually located bridging social capital (new contacts) and bonding capital (enhanced existing relationships). Not readily absorbed by firms, so remains located in personal relationships.	ML "… national figures, I've been able to chat to them, when they're a bit more relaxed" [Broker CEO] LE "I've tried different ones [networking forums] … whilst I don't get loads of work from it, I do find it really beneficial. … most people face the same challenges and problems [SME MD]
Brokering	Effecting connections between people and therefore organisations. Provides access to knowledge, funding and other resources. Often undertake by third-party organisations such as trade associations; business development programmes; social enterprises; large organisations promoting innovation into their supply chains. Varies from light-touch introductions to active consortium construction.	Individual leaders of broker organisations develop social capital, power, reference and human capital. Linked individuals also may develop human and social capital. Org benefits are indirect.	ML "It's more brokering … some might be intuitive … I've sort of linked people by e-mail and thought … you'll really get on and have a productive relationship … [for others] it is more sort of planning and positioning" [Broker CEO] DG "because of our contacts, and because we have a good understanding of what each of our member companies are doing, we have the ability to build consortia for whatever type of opportunity ... engaging internationally or nationally" [Broker CEO]
Allying	Connecting process leading to peer alliances, from simple dyads to new associations. Bottom-up aggregation process in contrast to *brokering*. Alliances may be short-term bid collaborations or longer-term associations that may then lead to subsequent lobbying and brokering activity.	Vanguards increase social capital, power, reference, and human capital. Organisations benefit from reduced costs and increased market activity.	QR "… we established the trade association because we've all got this common problem …" [SME MD]

Table 2 - Collaboration process typology

Brokering and allying processes can facilitate each of the other collaboration processes. Proactive brokers particularly, can significantly enhance collaborative interaction, even to the point of building consortia. Brokering actions however, may also inhibit innovation where brokers undertake 'match-making' between similar, rather than dissimilar contacts.

Personal and behavioural factors

Relationship formation was noted in many instances to be limited by personal and behavioural factors. Weak social skills, an unwillingness to socialise widely, and risk aversion, were each noted to compromise severely an individual's potential for developing weak-tie networks or strengthening closer ties. The director of one company described themselves as "not very pushy people". The company had briefly attempted to strengthen forward and backward supply chain relationships but quickly retreated [Phase 1 field notes]. People's perception of their social skills however, was not necessarily indicative of performance. In the case above, negative perceptions of social skill may have contributed to a reluctance to network, but in two other cases, two SME directors, each of whom described themselves as 'unsociable', were clearly very effective networkers.

Situational suitability.

Few interviewees described any particular strategy for establishing new collaborative relationships and many reported negative experiences of networking, either due to their own naivety: "It's a very complicated dynamic which SME's don't always realise …" [Trade association head], or due to poor event organisation: "sometimes you can be invited along to business networking, and it's just shabby … put together with the wrong people and there isn't enough thoughtfulness behind it" [Social enterprise CEO]. Concerns about the perceived suitability of attendees at events led some to seek out those with a similar identity. One SME owner, for instance, identifies himself as an "engineer" and courts "…like-minded engineers and manufacturing people" to collaborate with on new projects and products.

Suitability of interactants is complex. In the first example below an unexpectedly productive conversation occurred at a social event, whereas in the second a professionally organised networking forum was unproductive. At the social event a new marker for use in international cotton regulation was identified during a discussion on problems of authentication, between a banker and a cotton regulator. In the second case however, the marketing director of an ICT company who attended many networking events in the maritime sector lamented: "nobody was interested … we never got a single sale out of it". Their services were potentially of interest to all companies, but maritime company directors had little interest in ICT and little understanding of the issues. In the first instance, despite their different backgrounds, a productive dialogue was established, whereas in the second case common ground was not established.

Collaborative compatibility

Collaborative compatibility is reported as a second-order (abstract) concept that helps to explain how the identified social processes are moderated by behavioural and situational factors. Compatibility is a complex concept that considers ultimately how individuals establish legitimacy in each other's right to participate in collaborative action, and how individuals establish agency in relation to subsequent interaction. The concept is represented (Figure 2) in three dimensions to represent the personal, social and organisational factors that collectively determine the competence, commitment and cohesion with which a collaborative interaction is undertaken.

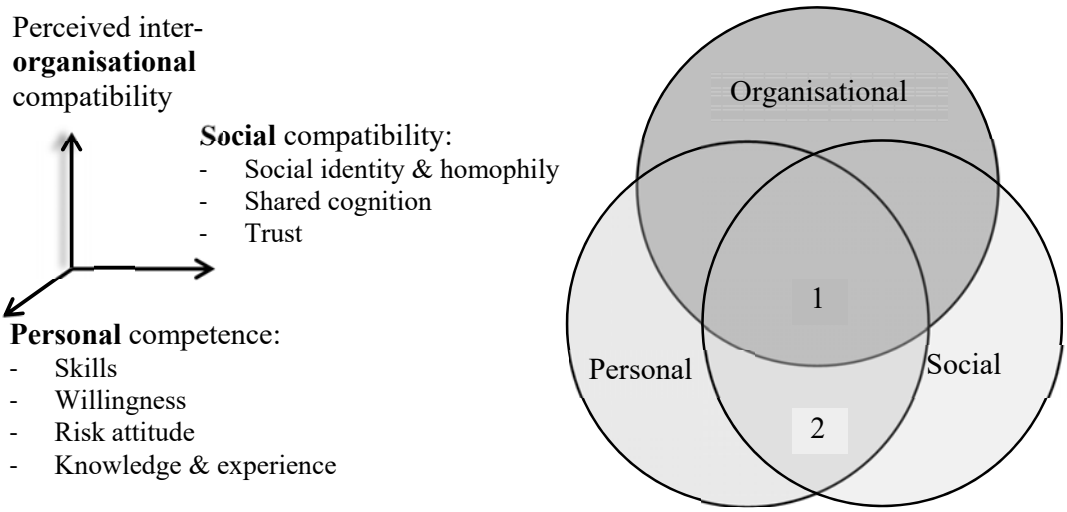

Figure 2- The 3 dimensions of collaborative compatibility

Personal dimension: Firstly, collaboration depends on personal competency and commitment. Individuals must be competent in both the subject matter and in social interaction. Only then will connections be established; social rapport be built, and effective communication established, enabling potential innovations to be identified. Each collaborating individual in a situation must have these skills and be willing to collaborate.

Social dimension: An actor's willingness to collaborate depends on their perception of the legitimacy of that interaction. The potential to interact (agency) is enhanced where social identity, previously established social capital, or newly perceived common cause encourage actors to explore further their collaborative potential.

Organisational dimension: This is a subjective assessment by individual actors that their interaction could lead to commercial value for their respective organisations. It is an assessment of potential suitability that could be a vertical supply-chain relationship or a potential peer-to-peer collaboration.

Collaboration effectiveness is optimised where the greatest congruence occurs between the three dimensions (area 1 in Figure 2). Congruence occurs when two or more competent and socially compatible individuals, representing two or more organisations, are fully committed and empowered to interact. However, collaboration between compatible and competent individuals is also possible when organisational compatibility is not perceived (area 2). Individuals collaborating at industry events and even in social settings are creating value which may by-pass their parent organisations. Conceptually, this is noteworthy because it suggests that of the three dimensions, only organisational compatibility, the unit of analysis for many studies, is optional.

Discussion

The study identifies the basic social processes through which people collaborate and proposes a model, through which, the way personal and social factors affect those processes can be explained. This richer understanding of how people collaborate, especially in the formative stage, will help organisations to identify appropriate collaboration personnel, and help to increase the likelihood of innovation collaborations arising through business networking.

The development of new collaboration relationships, founded on innovation, is complex, being affected by the way people learn, the way they connect, who they connect with, and how competently they forge new social links. Each of these facets may exhibit contrasting forces. The learning literature, through the concepts of absorption capacity and cognitive distance, establishes the benefits of relationships with more distant knowledge sources, but only as far as those ideas remain understandable and accessible (Enkel & Heil, 2014). People need broad, rather than deep knowledge, to engage diverse sources in productive dialogue, to identify relevant new ideas. However, those responsible for developing and exploiting ideas need deeper technical knowledge, and the capability to develop close social relationships.

The way people connect is reflected in their accumulated social capital. In an innovation context, those with extensive weak-tie networks, are much better positioned to access rare and valuable innovation opportunities. Contrastingly, those with strong-tie connections are better positioned to collaborate deeply over an extended period to develop knowledge. Innovation *prospecting* is best performed by relationship managers with broad, rather than deep, human capital, and extensive (and therefore weak) social networks, whereas the exploitation of relationships, once formed, requires people with deeper knowledge and the development of strong-tie relationships. Exploitation resources are most likely to exist in design and/or operations functions, but organisations need to consider where the best prospectors are likely to be situated. In larger organisations, strategic sourcing professionals, with extensive networks of external contacts, are potentially ideally qualified prospectors, but in smaller organisations, only the entrepreneurial heads may have sufficient social and human capital.

The effectiveness of innovation-oriented business networking; the way people connect, is also affected by their social inclinations. The more people have in common, the more inclined they are to interact socially. Homophily (McPherson, Smith-Lovin, & Cook, 2001) describes the natural tendency for those with common traits to aggregate. The SME owner who identifies himself as an "engineer" and courts "like-minded" people to collaborate with on new projects, exhibits homophily and a social identity (Ashforth & Mael, 1989). Such groups benefit from common knowledge and a shared language that facilitates the exchange of complex technical knowledge. However, homophily also runs the risk of closing, rather than widening people's networks, reducing their chances of innovation encounters. Sector based membership organisations, such as trade associations, may therefore constrain their members exposure to radical innovation sources. Networking events need to group people from diverse organisational backgrounds, but who share enough in common to be willing to interact.

The importance of collaborative compatibility

Social compatibility needs to be recognised as having pre-eminence over organisational compatibility. For effective dialogue to occur, individual competences and social compatibility are essential, whereas organisational compatibility acts as an influence on assessments of social compatibility but is not essential; individuals can develop their own business relationships. Potential collaborators need to have the requisite social skills, technical knowledge and motivation to collaborate, yet even the most competent individuals will not form an effective relationship unless social compatibility is established.

Structuration theory (Giddens, 1993) suggests that the power of would-be collaborators to interact (agency), influences, but is also constrained by their social environment (structure). In a business context, both individual and organisational perceptions by each party, of each other party, contribute to this social environment. Each party's judgement of the legitimacy of the interaction will be based on assessments of the other's status and influence, and perceptions of the status and relevance of the organisation they represent. Although competent individuals

influence their environment, ultimately agency is linked to the establishment of shared language, a compatible power-regime and recognition by the other party(ies) of the legitimacy of the interaction (Giddens, 1993). This social compatibility is illustrated by two contrasting examples reported in the findings. In the first, the absence of a common language between an ICT executive and maritime sector businesses, the technical importance was not understood, legitimacy was not established, and relationships failed to develop. In the second, a valued innovation was developed following an initial encounter at a social event in which two individuals, from different business sectors, quickly established a rapport enabling them to discuss common issues from which an innovative application of technology was generated.

Contribution to theory

Collaborations are not all equally effective (Al-Laham et al., 2010) and this research contributes to theory with a topology of distinct social processes through which collaboration is undertaken, and identifies behavioural and situational factors that moderate the effectiveness of those processes. This breakdown of collaboration processes then enables the contrasting benefits of the bridging and bonding forms of social capital to be revealed, thereby highlighting the contrasting skillsets required at different stages of relationship development. For the development of new relationships in an innovation context, where the initial social interaction is by necessity with an acquaintance (weak-tie) from a dissimilar organisation, the research reveals a set of personal, social and situational factors through which collaborating parties firstly establish the legitimacy of the interaction and subsequently establish an effective dialogue. These factors are collated in an abstract model of collaborative compatibility that complements and extends recent work on personal collaboration motivation (Schillebeeckx et al., 2016), by highlighting the pre-eminent importance of the personal and social dimensions of collaborative compatibility, without which inter-organisational potential would not be identified or realised.

Practical implications:

The collaborative compatibility model has implications for how organisations plan and execute B2B collaboration. Organisations need to consider that the personal attributes, experience, social status and accumulated social capital will all affect the efficacy with which innovation potential is realised. Strategic sourcing managers (SSMs) with extensive industry contacts (weak-tie networks), are well placed to identify new sources of innovation, at the prospecting phase of relationships, whereas supplier relationship managers (SRMs) and technical experts, with fewer but more closely-bonded relationships, are suited to exploiting innovation potential but would be less effective in a scouting role. Given that the greatest innovation potential lies in more distant relationships, SSMs need to establish links outside their established sector supply-chain network, by engaging similar firms that work in other sectors, or firms with synergistic capabilities but with products and services that contrast with those of established suppliers. Innovation in existing products and services may arise through this broadened supply-chain perspective, whilst new products and services may arise through horizontal as well as vertical collaboration. Organisations need therefore to consider which roles are best suited to innovation sourcing, and SSMs, with broad subject-area knowledge and extensive business networks, may be particularly well positioned to fulfil this role through both horizontal and vertical relationships.

Summary: Public clients both drive and face ongoing changes in the instruments used to procure supplies, works and services. Keeping an appropriate balance between exploitation of extant procurement instruments and exploration of new instruments is a challenge, as general problems, such as the stickiness of knowledge, scarcity of resources and the project based character of multi-project clients impede effective exploitation. This paper reports on an Action Research approach to further develop this exploitation capability in a public client's procurement department. It is concluded that without deliberate efforts to improve the procurement instrument exploitation capability, an efficient and effective reuse of newly developed procurement instruments is likely to remain out of reach.

Acknowledgements: The authors wish to thank ProRail, the Netherlands rail infrastructure manager, for making this paper possible.

Keywords: organizational learning, procurement function, organizational capability.

Submission category: working paper

Introduction

Multi-project public clients generally operate a variety of procurement instruments such as contracts, supplier selection systems and contract award methods. Over time, these procurement instruments change. Changes may be imposed or influenced externally, for instance by changes in tendering legislation, public values or government procurement policy. Changes can also be driven by clients themselves, for instance to achieve more value for money in a complex and demanding project. Either way, new instruments emerge that form necessary substitutions of, or valuable additions to the client's current set of instruments.

Some changes are important but simple, such as updating a contract template's references to a new version of standard terms and conditions. However, other changes involve time consuming and risky development processes, such as the development of a CO2-reduction procurement instrument (e.g. Rietbergen & Blok, 2013) or the application of new types of contractual arrangements such as public-private-partnerships (Liu, Love, Smith, Regan, & Davis, 2014) and project alliancing (Lahdenperä, 2012). To exploit this spectrum of changes to the most, clients need to structurally evaluate the potential added value and select appropriate ways to share knowledge about modified or new instruments throughout the organisation.

However, several barriers, such as the stickiness of knowledge, scarcity of resources and the project based character of multi-project clients, restrain the organizational capability to structurally exploit developments in procurement instruments. Especially for clients employing dozens of procurement officers to run hundreds of tender procedures each year, sustaining and improving this exploitation capability is essential.

Therefore, it is key to identify impediments to the exploitation of procurement instrument developments and understand how these can be overcome. This paper reports on an embedded

case study (Yin, 2014) to improve this capability in a multi-project public client's organization. Action Research (Maestrini, Luzzini, Shani, & Canterino, 2016) is applied to identify and overcome empirical barriers encountered during the improvement efforts.
While the study is not finished yet, results achieved so far indicate that improving the exploitation capability can prevent overlapping work, enhance the efficient and effective reuse of instruments, and facilitate learning. The study also confirms that generally known barriers such as prioritization issues limit this exploitation capability. It is concluded that without deliberate efforts to improve the procurement instrument exploitation capability, an efficient and effective reuse of newly developed procurement instruments is likely to remain out of reach.

Theoretical approach

Organizational capabilities

Capabilities are defined as the knowledge residing in the routines of an organization to integrate and coordinate its specific resources, skills and competencies to perform various activities (Hartmann, Davies, & Frederiksen, 2010; Zollo & Winter, 2002). The specific capability this study hones into is related to, but distinct from contractual capability. Contractually capable public agencies are able to foresee major hazards of opportunism in the transaction relationships and address them *during* the drafting, tendering and negotiating of contract documents (Hartmann et al., 2010). In contrast, this study aims at the capability to structurally consider and facilitate general future exploitation of contract documents and other types of procurement instruments *after* these have been developed (in short: exploitation capability).
We assume that the routines that constitute exploitation capability encompass two main actions. The first action concerns the consideration of the potential reuse of significantly modified or newly developed procurement instruments. If reuse – in whatever form – indeed is considered worthwhile, then the second action becomes relevant: the facilitation of knowledge sharing on the instrument.

Organizational learning

As indicated in the introduction section, the capability examined in this study is perceived as an exploitation-exploration balancing problem (March, 1991). Exploitation and exploration are linked by the consideration to reuse newly developed procurement instruments. Without reuse, the resources spent on instrument development will be returned by a one-off application only. Too much exploration will thus result in inefficient procurement processes. On the other hand, too much exploitation may result in a rigid application of extant procurement instruments that insufficiently address the client's current procurement challenges.
Maintaining an appropriate balance relates to the central topic of organizational learning (March, 1991). Therefore, this study employs the perspective of organizational learning. According to the 4i-framework of (Crossan, Lane, & White, 1999), organizational learning concerns four social and psychological processes: intuiting, interpreting, integrating and institutionalizing. These processes link the assimilation of new learning (exploration) and the use of what has been learned (exploitation) at individual, group and organizational level. Intuiting and interpreting occur at the individual level, interpreting and integrating occur at the group level, and integrating and institutionalizing at organizational level.
Crossan et al. (1999) hold that organizational learning is different from the simple sum of the learning of its members. Although individuals may join or leave an organization, what they have learned does not necessarily leave with them. Some learning is institutionalized, i.e. embedded in the systems, structures, strategy, routines, prescribed practices of the organization, and investments in information systems and infrastructure.
The process of institutionalizing not only embeds learned behaviours that have worked in the past into the routines of the organization. It also feeds back to the group and individual level by

creating a context through which subsequent events and experiences are interpreted (Crossan et al., 1999). It would therefore follow that, for a public client to maintain the capability to deliberately consider and facilitate the exploitation of newly developed procurement instruments, the learning about how to do this must become institutionalized. This means that routines, procedures or diagnostic systems should be created to facilitate feedback to the group and individual level.

Barriers derived from literature

It can be anticipated that several barriers impede the exploitation capability. In the preliminary stage of this study, the following barriers were derived from literature.

Complicated trade-off - Keeping a proper balance between exploitation and exploration is problematic. Literature holds that decision making on the trade-off between exploration and exploitation is complicated by the fact that returns from the two options vary in many respects, that learning on individual and organizational level involves conflicts between short-run and long-run concerns and between gains to individual and collective knowledge, and that exploitation and exploration compete for scarce resources (March, 1991). This general statement is likely applicable on procurement instruments as well.

Fragmented knowledge - Literature on the development of contract templates – which in our study are seen as a particular type of procurement instruments – indicates that contracting knowledge is dispersed throughout the organization (Argyres & Mayer, 2007). This problem of fragmented knowledge is also identified in literature on cross-functional sourcing teams (Driedonks, Gevers, & van Weele, 2014; Moses & Åhlström, 2008). The more fragmented the knowledge about a procurement instrument, the more likely reuse is considered one-sidedly.

Tacit Knowledge – A major stream in literature holds that knowledge transfer relies to a great extent on the storage, retrieval and transfer of explicit knowledge. Knowledge is seen as a continuum between explicit and tacit knowledge (Nonaka & Von Krogh, 2009). The more implicit or embedded knowledge is, the harder it is to share that knowledge. Consequently, the more implicit the knowledge about the design and functioning of a procurement instrument is, the more difficult it is to properly consider and facilitate its reuse.

Barriers to knowledge transfer – Several barriers to knowledge transfer have been reported in construction management literature, such as lack of time and resources to capture lessons learned, lack of usefulness of captured knowledge, focus on failures, lack of purpose, and lacking commitment of staff and management to knowledge sharing initiatives (Hartmann & Dorée, 2015). In addition, employees may resist knowledge sharing because of fear to lose their unique value for the organization and thus reduce chances of promotion. This resistance may be amplified by the organization's lack of recognition or reward for knowledge sharing (Ragab & Arisha, 2013).

Limitations to knowledge sharing strategies – The three main knowledge sharing strategies of codification, personalisation and people finder each has its limitations (Ragab & Arisha, 2013). For instance, codification requires time to write out knowledge and reading by others, while the more tacit aspects of the knowledge base will not be transferred.

Project-based organizations - Project based organizations seem to be caught up in the learning paradox of projects. Due to their fluid, temporary and interdisciplinary nature, projects are both seen as stimulating learning and the creation of knowledge, and as restricting the assimilation of created knowledge by other organizational units (Hartmann & Dorée, 2015).

Research design

The study is performed at the procurement department of a high-outsourcing, multi-project public infrastructure management organization. While this department had procedures in place for maintaining a portfolio of procurement instruments, there were indications that newly

developed procurement instruments could be reused more effectively. The research was therefore designed to assess and improve the organisation's exploitation capability.
According to organizational learning theory, once a sequence of actions has become an organizational routine, it will facilitate feedback to the group level and individual level. Having established an exploitation routine in the client's organization is therefore the desired end state that this study should contribute to.
The aim was to design an effective procedure for considering and facilitating the future reuse of newly developed procurement instruments, and incorporate it in the client's Quality Management System (QMS). Once part of the QMS, it will help both individuals (such as procurement officers, category managers, and cost engineers), and groups (procurement teams, project teams, cross-functional sourcing teams) to consider the potential added value of reusing recently developed procurement instruments. However, for the procedure to be actually used, it should also be embraced by management and staff. It was therefore anticipated that supportive actions would also be needed to stimulate the procedure's use.
Since this approach implies making interventions in practice, Action Research (Maestrini et al., 2016) is applied. In the PSM research community, Action Research (AR) has been identified as highly appropriate for public procurement because of its complex, practical and dynamically changing nature (Walker, Harland, Knight, Uden and Forrest, 2008). In particular, AR is often used to address practical implementation challenges (Walker et al., 2008).
The research is divided into a preliminary phase and three main phases. It was decided to first assess the as-is situation (preliminary phase), before developing a procedure design (phase 1), improve it by testing it in practice on a procurement instrument (phase 2), and finally get it incorporated in the client's QMS (phase 3). It was anticipated that along the way towards achieving an organizational routine, the learning processes of intuiting, interpreting, integrating and institutionalizing could lead to the identification of additional barriers. In turn, solutions to cope with these barriers could lead to procedure improvements and supportive actions (see figure 1).

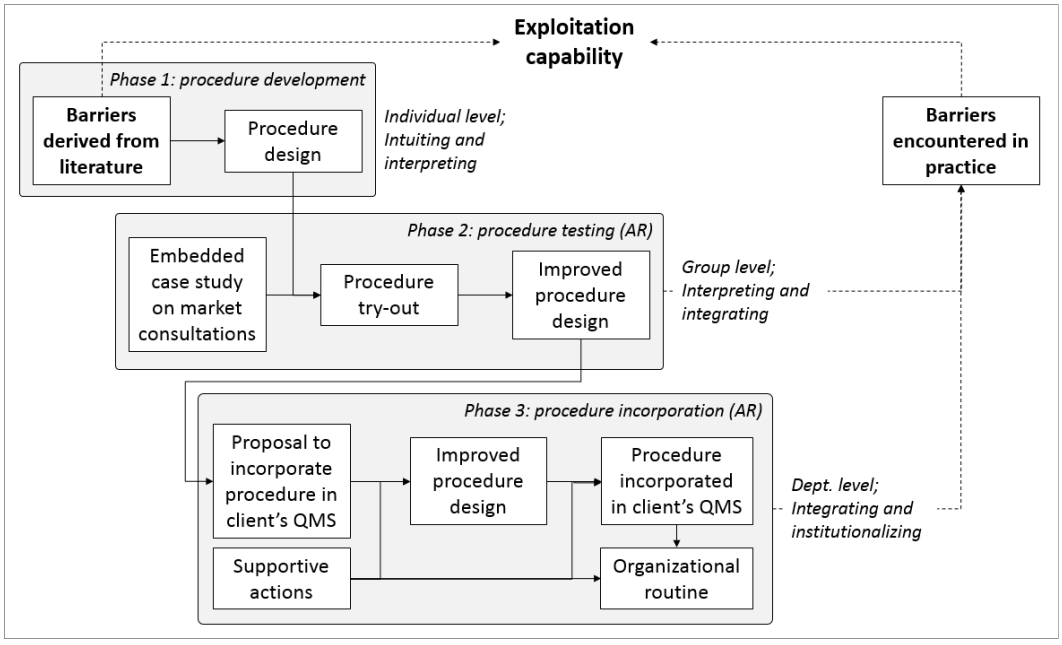

Figure 1: Research design

Both to create more in-depth insight in the way processes were run in the client's organization, and to serve as input for testing the procedure design, phase 2 includes an embedded case study.

The case concerned the client's use of documentation to run market consultations. This case was selected, since there were indications that the number of applications had been growing extensively. However, while standardisation had been proposed once, as yet no document template had been created. Anticipating that developing a template for this instrument indeed would be the desired outcome, this case would allow for running the procedure in its most extensive form. The case also seemed appropriate because it concerns a fairly uncomplicated instrument, and would thus not draw off too much attention from testing the procedure.

Results

The following sections present the results of research phases. Given the purpose of this paper, the identification of, and dealing with barriers in each phase is brought to the fore.

Preliminary phase: as-is situation assessment

The overall perception of the as-is situation was first checked by a fact finding effort. The fact finding involved several activities, such as scanning the client's quality management system (QMS) for relevant texts (e.g. that describe *how* to consider potential future reuse of newly developed procurement instruments, or state *that* reuse should be considered), interviewing procurement officers, and searching project archives for relevant examples of frequently reoccurring procurement instruments that are nonetheless not included in the portfolio. Practitioners raised several issues, such as limited sharing of knowledge on new developed instruments at department level, no long term vision on procurement instrument development, low priority for template development in certain procurement categories, and having no procedure present in the department's QMS that addresses template development. The final conclusion was therefore that the processes run to consider the potential future reuse of newly developed procurement instruments were at an 'initial state' process maturity level (De Bruin & Rosemann, 2005). Consequently, it was deemed worthwhile to attempt to improve the client's exploitation capability.

Phase 1: Procedure design

The procedure design describes how to run a sequence of actions that essentially results in two main outcomes: a) the decision to reuse, reconfigure or retire the instrument, and b) the selection of the most appropriate knowledge management strategy. Figure 2 shows in more detail which steps the procedure design entails. Procurement officers are the main actors in this procedure.
Each step in the procedure design comes forth from the literature on barriers. While some steps may be evident, others are less so. The following texts shortly illustrate a selection of main problems the procedure design is meant to deal with.

- *Instrument identification problems* – Procedure step 1 checks whether a (re-)developed procurement instrument represents a potential addition to the client's portfolio of instruments. This involves identification of the main features of the instrument and comparison with what is already there in the portfolio. Since instruments may show close resemblance, identification may be evident in certain cases, but difficult in others. The concepts of an 'ideal type' (Weber, 2009) and a 'Wittgenstein family-resemblance' (Yeung, Chan, & Chan, 2007) can be helpful to distinguish the instrument from similar instruments.
- *Tacit knowledge* – Procedure step 2 develops a trade-off between exploitation opportunities and costs. However, to assess the instrument's potential value for general exploitation, one first has to know how it 'works'. This is requisite input for assessing how often it may be reused, and how it may strategically align with higher level strategies. Both require adequate knowledge that in part may be tacit (Polanyi, 1966). Literature holds that communicating, in the sense of interpreting and integrating, helps to convert tacit knowledge into explicit

knowledge (Crossan et al., 1999; Nonaka & Takeuchi, 1995). Similarly, causal mapping (Bryson, Ackermann, Eden, & Finn, 2004) is held to facilitate knowledge conversion (Ambrosini & Bowman, 2001).

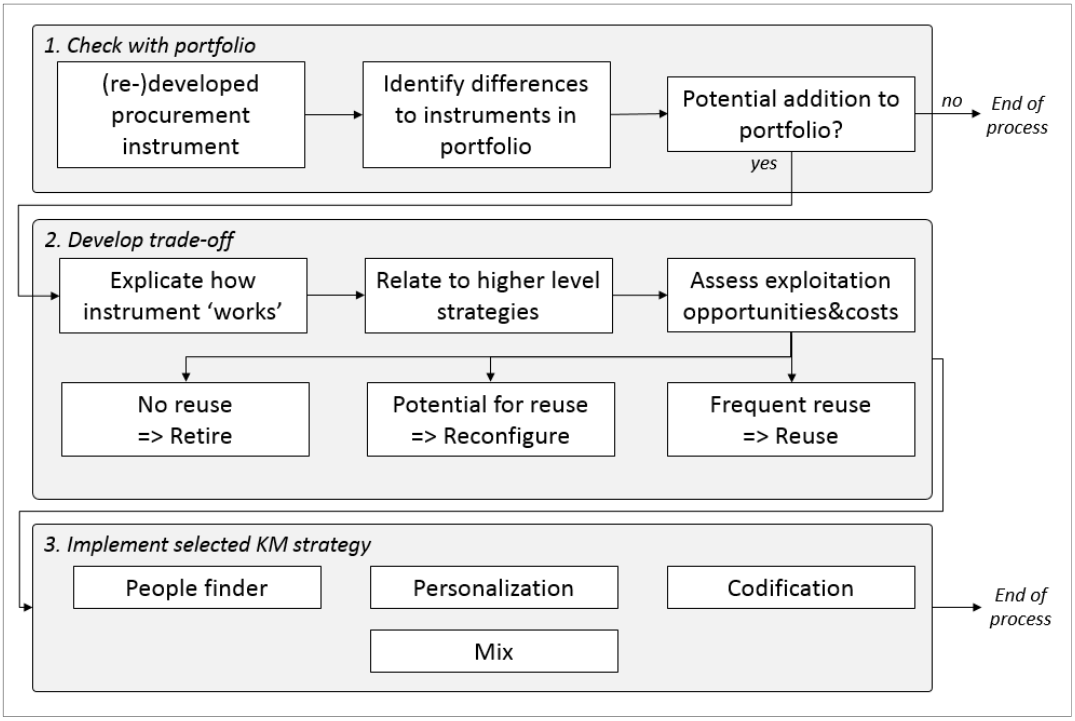

Figure 2: Procedure design (simplified)

- *Complicated trade-offs* – To decide for reuse, reconfiguration or retirement of the instrument in procedure step 2, the *added* value compared to similar instruments (if any) in the portfolio needs to be assessed. Also, if reuse seems preferable, one has to trade off the estimated impact on resources associated with the correspondingly required knowledge management strategy and the estimated returns in terms of future reuse (efficiency) or contribution to higher level strategy (effectivity). This assessment can be complicated by lacking insight into needs of other procurement categories and the content of other category or higher level strategies.
- *Project management issues* – Procedure step 3 concerns the follow-up on the decision to implement a certain knowledge management strategy. However, implementation can become a project in its own right. For instance, if reuse by applying a codification strategy is decided for, then the development of a procurement instrument standard (e.g. a document template plus manual) may face competition for scarce resources, risks and conflicting interests of stakeholders.

Phase 2: Procedure testing

This phase includes the embedded case study on market consultations, which is input to the subsequent first AR-cycle.

Embedded case study results - By searching the project archives for applications of market consultations over the past ten years, the incidence rate per year, the names of the involved procurement officers and the sources for drafting the documentation were retrieved. It was found that market consultations had been increasingly applied over the years, with the most recent year surpassing over 15 applications. Only few procurement officers had run market consultations more than once. While three distinct documents appeared to have served as root

documents for applications later on, the majority of market consultation documents could not be traced back to one of these informal templates. This indicates overlapping work and hampered learning between projects. Presentation of the results to practitioners led to surprise, confirmation of suspicions, recognition and immediate hypothesizing on the causes for the revealed pattern.

AR cycle 1 – The first AR-cycle was aimed at experiencing in a small group of procurement officers the learning processes of interpretation and integration (Crossan et al., 1999) with regards to the procedure design. A two hour session with six practitioners was organized, in which the procedure design and a graph of the market consultation case results was presented. The practitioners concluded that a standard for market consultations should be created. This standard should consist of a template consultation document and a manual for using that document (i.e. codification strategy). After the session, eight practitioners were involved in setting up the standard, mostly by reviewing draft versions. The first author influenced the development process by defining the desired content and creating deadlines.

Barriers – Several of the anticipated barriers were encountered. However, two barriers stood out. These were scarcity of resources and knowledge explication. The participants were struggling with their individual competitive priorities: attending the meeting (no direct relieve of work pressure) versus skipping this meeting to address urgent business issues. While planned long before, and invitations were accepted, attendance proved rather mediate. Also, while the procedure design was quickly accepted as the logical thing to do, and all agreed on applying a codification strategy, progress afterwards in setting up the standard for market consultations was slow. Although process and actors were agreed upon, the first author almost felt like acting as a project manager to get the standard completed. This all indicates that prioritizing currently is the organization's most prominent challenge.

Also, participants were having difficulties in explicating the reasoning behind the procurement instrument. Hypothesizing about 'how it works' and writing precisely that down to instruct future users of the template, appeared to be the most troublesome part of template creation.

Phase 3: Procedure incorporation

Institutionalizing is the process of ensuring that routinized actions occur, and is enacted by establishing rules and procedures, diagnostic systems and routines (Crossan et al., 1999). The third research phase was therefore aimed at incorporating the procedure design in the client's QMS (AR cycle 2) and setting up diagnostic systems (AR cycle 3). While both are to trigger the learning process of institutionalizing, the learning processes of interpretation and integration were anticipated to come up as well, since each AR cycle involved other groups of practitioners.

AR cycle 2 –To make the procedure fit into the QMS, the procedure design was rewritten to the client's format and improved by several clarifications. Also, a number of minor change proposals to other QMS documents were generated. Finally, a draft policy document illustrating the researcher's view on organizational processes with regards to procurement instruments was created. These documents were reviewed by one practitioner and one scholar. The final versions were submitted to the department's committee responsible for procurement documentation. This action was based on the hypothesis that concrete text proposals would help contrast the current versus desired state ("we make sense of the world through comparison and contrast", (Bryson et al., 2004, p. xx)). In addition, the first author illustrated the logic behind all these documents to the committee via an accompanying memo and a presentation during the meeting.

Barriers – Again, prioritization proved an issue. The committee's meeting schedule allowed for only half an hour to discuss all documents. The concluded to address these topics in next meeting again.

During the next meeting one new barrier came up. This concerned an authority issue. Since the committee members all worked for either the procurement or the legal department, and not for

other functional units, the committee's recently appointed new chairman questioned the committee's authority to decide on contract templates. The standard for market consultations was accepted, since it was considered not to be affected by this issue. However, it was decided not to accept the procedure and the QMS change proposals as yet, but to change the QMS at the moment that this authority issue was solved as well.

AR-cycle 3 – According to (Crossan et al., 1999), ensuring that routinized actions occur also involves the use of diagnostic systems. It was decided to address this point by simply asking management to support and supervise the use of the procedure, before setting up more sophisticated diagnostic systems. For this purpose the third AR cycle was initiated directly after the committee's first meeting in AR cycle 2.

This third AR cycle is not finished yet. It started off with a preparatory meeting with the procurement department's management team. The aim was to convince management of the need to create and sustain exploitation capabilities, and to commit each manager to ensuring that the procedure would be used. To this aim, the first author presented the market consultation case results, the logic behind the procedure and a model for identifying the organisational processes involved in the use of procurement instruments. The first author proposed a future decision moment, clarifying that the committee's acceptance of the change proposals would also require approval and management involvement afterwards to ensure that the procedure's use would develop into an organizational routine.

Barriers – Once again, prioritization proved an issue. The management's meeting schedule allowed for only half an hour. While management accepted the need to improve current exploitation capabilities, the main point raised concerned the question which manager should become primarily responsible. Also, follow up on the meeting was left to the initiative of the first author.

Discussion

While the embedded case study quickly convinced practitioners of the need to more deliberately manage the balance between exploitation and exploration of procurement instruments, the challenge is to operationalize this notion into a concrete set of actions and to subsequently develop that into an organizational routine. Although this study is not finished yet, several barriers to developing the exploitation routine have emerged already. The main barrier encountered so far concerns competitive priorities. This is illustrated by the case study on market consultations, as well as by the efforts to develop and institutionalize the procurement instrument exploitation capability.

As the market consultation case showed, lack of priority to spend time on an effective knowledge management strategy results in outcomes such as overlapping work, hampered learning of procurement instrument applications, and unintentional development processes. In a similar way, a lacking priority to incorporate the procedure design in the QMS and to subsequently turn this into an organisational routine is perceptible in the reaction of practitioners on the interventions so far. While the procedure design itself was received as the straightforward thing to do, incorporation in the QMS is made dependent on solving an adjacent problem first.

Perhaps the lacking priority can be explained by the difficulties to unambiguously quantify the negative effects of a shortcoming exploitation capability, and to appoint a problem owner. The reactions on the market consultation case seem to indicate that this is rather an organisational problem than an individual's problem. Also, since the client's current portfolio of procurement instruments appears to be maintained very well, how big is this problem anyway compared to other pressing issues the department is facing? While several practitioners indicated that the market consultation case probably is one in a series of similar cases, a complete overview is not created by this study. Such an overview may create a more compelling argument than a single

case, but requires significantly more research efforts. This way, the study confirms the general statement that decision making on the trade-off between exploration and exploitation is complicated by the fact that returns from the two options vary in many respects (March, 1991). As yet, other barriers seemed to play a less prominent role. However, these probably will become more pressing once prioritization is solved. Knowledge explication presumably is such a barrier. In the market consultation case, explication of how the instrument works proved a challenge. However, without proper explication, assessing an instrument's potential added value and the corresponding appropriate knowledge sharing strategy becomes complicated. In that case, the procedure's outcomes may be suboptimal.

The authority question raised in the committee's meeting came up as an unexpected barrier. While this probably concerns a one-off issue only that can be solved quickly, the progress in incorporating the procedure design in the QMS is impeded by it.

The study applies the 4i-framework of organizational learning (Crossan et al., 1999) as theoretical lens. This framework is primarily intended to explain strategic renewal through the processes of organizational learning (Crossan, Maurer, & White, 2011). While the exploitation of procurement instrument developments counts as renewal, it is open for debate whether it is also strategic. According to (Crossan et al., 1999), for renewal to be strategic it should encompass the entire organization and it should recognize that the organization operates in an open system, rather than having a solely internal focus. The first criterion seems to be the bottleneck here, since changes in procurement instruments may vary from marginal to radical.

In our view, this does not reduce the value of the 4i-framework for our study. Crossan et al. (1999) state that recognizing and managing the tension between exploitation and exploration are the two critical challenges of renewal, and that is exactly the organizational capability this study is investigating. More concrete, the framework proved helpful in providing guidance for demarcating and running the AR-cycles.

There are however some difficulties in applying the framework for this study. Organizational learning is an ongoing process, whereas this study aims to achieve a concrete end goal. The difference becomes visible in the sense that (Crossan et al., 1999) regard routines, procedures and diagnostic systems both as inputs and outputs of institutionalizing. Instead, in this study, the current exploitation capability is improved by creating a departmental routine. This is the intended end goal, which is to be achieved via the incorporation of a procedure and the setting up of diagnostic systems. This also points at another difficulty. Creating a routine may take a long time and its progress is difficult to measure unambiguously.

Conclusion

This paper investigates barriers to the organizational capability to exploit developments in procurement instruments. So far, prioritization issues emerged as a main barrier. Prioritization issues may be explained by the difficulties to unambiguously quantify the negative effects of a shortcoming exploitation capability, and to appoint a problem owner. Other barriers are anticipated to come up as the study proceeds. Given these barriers, it is concluded that without deliberate efforts to improve the procurement instrument exploitation capability, an efficient and effective reuse of newly developed procurement instruments is likely to remain out of reach.

Reputational value: how buyer status and supplier awards affect supplier performance

Niels Pulles[1], Jenny Bäckstrand[2], Paul Idling[3] and Oguzhan Akdemir[3]

3 University of Twente, The Netherlands

Abstract
Not all buying firms receive similar treatment from suppliers. The literature describes supplier value (i.e., the benefits a supplier receives from interacting with a specific customer) as an important determinant for how suppliers differentiate their performance for different buyers. This article adds an examination of reputational value: the benefits a supplier receives from reputational gains of collaborating with a specific buying firm. Contrary to other sources of supplier value, which refer to the benefits that a supplier perceives within a relationship, reputational value refers to the benefits of a supplier outside the relationship with a focal buyer. We examine how two sources of reputational value (i.e., collaborating with a high-status buying firm and winning a supplier award) explain differentiated supplier performance. We do so in a three-stage empirical study combining different methodologies. Implications are discussed.

Introduction
Suppliers differentiate in how they treat their customers. The literature provides several examples of how some buying firms managed to obtain better resources than competitors even though they shared their supply base with these same competitors (Castellucci and Ertug, 2010; Dyer and Hatch, 2006; Pulles et al., 2014; Takeishi, 2002). Within the supply management literature, several concepts specifically address this phenomenon and examine how industrial buyers can become a preferred customer (Hüttinger et al., 2012; Pulles et al., 2016; Schiele et al., 2012) or improve supplier resource mobilization (Ellegaard and Koch, 2012; Villanueva et al., 2012). Indeed, the marketing literature describes how supplier prioritize their customers in an attempt to improve customer loyalty (Wetzel et al., 2014; Wieseke et al., 2014).

A key mechanism that explains differentiated supplier performance is the notion of supplier value (i.e., the benefits a supplier receives from interacting with a specific customer; Ramsay and Wagner, 2009). When a supplier perceives a relationship to be valuable, it is more likely to invest resource in this relationship. This mechanism can be explained from both a social and an economic perspective. The social perspective, builds on a reciprocity rationale: if a supplier perceives a relationship to be valuable, the notion of reciprocity implies that the supplier may feel socially indebted to make relational investments to repay this value (Nyaga et al., 2013). Then, a supplier can be expected to make more relational investments in the valuable relationships compared to less valuable relationships (Pulles et al., 2016; Ramsay and Wagner, 2009). From an economic perspective, it is in the best interest of the supplier to allocate resources to the projects of a valuable buyer. For instance, a supplier might improve performance for a buyer that invests in supplier development projects because higher performance for those buyers are likely to yield more investments. Then, in choosing between buyers, a supplier is most likely to choose the option where the expected benefits will be greater (Griffith et al., 2006).

Many studies have examined how supplier value affects the buyer-supplier relationship (Benton and Maloni, 2005; Krause et al., 2007; Modi and Mabert, 2007; Pulles et al., 2016; Ramsay and Wagner, 2009). However, most of these studies have focused on the relational value that a supplier perceives within a relationship, thereby ignoring the value of supplier's relationship with a specific buyer outside the relationship with this buyer. For instance, an endorsement of a major automobile manufacturer may help a supplier signal capabilities to other potential buyers. Such reputation effects can help the supplier gain business outside the relationship with this automobile manufacturer (Kang et al., 2009). Similar to value *within* the relationship, value that a supplier can use *outside* the relationship can incentivize the supplier to invest in the relationship with the focal buyer (Brito and Miguel, 2017; Tanskanen and Aminoff, 2015).

This article examines the effects of reputational value on supplier performance. Reputational value refers to the benefits a supplier receives from reputational gains of collaborating with a specific buying firm. We examine two sources of reputational value: (1) collaborating with a high-status buying firm and (2) winning a supplier award. We do so in a three-stage empirical study combining different methodologies (Wacker, 1998).

We make three distinct contributions. First, we contribute to the supply management literature examining the mechanisms that explain differentiated supplier performance. Whereas the majority of this literature examines the effects of supplier value within the relationship with a specific buyer, we add the notion of reputational value, which is a type of value that enables the supplier to gain benefits outside the relationship with this buyer. Second, we contribute an examination of the effects of buyer status on supplier performance. Although other studies have examined the effects of status on inter-firm interactions (Kang et al., 2009; Mayer, 2006), an examination on the effects of buyer status on dimensions central to a firm's supply management function is lacking. Third, this article contributes by explicitly examining the impact of supplier awards on supplier performance. Although supplier awards programs have become common practice, we know little about their effects relational effects of supplier awards. An emerging body of empirical literature on employee and CEO awards suggest that awards can have a significant effect on employee behavior (Gallus and Frey, 2016; Shi et al., 2017). However, how these findings relate to inter-firm effects is unknown and the literature on the performance effects of supplier awards is scarce.

Literature background

The concept of organizational reputation refers to a categorization of perceived historical quality and performance (Washington and Zajac, 2005). Because reputation is based on past demonstrations of certain behavior, it provides an indication of expected future behavior (Lin et al., 2009). In this way, a positive reputation signals that a firm has the capabilities to demonstrate high performance. In selecting exchange partners, reputation is an important factor for buyers since it may reduce uncertainty about a supplier's future alliance performance and shift the buyer's focus to the high reputation supplier (Jensen and Roy, 2008). In general, good reputations have strategic value for the firms that possess them, and actions that improve firm reputation have a positive effect on profits over time (Roberts and Dowling, 2002). For industrial suppliers specifically, reputational value can lead to additional turnover since good reputation provide potential buyers with a positive expectation of the supplier's capabilities.

Reputational effects of high-status partners

Being associated with high-status partners positively reflects on suppliers. Relationships with prominent organizations conveys that a supplier has earned positive evaluations from influential and experienced actors (Stuart et al., 1999). This positively affects the supplier since other buyers often trust the judgements of high-status buyers and imitate the choices of the high-status buyer. Suppliers are often aware of this and may actively seek collaboration with high-status buyers. High status of a buyer may spill over to a supplier, which incentivizes the supplier to invest in the relationship with the high-status buyer. In fact, if the value of a status spillover is large enough, the supplier might make investments that are not justified by the value of the relationship itself. Kang et al. (2009) discuss how suppliers are willing to make unilateral investments in relationships with high-status buyers, because the reputation effects of being classified as a top-tier supplier will lead to strategic advantages in dealing with other buyers. In this way, relationships with high-status buyers positively affects the competitiveness of suppliers (Stuart et al., 1999). Because suppliers realize this, they are more willing to make investments in relationships with high-status buyers as compared to low-status buyers (Castellucci and Ertug, 2010; Kang et al., 2009).

Reputational effects of supplier awards

In many industries, supplier award programs have become common practice. Awards can be seen as nonfinancial incentives, whose value reside primarily in public recognition (Gallus and Frey, 2016). For the supplier, receiving an award may help in terms of press coverage, improved reputation and increased transactions of the awarding buyer (Beer et al., 2017). Receiving an award positively affects a supplier's reputation as it signals a "best amongst peers" valuation. Awards can serve as quality indicator for buyers because supplier awards predict future performance of the supplier (Azadegan and Pai, 2008; Hendricks and Singhal, 2001).

From the buyer's perspective, supplier awards programs appear to be a low-cost and effective means to recognize supplier efforts and to strengthen the relationship between the firms. In addition, because of the reputational value of such awards, suppliers can be expected to improve performance to win the award. However, the effects of awards may be more complex. For instance, within the relationship, an award can signal that the supplier is of strategic value for the buyer, which can lead to opportunistic behavior. In addition, suppliers that do not win the award can become demotivated and show less commitment to the relationship. Gallus and Frey (2016) argue that the risk of demotivation is especially high in case of confirmatory awards with high ex ante performance criteria on a limited range of dimensions because many subjects may feel they have no chance of winning and give up. Deci et al. (1999) support this notion and show that winners might decrease in performance after winning an award due to unintended motivational effects. These studies were however conducted on an employee level. On a firm-level, there are studies both supporting the moderating effect of supplier awards on supplier performance (e.g., Fynes et al., 2008) and studies that have found that awards, such as ISO 9000 certification, did not have a positive effect on overall quality performance (e.g., Terziovski et al., 1997). Other studies have integrated the concept into broader relational constructs such as communication or evaluation (Klassen and Vachon, 2009; Wagner, 2006) or recommend supplier awards as best practice to motivate suppliers (Krause et al., 2007; Trent and Monczka, 1999). However, the exact effects of supplier awards, on supplier performance of the awarding buying firm are under examined.

Study 1

Experimental design

Study 1 examines the effects of buyer status on supplier performance dimensions. We draw on a scenario-based experiment using descriptive vignettes. Such an experiment uses varying versions of a descriptive vignette to convey scripted information about specific factors of interest to participants (Rungtusanatham et al., 2011). We followed the vignette design stages by Rungtusanatham et al. (2011) in developing and pre-testing our vignettes, including a pre-test by 25 student participants. Our final sample consisted of 105 students at universities in the Netherlands and Sweden. Of these, 43% were female and 57% male with an average age of 23 years. The main nationalities of the participants were Swedish (52%), Dutch (19%) and German (10%).

Our vignettes introduced PintBoards Electronics, a leading supplier of printed circuit boards in Europe, of which the participants were instructed to take the role of CEO. It described how PrintBoards has been a supplier for a leading manufacturer of systems for power generation and transmission for over 10 years. We manipulated the status of this manufacturer. In half of the vignettes, Siemens was the buyer that was introduced as an internationally recognized exemplar firm. The other vignettes describe Lithograph as the buyer that was described to be not an exemplar firm. Participants were randomly assigned to these treatment conditions.

Manipulation checks

As suggested by Bachrach and Bendoly (2011), three separate treatment checks were conducted to assess whether the applied manipulations were effective in creating the specific context of interest. Appendix A shows the items of these treatment checks.

First, we tested if the participants responded as planned to our manipulations. To assess the manipulation of buyer status, we used two items that asked whether the participants considered the buyer to be perceived as high-status and admirable among its peers. The high-status buyer scored significantly higher on these dimensions than the low-status buyer ($mean_{high\text{-}status} = 4.32$, $mean_{low\text{-}status} = 2.23$, $p < 0.01$). From this test we conclude that our manipulations were successful. Second, we conducted Hawthorne checks, using items that are not relevant to our factors of interest but included for the purpose to test extraneous perceptual effects of the manipulations. We included two items on the innovativeness and relational capabilities of PrintBoards. The averaged scores for these items did not show any significant differences between the winner versus non-winner and high versus low-status groups ($p > 0.1$). Therefore, the Hawthorne check indicates that our manipulations did not affect factors and projections other than the intended manipulation factors. Third, we assessed the realism of the scenarios. The participants evaluated two items about the realism and the likelihood of the scenario occurring in real-life. The mean score across these items was 3.74 on a 5-points scale, which indicates a realistic scenario and is comparable to other scenario-based experiments (e.g., Chen et al., 2016).

Dependent variables

We examined the influence of buyer status on two factors important for many buying firms: pricing and resource allocation towards the buyer's projects. To examine the impact of the manipulation factors on price, the scenario described how two weeks ago the buying firm discussed a new project that could result in annual orders of around 200,000 products. The vignette described that PrintBoards indicated that it could sell the components for around €10. However, PrintBoards also indicated that the final price could be either 10% higher or 10%

lower, depending on final calculations. The participants would then read that two weeks later, after long discussions with PrintBoards engineers, they were certain that PrintBoards could produce the components for a cost price €8.50 each and that common margins within the industry are 15-20%. We then asked which price per product (between €8.00 and €12.00) they would offer the buyer.

To examine supplier resource allocation, the scenario described that, in addition to the annual order of 2000,000 products, the buyer was developing a new product for which it needed high-quality print boards. Therefore, the buyer invited PrintBoards to join the development team. The scenario described that, although these projects always involve risk and initial investments, PrintBoards expected the project to be profitable. We then asked the participants to assess PrintBoards' willingness to invest company's prime resources (i.e., best engineers, best ideas, substantial innovation resources; Pulles et al., 2014).

Results

The results show a consistent positive effect of buyer status on supplier pricing and resource allocation towards the buyer. Comparative tests show that the pricing of the scenarios with a high-status buyer show significantly lower prices (i.e., better for the buyer) than the pricing in the scenarios with the low-status buyer ($mean_{high\text{-}status}$ = €10.22, $mean_{low\text{-}status}$= €10.42, $p < 0.10$[1]). For supplier resource allocation, the high-status buyer also scored significantly better than the low-status buyer ($mean_{high\text{-}status}$ = 3.67, $mean_{low\text{-}status}$= 3.40, $p < 0.10$).

Study 2

The results of study 1 show a positive effect of buyer status on supplier performance. Study 2 builds on this finding and adds supplier award as a factor of reputational value. To test the effect of supplier awards, we conducted the same experiment as in study 1, but this time with a supplier award program.

Experimental design and manipulation check

For study 2, we used a similar sample as in study 1. Our final sample consisted of 99 students from the same universities in the Netherlands and Sweden, but in a different study year than in study 1. Of these participants, 35% were female and 65% male with an average age of 22 years. The main nationalities of the participants were Swedish (34%), Dutch (33%) and German (15%).

As noted, study 2 draws on a similar scenario as study 1. The only difference is that a supplier award section has been added as a manipulation. We varied the vignettes into version where PrintBoards received a "supplier quality award" and versions where PrintBoards' major competitor won the award. We randomly assigned participants to the four (2x2) treatment conditions. Similar as in study 1, our manipulation of buyer status was successful ($mean_{high\text{-}status}$ = 4.25, $mean_{low\text{-}status}$= 2.57, $p < 0.01$). We assessed award winners versus non-winners using two items that measured the extent to which the participants felt publicly appreciated and recognized by the buyer. On a 5-points scale, winners scored significantly higher on these dimensions than non-winners ($mean_{winners}$ = 4.29, $mean_{non\text{-}winners}$ = 3.10, $p < 0.01$). From these tests, we conclude that our manipulations were successful. Again, the Hawthorne checks indicates that our manipulations did not affect factors and projections other than the intended manipulation factors ($p > 0.1$). The realism of the scenarios scored a 3.83.

[1] All reported p-values are two-tailed.

Results

Two-way ANOVA tests were conducted to measure the main and interaction effects of supplier awards and buyer status. First, we examined the effects of these factors on supplier pricing. Award winners offered their buyer a higher (i.e., worse) price than non-winners ($mean_{winners}$ = €10.15, $mean_{non\text{-}winners}$ = €10.00), but the results revealed that this difference is non-significant ($F = 0.76$, $p > 0.10$). Concerning buyer status, participants that supplied the high-status firm offered their buyer a lower (i.e., better) price those who supplied the low-status buyer ($mean_{high\text{-}status}$ = €9.87, $mean_{low\text{-}status}$= €10.29). This result was significant ($F = 4.62$, $p < 0.05$). In addition, the results showed that there appears to be some interaction effect between supplier awards and buyer status for pricing ($F = 2.89$, $p < 0.10$). Interestingly, for low-status buyers, award winners offered better prices than non-winners ($mean_{low\text{-}status\text{-}winners}$ = €10.20, $mean_{low\text{-}status\text{-}non\text{-}winners}$ = €10.36) while for high-status buyers, award winners offered worse prices than non-winners ($mean_{high\text{-}status\text{-}winners}$ = €10.36, $mean_{high\text{-}status\text{-}non\text{-}winners}$ = €9.60).

Second, we examined the effects for supplier resource allocation. Award winners did not give substantially different score on the resource allocation items than non-winners ($mean_{winners}$ = 3.62, $mean_{non\text{-}winners}$ = 3.56) and these results were non-significant ($F = 0.12$, $p > 0.10$). Participants that supplied the high-status buyer scored higher on the resource allocation items than those that supplied the low-status buyer ($mean_{high\text{-}status}$ = 3.75, $mean_{low\text{-}status}$= 3.42). This result was significant ($F = 6.78$, $p < 0.05$). The results showed that there is no interaction effect concerning supplier resource allocation between supplier awards and buyer status ($F = 0.18$, $p > 0.10$).

Comparing study 1 and study 2

Similar to study 1, buyer status has a significant and positive effect on both supplier pricing and supplier resource allocation. The results also indicate that winning a supplier awards has a limited or even negative effect on supplier performance. However, to examine the effects of the reputational value of supplier awards we need compare the results of study 1 and 2. If a supplier award program would have perceived reputational value, it can be expected that the overall pricing and resource allocation of study 2 would be better than in study 1. To test this thesis, we conducted comparative tests on the results of study 1 and 2. The results show that the pricing of the scenarios with a supplier award program is significantly lower (i.e., better for the buyer) than the pricing in the scenarios without the award program ($mean_{awards}$ = €10.07, $mean_{no\text{-}awards}$= €10.32, $p < 0.05$). On the resource allocation measures, the supplier award program appeared to have a small positive but not significant effect ($mean_{awards}$ = 3.59, $mean_{no\text{-}awards}$= 3.54, $p > 0.10$). These results imply an overall positive effect of a supplier award program: compared to the scenario without a supplier award program, the prices are significantly better.

Stage two: Multiple case study

The experimental study showed a clear effect of buyer status on both pricing and supplier resource allocation. In addition, a supplier award program appeared to positively influence pricing decisions compared to the scenario without an award program. However, winning versus not winning the supplier award itself did not reveal a clear (i.e., significant effect) effect. Therefore, to further explore the effects of winning a supplier awards on supplier performance, we conducted a multiple case study. In doing so, we distinguish between pre-award performance and post-award performance. In selecting the cases we applied a theoretical sampling approach that follows a replication logic (Yin, 2003). The aim was to

select cases to fill theoretical categories (Eisenhardt, 1989) of winners versus non-winners with low and high-status awardees.

Sample and data collection

We searched for cases on the internet using search terms such as "supplier award" or "supplier award nominees". Suppliers that were mentioned as nominees or winners were then contacted via an e-mail in which we explained our research objectives. At suppliers that agreed with an interview, we aimed to interview the key informant (i.e., the person most knowledgeable on the effects of supplier award). In addition, we interviewed two award issuers. Table 1 provides the descriptives of the selected cases.

Table 1. Cases

Case	Industry	Country	Revenue recipient (mln. €)	Revenue issuer (mln. €)	Perceived status of issuer	Informant
Recipient1	Food	Germany	3	145	Average	Owner
Recipient2	Machinery	Germany	35	1,800	Average	Head of sales
Recipient3	Rail industry	Netherlands	25	1,000	High	Business consultant
Recipient4	Machinery	Netherlands	50	3,000	High	CEO
Recipient5	Logistics	Germany	56	3,900	High	Head of marketing
Recipient6	Recruitment	Netherlands	70	20,000	Very high	BU manager
Recipient7	Telecom	Germany	70	41,000	Very high	CPO
Recipient8	Automotive	Germany	488	153,000	Very high	Managing director
Recipient9	Agriculture	Australia	500	--	Very high	Head of sales
Recipient10	Machinery	Sweden	--	--	Very high	Key accountant
Non-recipient1	Machinery	Germany	10	3,900	High	Owner
Non-recipient2	Machinery	Germany	15	3,770	High	Owner
Non-recipient3*	Rail industry	Netherlands	30	1,000	High	Business consultant
Non-recipient4*	Security	Netherlands	400	1,000	High	Solutions devel. mgr.
Non-recipient5*	Rail industry	Netherlands	2,400	1,000	High	Business consultant
Issuer1	Food	Germany		145		CPO
Issuer2	Machinery	Netherlands		3,000		CPO

*= Non-recipient 3-5 were nominated by the same issuer, but in different award categories.

The interviews were conducted either at the case company's premises or via Skype with an average of 30 minutes per interview. This stage of the study relied on a semi-structured interview protocol. We followed the suggestion of Galletta (2013) who proposed to structure the interview into three segments: (1) the early part of the interview, questions are open-ended to create space for the informants to narrate their experiences, (2) the middle segment is designed to pursue pre-defined topics in more depth and (3) the final segment offers the opportunity to return to earlier discussions and remaining topics that are still open. The interviews were conducted in the interviewees' native language and all interviews were recorded and transcribed.

Data coding

To structure our qualitative analysis, we used a coding scheme to structure the data. Table 2 shows the main categories and includes example quotes in that category. The performance, resource allocation and relationship categories were added to examine performance effects of

supplier awards. Status was added to examine the effects of perceived status of the issuing buying firm. Motivation, dependence and emotions were added based on findings from previous studies on employee awards. For instance, Gallus and Frey (2016) and Deci et al. (Deci et al., 1999) argue that (de)motivation is important in explaining performance effects of supplier awards. In addition, awards might signal dependence of the buyer on the supplier, which can influence negotiations and pricing decisions.

Table 2. Coding categories

Category	Observation (Code set if…)	Example quote
Pre/Post- award Performance	…performance changes, which link to the award itself, occurred prior or post award.	"The award is a driver to perform better […]."
Pre/Post- award Resource Allocation	… supplier resource allocation behavior was reported.	"Returning the favor should be searched in future collaboration and preferential resources. This is what exactly happened."
Pre/Post- award Relationship	… award affected business relationship.	"I think in the long- term, we are going to do more business with […]."
Status	… status of issuing firm relates to effects of award.	"If you are going on stage for […], it is of high value and attraction."
Motivation	… an expression of motivation has been observed prior or post award.	"There was no conscious effort to go out to win the award"
Dependency	… changes in dependency perception due to (non-)winning the award were observed.	"Our products are exchangeable, therefore dependency is not bigger."
Emotions	.. the award influenced the emotions of the recipient.	"A little bit of happiness was noticeable."

Results

Table 3 shows a summary of the pre- and post-award effects within the different cases. The effects of an award program on pre-award performance appear to be limited. Non-recipient 5 is the only case that reported an increase in performance with the intensions to win the award: "A supplier award is important. The award is a driver to performance better, so it does work". The other informants all indicated that, although they did feel to performance good for the buyer, the award program itself was not an incentive to improve performance: "Beforehand, it was not important, but afterwards it was. Initially, we were not concerned with [the award]" (recipient 6); "Besides our daily work in which we deliver good performance, we did not do anything special" (recipient 8).

Awards appear to have more effect on the post-award performance. Four recipients did report a positive post-award effect: "The key product that we supply to them has a very short peak season […]. So, we decided to perform better in non-peak seasons and try to supply as much as we could in order to fill up the stocks." (recipient 9); "[…] we always try to create some degree of value you know. And because of this nice gesture, I mean because of the supplier award, I definitely felt like I should return the favor in thinking more with the customer in meeting their needs and to excel in that. We will try to keep it up for the next time" (recipient 4). Five recipients did not increase performance, mostly because they indicated that performance was already at a high level. For instance, recipient 5 indicated that "At the

moment it is not foreseeable that we perform better because we are already doing very good". In general, the non-recipients were happy to be nominated and not frustrated about not winning: "We are a small firm. It is nice be nominated at all" (non-recipient 1); "It is a pity that we did not win the award. Nevertheless, it is not possible for us to change our services. We perform as best we can and we continue to try […]"(non-recipient 2).). One recipient reported on a decrease in performance after the award "I woke up, literary the day after the award ceremony, and had tree missed calls since our delivery performance was affecting the customers' productivity. This was of course not connected to the award, but it was really embarrassing." (recipient 10). Only non-recipient 5 expressed frustration: "I found it annoying and frustrating that we did not win it. I think the winner in my eyes is not a legitimate winner. The jury was also very vague in their answers. We did not get feedback why we did not win it. […] But, OK, fine there was no reward so let's forget about it."

Table 3. Case summary

Case	Pre-award performance	Post-award performance	Negative effects
Recipient1	High, but not due to the award: slight preferential treatment in product innovation	Similar to pre-award performance	
Recipient2	High, but not due to the award: low prices	Similar to pre-award, increase in motivation but no further improvements	Feels increased dependence of buying firm
Recipient3	High, but not due to the award	Similar to pre-award, already highly committed, no further improvements possible	
Recipient4	High, but not due to the award	Improved, motivation to intensify collaboration and integration initiatives	
Recipient5	High, but not due to the award: capacity allocation	Similar to pre-award, sees award as symbol for strategic partnership; employees are more motivated	
Recipient6	High, but not due to the award	Improved, friendlier relationship and allocated best personnel to buyer's account	
Recipient7	High, but not due to the award: low prices	Similar to pre-award, motivation to intensify relationship	Could take price adjustments into considerations
Recipient8	High, but not due to the award: slight preferential treatment in product innovation	Similar to pre-award performance	
Recipient9	High, but not due to the award	Improved, better performance in non-peak seasons	
Recipient10	High, but not due to the award	Declined, but not due to the award	Feel like they can negotiate "tougher"
Non-recipient1	High, but not due to the award	Similar to pre-award, motivated to intensify projects with the buyer	
Non-recipient2	High, but not due to the award	Similar to pre-award performance	
Non-recipient3	High, but not due to the award	Similar to pre-award performance	
Non-recipient4	High, but not due to the award	Similar to pre-award performance	
Non-recipient5	High, because of the award	Similar to pre-award performance, but motivated to win because of the perceived value of the award	Frustration because award was not won

Almost none of the cases showed effects that could potentially hurt the awards issuer. After being asked, some informants discussed how the award could increase the issuer's

dependence on the recipient firm. Recipient 7 explained: "[…] I would partly say that the dependency has increased a bit by the award […] contracts are fixed for 5 years and the prices as well. But over time, of course, we will also be thinking strategically, to position ourselves differently. This is quite clear. However, it is simply so that you cannot overdo this." Recipient 2: "To use the award opportunistically, we are simply interchangeable. Of course, it would give [issuer] bad press, when it turns out that an award winner suddenly loses the bid and is thrown out. That will not happen. And that is why there is an emotional dependence." Recipient 10 reported on better self-confidence in price negotiations with the issuer "You know, when you negotiate with their French purchasers, their culture is to scream at us and tell us how lousy we are. It doesn't stick the same way after we have been globally recognized as with the award"

Although the cases do not have a great diversity in terms of status, the results do seem to indicate that status of the award issuer does influence the perceived value of the award. For instance, non-recipient 5 explained: "The nomination is great already. Especially because it is a nomination from such a large firm." Recipient 5 who described the reputation of their customer "top, absolutely top" explained the happiness of winning the award: "at the supplier's day mr. [owner] sent us pictures almost every minute and kept us up-to-date […] we have all been very happy about it and it is of course also emotional and important for the employees who are not directly involved." Finally, recipient 10 noted: "since it is such a high-status customer and since we won the 'over-all performance' award, it really boosted our self-esteem."

Indirect effects of supplier award programs

From the literature we know that awards provide a valuable means for motivation because they increase the recipient's status and social recognition (Shi et al., 2017). This rationale explains the lower prices of study 2 (the supplier base with an award program) compared to study 1 (the supplier base without the award program). Study 3, however, nuances this picture because pre-award performance was not observably higher because of the award program itself. Instead, an increase of performance was mainly observed post-award and this increase in performance appeared to be not directly linked to the award itself. Although the recipients were generally happy with their awards, the improved status of the buyer appears to be not a consequence of the award itself, but rather by the professionalism that a buyer signals by the quality of the award program. Award ceremonies are often part of a "supplier day" where suppliers are invited to the buying firm. At a supplier day, suppliers feel appreciated and taken seriously and a well-organized award program contributes to that perception. It is likely that improved motivation stems from this effect rather than from the value perceptions of the award itself.

Discussion

This article adds an examination of reputational value: the benefits a supplier receives from reputational gains of collaborating with a specific buying firm. Based on an experimental design, study 1 and study 2 found a positive effect of buyer status and supplier award programs on supplier performance dimensions. Buyer status positively influenced decisions on supplier pricing behavior and supplier resource allocation. High-status buyers, compared to low-status buyers, received better price offers and supplier resource allocations. The scenarios with a supplier award program showed significantly better prices than the scenarios without such a program, but not significantly better resource allocations. In addition, study 2 examined differences in performance between award winners and non-winners, but did not

show clear effects. Therefore, study 3 examined the effects of supplier awards on pre- and post-award performance using a multiple case study among supplier winners and non-winners. Suppliers generally indicated that their pre-award performance was high (a statement that was reinforced by their nomination), but that the supplier award program of the buying firm had little to do with that. A larger effect was found in post-award performance. After the award program, several of the recipients indicated to have improved their performance. With few exceptions, negative effects of the award program were not observed. Non-recipients, in general, were not frustrated or disappointed by not winning. Although the buying firms in our sample did not show much variation in status, there is some evidence that status affects the perceived importance of the supplier award. The findings of study 3 imply an overall positive effect of supplier award programs, which is in line with the conclusions from comparing study 1 and 2. However, contrary to the rationale derived from study 2, the effects of supplier award programs in study 3 seem not to stem from motivational effects due to reputational value of the award itself, but because of an increased status of the buyer due to public appreciation and professionally organized award processes.

Implications for the literature and theory

The above findings yield three distinct contributions to the purchasing and supply management literature: First, this study contributes to the literature examining differentiated supplier performance. Specifically, several authors examined supplier value as a mechanism that explains why suppliers treat their customers differently. Examples of supplier value are attractive payment conditions, trust, communication, growth potential, information exchange, buyer commitment (Essig and Amann, 2009; Ghijsen et al., 2010; Hüttinger et al., 2012; Ramsay and Wagner, 2009; Vos et al., 2016). These sources of supplier value have been linked to differentiated supplier performance. For instance, relational trust helps to improve relationship efficiency and thus the relative value a supplier gains from the relationship. Consequently, the supplier might show larger commitment to in the trustworthy partner since this partner is likely to yield larger benefits compared to less trustworthy partners. Similarly, growth potential with a particular buyer might be a reason for the supplier to invest in the relationship since this investment is likely to actually realize the growth potential. Reputational value functions differently. The value of an improved reputation lays not within a more efficient or profitable relationship with the buyer itself. Instead, reputational value helps the supplier generated higher benefits in relationships outside the relationship of the focal buyer. Similar to supplier value within the relationship, reputational value incentivizes suppliers to invest in the relationship. Many of the studies referred above do touch upon different types of supplier value outside the focal relationship and some studies have examined "outside dyad" value in terms of capability spillovers (Brito and Miguel, 2017; Tanskanen and Aminoff, 2015). This article continues on these perspectives and adds reputational value as a new type of supplier value external to the relationship with the focal buyer.

Second, our findings show that buyer status has an important influence on supplier performance. In the strategic management literature, a firm's status and reputation has showed to be a relevant factor in how firms interaction (Castellucci and Ertug, 2010; Lin et al., 2009). However, in the supply management literature, the concept of buyer status received relatively little attention (Kaufmann et al., 2017). Concepts such as competence trust (van der Valk et al., 2016) or preferred customer status (Pulles et al., 2016) are related, but these concepts refer to the supplier's perception within the relationship rather the holistic status of the buying firm in the wider business environment. Given the dominant effects of status in our studies, other

studies should consider integrating status as a contingency in their examination of supply management mechanisms.

Third, this article contributes to the purchasing and supply literature by introducing a topic that remained largely under examined: supplier awards. Supplier awards are much used in practice and are therefore not a trivial concept. In many industries, supplier award programs have become common practice. For instance, Boeing implemented supplier recognition programs to award "who achieve the high performance standards" (Boeing, 2016) and the BMW Group awards suppliers "for their outstanding achievements in innovation and development" (BMW Group, 2016). Previous works on intra-firm employee awards suggest that awards can have a significant effect on firm performance (Gallus and Frey, 2016; Shi et al., 2017). Several supply management authors mention supplier awards as general best practice (e.g., Trent and Monczka, 1999) and argue that supplier awards may stimulate competition among suppliers and motivate suppliers to improve (e.g., Krause and Scannell, 2002). However, how supplier awards influence supplier performance for the buyer remains unclear. Similar to commonly examined mechanisms such as supplier development and knowledge sharing, supplier awards influence the relationship between a buying firm and its suppliers. Therefore, a more explicit examination of the impact of supplier awards on buyer-supplier relationships provides an interesting direction for the purchasing and supply management literature.

Implications for practice

This article yields several implications for practice. For instance, because preferential treatment by suppliers positively relates to buyer performance, buying firms can benefit from offering improved supplier value. The findings in our studies imply that such value does not necessarily have to relate to the relationship with the buying firm itself. Instead, buyers that help the supplier improve its reputation can expect improved commitment and performance in return. By becoming aware of these mechanisms, supply managers can more effectively manage their interactions with suppliers. In addition, an important implication for practice relates to our findings on supplier awards. For the buying firms, supplier awards appear to be a rather low-cost and effective tool in awarding suppliers for good performance. In general, supplier awards foster supplier performance, although subtly. To effectively design a supplier award program, the buying firm should clearly understand purpose of the program. Supplier award programs often serve a secondary, arguably even a primary objective, to enhance the relationship between the buying firm and its supply base. Professionalism of the award program appears to be an important factor here. The quality of the supplier day(s) of which the "award show" is often a part and follow-up meetings with both recipients and non-recipients seem to be an important factor in how the supplier award program is perceived and how it eventually affects the relationship.

Limitations

The findings reported in this study should be interpreted in the light of some limitations. One issue is the use of students in our samples of study 1 and 2. There is a strong justification for using students as subjects when key sample characteristics such as age or experience do not interact with the independent variables being studied (Ribbink and Grimm, 2014; Stevens, 2011). Similar to the results found in our sample, results from previous works indicate that buyer status and awards affect decision makers in a business practitioner sample (Castellucci and Ertug, 2010; Gallus and Frey, 2016). Still, samples consisting of business practitioners would be preferred over student samples in future studies. Another issue is that there are

different types of supplier awards. For instance, Beer et al. (2017) distinguish between public and private awards in which the latter is awarded privately and informally. We focused on public awards where the supplier is praised in public, because our interest in reputational value. Still, because the effects of public and private supplier awards differ (Beer et al., 2017), future research should incorporate these differences when examining the effects of supplier awards. In addition, in some industries and countries, supplier awards are more common than in other industries/countries. It can be argued that the effects of supplier awards differ in environments where they are more common compared to those where they are less common. Previous work in the operations research literature shows that when an award is given too often its prestige is diluted (Gavrila et al., 2005). Our study did not integrate this perspective, but future research could examine how newness of supplier award programs in an industry impact the perceived reputational value. Related, our examination of non-recipients in study 3 included only suppliers that were nominated and not non-recipients that were not nominated. Arguably, non-recipient nominees might differ from non-recipient non-nominees. Future research should consider this. Finally, as in many studies, culture is likely to impact some of the effects reported in this study. The samples in our study mainly reflect Western cultures. Future studies might want to examine the impact of culture on the effects of reputational value more explicitly.

Appendix A– Treatment checks

Manipulation check: supplier award
Please assess the appreciation of [BUYER]
(from "1 , no, I completely disagree" to "5, yes, I completely agree".)

- [BUYER] appreciates the efforts of PrintBoards Electronics
- [BUYER] recognizes the quality of my firm in public.

Manipulation check: buyer status
Please assess the status of [BUYER]
(from "1 , no, I completely disagree" to "5, yes, I completely agree".)

- Among its peers, [BUYER] is highly admired
- Compared to competitors, [BUYER] is a high-status firm

Hawthorn check
How would you rate…
(from "1, very bad" to "5, very good".)

- … the innovativeness of PrintBoards Electronics?
- … the relational capability of PrintBoards Electronics?

Realism check
Please assess the realism of the case
(from "1, not realistic at all" to "5, very realistic".)

- How realistic is this case?
- How likely would this case occur in real-life?

BUILDING THE CASE FOR SOCIAL IMPACT SUPPLY CHAIN MANAGEMENT: CONCEPTUALIZATION AND RESEARCH AGENDA

Summary: This study builds a conceptualization of social impact supply chain management (SISCM). Our contribution is to consider those socially motivated organizations that lie on the continuum between purely social and purely commercial enterprises. We consider these organizations and managerial issues through the lens of institutional complexity. We propose that for these organizations, specific supply chain factors might differentiate SISCM from traditional supply chain management. And as a result, we offer future research directions that might add clarity to effective SISCM.

BUILDING THE CASE FORSOCIAL IMPACT SUPPLY CHAIN MANAGEMENT: CONCEPTUALIZATION AND RESEARCH AGENDA

Introduction

Can businesses really solve social problems? Many are questioning if any firm can manage its supply chain to do this job in a long term sustainable way (Pagell & Shevchenko, 2014). A firm may come up with a treatment for a major disease, a noble social goal, but that firm and its supply chain partners mark that treatment up to exorbitant price levels to meet their shareholder priorities. From cancer and AIDS treatments to remedies for snake bites or bee sting allergies, firms often extract high profits at the expense of the needy patients (Kantarjian, 2015; Lewis, 2015; Woodyard & Layton, 2016). Likewise, many businesses feel that job creation contributes to their community and society but then lay off employees or shutter plants as soon as profitability goals are not met (Moon & Sochacki, 1996). On the other hand, non-profit organizations must depend on external sources of funding such as public money or charity and thus lack financial stability. Increasingly, for-profit businesses are being pressured to take social objectives more seriously not only from consumers but from investors, employees, and social media. Thus, their level of participation in social programs correlates with investor interest, market value and the bottom line (The Economist, December 2017).

Either way, the trade-offs created by social goals and profit motivation rarely create long term sustainable solutions. Firms struggle to both reconcile incompatible prescriptions that arise from multiple logics characterizing their institutional environment, namely a commercial and a social-welfare logic, and implement these prescriptions into viable supply chain management (SCM) approaches. Social enterprises have emerged as a possible answer: they pursue a social goal enabled by an economic activity and manage their supply chain accordingly. For example, Semi Di Libertà, an Italian social enterprise integrates incarcerated prisoners into the production of a high quality artisan beer so that they can be trained and placed in brewery jobs when their prison term finishes (Mapelli, Arena & Strano, 2016). What makes social enterprises interesting is their hybrid nature. They try to provide organizational answers to the social-welfare and the commercial logics characterizing the institutional environment in which they are embedded (Pache and Santos, 2013). While for-profit businesses rely on market activities and non-profits and NGOs that are specifically social mission-oriented rely on contributions from donors, social enterprises are mission-oriented ventures that both compete in the market and address complex social problems (Battilana & Lee 2014). This hybrid nature gives rise to unusual organizational strategies and structures that have increasingly attracted research attention (e.g. Battilana & Lee, 2014), as a social enterprise steps in when public and private organizations fail to provide long term solutions to a social problem.

At the supply chain level, making sense of and responding to both social-welfare and commercial logics is also challenging. However, while we are seeing the emergence of research considering non-governmental organizations (NGO) partnerships in supply chains (Pagell & Wu, 2009; Rodríguez, Giménez, Arenas, & Pagell, 2016), very little research has examined how other types of entities including social enterprises act as focal actors in supply chains to achieve a social goal while being economically viable. In this study, we examine the case of social enterprises that pursue their mission as focal actors and discuss how they can manage their supply chains. We will refer to this focus area as *social impact supply chain management* (SISCM), meaning *how a social enterprise manages its supply chain to fulfil its social mission and achieve economic viability*.

Social Impact Supply Chain Management

Supply chain management can be defined as the "management of a network of relationships within a w and between interdependent organizations and business units" and also "the forward and reverse flow of materials, services, finances and information" (Stock & Boyer 2009, p. 691). For supply chain researchers, a focal firm or organization creates and manages the supply chain but may or may not be the firm that provides the final good or service to the end customer. The focal organizations involved with SISCM, social enterprises, fall under the social entrepreneurship literature, a common "umbrella" under which studies about the formation of organizations addressing a social issue are collected (Battilana & Lee, 2014). Most social enterprise literature neglects supply chain management while, in the supply chain literature, few studies investigate social enterprises and it lacks a framework to study the phenomenon.

In order to understand how social enterprises blend into their supply chain management both commercial and social-welfare logics, we introduce an institutional logics perspective of SISCM. Additionally, we describe different approaches to SISCM that social enterprises adopt when combining commercial and social-welfare logics. Previous literature on social enterprises and institutional logics proposes a continuum between two types: the purely commercial and the purely social (Dees & Elias, 1998). These organizations follow different *institutional logics*, meaning principles that prescribe "how to interpret organizational reality, what constitutes appropriate behavior, and how to succeed" (Thornton, 2004, p. 70). Institutional complexity is the term used in the literature to indicate the presence of multiple and potentially conflicting institutional logics (Greenwood et al., 2011, p. 317). A particular logic may be core to organizational functioning such that it determines the core work tasks; another logic may be accommodated through activities and structures more peripheral to organizational functioning (Meyer & Rowan, 1977). In some cases, multiple institutional logics occur at the core, permeating all work tasks, rather than being split into core and periphery (Pache & Santos, 2013). Besharov and Smith (2014) refer to centrality as the degree to which multiple logics are treated as equally valid and relevant. Since social enterprises answer to multiple logics, we expect that – as focal organizations – they will manage their supply chains differently than for-profit enterprises, where the commercial logic prevails.

SISCM Continuum

We argue that social enterprises adopt different SISCM approaches as a response to multiple institutional logics along a continuum between the purely commercial and purely social types. These SISCM approaches are different from traditional SCM due to its limited capability to address this kind of institutional complexity. We take the perspective of the social enterprise as the focal organization managing its supply chain and the object of analysis is its SISCM approach.

At the extremes of this continuum there will be focal organizations that manage their supply chains through a purely commercial or social-welfare, respectively. The former is structured around the goal to sell products and services on the market to produce an economic surplus that can ultimately be appropriated by owners (Friedland & Alford, 1991); whereas the latter mainly makes products and services available to address social needs (Pache & Santos, 2013). At either end, organizations consciously or unconsciously reject institutional complexity when dealing with SCM decisions in favor of a more simplistic view that privileges a commercial or social-welfare logic. Despite the simplification, some limitations might arise due to this choice. On the one hand, purely commercial SCM might result in a limited scope of social impact; on the other

hand, purely social SCM might result in financial instability depending on the availability of funding. Alternatively, social enterprises that are in the continuum between the purely commercial and purely social extremes manage their supply chains in innovative ways to deliver social good and while protecting their economic viability.

We move beyond traditional SCM dominated by one logic to describe three hybrid approaches to SISCM: Decoupled, Combinatory, and Coupled. These three approaches are neither exhaustive of the potential types nor can we claim that they are mutually exclusive or complete; instead they are a starting point in the discussion of SISCM and how it might be different than traditional SCM. We highlight their specificities in terms of strategies, stakeholder identification and engagement, and relationship management in the supply chain as a response to the institutional complexity generated by the combination of the social and commercial logics. Table 1 and Figure 1 summarize the main characteristics of these approaches.

Decoupled SISCM

We define Decoupled SISCM as a situation characterized by a focal organization in which the one logic is core and the other logic is peripheral. We discuss the situation where the commercial logic is core because this is presently much more common in practice, but we address the situation of the social-welfare logic being core when discussing future research opportunities. Pache and Santos (2013) propose that when an organization is primarily embedded in one logic but operating in a complex institutional environment characterized by both commercial and social-welfare logics, it can decouple its formal structure from its operational structure to reduce logic conflicts. In other words, this means that the organization symbolically endorses practices prescribed by one logic while actually implementing practices promoted by another logic, often one that is more aligned with its organizational goals.

The focal organization adopting the Decoupled SISCM approach might be a firm that identifies business opportunities in an emerging market and designs a product or service to address needs of people living in these areas by establishing a new business or brand. In many of these cases, these enterprises describe themselves as promoters of better living conditions for these people (social-welfare logic), who are indeed seen as potential final customers and consumers (commercial logic). We expect the same decoupling approach to happen in the management of their supply chain. In particular, the focal organization will set up a socio-commercial supply chain, where the commercial logic prevails while formally addressing the social-welfare logic by delivering products or services to people in-need.

Supply chain strategy. As the commercial logic is at the core of the focal organization in Decoupled SISCM, the supply chain strategy will essentially be profit oriented, meaning a way to create value through delivering a product or a service to people in-need. Sodhi and Tang (2016) find that emerging markets present a market opportunity for growth for large fast-moving-consumer-goods and durable goods companies. These enterprises benefit directly from designing a product or a service for these people and selling it to them. Prahalad and Hart (2002) popularized this idea as the Bottom of the Pyramid concept, a proposition that multinational corporations could simultaneously generate profits and make a social contribution through marketing to the poor, the lowest tier of the world's economic pyramid. For example, Unilever produced a small, inexpensive bar of soap which was large enough for washing the face and hands once each day for 10 weeks as part of their Lifebuoy soap brand. Since 2002, the soap has been sold in India and promoted as a way to improve hygiene and prevent diarrhoea. In the first

four years, the promotion campaign reached 80 million people; a more recent goal is to reach 1 billion people. This social goal internally translated into a requirement of doubling of sales in five years. This ultimate goal, in line with the commercial logic, resulted in a series of activities that aimed to increase sales and establish distribution networks in both rural and non-rural areas, where people were richer, to more effectively achieve financial goals (Bartlett, 2017).

However, different from traditional SCM, Decoupled SISCM requires the focal organization to not only establish direct relationships in its supply chain with for-profit organizations but also incorporate social entities that understand the target communities. These social entities have earned the trust and loyalty of local communities that they have assisted during challenging times such as war, natural disaster, or poverty relief. Managing the social side of the supply chain is different not only because poor infrastructure and availability of worker skills can limit the size and scope of business units but because the social entities cannot be seen as exploiting the communities for profit. The operational context is similar to the case of humanitarian logistics, but the objective is not to solve a temporary crisis due to exceptional events but to establish long term profitable operations with social benefit implications. Therefore, the basic conditions for applicability of classic SCM or humanitarian logistics strategies might not apply and a specific strategy may be required.

Stakeholder identification and engagement. Because commercial logic is at the core of Decoupled SISCM, the focal organization prioritizes both shareholders and beneficiaries intended as customers. But, this focal organization will need to identify and engage directly in its supply chain with stakeholders different from traditional for-profit actors to achieve their ultimate commercial intention. They might need to design a product or service specifically for the identified population in collaboration with local authorities or social entities as well as build and coordinate a local supply chain to distribute products or services that might include both profit and non-profit actors, governments and regulators to deliver the product or service. The focal company will see NGOs, governments or social entities as intermediaries to expand their brand into developing markets.

For example, most Unilever Lifebuoy soap customers live in remote rural areas that are difficult to reach through conventional channels. Unilever worked with NGOs, local entities, and governments to create a direct communication campaign specifically designed to raise awareness among India's largely rural and often illiterate population. Companies like Nestlé, SC Johnson, and PepsiCo have redesigned food products, cleaners and insecticides to serve the poor. All required rethinking the distribution and financing side of the equation to include local health organizations for delivery of nutrition education and microfinance organizations for payments and loan infrastructure (Brugmann & Prahalad, 2009; Simanis & Duke, 2014).

Relationship management. In Decoupled SISCM, the commercial logic is dominant in the focal organization with managers trying to replicate the formal and transactional style of its traditional SCM and understand relationships in terms of power-dependence determined by resource ownership. At the same time, when local social actors act as intermediaries between local communities and the focal organization, the latter might face the challenge of forgoing an arm's length relationship management style in favor of more relationalism.

As a consequence, in Decoupled SISCM, the focal organization most likely maintains traditional power-dominated relationships with some stakeholders, such as market players, donors, and governments. However, to gain legitimacy, focal organizations often need the

endorsement and support of social actors for their trust. Social actors like NGOs and local community organizations in developed countries are able to influence their localities because they are trustworthy and usually do not exercise power in coercive or formal ways. The focal organization typically needs their help in managing their relationship with local communities. The enforcement of international certification systems for food commodities, such as Utz or Rainforest Alliance, passes through the engagement of local actors that are not merely standard-takers but become directly involved in the implementation, yet not only via classic hierarchical value chains but via an emergent public space (Vellema & Wjik, 2015).

Combinatory SISC

The second approach we describe is Combinatory SISCM. In this case, the focal actor is characterized by high centrality with both commercial and social-welfare logics at its core. According to the institutional logics literature, organizations reconcile competing logics by enacting a combination of activities drawn from each logic in an attempt to secure endorsement from a wide range of field-level actors (Pache & Santos, 2013). The focal organization in this case could be a NGO or non-profit organization (NPO) moving to be more financially self-supporting through the management of its social activities, a for-profit moving to Benefit (B) corporation status (B Lab, 2018), or a purposefully formed social enterprise, all combining the social-welfare and commercial logics. This combination will be reflected in the supply chain management of the focal organization.

Supply chain strategy. In Combinatory SCM, the focal organization combines, in the same supply chain, actors that mainly adopt a social-welfare logic with actors that mainly adopt a commercial logic, often separated into the downstream or upstream side of their supply chain. For example, when actors adopting the social-welfare logic are on the downstream side, they might employ people-in-need to assemble, distribute, or sell social impact products or services. A popular example of this approach is employed by social enterprises managing the supply chain for solar-products to improve the quality of life for the poor in places like Africa (McKibben, 2017), Haiti (Knuckles, 2016; Bals & Tate, 2017) and India (Sawal et al., 2015). In these countries, the social enterprises work to set up assembly and/or distribution centres and hire locals to market, distribute and install solar products and parts. Another downstream logic example, Vision Spring sells affordable reading glasses to low-income individuals through a network of micro-entrepreneurs in various developing countries; here both the entrepreneurs and eye glass purchasers benefit (Bhattacharya et al., 2010).

Alternatively, when the social-welfare logic actors dominate the upstream side of the supply chain, the focal organization works to include people in need on the supplier side. For example, the social enterprise, Arzu, has the mission of improving the lives of Afghani women so they created an online retail portal to sell traditional and custom designed rugs produced by the women; the social enterprise provides design services to the women and fair prices as well as other social support (Sodhi & Tang, 2016). The social enterprise, CIFEA provides beekeeping training to members of a Tunisian region with high unemployment but favourable agricultural conditions and a unique ecosystem. After members are in full production, CIFEA then collects, distributes, and commercializes the specially branded organic certified honey and hive products (YUNUS, 2018). Depending on which side of the chain the Combinatory SISCM engages in social impact activities, the commercial side of the chain either finances and distributes needed products or services on the supply side for downstream social impact or sells the products or

services to generate economic resources to support the social enterprise activities for the upstream social impact.

The context of the Combinatory SISCM strategy is extremely challenging and unusual compared to traditional SCM strategies. While the focal organization benefits from a broader scope and scale for the distribution of their products (downstream Combinatory) or from unique products and branding opportunities from marginalized group suppliers (upstream Combinatory), they must understand and work with unique SCM challenges such as inadequate infrastructure, novel distribution channels, inadequate training, and different cultural norms around work and financial transactions. Here, the focal organization must actively engage in identifying potential supply chain partners among people in-need, help them to improve or change their products or services to appeal to their customer base, extensively train them in production or distribution skills, manage supply flows in challenging localities, providing information to these partners to operate in the market (Liao & Chen, 2017; Sodhi & Tang, 2011).

Additionally, the focal organization goes beyond just employing the workers. The social impact locations are particularly vulnerable not only to life threatening interferences but disruptions in material, labour, or product availability, incoming and outgoing deliveries, and exporting and importing regulations that are subject to shifting political agendas. Many focal organizations also participate in the targeted social group's communities and interact with community decision makers to understand how they can help improve social conditions.

Stakeholder identification and engagement. The focal organization combines the social-welfare and commercial logics in identifying and engaging with relevant stakeholders. Specifically, they will serve beneficiaries, financers, and customers as distinct groups. In Combinatory SISCM, different stakeholders are targeted as a result of different logics. The social-welfare logic prescribes to identify and engage the people in-need at one side of the supply chain and to collaborate with local social actors to help include people in-need in their supply chains. The commercial logic requires identification and engagement with market players that enable the economic activity. Each type of stakeholder will serve a specific role, either on the social or the commercial side. In this sense, stakeholder identification and engagement is about orchestrating the commercial and social stakeholders to comply with the social mission rather than addressing shareholder needs to achieve optimal financial performance. This will imply the inclusion of new actors and roles in the focal organization's supply chain compared to traditional supply chains.

In both downstream and upstream Combinatory SISCM, the social enterprise will need to identify people in-need to become suppliers and/or distributor or retailers (Sodhi & Tang, 2016). Additionally, it will be crucial to identify partners to support the economic and financial growth of these people (Karnani, 2007). For the solar supply chains mentioned above, the focal social enterprises have identified social impact inventors who then contributed funding to micro-financers and the focal organization to support the development of the supply chain (McKibben, 2017). Generally, the focal organization mobilizes resources and capabilities from better endowed stakeholders to offset other stakeholder's constrained resources (Knuckles, 2016). To accomplish this, the focal organization needs to identify and engage with local entrepreneurs, NPOs, NGOs, and venture capital impact investors for traditional or micro financing consumer loans and supply chain activities.

Relationship management. With social-welfare and commercial logics having high centrality at the core of the focal organization, Combinatory SISCM aims to protect less powerful actors at one tier of the supply chain and therefore tends to establish collaborative, long-term and altruistic relationships locally, while managing formal and transactional relationships with market actors representing for-profit customers/suppliers. The social enterprise connects people in need with market actors integrating the different relationship management styles prescribed by social-welfare and commercial logics.

Instead of having a market player who needs to gain the trust of local and social actors (like in the Decoupled SISCM), we have a social enterprise operating at one tier of the supply chain who is dependent on market entities' economic resources to achieve its social goal. Therefore, the social enterprise experienced in trust-based relationship with people in need, must also operate in a typically power-dominated, market context. Depending on the varying levels of power asymmetries, trust can be more or less difficult to build. As in the Decoupled, Combinatory SISCM which include a powerful supplier or distributor will need to use formalized contracts to compensate for power asymmetries or the powerful buyer can invest in site-specific assets for less powerful partners.

Coupled SISCM

The last approach we describe is Coupled SISCM where the focal organizations operate at the nexus of two different supply chains to address respectively social and commercial activities. We focus on socially-focused Coupled SISCM where the focal organization is a social enterprise in which the social-welfare logic is core and the commercial logic is peripheral. We address the situation of the commercial logic being core when discussing future research opportunities. Unlike the Decoupled SISCM, the coupled market and social chains are bridged by a social enterprise as the coupling agent (Gulati & Puranam, 2009). This coupled fit is also reflected in the management of its supply chain. With a social core, the social enterprise has a main mission to address a social need and an economic activity running in parallel to support this social mission and augment its effectiveness. Each of these parallel supply chains, has suppliers and customers with the focal organization as the connection.

Supply chain strategy. In Coupled SISCM, focal organizations operate separate but consistent supply chain strategies to feed the social one. In the social supply chain, people in-need are the beneficiaries of a transformative social service where the output is a skilled person; the commercial supply chain performs a separate economic activity providing economic resources for the social supply chain so it can continue operating without depending on donations and external funding. The focal organization is the bridge between these two chains.

An example of Coupled SISCM is provided by the case of the Work Integration Social Enterprises (WISEs) and their supply chains. These social enterprises aim to help unemployed people integrate into the workforce and labour markets (Pache & Santos, 2013). They deliver their social mission by hiring unemployed people, those with physical or psychological disabilities and populations excluded by the society such as inmates or migrants, for a limited period of time with the objective of helping them acquire the social and technical skills they need to find a job. Thus, they have a social supply chain in place that allows them to identify people in need to hire and place them in the job market. As they work for the WISE, these people produce products and/or services that are then sold to generate revenue, while also developing the technical skills that they need to obtain stable, long-term employment. Thus, the focal

organization has a commercial supply chain in place to produce the goods and sell them to the market. The WISE will be the focal actor actively connecting the two supply chains and managing contradictions and synergies between the two.

Another example is the UK organization, Redemption Roasters, which aims to train young prisoners in Aylesbury prison as baristas and coffee roasters. By locating their roasting facility and one of their cafes within the prison itself, Redemption teaches prisoner-students all about coffee origins and taste profiles, roasting, and drink-making as a mechanism to help prisoners get jobs after completing their prison terms and reduce recidivism. The costs of shipping raw materials in and out of prison can be as much as three times higher that of a normal commercial site but Redemption covers the training and additional costs from their profits (Lander, 2017). Here the social supply chain consists of prisoners with their future employers as employer-customers of trained coffee experts while the commercial supply chain includes the raw materials upstream, roasting process, and the coffee purchasers as customers.

Stakeholder identification and engagement. Like the previous cases, stakeholders can be identified according to their dominant institutional logic. In other words, for-profit actors can be engaged in the commercial supply chain while social actors are engaged in the social supply chain. However, in Coupled SISCM, it might become difficult to clearly distinguish these stakeholder types and the stakeholders themselves will display a hybridization of logics.

In the examples of WISE or Redemption Roasters, on the social supply chain side, the focal firm will engage with social actors as supplier of potential employees as well as social counselling and training services. Additionally, after their value-added training, the focal actor helps the employee find long-term employment. The focal organization interacts with social entities and other partners involved in the inclusion of these people in the society and in the job market. A WISE restaurant that trains disadvantaged workers will engage with other restaurants and hotels as customers. The firms hiring trainees can be considered as pure market actors that hire personnel from the social enterprise just like from any other channel. However, it is not uncommon that these clients are sensitive to the social mission and treat trainees from the social enterprise differently, helping them well beyond what is expected in a traditional business context. Similarly, in the commercial supply chain of the WISE, suppliers are often selected because of shared social goals with the focal organization and customers are usually sensitive to its social mission. Social enterprises adopting Coupled SISCM look for stakeholders to be part of their supply chain that display both social-welfare and commercial logics and do not just orchestrate them as providers of specific resources but actively involve them as partners of both the social and commercial supply chain, sometimes even delegating crucial tasks for the mission achievement.

Relationship management. The focal organization adopting Coupled SISCM is part of two separate supply chains that adopt different logics, have different scopes and strategies, and thus require different relationship management styles. The focal organization could simply adopt more relationalism in the social supply chain and more traditional arm's length style in the commercial supply chain. However, the focal organization might be capable of finding synergies between the two approaches. That happens when, on the one hand, market-oriented relationships with economic actors are reoccurring, building trust as well as enhancing informal and altruistic relationships. On the other hand, the relational intensity with the social actors becomes more efficient thanks to methods and tools that reduce the transaction costs.

The social enterprise orchestrates two interconnected supply chains creating complex power dynamics. In the supply chain dominated by the social-welfare logic, the shared dedication to a common cause would support trust and informal relationships while potentially generating risks of opportunistic behaviours, contrasting objectives, and inefficiencies. For example, a Spanish social enterprise, Mescladis, trains migrant employees in their restaurant for future placement in other hotels and restaurants. Language barriers and employee country-of-origin custom differences create challenging customer experiences such as order miscommunications and slow service (Longoni, Luzzini & Pullman, 2017). In the commercial supply chain, the relationships between the focal firm and its market customers/suppliers would be subject to power asymmetries. However, market players might be sensitive to the role and mission of the social enterprise and want to be associated with it to enhance their image; they can gradually complement or even substitute traditional power-dependent relationships with trust. This can be seen in the Mescladis restaurant where the hiring hotels and restaurants trust the social enterprise in the hiring relationship and even take migrant trainees with questionable legal status and severe personal problems (Longoni et. al., 2017). Typically, it is up to the social enterprise to act as a catalyst and create the basis for a trusting and cooperative climate between the two supply chains characterized by shared values, synergies and resource exchange, and minimum conflicts.

Future Research in Social Impact Supply Chain Management

We argue that the combination of social-welfare and commercial logics in focal organizations will lead to differences between SISCM and traditional SCM. We expect the institutional complexity derived by the combination of social-welfare and the commercial logics to inform different supply chain strategies, stakeholder identification and engagement, and relationship management styles. In the next section, we further elaborate on how extant research in these areas falls short if applied in the context of SISCM and propose corresponding future research directions.

Supply chain strategy

The first specificity of SISCM is the need to combine the commercial and social-welfare logics in the supply chain strategy. Indeed, focal organizations are embedded in a commercial and a social-welfare logic and need to develop unusual supply chains strategies to address such institutional complexity. The traditional SCM literature usually identifies supply chain strategies as a function of product characteristics such as demand and supply uncertainty leading to the classic supply chain strategies of efficiency, responsiveness, risk hedging, agility (Fisher et al., 1997; Lee, 2002). These strategies all imply a commercial logic in that the ultimate objective of focal organizations is to maximize profits by finding the appropriate combination between the cost of managing the supply chain and the service level to customers. In this literature, the idea of combing multiple objectives is not new and requires the development of hybrid supply chain strategies, as the literature on mass customization, agility, and lean testifies. However, these studies only consider hybridization of multiple commercial objectives, such as cost and quality (lean strategy) or responsiveness and risk-hedging (agile strategy). Instead, in the SISCM context hybridity can be defined as the combination of social-welfare and commercial logics in an economically viable way (Battilana & Lee, 2014). This will require future research to understand how to effectively design supply chain strategies that prioritize social objectives, or at least combine social and commercial objectives. Future research might deal with this research direction in descriptive and in normative ways.

Descriptive research opportunities: Identifying SISCM hybrid strategies. Previous research suggests hybridity in traditional SCM, multiple commercial objectives are combined synergistically. For instance, an organization applying lean operations performs the same set of activities to both reduce cost and increase quality (Womack & Jones, 2010). In the context of SISCM it is not clear what supply chain strategies are available to cope with institutional complexity. Moving beyond the classic cost vs. service trade off, new strategies are needed to achieve a social impact while making economic sense. Additionally, moving toward social goals might imply riskier and sub-optimal strategies in terms of economic goals compared to traditional SCM strategies.

Going beyond the three SISCM approaches we propose, future research could address other configurations of SISCM such as Decoupled with a social core and commercial peripheral and Coupled SISCM with a commercial core and social peripheral. UK-based non-profits Emmaus and Sue Ryder, have become sophisticated retailers and supply chain managers, generating a significant portion of their income to support hospice activities and other projects for the needy by generating additional income selling baked goods or used household good (Economist, September 2017). Similarly, Coupled SISCM with a commercial core and social peripheral are seen with corporations such as Ben & Jerry's Partnershops®. Similar to WISE programs, Partnershops® are community-based non-profits which offer job and entrepreneurial training to homeless youth in Ben & Jerry's ice cream stores with a parallel social supply chain with social agencies and potential employers. Here, the corporation provides support and waives franchise fees to Partnershops® (Ben & Jerry's, 2018). Future research might look at where these types of SISCM fall on the continuum of social impact as well as taxonomies of different SISCM strategies to understand how such strategies can be implemented across the supply chain and the implications for social impact and financial viability outcomes.

Normative research opportunities: Innovative SISCM strategies. The combination of social-welfare and commercial logics by a focal organization in SISCM might require different solutions than doing it through multiple goal combination or co-joined as prescribed by the institutional logics literature (Pache & Santos, 2013) and traditional SCM literature (Womack & Jones, 2010; Christopher & Towill, 2000). Based on the literature on institutional logics, the combination of multiple logics in SISCM might create different challenges such as risk of mission drift, when one logic (i.e., commercial logic) prevails on the other leading to deprioritizing or abandonment of social concerns in favor of profit-seeking activities (Battilana et al. 2014; Mair et al. 2012). Decoupling instead might lead to identity problems when different activities are managed following different logics (Battilana et al. 2014).

We propose innovative SISCM strategies beyond logic combination and decoupling strategies are needed for social enterprises to effectively manage their supply chains. The innovation occurring in SISCM is expected to include all parties, such as multiple tiers of suppliers, focal organizations, intermediaries, retailers, and consumers (Gao et al., 2017). Thus, the aim is not only to create value for the focal organization, but also to consider the needs of all stakeholders. Accordingly, innovativeness has been identified has a crucial capability needed to manage supply chains in social contexts compared to traditional SCM (Klassen & Vereecke, 2012; Pagell & Schevchenko, 2014; Longoni & Cagliano, 2016). In our continuum, Coupled SISCM is a more innovative approach than Decoupled or Combinatory approaches. In Coupled SISCM, stakeholders typically associated to one core logic (i.e., social-welfare) are called to integrate elements from the other logic to effectively deliver a social mission. This requires

innovative supply chain structures, roles and relationship management in the social enterprise's supply chain. Future research should investigate innovative SISCM strategies that social enterprises put in place to manage their supply chain and evaluate their effectiveness in enacting multiple logics, preventing mission drift, and improving their efficiency while maintaining their social commitment.

Stakeholder identification and engagement

Traditionally, organizations characterized by a commercial logic identify stakeholders accordingly to a firm's profit orientation as suggested by stakeholder theory (Freeman, 1984). In such a context, stakeholders have been classified as primary and secondary stakeholders (Clarkson, 1995). Primary stakeholders include those stakeholders continuously part of the value creation in the focal organization's supply network such as traditional suppliers and customers, a rather homogenous set of stakeholders characterized by profit orientation with clear roles in the focal organization's supply chain. If any primary stakeholder group, such as customers or suppliers, becomes dissatisfied the focal firm will be seriously damaged or unable to continue as a going concern. Secondary stakeholders are a more heterogeneous set of stakeholders including NGOs and mass media that are able to mobilize public opinion in favor of, or in opposition to, an organization. Traditionally, they have been considered as influencers, but they are not engaged in transactions with the corporation nor are they essential for its survival.

Conversely, focal organizations in SISCM identify stakeholders based on the combination of the social-welfare and commercial logics leading to different types of primary and secondary stakeholders. More specifically, in SISCM, primary stakeholders are characterized by greater heterogeneity than in traditional SCM. These actors include profit-oriented organizations such as good and service suppliers, private or corporate donors, as well as socially-oriented organizations such as other social entities and NGOs who are committed to the social mission of the focal organizations. All of these stakeholders take an active part in the supply chain, as volunteers, influencers or formal collaborators.

Each stakeholder is providing a different type of resource to the focal organization that is needed for its daily operations and can cover supply chain roles such as customers, supplier, intermediaries, distributors (Sodhi, 2015). In this context, those stakeholders normally considered secondary in traditional SCM and a source of pressure, could be identified as core actors in the focal organization's supply chain and are proactively engaged. This shift might require future research on how these stakeholders behave and take part in SISCM. Future research might deal with this research direction in descriptive and in normative ways.

Descriptive research opportunities: Identifying stakeholders' roles in SISCM. In traditional SCM, the roles of primary stakeholders such as suppliers and customers in value creation are clearly defined. They are economic actors participating in the physical and informational flows enabling the focal organization to produce and deliver its goods or services and taking a stake in the value created though economic transactions. In this context, the identification of stakeholders and their roles in the supply chain does not need specific analysis. But in SISCM, a focal organization has to identify who its primary stakeholders are in terms of profits vs non-profit, public vs private, and corporate vs citizens, which logic characterizes them and what their role is in the supply chain. It could be that in the supply chain of a social enterprise, NGOs might act as suppliers of information about people in need. This type of supplier will adopt a social-welfare logic in the way it acts and interacts with the social enterprise

as opposed to a traditional supplier with a commercial logic. In some cases, NGOs act as intermediaries in the focal firm's supply chain with people in need. We expect NGOs to be a different kind of intermediary than traditional traders, as they prioritize a social-welfare logic and possess a different set of skills and capabilities. Also, in some cases, suppliers, distributors or customers might be people in need which might introduce sources of risk and uncertainty and thus require specific engagement mechanisms such as non-contractual arrangements and non-coercive power mechanisms. Therefore, focal organizations in SISCM need to understand who their stakeholders are, what their institutional logic(s) is, what role they play in their supply chain and how to engage them in achieving the focal organization's goals.

Normative research opportunities: Balancing stakeholders' characteristics. The inclusion of stakeholders that are not profit-oriented might lead to suboptimal financial performance because of different priorities and working mechanisms. However, these actors are core to providing legitimation, social skills, and resources fundamental to the functioning of the focal organization's supply chain. Thus, focal organizations should be able to identify their stakeholders according to both social-welfare and commercial logics and balance them in order to achieve both social effectiveness and economic viability. Sodhi (2015) proposes the stakeholder resource based view (SRBV) as a framework to inform the decision-making of managers of a company towards maximizing their utility and also those of the company's stakeholders. Designing and managing supply chain partners with complementary capabilities has a positive impact on sustainability and value creation. Here, each stakeholder (or stakeholder group), with its individual view of the operations, has specific resources and capabilities. Therefore, the focal organization should be able to identify the resources needed according to both commercial and social-welfare logics and engage with a set of the stakeholders able to provide them.

Relationship management

Several disciplines have investigated inter-organizational relationships and their performance implications (Autry & Golicic, 2010). In traditional SCM literature, according to the commercial logic, these studies have focused on buyer-supplier vertical relationships (Terpend et al., 2008) and several classifications have been provided (e.g., Ahmed et al., 2017; Tangpong et al., 2015; Terpend et al., 2012). Among them, Tangpong et al. (2015) proposed a classification based on two main aspects: relationalism, the degree to which buyer and supplier firms promote behaviours that maintain or improve their relationship, and power dependence such as buyer/supplier dependence.

We expect that in SISCM, focal organizations will establish relationships not only with traditional profit-oriented organizations as in traditional SCM, but with all stakeholders identified above. This will result in inter-organizational relationships with a distinctive character relative to traditional SCM relationships in terms of relationalism and power dependence approaches. In contexts characterized by social-welfare logic stakeholders, relationships will have the goal of reciprocal exchange and will not only concern information, products, labor force, and/or financial means, but also more intangible elements such as compassion, education, and care (Tate & Bals, 2016). This leads to a new research direction on how stakeholder relationships are managed in a context characterized by greater institutional complexity particularly combining social-welfare and commercial logics. This research topic can also be investigated in a descriptive and normative way.

Descriptive research opportunities: Describing relationalism and power in SISCM. In terms of relationalism, the combination of social-welfare logic with the commercial logic might require additional altruistic rather than purely economic motives to define stakeholder relationship management (Tate & Bals, 2016). This can happen when the social enterprise is dealing with people in need, other social entities, or NGOs and it interacts with them in an altruistic fashion. On the other side, profit-oriented stakeholders, providing financial resources to the social enterprise, might act in an altruistic fashion toward the social enterprise if moved by shared goals or because of a desire to be associated with the social mission. This might require a new definition and typology of relationalism.

Additionally, power-dependence might be defined in a different way than in traditional SCM. In a commercial logic, the more powerful actor would likely exert control over the less powerful, possibly acting in its own interest. When an organization depends upon another for resources or performance and few alternative sources exist, we are likely to witness a power-dominated relationship. A classic example is when a buyer has power as a result of a high share of supplier revenues with that buyer and the availability of alternative suppliers or – vice versa – a powerful supplier as a result of high asset specificity and a limited supplier pool. Instead of being based on a commercial logic, in SISCM, power might be defined according to a social-welfare logic or a blend of the two logics. Based on a commercial logic, the social enterprise might be power dependent to market-entities because of funding and other resources needs. However, in a social-welfare logic, these organizations might have a different type of power in the relationship with market-entities, such as legitimacy-based and referent-based power which are proposed to be at the basis of social power (French & Raven, 1959). Legitimacy-based forms of social power stem from internalized values by the stakeholders who recognize the social enterprise to have legitimate authority to influence them in a specific social context; referent-based forms of social power stem from the willingness of the stakeholders to be associated to the social organization and recognize its influence.

Normative research opportunities: Investing in trust-based relationships to contribute to network stability, social effectiveness and financial viability. Shared experiences and information exchanges are vitally important for the focal organization's management of many different types of stakeholder relationships to identify key collaborators in the supply chain whose interests align with the social enterprise's mission, such as public, private, hybrids, community, and third party financiers (Kolk and Lenfant, 2015). As the nature of these relationships moves toward extreme aspects of relationalism, such as altruism and legitimacy- and referent-based power, institutional complexity might increase the role of trust in SISCM relative to traditional SCM. Trust refers to the confidence in another's goodwill and conformance to expectations (Ring & Van de Ven, 1994). Even though there is evidence that trust can have a positive effect on supply chain relationships, power dynamics have traditionally dominated relationships in traditional SCM.

Power and trust exist as different means through which a firm seeks to promote desired behaviours in a partner. They are complementary and opposing components of social behaviour through which firms can adjust social relations to achieve a desired outcome (Ireland & Webb, 2007). Usually one can substitute for another when one fails to achieve desired results. We propose that in an institutionally complex environment resulting from the combination of social-welfare and commercial logics, trust-based relationship might be more effective than traditional power-based relationships. However, previous studies show that increasing amounts of informal

trust-based relationships can magnify the chances of opportunistic behaviours (Ireland & Webb, 2007). Another risk of an excess of trust is the over-embeddedness stemming from the emotional attachment and efficiency of high-trust relationships rather than looking for alternative partners that might increase its effectiveness. In SISCM, the focal organization might stick to stagnating relationships, eventually compromising the social mission achievement. These risks can be hedged through specific control mechanisms that prevent opportunistic behaviours and reward innovation. In this sense, power can become complementary to rather than conflicting with a trust-based relationship. Thus, future research might investigate all these different relational nuances in SISCM and the most effective way toward social mission achievement and financial viability.

Conclusion

Previous SCM research has mainly focused on ways to achieve economic goals when dealing with sustainability issues leading to "less harm" solutions. Research about NGOs or humanitarian logistics has focused on the study of supply chains that address temporary and local social needs. In this study, we highlight a gap in theorizing and investigate focal organizations who provide a social good with the intention of being financially viable in the long term. Thus, we propose a definition of SISCM and describe different approaches taken by focal organizations combining commercial and social-welfare logics. SISCM appears fundamentally distinct from traditional SCM in terms of supply chain strategy, stakeholder identification and engagement, and relationship management due to the combination. This is the result of social enterprises experiencing institutional complexity and adopting hybrid SISCM approaches (i.e., Decoupled, Combinatory, Coupled).

We can envisage that SISCM approaches may also influence traditional SCM strategies and practices. For example, several for-profit companies are showing signs of going beyond Decoupled SISCM in their effort to improve the conditions of people in-need across their supply chain while simultaneously achieving economic goals. Illy, a global coffee roaster has worked for decades to improve the working and living conditions of farmers as a social goal per se but also as a way to ensure the quality and sustainability of green coffee (Longoni & Luzzini, 2016), and similar initiatives have been launched by companies like Nestle or Starbucks (Alvarez, Pilbeam, & Wilding, 2010). Future research might investigate the transition process of focal organizations from one SISCM approach to the other, possibly highlighting some intermediate stages in the continuum. The focal organization could potentially be any type of organization ranging from for-profit, benefit or B corporations to social entities. What will distinguish their approaches will be whether the social-welfare logic is peripheral or core as well as the level of centrality. Our fundamental argument is that hybrid innovative SISCM approaches emerging from the combination of social-welfare and commercial logics can foster social impact effectiveness in economically viable organizations. However, we do not deny the drawbacks and tensions arising from SISCM related to sub-optimal economic outcomes compared to traditional SCM or exposure to social mission drift. Thus, we encourage future researchers to explore this rich and complex area to understand how we can create more socially effective organizations and supply chains.

Figure 1
Continuum of SISCM Approaches

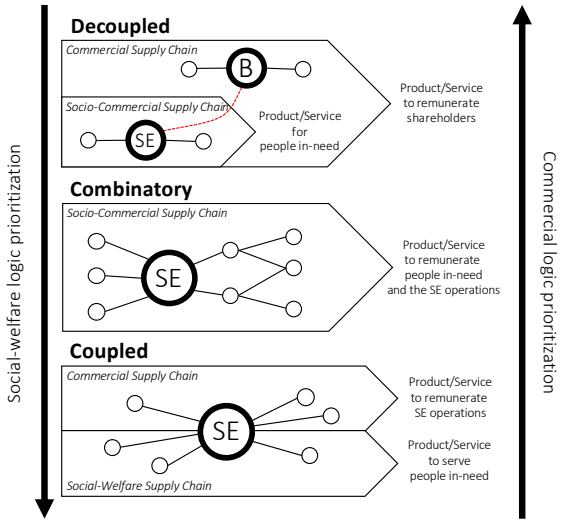

Table 1
SISCM Approaches Summary

SCM factors		Decoupled (Commercial)	Combinatory	Coupled (Social)
Context	**Focal organization**	Multinational company/ corporation or subsidiary	Social enterprise	Social enterprise
	Institutional complexity	Commercial logic core, social-welfare logic peripheral	Commercial and social-welfare logic centrality	Social-welfare logic core, commercial logic peripheral
SISCM strategy	**SISCM definition**	The for-profit focal organization sets up a SC to address business opport. in emerging markets	The social enterprise focal organization develops and manages a SC combining social and market logics	The social enterprise focal organization sets up two supply chains, a "pure" social supply chain to deliver a social service and a commercial supply chain to sell a product/service
	Primary SISCM purpose	Profit	Social and profit	Social and economic independence to serve the ultimate social goal
	Social provisional category design	Design product/service for people in need	Design a SC to include people in need in economic activities	Design a SC to provide skills and opportunities for people in need
	Focal organization operations management	Sell and distribute the product in emerging/bottom of the pyramid markets	Share information, provide resources and train people in-need	Manage flexible operations combining the social and commercial supply chains
	Focal organization supplier management	Build and coordinate a local "commercial" SC to deliver a product/service to local people	Connect people in need with local and international commercial organizations	Build a social SC to bring social issues from social entities to economic entities filling institutional voids; and an economic SC acting as a supplier/buyer in the market.
Stakeholder identification and engagement	**Customers**	People in need	Consumer/Clients	*Social SC*: People in need *Commercial SC*: Consumer/Clients
	Suppliers/Distributors	For-profit organizations	People in need	*Social SC*: Social entities *Commercial SC*: For-profit and/or not for-profit organizations
	Intermediaries	NGOs, social entities, governments	NGOs, social entities, governments	*Social SC*: Social-oriented organizations *Commercial SC*: For-profit and/or for-profit organizations
	Financing entities	Banks, shareholders	Local entrepreneur networks, donors, governments	*Social SC*: Local entrepreneur networks, donors, governments *Commercial SC*: Banks, shareholders
Relationship management	**Relationalism approach**	Transactional	Altruistic	*Social SC:*, Altruistic *Commercial SC:* Transactional
	Power dominance	Power-based Legitimacy-based with Suppliers/Distributors	Trust-based Power-based with Customers	*Social SC:* Referent-based with Clients and Suppliers/Distributors Trust-based with Intermediaries and Financing entities *Commercial SC:* Referent-based with Customers Trust-based with Suppliers/Distributors

Supplier Performance Impact on Construction Project Financial Result

Abstract
The objective of this research is to examine the impact of supplier performance on financial result of construction projects (projects' financial result). The research is a case research and is limited to project data specific to a single company. The study is conducted in a case construction company using the performance measurement data and project financial data collected from the company's reporting system. The performance indicators are calculated and the impact on project success is examined using Partial Least Squares (PLS) method. This study aims to establish the connection between best performing suppliers and best performing projects.

Keywords: Supplier performance, supplier management, procurement

Research background

Purchasing in project business and construction
Previous research regarding purchasing in project business have focused on buying processes and performance evaluations. It is found that the procurement procedures affect project performance (Eriksson and Westerberg, 2011). Furthermore, assessing supplier performance in projects and developing partnering mechanisms improve the operational and financial performance of the suppliers and thus the overall project (Cheng and Carillo, 2011). It is also noticed that buyers prefer suppliers' technical, operational and business capabilities instead of relational and developmental capabilities (Ruuska et al., 2012). Moreover, it is stated that the purchasing strategy selected in projects affects value creation. Short-term value elements have product focus and a competitive tendering basis whereas long-term value elements in projects focus on relationships with customers and suppliers and innovations (Ahola et al., 2008). In the project business environment, various project characteristics moderate purchasing procedures and project performance. The more challenging the project characteristics (complexity, customization, uncertainty value/size, time

pressure) are, the more cooperative purchasing procedures improve overall project performance (Eriksson and Westerberg, 2011).

Purchasing and supply management can have a major impact on the success of the construction project (Eriksson and Westerberg, 2011). However, numerous barriers to pursuing effective purchasing in projects have been reported in the previous literature (Gadde and Dubois, 2010). Especially, supplier management and partnering has been found challenging in construction projects (Bygballe et al., 2010) and mixed research results exists. For example, Dubois and Gadde (2002) have studied relationships correspondence with production in construction industry and have found that both tight and loose couplings favor short term productivity and seems to hinder innovation and learning. In other words tight relationships with suppliers do not lead to better project outcomes. In addition, Kamann et al., (2006) had similar findings but also recognized that stable and fixed individual contacts with the supplier firm limit coordination and transaction costs and enhance long-run supplier performance.

The previous findings are due to the fact that projects are unique, one-off settings and carry inherited risk and uncertainty because of their temporary nature (Baily et al., 2008). Moreover, decentralized purchasing in projects and competitive tendering is the prevailing practice in buying companies. Therefore, collaboration and supplier development in terms of improve supplier performance in projects is difficult to put in practice and integrated supplier network and close supplier relationships have not yet been widely adopted in project business (Crespin-Mazet and Portier, 2010).

Supplier performance and firm performance

As companies in project-based business have been pushed to seek performance improvements, they have recognized the potential of their supplier base and start to manage it as an extension of the company's manufacturing system (Carter, 1996; Sheth and Sharma, 1997). It is acknowledged that the performance of the supplier base is critical to the success of supply management function and company business (Tan et al., 1998), and thus, supplier performance measurement is one of the most important tasks in purchasing operations (Monczka et al., 1993). Large share of studies have demonstrated the positive relationship between purchasing and supply management activities and a multitude financial and operational performance metrics (e.g. Carr and Pearson, 1999; Narasimhan and Das, 1999; Ellram et al., 2002; Sanchez-Rodriguez et al., 2003). In addition, purchasing is viewed to contribute more than solely costs (Das and Narasimhan, 2000): vice versa, purchasing performance has been researched against financial measures such as return on investment, return on assets, market share, profits (% of sales), and net income.

Recently, suppliers's direct impact (Jajja et al., 2016) and indirect impact (Foerstl et al., 2013) on a buying firm performance has been in scientific discussion. Jajja et al. (2016) found firm's strategic supply chain (lean and responsiveness) correspondence with key supplier practices (quality, cost effectiveness, delivery, and flexibility) that have a positive impact on firm performance (operational, quality and market, and financial). Foerstl et al. (2013) results instead indicated purchasing and supply management indirect impact to financial performance lacking outward bound practices such as supplier integration, building buyer-supplier and supplier development. Nevertheless, firms and the density of the supply networks, along with the interaction between them, have been recognized to have a positive direct influence on the performance of firms as measured by the firm's asset utilization, cost performance, and operational efficiency (Basole et al., 2018). Further research by Al-Shboul et al. (2017) suggests also that higher levels of supply chain management practices (one being supplier performance) can lead to enhanced supply chain and firms' performance. Consequently, companies have paid more attention on supplier

relationships (Kannan and Tan, 2006) and an effective supplier management have become as a core competency of firms (Paulraj et. al., 2006). This has led to an increasing need of supplier performance data (Carr and Pearson, 2002).

Supplier performance and project performance: the research gap

Even though supplier's impact on firm performance is widely studied, supplier performance impact on project performance has stayed as rarely studied research topic. One of the few researches that studies the supplier performance correspondence with project performance is made by de Araújo et al. (2017). The results of the research emphasize selecting the right supplier and evaluating supplier's performance is important to ensure a good project outcome. Even though the results of the de Araújo et al. (2017) research are promising, the limitation in this context is that the research is a literature review and there are no primary research performed to test the taxonomy of the literature review. In construction industry context the topic is even less researched. However, some research close to the topic is conducted. For example, in this framework, similar researched topics such as partnering and construction supply chain (Gransberg et al. 1999; Eom et al., 2008) and supplier relationships contribution to project performance (Heredia-Rojas et al., 2015) are researched but these researches lack supplier performance perspective. Otherwise the supplier performance research is focused more on manufacturing performance such as the research by (Wegelius-Lehtonen, 2001) that acknowledge supplier performance measures to be used as a basis for progressive improvement of company productivity. Or research is focused more on supplier development strategies to identify the best suppliers and to improve suppliers' production processes and performance (e.g. Rogers et al., 2007).

Research approach

Despite the fact, there are several studies that explores similar type of research questions through case studies, this research addresses this topic quantitatively. In this research the research topic, supplier performance's impact on project performance, is researched through the case data. The link between purchasing practices and the overall performance of the company is investigated through quantitative studies, where financial performance of the case company's projects is applied as a success variable. Supplier performance evaluations are applied to complement studies and have an insight into more operational areas. In addition, contrary to previous studies (e.g. Carr and Pearson, 1999; David et. al., 2002; Ellram et. al., 2002) this study utilizes more objective success variable – profit margin of the project, instead of focusing to investigate the link between purchasing and supply management activities and corporate success through generic high-level measures such as return on investment or those mentioned earlier.

The objective of this study is to empirically examine the impact of supplier performance to the financial result of the construction project. The study is conducted in a construction company using the performance measurement data collected from the company's reporting system. The performance indicators are calculated and the impact on project success is examined using Partial Least Squares (PLS) method.

Supplier performance drivers in this research

The selection of supplier performance drivers in this research is based on the purchasing and supply management literature, the purchasing strategy of the case company and industry-specific requirements for the suppliers. Supplier performance management typically adopts different metrics for the evaluation. For example, cost, quality, flexibility, on-time delivery, and responsiveness indicators are utilized for measuring supplier performance (Paulraj et al., 2006). Supplier performance indicators and purchasing strategy form the basis for supplier classification

and describe the output of the purchasing and supplier management system. The assessment of supplier performance in projects and development of partnering mechanisms improve operational and financial performance of the suppliers and thus the overall project (Cheng and Carillo, 2011; Eriksson and Westerberg 2011).

Industry-specific requirements are necessary to take into account in this research as in the construction industry supply chains are non-traditional supply chains. In a traditional supply chain (e.g. Christopher, 1992) materials are sent to one factory, but in a typical construction supply chain a company needs to build its own factory around each object (Bengtsson and Gustad, 2008). Therefore supply chain and its suppliers' performance is dependent on contractors' internal processes and ways of working (Bertelsen and Nielsen, 1997). Thus purchasing performance is dependent on supplier's learning curve in terms of doing business with the firm – which may include understanding the firm's value, culture, and quality requirements among other issues (Janda and Seshadri, 2001). For example, suppliers work usually physically on the construction sites, which emphasizes the importance of work safety and site order aspects in supply – the common industry-specific issue. In addition to the drivers mentioned, the Net Promoter Score (NPS) is also included in as a performance driver. NPS measures the loyalty that exists between a *provider* and a *consumer* and presents the score that describes the loyalty (Reichheld, 2003). NPS is usually researched in customer satisfaction research e.g. to predict business performance (Morgan and Rego, 2006) and revenue growth (Keiningham et al., 2007) but is also tested how it improves business performance in supply chain (Ucenic and Ratiu, 2017). In this framework we aim to find possible impact of supplier recommendation on project performance. The supplier performance indicators used in this study are presented in the table 1 below.

Table 1: Supplier performance drivers in this research

Safety	**Reliability**	**Quality**	**Net Promoter Score**
Attitude towards safety	Representatives/supervisor's availability & expertise	Contract compliance	Recommendation to next projects (Yes/No)
Cleanliness, order & environmental consideration	Compliance with agreed timetables	Quality of the products / performance	
Compliance with safety instructions	Unfounded demands related to the contract	Development activity	
Development activity with safety	Billing & payment terms	Reactions and corrective actions towards claims/remarks	

Research question

The research questions is: *How supplier performance affects projects' financial result?* The objective is to find out the supplier performance relation to projects' financial result - in other words to find out the most critical supplier performance drivers that affects positively to project financial result.

Hypothesis

H1: Best performing suppliers are involved in projects with best financial result

Research framework

Research framework (Figure 1) presents the basic approach to this research. In core of this research, supplier performance drivers' impact on supplier performance is established and further on the supplier performance impact on projects' financial result is researched.

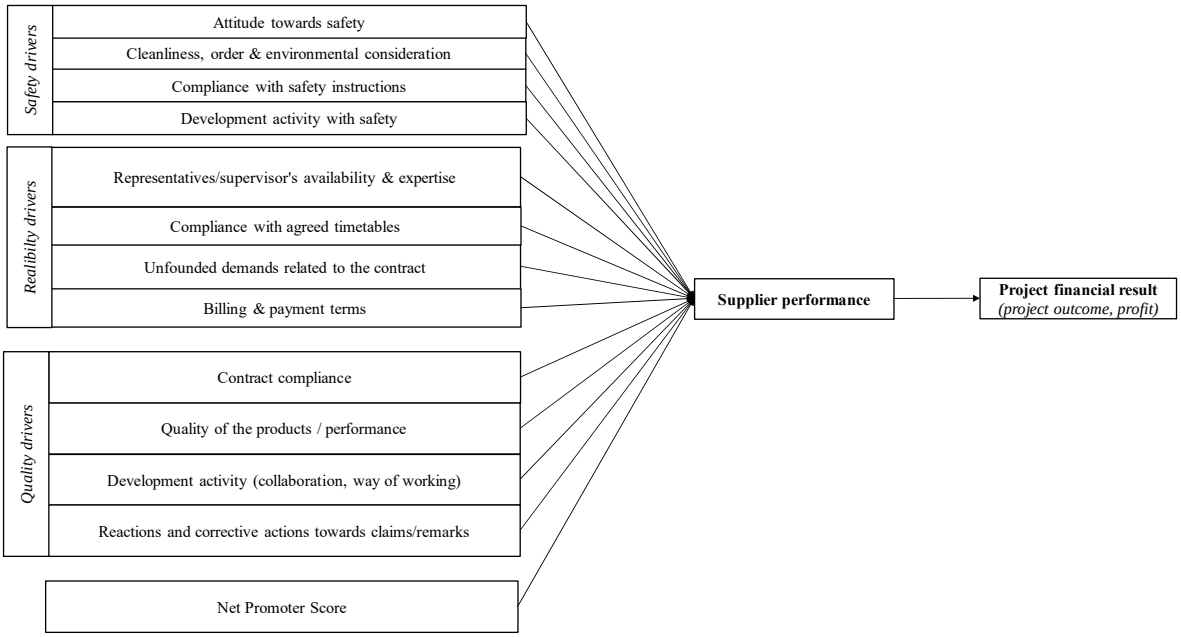

Figure 1: Research framework

Empirical Study

Methodology

The empirical study is based on the supplier performance and project data in the case construction company. The sample consists of altogether 241 projects in Finland and the supplier data includes performance assessment of 723 suppliers. The collected database consisted of variables from supplier performance and project performance. This research is a mixed method research where a case research is built around the quantitative research. In order to reduce the possible problem associated to the common method bias (CMB), the supplier performance and project performance data were combined from different data sources.

The collected data is based on the supplier performance evaluation instrument, which includes questions related to the supplier *Work Safety, Quality and Reliability* and *Net Promoter Score* using a Likert scale from 1 to 5. Suppliers in the each project were evaluated based on the instrument after the project was completed. This data was then combined with the direct project performance data of the case projects.

Survey Instrument

The measurement reliability of the constructs was assessed using construct reliability ('CR') and the variance captured by latent construct by average variance extracted ('AVE') (see e.g. Fornell and Larcker, 1981). According to Kline (2011) the CR coefficient should exceed .50 to indicate acceptable if the model validity otherwise is good. The measurement reliabilities are reported in the Table 2. The project margin variable uses standardized measures. It can be stated that all of the latent variables had acceptable reliability for further analyses. Only Margidevelopment variable does not has significant p-value, however, it will be used because construct measure are otherwise acceptable.

Table 2: Measurement reliabilities

	Loading	p-value	Mean	SD	AVE	CR
Safety					**0.567**	**0,839**
Safety1 *Attitude towards safety*	0.780	****	3.786	0.391		
Safety2 *Cleanliness, order and environment*	0.735	****	3.742	0.398		
Safety3 *Compliance with safety*	0.803	****	3.817	0.399		
Safety4 *Development activity with safety*	0.688	****	3.373	0.490		
Quality					**0.521**	**0.812**
Quality1 *Contract compliance*	0.746	****	4.080	0.403		
Quality2 *Quality of the product*	0.791	****	3.909	0.388		
Quality3 *Development activity*	0.710	****	3.654	0.464		
Quality4 *Corrective actions towards claims*	0.630	****	4.053	0.441		
Reliability					**0.493**	**0.795**
Reliability1 *Supervisor's expertise*	0.667	****	3.861	0.401		
Reliability2 Compliance with timetables	0.712	****	3.865	0.416

n) not significant, *) Statistically significant at p<0.1, **) Statistically significant at p<0.05, ***) Statistically significan
p<0.01, ****) Statistically significant at p<0.001

PLS Path Model

We analyzed the main effects in the model which are defined in the Figure 2. The path model presents only significant relationships. Other direct relationships were also tested, however, they were not defined significant. Mediation of the indirect effects were also assessed. The resampling of the data was repeated 5000 times with traditional Bootstrapping method analysis which is adequate for estimation of parameters in the model (Kline, 2011). We tested and validated quality of the structural model through the following steps; (1) collinearity issues and overall fit, (3) explanatory power, (4) path significances.

The collinearity and the model fit to the data was assessed in order to validate the structural model. The latent constructs did not indicate collinearity issues where the values remain clearly below critical value of 5. Root mean square residual covariance (RMStheta, critical value >.12) was also assessed to specify to assess the overall fit of the structural model (see Hair et al., 2016).

Here, model fit by RMStheta= .185 indicates that serious misspecification of the structural model does not occur.

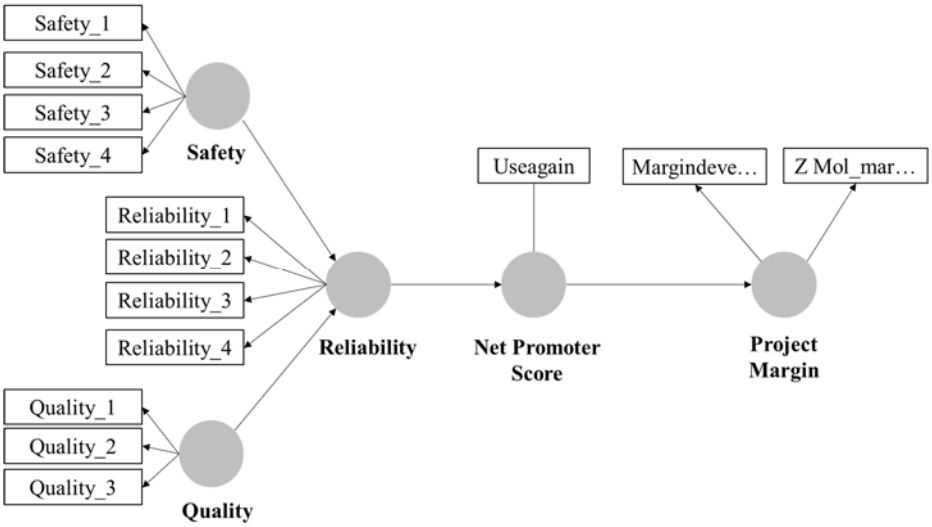

Figure 2: Conceptual model with t-values and (p-values).

The r-squared for the latent variables in the path model were; "Reliability " = .60, "Net Promoter Score" = 0.07 and "Project Margin" = 0.05. The default model (see Table 3) shows that the supplier "Quality" and the supplier "Safety" (Interop) have strong and significant positive influence on the supplier "Reliability" (SCI) which confirms these hypotheses paths in the conceptual model.

Table 3: Direct effects in the structural model to test the main hypothesis of the study

Hypothesis	**Path**	***β***	***T Statistics***	***P Values***
	Net Promoter Score -> Project Margin	0.217	1.754	*
	Quality -> Reliability	0.770	14.523	**
	Reliability -> Net Promoter Score	0.182	3.811	**
	Safety -> Reliability	0.139	2.380	**

n) not significant, *) Statistically significant at p<0.1, **) Statistically significant at p<0.05

The model also illustrates that supplier "Reliability" has positive influence on the supplier "Net Promoter Score" and the supplier "Net Promoter Score" has positive and significant influence on the "Project Margin". Furthermore, the assessment of indirect paths strongly indicates that the supplier "Reliability" mediates the relationships between supplier "Safety" and the supplier "Net Promoter Score", and supplier "Quality" and the supplier "Net Promoter Score".

Discussion and conclusions

In this study the impact of supplier performance in terms of quality, safety and reliability on project financial result were examined. It was found that there was no direct effect of performance indicators to financial result. Interestingly, it was found that the supplier performance influence logically buyer's recommendation to use the supplier again in future projects and buyer's recommendation had direct effect on project margin. Therefore the adaptation of Net Promoter Score defines the best performing suppliers that are involved in projects with best financial result. This seems to be supplier relationship issue: as more the supplier has received recommendations the more it has been used in projects. Within Transaction Cost Economics (TCE), the research

results indicate the emphasis of long-term supplier relationships with suppliers. Similar type of connection were found in the Carr and Pearson research (1999) where strategically managed long-term relationships with key suppliers was found (possibly) to have a positive impact on the firm's financial performance. These findings lead to an assumption that longer supplier relationships are beneficial for project outcomes. This is not uncommon phenomenon as the trend is somewhat recognized. Supply chain collaboration is noticed to increase in future (Sigh et al., 2018). Also, partnering and shared understanding has been recognized to offer improved construction at least in manufacturing industries (Bygballe et al., 2010). This indicates that at least early supplier involvement has landed into construction industry and project business: the typical transactional business within suppliers is not the only choice for project business.

The outcome of the research implicates that supplier performance drivers must be researched further as this research hypothesis were not found to hold unambiguously. In addition, factors that affects the success of a construction project must be researched and try to test against supplier performance drivers to find out how best performing suppliers are involved in projects with best financial result.

Biodiversity Preservation:
A Case Study of Sustainable Supply Chain Management Practices

Anne Quarshie[1], Asta Salmi[1], Joanna Scott-Kennel[2] and Anni-Kaisa Kähkönen[1]
1 Lappeenranta University of Technology, Finland
2 University of Waikato, New Zealand

Abstract
This paper addresses biodiversity preservation – one of the most critical environmental issues currently facing our planet. Yet, rather surprisingly, biodiversity preservation has received very little attention by management scholars. This paper aims for greater understanding of these issues by focusing on exemplary practices of sustainable supply chain management that specifically address biodiversity. Our four company cases, representing natural resources-based sectors from Finland and New Zealand, show how companies can develop novel sustainability practices to help slow down or halt biodiversity loss in practice.

Keywords: Sustainable supply chain management, Biodiversity, Environment

Introduction

Biodiversity preservation has emerged as one of the most pressing environmental challenges facing the planet today and in the future (Crist et al., 2017; Steffen et al., 2015). While environmental scientists fear that a mass extinction event may already be under way (Ripple et al., 2017), the effects of biodiversity reduction are often invisible or appear disconnected from the activities that caused them, making the issue difficult for firms and individuals to address in practice. In many industries, the negative impacts on biodiversity are greatest at sub-tier supplier level where resources and raw materials are produced or extracted. Hence, cooperation with supply chain partners can provide an important way for firms to tackle the biodiversity loss that results from, or is otherwise connected with, their products and business operations.

While scholars have recently turned increasing attention to other environmental issues such as climate change, biodiversity preservation has, to date, received very little attention in the management research field (Whiteman et al., 2013). This is also the case in sustainable supply chain management (SSCM) research (Carter and Rogers, 2008; Seuring and Müller, 2008), where environmental sustainability has raised considerable interest (Lintukangas et al., 2016; Tate et al., 2013), but with scant focus on biodiversity in particular (Quarshie et al., 2016). To extend findings of previous studies, we adopt a multiple case study approach centered on companies who have taken an active approach to this challenge. In order to analyze company activities in depth, we carry out a qualitative investigation of four companies' SSCM practices that drills down into this issue of potential biodiversity loss. Our empirical material comes from natural resources-based sectors in two national contexts: Finland and New Zealand.

The biodiversity imperative and supply chain management

Biodiversity can be understood as the variability of life on the planet (CBD, 2000). Degradation of ecosystems – more dramatic in the past 50 years than any other time in history – is inextricably linked to human activity, wellbeing and political, economic, and technological change (Reid, 2005). Therefore, loss of ecological diversity becomes a critical issue not only for individuals, national governments and global institutions but also for corporations (Ripple et al., 2017; Salmi and Quarshie, 2017). Biodiversity loss is especially relevant for firms

operating in natural resources-based industries, such as agriculture and forestry, where land conversion, pesticide and agrochemical use, pollution, and modern production practices cause significant threats to ecosystems, habitats and species (Hanski, 2016; WWF, 2012).

The topic of biodiversity seems to bring new actions, trade-offs and impacts to firms' sustainability agendas. Unfortunately, although sustainability is often addressed at a strategic level, there is overemphasis on reporting of visions rather than meaningful change to firms' and suppliers' potentially harmful practices at operational level. These frequently remain entrenched and more challenging to address. Thus, SCM can be an important area for addressing biodiversity issues because of its boundary-spanning role and the firm's influence over suppliers. It centers directly on impacts occurring at operational level.

In the SCM discipline, research on sustainability and responsibility continues to grow steadily (Crespin-Mazet and Dontenwill, 2012; Miemczyk et al., 2012; Quarshie et al., 2016), and there is a fairly comprehensive body of knowledge on how firms may seek to create more sustainable (or less harmful) supply chains (Pagell and Shevchenko, 2014). Nevertheless, relatively few studies aim to generate understanding of more fundamentally different SCM approaches and practices. Amongst such studies, Montabon et al. (2016) present a competing logic to conventional SCM that aims at true, ecologically-dominant sustainability where practices are optimized to eliminate harm with a long-term view, rather than to maximize profits in the short-term. Montabon et al. (2016) further argue that by adopting such radical perspectives companies could develop significantly more sustainable supply chains operating within broader social and ecological systems.

Several previous studies have focused on SSCM practices, and categorized these into internal and external practices based on organizational structure (Gualandris et al., 2014; Vachon and Klassen, 2006), green and social practices based on the dimension of sustainability (Hollos et al., 2012), or according to the nature of the practices (Beske and Seuring, 2014). Based on their literature review, Hoejmose and Adrien-Kirby (2012) state that codes of conduct are the most common way of implementing and extending CSR practices in buyer-supplier relationships. A code of conduct builds on a company's CSR policy and has to be transformed into purchasing principles and supplier selection criteria in order for it to be implemented (Leire and Mont, 2010). Moreover, supplier selection criteria based on sustainability factors have been found to be critical for ensuring sustainability in supply chains (Datta et al., 2012; Roerich et al., 2017). The role of supplier auditing has also been highlighted as a key practice (e.g., Grosvold et al., 2014; Leire and Mont, 2010) and studies have pointed out the importance of adopting international standards both in the buying company and in the supplier company (Vachon and Klassen, 2006). The depth and quality of supply chain relationships are seen as critical facilitators of sustainability in supply chains (Touboulic and Walker, 2015), and recent studies (e.g., Beske et al., 2014) have shown the importance of collaboration in ensuring sustainability. Overall, exploring the different governance mechanisms and relationship types has been one of the main foci of SSCM research (Govindan et al., 2016; Quarshie et al., 2016).

However, current SCM literature discusses sustainability as quite a generic overall concept and more detailed phenomena, like biodiversity preservation, are rarely the focus of SSCM studies. There is also little inquiry into practical examples on how companies manage such sustainability-related phenomena. To further contribute to an understanding of biodiversity management in supply chains, the objective of this paper is to provide illustration of exemplary practice being implemented in the supply chains of four case companies. We focus on natural resources-based industries, namely textiles, forestry, agriculture, and fishing, where biodiversity is a particularly important issue (WWF, 2012, Salmi and Quarshie, 2017).

Methodology

A multiple case study methodology (Yin, 2009) is used in this study. The four case companies represent natural resources-based sectors: textiles, forestry, agriculture, and fishing. As our study focuses on exemplary SCM practices that address the issue of biodiversity, we sampled organizations considered to be leaders in sustainability and biodiversity management. We selected cases from Finland and New Zealand through a sampling process that involved searching through sustainability-related professional associations' websites and other relevant forums as well as asking professional and academic experts in the area of sustainability to suggest exemplary firms as case companies. After identifying such firms, we approached them and proceeded to select and interview knowledgeable informants from these firms regarding biodiversity-related business and SCM practices. Semi-structured interviews in the case companies form the main source of data for this study. Furthermore, we retrieved relevant company documents and other archival materials. Our data analysis and reporting procedures involved us searching for patterns related to biodiversity management, firm practices, and impacts of firm activities in the interview tapes, notes and other materials. We then wrote case descriptions of the companies' activities and practices based on them. The results are described in detail next, as well as summarized in Table 1 in the discussion and conclusions section.

Findings

In this section, we present our four empirical cases, focusing especially on the sustainability practices that these firms have developed to enhance biodiversity in their own operations and those of their supply chains. Each of these firms have been recognized in their efforts to further sustainability through their core business and SCM activities. Their novel practices and strategies for addressing biodiversity reduction offer examples that other firms can follow.

Case 1: Textile Company

The first case company, Finlayson, is a Finnish textile firm with a global supply network. The company's business and products derive from natural resources, with cotton being the most important raw material. The final products are manufactured in audited textile factories in Turkey and other European countries, but the company's supply chains are highly complex and extend to other continents as well.

The most significant biodiversity impacts relating to Finlayson's operations and supply chain occur in cotton production at the sub-tier supplier level. Cotton production causes various (negative) biodiversity impacts attributable to heavy agrochemical use, irrigation (which reduces local, often scarce, water supplies), and habitat loss (WWF, 2012). Moreover, the processing of cotton has considerable biodiversity and other environmental impacts along the supply chain. As in textile supply networks more generally, our case company's raw materials are difficult to trace to the farm-level. Through extensive efforts to improve transparency and traceability, the company has been able to establish that the most important production countries for the cotton used in its products are India, Pakistan, Turkey and the USA.

To decrease the biodiversity (and other sustainability) related impacts of its products, the firm has adopted or developed several SSCM practices. First, improving traceability is important. Second, the company supports full transparency, and has published the list of factories where its products are made, as well as the countries of origin for its raw materials. Further, the company is increasing the percentage of certified (e.g. Faitrade and organic) cotton used in its product portfolio, because otherwise it has very little control over the production methods of sub-tier suppliers. At the same time, it has started substituting cotton for other, more

environmentally friendly raw materials, including linen, wood fibers and recycled materials, where possible and feasible (e.g. considering product attributes and raw material prices). Finally, Finlayson has started collaborating closely with several of its first-tier suppliers in an effort to embed sustainability into extended supply chains. For example, it is launching pilot projects that focus on reducing the detrimental water impacts of its supply chains. Such measures are beneficial to enhancing biodiversity in cotton production, as well as in local communities surrounding producers and processing facilities.

Case 2: Forestry Company

The second case company, UPM, is a Finnish-based forestry company, which has developed an extensive, internationally recognized biodiversity management program as part of its overall sustainability initiatives. The biodiversity program helps to ensure sustainable forestry and maintenance and enhancement of biodiversity in the company's commercial forests.

UPM especially focuses on six aspects of forest biodiversity, and has developed ambitious global targets to guide its local activities and efforts in these areas. The elements are: 1) Native tree species, 2) Deadwood, 3) Valuable habitats, 4) Forest structure, 5) Water resources, and 6) Natural forests. The biodiversity program has been found to have had a broad range of positive impacts in these areas, including the diversification of tree species, an increase in the amount of deadwood in forests and the number of protected forests, the identification and protection of valuable habitats, changes in the structure of forests, and improved impacts on water resources.

The company has also developed multiple best practices for sustainable forest management and harvesting, as well as wood sourcing. The forest management and harvesting practices are not only piloted and adopted in forests owned by the company itself, but also diffused to privately-owned forests through long-term (forestry services) contracts and supplier development. Further, the company promotes sustainability certification standards to private forest owners in an effort to help raise industry standards. Overall, through such forestry management and wood harvesting practices, a wide range of biodiversity impacts get addressed in forests. For example, it is now considered essential to leave deadwood also in commercial forests, as well as to identify those sites and habitats that will not be exploited or touched at all. Moreover, the firm promotes mixed forests where several tree species are grown together, because biodiversity is richer in such forests than in monoculture forests.

As for UPM's sustainable sourcing practices, it only accepts legal and controlled wood, and will not purchase wood from rainforests or from plantations that are located on converted forests. Further, its 2030 supply chain sustainability goals include being able to trace 100 % of the raw materials it buys, and sourcing all of the raw materials from suppliers covered by the supplier code. As for progress made to date, the company has already reached its traceability target, and 94 % of the suppliers (measured in contract value) have signed the code of conduct.

In addition to the forestry management and sourcing practices, UPM has developed two additional sets of practices that are key components of the biodiversity program. First, the firm has initiated a broad range of collaborative stakeholder and partnering efforts related to biodiversity preservation. Indeed, the company considers a wide range of supply chain members (e.g. customers and suppliers) and non-traditional partners (e.g. NGOs, government agencies, communities, researchers, and the media) to be critical partners in the work for biodiversity. Second, the company has participated in voluntary activities related to the protection of forests, including the establishment of a new national park. Because of its extensive efforts to protect biodiversity, UPM is widely considered a sustainability leader in this area in Finland and internationally.

Case 3: Agriculture Company

Soilfood is a Finnish agriculture company that seeks to provide farmers a comprehensive portfolio of recycled fertilisers, soil amendments, and ecological farming training and guidance. Its products and services are designed to help farmers to decrease the negative environmental impacts of farming, while increasing crops, reducing production costs, and improving profitability. The company is an SME firm with 15 staff and an annual turnover of over 4.5 million euros.

Soilfood's business model is based on circular flows, as it uses side-streams and by-products from the forestry and bioenergy industries as raw materials. From these locally sourced raw materials, it produces ecological, recycled fertilisers and soil amendments for sustainable farming, in particular, which suggests that biodiversity is central to the company's business model. Suppliers have partnered with the company in order to be able to effectively dispose of production side streams and by-products in an environmentally friendly way. Because its upstream supply chains are based on circular flows or near sourcing of (recycled) inputs, the company's operations are always highly local.

Soilfood seeks to address biodiversity impacts in its downstream supply chain especially through selling ecological fertilisers and soil amendments to its customers (individual farmers). Indeed, the products it sells help to add organic matter to the soil in farmlands, which helps to create healthier ecosystems and to increase the diversity of microbes, algae, fungi, insects, and other animal and plant species below and above-ground. In addition, the training and guidance that the company provides the farmers concerns the choice of species and other environmentally-friendly farming practices, for example. These two practices can considerably increase biodiversity on farmlands. Overall, the company hopes to participate in the transformation of the agriculture sector, by helping to mainstream a new biodiversity paradigm, where a larger number of crops are grown together, using ecological farming techniques and fertilizers. To try to achieve such a transformation, the company seeks to ensure that its products are easy and affordable for farmers to purchase and apply, and that the farming techniques help to maintain farm productivity and profitability.

Case 4: Fishing Company

New Zealand's seafood industry is described as world-leading (www.mpi.govt.nz/protection-and-response/sustainable-fisheries/) thanks to the establishment of a quota management system (QMS) twenty years ago. As the largest quota holder, the case company Sanford has embedded sustainability across all facets of operations. This is fundamental to its success and continuous value creation – from reputational to bottom line benefits. Sanford's role in the QMS by scale and diversity of species involved (encompassing 87 species and 313 fish stocks) is notable, being uncommon in fisheries elsewhere (Sanford, 2016, pp. 86-87).

Maintaining healthy oceans through sustainable fishing is key to Sanford's business model and one of the CEO's core messages is that the seafood industry has to be sustainable to survive (Sanford, 2016; Hunter, 2017). The company believes strongly that biodiversity of marine resources, as part of a wider sustainability focus, has a direct or indirect impact on Sanford's ability to create, preserve or erode economic, environmental or social value for itself, its stakeholders and society, at large. Sandford's business model focuses on value creation – transitioning from a traditional commodity-driven high volume business, to creating more value for every kilogram of raw material produced, which means making more money from each fish sold rather than selling more fish.

Sanford integrates a number of sustainability initiatives throughout its operational supply chain consisting of 474 independent sharefishers, 50 fishing vessels and seven processing sites.

Initiatives include zero tolerance for overfishing, underreporting and discarding catch; avoiding fishing areas with young fish stocks; electronically monitoring catch by species and size to preserve breeding capacity and diversity; and prohibiting use of fish aggregation devices (FADs) in tuna fishing (Sanford, 2016). Further, Sanford has invested over NZ$200,000 into developing and installing cameras in fishing vessels in order to monitor catch and processing activities on board. Traditional fishing methods have also been adapted to minimise accidental by-catch, particularly of protected species, such as the New Zealand sea lion (www.sanford.co.nz/sustainability/environmental-impact/). In partnership with two other fishing companies (Moana New Zealand and Sealord), the Ministry for Primary Industries (MPI) and scientists from Plant & Food Research Precision Seafood Harvesting (PSH) technology is being developed and may eventually eliminate traditional trawl nets (www.sanford.co.nz/sustainability/precision-seafood-harvesting/).

Sanford operates 210 aquaculture farms across New Zealand. Its salmon farms are regularly relocated to limit their environmental impact, and the company works closely with suppliers to ensure protein levels in fish feed are optimal, then controls feeding through underwater camera monitoring to prevent feed loss and nutrient enrichment in the ocean. In 2015, joint development by Sanford and MPI saw the establishment of a pilot-scale mussel hatchery ($SPAT_{NZ}$), which aims to produce mussel spat to reduce pressure on, and variability of, wild spat from New Zealand's unique green-lipped mussel population. Selective breeding for commercially desirable traits in a controlled environment, and ensures safe and sustainable supply of spat, thus maintaining security of supply and biodiversity in the population.

Initiatives for protecting and enhancing the environment extend beyond the sea to encompass Sanford's whole value chain including staff, suppliers and a diverse range of stakeholders. Staff are encouraged to think innovatively and share ideas for potential sustainability initiatives, including taking action, for example, fishers who cut nets to release dolphins but lost the entire catch. Suppliers are evaluated on sustainability criteria to ensure participation and commitment to sustainable development principles, reduction of adverse impacts on the environment through use of biotechnologies, resource efficiency and waste production (for example, in relation to salmon feed). Continuous improvements to the eco-efficiency of the organisation include energy, emission and waste reduction and a zero fish waste policy.

Through stakeholder collaboration and consultation Sanford protects endangered species, including the threatened black petrel, by making vessels more 'seabird-smart'. Skipper training and mitigation devices have been installed on all vessels to keep birds at bay when landing catch. Working collaboratively with fishing company, Moana New Zealand, and WWF-New Zealand, Sanford has helped ensure Maui-safe fishing in the rare dolphin's habitat along the west coast of the North Island. Sanford is active in a number of industry working groups that advocate and support sustainable principles and the CEO co-chairs the business-government Natural Resources Sector (NRS) CEO group, which aims to improve the productivity of New Zealand's resource-related industries, while reducing their environmental impact.

Sanford prides itself on its leadership in New Zealand fishing with multiple accreditations and awards relating to their sustainable aquaculture practices and reporting, including 14 years of ISO14001 Environmental Management System certification, and Best Aquaculture Practices (BAP, Big Glory Bay King Salmon and Greenshell™ mussels). The company conforms to the Marine Stewardship Council (MSC) Chain of Custody requirements and follows international, professional benchmarks to promote robust and sustainable processes throughout the supply chain. The MSC chain-of-custody certification provides a scientific method for assessing ecologically sustainability across the supply chain and Sanford continues to engage with, and support, ongoing efforts to achieve certification for the major large volume deepwater species.

Discussion and conclusions

The analysis we presented above of the efforts of the four case firms in addressing biodiversity reduction in supply chains is intended to further our understanding of novel practices and other firm actions in this area. The relevance of our case selection is apparent when we consider that all firms operate in global industries known for adverse environmental impact on biodiversity (WWF, 2012; Hanski, 2016). Yet, our results suggest that one unifying aspect across the cases is that all have integrated biodiversity considerations into their overall sustainability and business strategies, and approach biodiversity as an integral part of their business operations. Further, sustainability extends beyond the company boundaries to incorporate supply chain participants and in some cases, governmental agencies, NGOs, and industry participants.

Table 1 presents a summary of key actions taken by the firms to promote (operational) sustainability, and more specifically, to enhance biodiversity in their supply chains. These include an ecological focus in terms of resource usage and waste, certification, and reporting of sustainability measures that raise stakeholder awareness. Although the impacts of their actions at operational level are positive, they are unlikely to make significant difference beyond the local sphere without wider industry participation. However, we can also see boundary spanning activities that encourage, engage and enforce supplier and wider industry participation and collaboration in improving sustainability and biodiversity in business practice. Industry engagement is not only reinforced through supplier choice and development, but also active involvement and leadership in industry initiatives and development of specialist technology. The importance of supply chain and industry collaboration, therefore, cannot be overstated as positive joint action reinforces change and enlarges impact beyond the boundaries of the firm.

Another important action is transitioning toward fundamentally different business models that emphasize sustainability principles (e.g. value over volume, circular economy and biodiversity paradigm). It remains to be seen whether firms embracing such business models are sustainable (relative to other firms) in terms of profitability in the longer-term. Complementarity rather than trade-off between ecological goals and profitability is imperative to the success of such models. Encouragingly, we find that our case firms favored a medium- to long-term approach toward biodiversity preservation. Casual distance between actions and long-term outcomes is likely to continue to impede attempts to measure and to monitor individual firm impact beyond the local sphere, hence the imperative for wider participation and transition to new business models embracing sustainability.

While this study is just another step toward understanding corporate biodiversity initiatives, it makes a number of contributions to existing SSCM research and managerial practice especially in the area of biodiversity management. First, our study can advance understanding of exemplary SSCM practices developed by firms operating in natural resources sectors that aim to address the issue of biodiversity protection in local communities along supply chains, under water, in forests and on agricultural lands. Second, these cases show innovative practices and concrete actions and in doing so, demonstrate the diversity of active response possible to address biodiversity reduction. As biodiversity preservation has so far received only limited attention by managers, particularly at the operational level, we expect our study to further understanding of how firms may tackle the issue in practice. Finally, with this empirical study we aim to bring the topic of biodiversity loss more centrally into the agenda of SSCM researchers, contributing to more scholarly work in the area. Future studies are needed in other industries and countries. Moreover, we have concentrated on practices from the companies' perspective but evidently we need richer first-hand understanding of how other actors and stakeholders act on this environmental challenge.

To conclude, this study shows how companies can develop novel sustainability practices that can help slow down or halt biodiversity loss in practice and thus act as part of the solution rather than (only) part of the problem.

Table 1: Summary of findings across cases

Sector	Textiles	Forestry	Agriculture	Fishing/Aquaculture
Key actions to promote sustainability at strategic and operational levels	Embedding sustainability in core business Sustainability reporting Reducing greenhouse gases Reducing waste Reducing water impacts	Embedding sustainability in core business Ambitious sustainability targets Sustainability reporting Biodiversity program	Business strategy based on sustainability Brand based on sustainability Embracing biodiversity paradigm	Embedding sustainability in core business Value rather than volume Eco-efficiency and zero waste Sustainability reporting
SSCM practices to enhance biodiversity in supply chain	Traceability Supplier management and relationships Certification Industry collaboration Raw material choice	Traceability Sustainable forestry management and harvesting practices Supplier code of conduct Supplier management and relationships (e.g. long-term contracts) Certification Stakeholder collaboration	Selling ecologically friendly products to farmers Training farmers Use of recycled raw materials (e.g. forestry side-streams)	Supplier management and relationships (e.g. commitment) Technological development Industry collaboration Benchmarking MSC Chain of Custody (Re)location of activities
Impacts at operational level	Decrease in use of toxic chemicals (through certification and raw material choice) Improved water impacts in ecosystems	Increase of deadwood & number of plant and animal species in forests Impacts on forest structure Impacts on valuable habitats Improved water resources Increase in natural forests	Enhanced soil quality Increase in plant and animal species on farmlands	Preservation of endangered species Minimisation of by-catch and under-size fish Enhanced breeding Controlled feeding
Long or short term (profit oriented) view of sustainability	Medium to long-term	Medium to long-term	Long-term	Medium to long-term

Abstract
Micro-retails in neighborhoods are still the main marketing channel for food and beverage items in Latin America and Africa. Neighborhoods of low income population present social challenges for the channel. For instance, small shop owners usually lack the permits to operate the business, get highly leveraged with informal money lenders, and have administrative problems in managing the incomes and costs of the businesses. Some food and beverage manufacturers are aware of this situation and are undertaking initiatives to enhance shop owners' administrative and leadership skills to increase the likelihood of continuity of these small businesses. This paper explores how focal firms can support micro-retailers to continue with their business in the long term. Specifically, this paper aims to answer the following research questions: 1) how is supply chain partners' continuity conceptualized in the context of urban BoP micro-retailers?; and 2) does capability-building interventions by focal firms enhance BoP micro-retailers continuity? The paper contributes to the literature of socially-responsible supply chains by improving our understanding on how distribution practices contribute to making supply chains sustainable.

Keywords: Social sustainability; Business continuity; BoP markets

Introduction

Small shops in neighborhoods are still the main marketing channel for food and beverage items in Latin America. Although the internet channel and large-area retailers have increased their participation, sales in neighborhood shops still account for about 50% of the food and beverage category (SCALA, 2015). This proportion is even higher in urban low-income neighborhoods, some estimations indicate that above 80% of customers in this segment purchase food and beverage items in neighborhood shops (SCALA, 2015). Yet, shop owners in low income neighborhoods are exposed to social, and environmental risks; and lack the resources or capabilities to grow their businesses for enhancing the economic sustainability of the supply chain. For instance, neighborhood shop owners are exposed to high social and environmental events such as: drug trafficking, robbery, homicides, and floods. In Latin America, crime rates and robbery incidents are usually higher in low income neighborhoods (Worldbank, 2014). Also, in developing countries low income population neighborhoods usually started as invasions, in risky settings such as hills, near rivers or mangles. As cities grow infrastructure is built around these areas, but natural risks, such as floods or landslides, remain (Moloney, 2017).

Additionally, neighborhood shop owners in urban low-income settings also lack the knowledge, information, or skills to make their businesses grow. For instance, most of them lack the permits to operate the business, get highly leveraged with informal money lenders, have administrative problems in managing income and costs of the business, and lack access to credits from local banks to invest in the infrastructure of their shops. Hence, food and beverage manufacturers should address the issues of this distribution channel to secure the generation of income in the long term.

Some food and beverage manufacturers are aware of neighborhood-shop owners' situation. For instance, AB InBev, has a training program for neighborhood-shop owners in several countries of Latin America. The training program aims to develop administrative and leadership skills of neighborhood shop owners (Jenkins, 2015). The results of the program indicate that shop owners have increased their profits and the orders made to AB InBev. In a similar way, Grupo DIFARE, a leading pharmaceutical distributor in Ecuador, has a training program for their franchisees' employees of *Farmacias Comunitarias*, a franchise that sells medicines and OTC (over the counter) products to low income population (DIFARE, 2015). However, there is scant research about how firms can enhance the business sustainability in the downstream supply chain of urban low-income markets.

Previous research in SCM literature has suggested the distribution in the Bottom of the Pyramid (BoP) as a promising research area (Sodhi and Tang, 2014). Sodhi and Tang (2014) suggested to focus on the design of distribution networks for rural and dispersed consumers, but the situation of distribution for neighborhood shops in large cities is different because these areas are highly dense. Additionally, low income urban areas have infrastructure challenges for efficient last-mile logistics, such as insecure environment for distributors, narrow and bad quality roads for trucks (Merchan et al., 2015). On the other hand, there are node-level challenges for the micro-retailers (e.g. social and environmental risks, and lack of resources). Consequently, there is little knowledge on how focal firms in the supply chain could enhance the business continuity of micro-retailers in low-income urban regions.

This paper builds upon the conceptualization of supply chain partners' continuity, which previous studies suggest it is a central concept of sustainable supply chain management (Beske and Seuring, 2014; Pagell and Wu, 2009). This concept emerged from the study of upstream sustainable supply chain management. Yet, this concept can be relevant in the downstream of BoP supply chains, because of the dependence of food and beverage manufacturers on micro-retailers for introducing their products in urban low-income population. Furthermore, previous studies in social sustainable supply chains suggest that capability-building interventions are effective to enhance the social sustainability of the upstream supply chain (Distelhorst et al., 2017). In this regard, it is proposed that capability-building interventions might be useful for other contexts in socially sustainable supply chains (Lee and Tang, 2017). Thus, this paper explores how business continuity is conceptualized in the context of urban low-income population markets; and assesses whether capability-building interventions (e.g. training to micro retailers in inventory management, bookkeeping, and leadership) enhance micro-retailers' business continuity.

This paper contributes to the literature of socially-responsible supply chains (Lee and Tang, 2017; Sodhi and Tang, 2014) by studying social supply chain practices in the context of BoP distribution. The results of this paper would enhance our understanding of the types of practices that supply chain managers can undertake to make their supply chains truly sustainable.

Literature review

Supply chain partners' continuity and sustainable supply chain management

Sustainable supply chain management (SSCM) refers to the cooperative approach between firms and its stakeholders for managing the material, financial, and information flows to achieve goals in the triple bottom line of the focal firm (Seuring and Müller, 2008). In this regard, truly sustainable supply chains are the ones whose operations have at least no negative effect on the environment and society (Pagell and Shevchenko, 2014).

Previous studies have proposed supply base continuity as a core concept within SSCM (Beske and Seuring, 2014; Pagell and Wu, 2009). Pagell and Wu (2009) proposed the concept of supply base continuity, which refers to buying firm's activities to support

suppliers to stay in business in a manner that allows them to thrive, innovate and grow. This concept includes decommoditization, supplier development programs, reducing supplier risks, and transparency. Furthermore, Beske and Seuring (2014) conceptualized continuity as a critical category of SSCM. The category contains the following issues: supply chain partner development, long-term relationships, and supply chain partner selection. The research about continuity within SSCM is scant, and most of it has been conceptual or case based research about the upstream relationships in the supply chain. To the best of our knowledge, there has not been studies about supply chain continuity in the downstream side of supply chains.

Socially responsible supply chain studies also indicate the relevance of supply chain members' continuity. Socially responsible operations refer to the study of operations management through the lens of corporate social responsibility (Sodhi, 2015). This means that operations analysis should take into consideration the expectations, utility, resources and capabilities of their stakeholders. Furthermore, others studies have suggested that socially responsible operations in the context of emerging economies is a promising research avenue to enhance our knowledge of operations management (Lee and Tang, 2017; Tang, 2018). The main theme of socially responsible supply chain literature is the creation of economic and social value through the incorporation of people living in the Base of the pyramid (BoP) to supply chains as suppliers or distributors (Sodhi and Tang, 2014). Therefore, supply chain partner continuity is also a relevant construct for this literature because it could provide insights on how focal firms could sustain the relationships with suppliers or distributors in the BoP.

The BoP business literature proposes that firms can be more profitable by serving the population which lives with less than 2 dollars (PPP adjusted) per day. However, this approach has been criticized because poor people are unable to develop capabilities that improve their economic conditions by purchasing affordable products and services (Karnani, 2007). Some scholars suggest that a better mechanism is to develop the capabilities of low-income population by integrating them in supply chains as suppliers or distributors. This observation bridges the literature of BoP business with SSCM. At this point, the common ground between these streams is the concepts of supply chain partner development; trustworthy, long-term relationships between multinationals, and BoP actors; and partner selection (Gold et al., 2013; Khalid et al., 2015). Both BoP business and SSCM fields of study emphasize the need to understand how focal firms in a supply chain develop the capabilities of other supply chain actors to stay in business for the long term.

Firms in the food and beverage industry must address several issues to be sustainable. For instance, the Global Reporting Initiative suggests that materials sourcing standards for biodiversity, soil management, GHG emissions, and water; packaging, energy consumption, waste management, consumer health and safety risks, local communities development are material aspects for this industry (GRI, 2013). Supply chain partner continuity is an integral mechanism through which focal firms in the supply chains generate socio-economic benefits to local communities. Since urban neighborhood shops is critical for the sustainability of food and beverage companies in emerging economies, this paper focuses on how focal firms contribute to neighborhood shops continuity for supply chain sustainability.

Distribution in the BOP context

Research initiatives in which the BoP population is incorporated as suppliers or distributors constitute an avenue for future research because most of previous studies have focused on initiatives in which the poor population were targeted as consumers (Kolk et al., 2014). Furthermore, Kolk et al (2014) also suggest that there is imprecision in the economic threshold for defining BoP population. Poverty lines vary if they are measuring rural or urban

population, or if they correspond to rich or poor countries. The World Bank has proposed the international poverty line at USD 1.90 PPP adjusted (2011 dollars), which is the measure for counting the people who live in extreme poverty (Ferreira et al., 2016). Furthermore, from 2017 the World Bank would also report the median poverty lines of middle income countries, and upper-middle income countries because achieving the same set of capabilities in different countries might require a different set of goods and services (Ferreira and Sanchez, 2017). Consequently, BoP business studies should specify the poverty line under which is the population of study.

There are few studies about socially sustainable or responsible supply chains (Beske and Seuring, 2014; Lee and Tang, 2017), and most of the research elaborated in this field have concentrated in the incorporation of BoP population as suppliers. On one hand, there are studies that focuses on suppliers' compliance to social standards, and on the monitoring schemes implemented by focal actors in the supply chain (Zorzini et al., 2015). On the other hand, there are studies adopting the collaboration approach with suppliers for social purposes. For instance, Distelhorst et al (2017) found that suppliers' training and education programs enhance the compliance to social standards. In this regard, capability-building interventions are a useful mechanism to create value, in the win-win sense, in socially sustainable supply chains (Lee and Tang, 2017).

Although previous research provides anecdotal evidence on how capability-building interventions are applied in sustainable distribution or micro-retailers programs (Lee and Tang, 2017; Tang, 2018), it is unknown whether this type of downstream supply chain practices contribute to micro-retailers' business continuity in urban low income neighborhoods. Thus, this paper follows an exploratory approach and aims to answer the following research questions: 1) how is supply chain partners' continuity conceptualized in the context of urban BoP micro-retailers?; and 2) does capability-building interventions by focal firms enhance BoP micro-retailers continuity?

Research design/ Methodology

This paper uses field work to explore the relationship between capability-building intervention and micro-retailers' business continuity. The research setting is the local program of a multinational beverage manufacturer in Ecuador. In 2017, the company sold about 500 millions of USD. 70% of the company's sales occur in the micro-retail marketing channel. The company distributed to approximately 100.000 micro-retails in Ecuador, and a high proportion of them are in low-income neighborhood.

This study only focuses on micro-retails that are in low-income neighborhood of Guayaquil. We chose Guayaquil because it is the largest city in Ecuador, and it has more than 50% of micro-retails in the whole country. The study has two stages. First, we undertook a qualitative study to understand the dynamics between the micro-retail and its environment. The driving question was to understand what risks and resources inhibit/enhance the business continuity of micro-retailers. The second stage of the study contains a survey to micro-retailers that have received the training program and micro-retailers in the same neighborhood that have not received the training program. Micro-retailers were not randomly chosen by the beverage manufacturer, so we have a quasi-experimental design of non-equivalent groups.

The qualitative part of the research was undertaken following a nested case study approach with two units of analysis. The first unit of analysis is the neighborhood, which is an area of 40-150 hectares delimited by the company. We chose three neighborhoods in terms of their sizes. A large (150 Ha) neighborhood with high density and commercial activity; a medium size neighborhood with high density and commercial activity; and a low size neighborhood with high density and commercial activities. In these neighborhoods live

low-income households, but there is heterogeneity between the inhabitants of the neighborhoods. The second unit of analysis is the micro-retail. We chose 4 to 6 retails in each neighborhood for in-depth interviews with the owners of the shop. The sampling of micro-retailers was based on the distance to main streets, the sales volume, and whether the micro-retailer entered in the training program. A total of 16 micro-retailers were interviewed.

Second, the authors would conduct a large-scale survey of micro-retailers in 5 low income neighborhoods of Guayaquil. The survey would gather data on the competences, risks, permits for the shop, and compliance with the law regarding the sale of alcohol, cigarettes, and the suggested prices by the manufacturer. Furthermore, secondary data about socioeconomic variables of the neighborhood would also be gathered. The secondary data would come from the National Socioeconomic Survey of Households. Finally, geographical data from the micro-retailers would also be obtained.

The empirical setting is the following. From May to October 2017 the beverage company invited about 4000 micro-retailers to a training program. The training program consisted in development of administrative skills (e.g inventory, bookkeeping), customer service, exhibition and product assortment to generate sales, and information about the procedures for obtaining the permits for the micro-retail. The training program consisted in three visits made by a trainer (about 1 hour per visit) in which the trainer went through the content and performed exercises to develop the skills. In addition, during the first visit the trainer delivered a book, a calculator and information about how the permits should be obtained. Also, during this visit the trainer performed an analysis of the status of the micro-retail in order to suggest improvements along the training program.

Since the company invited retailers who had already belonged to a loyalty program, we would perform a quasi-experimental design of non-equivalent groups (Shadish et al., 2002). A propensity score would be computed based on the years of experience of the micro-retailer, the density of retails around the micro-retailer, the distance to main roads, and the volume of sales. Then, based on the propensity score trained micro-retailers would be matched with non-trained micro-retailers.

Königstraße 5, 70173 Stuttgart, Germany
E-Mail: MRusch@ipri-institute.com, Phone: +49 (711) 6 20 32 68-80 11

Summary
Manufacturing companies often possess incomplete information regarding the products they purchase. Information and communication technologies (ICT) enable companies to share greater quantities of information with suppliers in a short period of time, giving them an opportunity to overcome such problems. Based on Organizational information processing theory (OIPT), a theoretical framework is developed, explaining the influence of ICT usage on procurement risk. Two conclusions are drawn from this paper. First, ICT usage influences procurement risk indirectly by effecting the amount of information shared. Second, the strength of this effect depends on specific characteristics of the procurement situation.

Key words: information sharing, procurement risk, OIPT
Submission category: working paper
IPSERA submission ID: 36

Context and research question

The information sharing problem

The impact of a manufacturing company's procurement activities on overall performance has increased substantially over the past decades. The main reasons for this are high outsourcing rates and the correspondingly high amount of products purchased by such companies. As a consequence, manufacturing companies need to increase the cooperation with suppliers, which at the same time increases supply chain complexity. This in turn leads to the occurrence of procurement risks, which may prevent a purchasing company to fulfill its overall procurement targets: receiving the right amount of products and services at the right quality and to the right time while paying the right price (Wannenwetsch, 2014; Schuh and Hoppe, 2013; Kreuzpointner and Reißer, 2006).

Manufacturing companies often possess incomplete information regarding quantity, quality, delivery date and price of the products they purchase, resulting in unachieved procurement targets (Busse et al., 2017). Extensive information sharing with suppliers might be a solution to overcome procurement risk (Busse et al., 2017). Information sharing within a supply chain is implemented using information and communication technologies (ICT) (Gleich et al., 2016), which enable companies to share greater quantities of information with suppliers in a short period of time and generally lead to improved procurement activities (Gardenal, 2013; Eei et al., 2012).

A high degree of information sharing might, however, not be appropriate in every procurement situation (Kolmykova, 2016; Stoll, 2008). On the one hand, extensive information sharing with suppliers requires substantial investments in ICT. On the other hand, companies ought to consider different security aspects, especially when sharing sensitive data within a supply chain. Hence, a high degree of information sharing with suppliers should only be established in such procurement situations, in which procurement risk can actually be decreased. The degree of information sharing a company engages in is dependent on specific characteristics of the procurement situation (Kolmykova, 2016).

Research question and motivation of this paper

The aim of this paper is to develop a theoretical framework that explains the influence of ICT usage on procurement risk. By doing so, this paper answers the following research question: How does ICT usage influence procurement risk?

The motivation of this paper is to give detailed view on ICT usage in supply chains by analyzing how the use of different kinds of ICT influences the amount of different types of information shared and how, in turn, this influences procurement risk.

Literature review

Information sharing in supply chains

Information sharing has become one of the major topics within supply chain literature. The topic is often discussed in terms of supply chain integration, in which information sharing is considered one of three integration aspects, the others being operation and relation (Leuschner et al., 2013). Supply chain integration literature generally discusses the level of integration between different members of a supply chain and its effect on firm performance. Literature mostly depicts a positive relation between supply chain integration and different company and supply chain performance metrics such as efficiency and effectivity (Leuschner et al., 2013; Schoenherr and Swink, 2012; Flynn et al., 2010; Yeung et al., 2009; Wang et al., 2006).

Information sharing, as part of supply chain integration literature, focuses on how members of a supply chain communicate, which types of information they share with each other and which effect this has on performance (Srinivasan and Swink, 2015; Zand et al., 2015; Montoya-Torres and Ortiz-Vargas, 2014; Huo et al., 2014). Thereby, different types of information that can be shared are considered and analyzed, mainly in terms of dyadic supply chains (either from a buyer's or a supplier's point of view).

However, while analyzing the effects of information sharing on performance metrics, the focus usually lies on single types of information, e.g. inventory levels or demand forecasts. More recent literature reviews give a broad overview of types of information that can be shared. Huang et al. (2003) review literature focusing on the impacts of sharing production information on supply chain dynamics. Montoya-Torres and Ortiz-Vargas (2014) review literature regarding possible types of information analyzed in literature, identifying six key types of information that can be shared (related to product, process, inventory, resource, order and planning), indicating that literature should focus more heavily on the effects of full information sharing. To the best of our knowledge, no paper incorporates all relevant types of information that can be shared. Moreover, information shared by the buying as well as the supplying side needs to be considered in such analyses simultaneously.

ICT usage

Related to aspects of information sharing in supply chains is literature regarding ICT usage. The focus hereby lies on how information is actually shared amongst members of a supply chain. Again, different aspects of this are considered in literature. One major topic is which technologies are used to share information with respect to different organizational settings (Schöning, 2006; Mieke, 2006). Another important area of research is how ICT usage adds value to a company (Kohli and Grover, 2008; Melville et al., 2004). Known as the „productivity paradox", a large number of studies shows that investments in ICT have no positive influence on firm performance (Zimmermann, 2013; Schryen, 2010; Brynjolfsson, 1993). However, more recent studies usually confirm that there is indeed a positive influence of such investments on firm performance, even though the implementation of ICT is associated with substantial costs (Zimmermann, 2013; Tallon and Pinsonneault, 2011; Gorla et al., 2010; Stratopoulos and Dehning, 2000; Dedrick et al., 2003; Melville et al., 2004).

ICT usage by a company's procurement function is generally discussed under the topic of e-procurement (Schuh et al., 2013; Essig and Arnold, 2001; Stoll, 2008). Since the

implementation of ICT is associated with substantial costs, scholars try to depict in which ways this has a positive influence on the performance of the procurement function. Examples are increased transparency due to higher information quality and quantity, or increased overall efficiency due to shorter lead times (Gardenal, 2013). In general, the influence of ICT on procurement performance is regarded as a positive one (Eei et al., 2012; Croom and Brandon-Jones, 2007; Presutti, 2003; Yen and Ng, 2003), even though most authors don't differnciate between effects of different types of supply chain technologies. Moreover, the degree of ICT usage as well as the degree of information sharing a company engages in is dependent on the procurement situation (Kolmykova, 2016), which is generally not considered in recent analyses.

Research gap

As discussed above, recent literature shows that information sharing as well as ICT usage have gernerally a positive effect on supply chain performance. However, no study incorporates all relevant types of ICT and types of information that manufacturing companies share with each other. In this sense, this study measures how using different types of ICT effects the degree of information sharing for different types of information. Thereby, a broad number of types of information is considered. Finally, the influence of sharing these different kinds of information on supply chain performance is measured. As a measure of performance, the reduction of risk is used, which is discussed later. The overall aim of this research is to extend existing literature by giving a complete picture of ICT usage and information sharing amongst manufacturing companies and their influence on supply chain performance.

Development of a theoretical framework

Organizational information processing theory

The theoretical background informing this paper is Galbraith's (1973; 1974) organizational information processing theory (OIPT), which explores and stresses the importance of information processing in organizations. By doing so, Galbraith draws one important conclusion from contingency theory, namely that there is no one best way to organize information sharing amongst organizations, but that the organization of information processing is rather dependent on organizational characteristics (Galbraith, 1973). When conducting organizational tasks, companies face uncertainty, which Galbraith defines as "the difference between the amount of information required to perform the task and the amount of information already possessed by the organization" (Galbraith, 1973). An effectively organized information processing helps to minimize uncertainty (Srinivasan and Swink, 2015).

In order to reduce uncertainty, companies need to reduce the gap between their information processing needs and their information processing capabilities. There are two strategies to align these two: A company can either reduce the amount of information required, hence lower the information processing needs, or it can increase its information processing capabilities (Zand et al., 2015; Qrunfleh and Tarafdar, 2014; Wong et al., 2011). Information processing capabilities can generally be increased by using ICT (Premkumar et al., 2005).

OIPT has different implications for this research. First, according to OIPT, information sharing decreases uncertainty and risks associated with uncertainty. With regard to a company's procurement activities, risk is reflected in a deviation of one of the following: quantity, quality, delivery date, and price. Information sharing itself is two-sided and consists of information provided by the buyer and information provided by the supplier. Both types of information flow affect procurement risk. Second, the use of information systems, either by the buyer or by the seller, affects information sharing. Third, and in line with contingency theory, the effects of ICT usage and information sharing procurement risk are moderated by the amount of uncertainty related to a specific procurement situation. According to OIPT, the degree of uncertainty depends on two factors. These are subunit task characteristics, represented by the

complexity of the procurement task, and the subunit task environment (Tushman and Nadler, 1978; Galbraith, 1973; Schoenherr and Swink, 2012).

Network theory

Even though OIPT discusses information processing problems in general, its focus lies on internal information processing problems and information sharing within a supply chain is not explicitly explained (Busse et al., 2017). Hence, while subunit task characteristics are explained by OIPT as an internal source of uncertainty, the theoretical basis of this research needs to be extended by a theory that discusses subunit task environment with regard to supply chains. Consequently, network theory is applied in order to explain the relationship between different entities (people or organizations) and the impact of these relationships (Ebers and Maurer, 2014; Granovetter, 1983). Network theory identifies the dominant factors influencing the behavior of organizations as well as the outcome of that behavior. These factors are the strength of the partners' relationship and the structural position of each partner within the network (Ebers and Maurer, 2014; Newbert et al., 2013; Adler and Kwon, 2002).

Network theory has different implications for this research. As discussed before, network theory describes the characteristics of the subunit task environment. Subunit task characteristics and subunit task environment constitute the characteristics of the procurement situation. In line with OIPT, the effects of ICT usage and information sharing on procurement risk are moderated by these factors. Subsequently, the term "task characteristics" is used to describe the procurement task, while subunit task environment is divided into the terms "relationship characteristics" and "environmental characteristics" (which describes structural position of each partner within the network).

Development of the theoretical framework

Before the overall theoretical framework is developed, procurement risk needs to be explained in more detail. Risk can be defined as a deviation from target values (Diederichs, 2013). As discussed before, in this analysis procurement risk is defined as not fulfilling a company's overall procurement targets: receiving the right amount of products and services at the right quality and to the right time while paying the right price. Hence, risk means a deviation from the defined taget quality, quantity, delivery date and price of the purchased goods (Zitzmann, 2015; Thiemt, 2003). In other words, in this study risk is defined in terms of supplier performance: this study suggests that increased ICT usage reduces the risk of deliveries by the supplier that don't meet the agreed upon conditions.

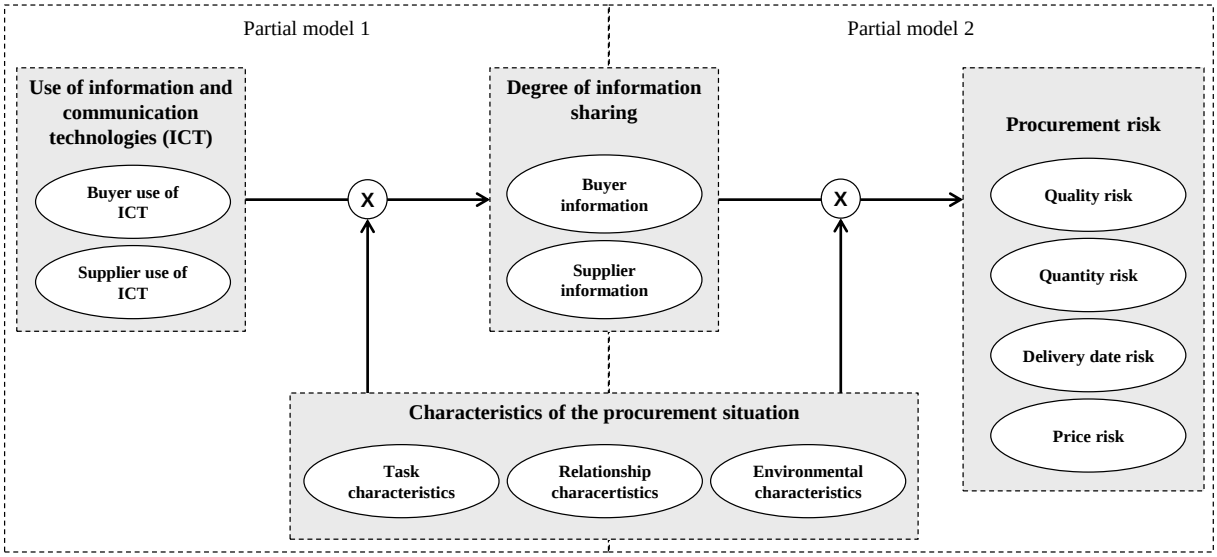

Figure 1: Theoretical framework

Figure 1 shows the theoretical framework which is derived from OIPT in combination with network theory. As discussed by OIPT, ICT usage has an indirect effect on procurement risk, as it influences the degree of information sharing. The degree of information sharing directly influences procurement risk. As a consequence, the framework is divided into two partial models, both of which need to be analyzed with regard to the characteristics of the procurement situation. As the theoretical framework shows, ICT usage influences procurement risk indirectly by effecting the amount of information shared. Moreover, the strength of this effect depends on specific characteristics of the procurement situation.

Construction of measures

Independent variables

As the theoretical framework in figure 1 shows, ICT usage, the degree of information sharing as well as the characteristics of a procurement situation need to be taken into account as independent variables. Each corresponding measure is discussed in turn, starting with the degree of information sharing, as different types of information that can be shared need to be discussed first. A large amount of studies focuses on single (or only a few) types of information that are shared within a supply chain, most commonly demand forecasts (e.g. Yan et al., 2016; Costantino et al., 2014; He et al,. 2014), inventory levels (e.g. He et al., 2014; Huo et al., 2014), production plans and production capacities (e.g. He et al., 2014; Huo et al., 2014; Lotfi et al., 2013) as well as order information (e.g. Shang et al., 2015; Lotfi et al., 2013). Table 1 gives an overview of recent literature and the corresponding types of information accounted for. In total, eighteen types of information are identified.

Table 1: Types of information shared with suppliers

■	Type of information	References
1	demand forecast	Yan et al. 2016; Costantino et al. 2014; Huo et al. 2014; Montoya-Torres and Ortiz-Vargas 2014; He et al. 2014; Lotfi et al. 2013; Datta and Christopher 2011; Yu et al. 2010; Klein and Rai 2009
2	inventory level	Huo et al. 2014; Montoya-Torres and Ortiz-Vargas 2014; He et al. 2014; Datta and Christopher 2011; Yu et al. 2010; Kelle and Akbulut 2005
3	(production/delivery) lead time	Montoya-Torres and Ortiz-Vargas 2014; Lotfi et al. 2013; Kelle and Akbulut 2005
4	production plans	Huo et al. 2014; Montoya-Torres and Ortiz-Vargas 2014; He et al. 2014; Klein and Rai 2009; Kelle and Akbulut 2005
5	inventory policy	Lotfi et al. 2013; Klein and Rai 2009
6	point of sales data	Huo et al. 2014
7	production capacity	Huo et al. 2014; He et al. 2014; Lotfi et al. 2013; Yu et al. 2010
8	sales promotion and marketing strategies	Klein and Rai 2009

13	production quality	Kelle and Akbulut 2005; Tsung 2000
14	product structure/quality	Montoya-Torres and Ortiz-Vargas 2014; Tsung 2000

■	Type of information	References
15	batch size	Ortiz-Vargas and Montoya-Torres 2012
16	production status	Kelle and Akbulut 2005
17	order information	Montoya-Torres and Ortiz-Vargas 2014; Lotfi et al. 2013; Yu et al. 2001
18	changing needs	Son et al. 2015; Li and Lin 2006

In order to draw a complete picture, all eighteen types of information are taken into account when measuring the degree of information sharing. One might measure the degree of information sharing as the percentage of total information shared. However, this would not give an indication about the actual amount of information shared. To overcome this problem, the degree of information shared is measured as the average interval (number of days) between two reports. This is essentially a measure for the quantity of information shared. This is measured for each type of information separately, rather than calculating one overall value for "degree of information sharing" (resulting in 18 variables). Also, the variables should be measured for buyers and suppliers separately.

Second, and in line with Bensaou and Venkatraman (1995), ICT usage might be measured as a dichotomous item, indicating whether each type of information is exchanged in electronic form or not. To expand on this, the type of technology used to exchange information is taken into account. The following technologies are integrated into the analysis: telephone, e-mail, electronic data interchange, extensible markup language, web-based electronic data interchange, supplier portals, cloud computing (Kolmykova, 2016; Stoll, 2008; Premkumar et al., 2005). ICT usage is measured on a nominal scale, indicating which type of ICT is used most frequently to exchange information between a buyer and a supplier.

Third, measures for characteristics of the procurement situation are constructed. Task characteristics are represented by the complexity of the procurement task. The complexity is rated using a combination of the value of the underlying goods (high/intermediate/low) and their consumption rate (constant/fluctuating/unsteady) (Piontek, 2016). In general, the lower the value of the underlying goods and the more constant the consumption rate, the less complex a procurement task is (measured as either high, intermediate, or low).

Relationship characteristics are represented by four different variables: duration of the relationship (number of days; Newbert et al., 2013), interaction frequency (average number of days between two interactions; Newbert et al., 2013), multiplexity (number of different products ordered by the buyer; Newbert et al., 2013), emotional intensity (using again four items, measured a seven-point scale, taken from Fang, 2011). The items to measure emotional intensity are as follows: (1) Both parties feel indebted to each other for what we have done for each other, (2) In this alliance, we share close social relations with each other, (3) The relationship between both parties can be defined as "mutually gratifying", (4) Both parties expect that we will be working together far into the future.

Following the discussion by Ebers and Maurer (2014), the structural position of the supply chain members is represented by three different variables: number of alternative buyers/suppliers (as discussed by Murray et al., 1995), number of alternative products (as discussed by Murray et al., 1995), and presence of structural holes, which is measured using the number of buyers a supplier possesses and vice versa (as discussed by Ahern, 2012).

Dependent variables

Finally, a measure for procurement risk is constructed, dividing overall procurement risk into four categories: quality risk, quantity risk, delivery date risk and price risk. Quality risk is measured using the number of rejected goods due to quality issues divided by the total number of deliveries. Similarly, quantity risk is measured using the number of rejected goods due to quantity issues divided by the total number of deliveries. Delivery date risk is measured using

the number of deliveries that didn‘t meet the scheduled delivery date divided by the total number of deliveries. All three measures are based on measures proposed by Piontek (2016). In addition, price risk is measured using the number of deliveries that didn‘t meet the agreed price divided by total number of deliveries.

Conclusion and outlook

As discussed in this paper, information sharing by using ICT can be an effective way for manufacturing companies to decrease procurement risk. This analysis identifies implications for buying companies in order to decrease procurement risk with respect to specific procurement situations. Two major conclusions can be drawn from this paper. First, ICT usage influences procurement risk in an indirect way. ICT usage influences the degree of information shared between two supply chain partners. The degree of information shared in turn influences procurement risk, which can be divided into quality risk, quantity risk, delivery date risk and price risk. Second, in order to measure this influence, ICT usage, the degree of information sharing, the characteristics of a procurement situation as well as procurement risk need to be taken into account. When measuring the degree of information sharing between buyer and supplier, all relevant types of information need to be taken into account. In this paper, eighteen types of information are identified. For all variables, corresponding measrues are proposed in this paper.

To give a brief outlook, the proposed measures (except for procurement risk) are used in a questionnaire for data collection. The questionnaire is sent to German manufacturing companies and their corresponding suppliers. Data regarding the proposed measures for procurement risk are taken out of the databases of the respective buying companies. Data collection will take place in the second half of 2018. This analysis is part of the author’s doctoral dissertation. The results of this analysis will be published within the scope of a monograph.

Abstract
For years, purchasing organizations have been conceptualized to take the form of centralization, decentralization or hybrid organizations. However, scholars have also registered a choice among each form is not that straightforward. This paper takes this discussion to the next level and purports that understanding of internal structural complexity of purchasing organizations is important before deciding on suitable form of it. Anchored in two Swedish Multinational Corporations and the theoretical lenses of bounded rationality and contingency theory this paper sheds light on why such choices among three forms are difficult by the demonstrating the effects of structural complexity on purchasing organization.

Keywords: Organization Complexity, Supply Management, Category Management

Introduction:
Researchers have acknowledged about a clear trend of continually increasing outsourcing and global sourcing activities of Multinational Corporations in the recent past. This is because both global sourcing and outsourcing strategies come with some difficult to overlook benefits such as cost reduction, increased quality and availability of purchased materials as well as an increased focus on core competencies for these MNCs (Cho & Kang, 2001; Jiang, Belohlav, & Young, 2007). However, one of the key challenges faced by MNCs for practicing global sourcing and outsourcing strategies is disintegration of purchasing units all over the world. As a result, integration and coordination of these dispersed purchasing units become problematic (Rozemeijer, van Weele, & Weggeman, 2003; Sarker, Azadegan, & Trucco, 2017).
Over the years, researchers have responded positively to these problems of large global corporates. As a result, the research on purchasing organization (PO) has flourished. One of the key areas of research on purchasing organization is its structure. The structure of purchasing

organization has been studied on three accounts (Glock & Hochrein, 2011). First, authors have conceptualized centralized, decentralized, or hybrid forms of PO and delineated the impact of each form on the efficiency of the purchasing process (Arnold, 1999; Corey, 1978). Second, researchers have identified the factors internal or external to the organization that facilitate the choice of the right form of PO (Bals, Laiho, & Laine, 2014). Third, authors have studied each form in various industries (Johnson, Leenders, Flynn, & Flynn, 2011). This research falls under the second domain and concentrate on the factors internal to the MNCs that may affect the choice among centralized, decentralized or hybrid forms of PO.

The guiding research question for this article is how internal structural complexities of MNCs effects the purchasing organization. For this research, purchasing organization is conceptualized to be comprised of multiple purchasing units of MNCs that are dispersed across the globe and internal structural complexity is defined as horizontal, vertical and spatial complexities (Hall, 1992). In this regard, horizontal complexity is referred to the differentiation among purchasing units at the same level. Vertical complexity is defined as the differentiation of tasks (roles) at different hierarchical levels and spatial complexity encompasses geographical dispersion of the purchasing units (Price, 1997).

In order to understand the effects of the internal structural complexity, this research uses theoretical underpinnings of contingency bounded rationality (H. A. Simon, 1955) and contingency theory (Fiedler, 1967).

point forward, this article is structured as follows. The theoretical perspective section outlines underpinnings of bounded rationality and contingency theory adopted for this research. The methodology section discusses case study method adopted for this research. The results section presents the different roles and contexts of the studied cases. In the discussion section, effects of internal structural complexities of MNCs are illustrated using the guidance of contingency theory and bounded rationality. Conclusion section sheds lights on the limitations of this research and provides recommendations for future research.

Theoretical Perspectives

Bounded rationality

In this paper, bounded rationality is used as a standalone lens following the guidelines of Allison (1969), who have utilized it to analyze the decisions during Cuban Missile Crisis. Though use of bounded rationality as a standalone lens to understand supply chain problems is also rare in purchasing and supply chain management (P&SCM) literature. However, as many popular organizational theories that are frequently used by P&SCM researchers, have bounded rationality as underlying assumption (Halldorsson, Kotzab, Mikkola, & Skjoett-Larsen, 2007). Hence, bounded rationality is not an alien perspective to be used for analyzing P&SCM problems.

The term “bounded rationality” was first introduced by Simon (1955), who argues that the decision making capabilities of organisms (e.g., people in organizations) are limited or bounded by two things: first, access to information and, second, information-processing capability or cognitive limitations. Extending this thought, Sarker et al. (2016) purports that roles in organizations are excellent predictor of the type of information gathered by the people performing those roles. The authors contended that “internal visibility” of organizational members are limited by the roles and responsibilities or tasks that they are required to perform to their job done. A similar line of thought is adopted in this paper. Consequently, roles of purchasing professionals from two MNCs were analyzed in order to understand the effects of internal structural complexity of MNCs.

Contingency theory

Unlike bounded rationality lens, P&SCM literature is deeply rooted in the contingency paradigm (Sousa & Voss, 2008; Spina, Caniato, Luzzini, & Ronchi, 2013). Scholars in the field has utilized contingency theory to study corporate purchasing synergy (Rozemeijer et al., 2003), purchasing department structure (Stanley, 1993), internal visibility (Sarker et al., 2016) and so on.

Contingency theory builds on two core assumptions. First, there is no "one" best way to organize. Second, no single way of organizing is equally effective in all situations (Fiedler, 1967). Based on the above assumptions, contingency theorists suggest that organizations must adapt their structures to fit their internal and external environment (Lawrence & Lorsch, 1967). To achieve the desired fit, integration and differentiation of tasks can be created (Galbraith, 1973). Differentiation means organizing each sub-task in a manner that enables effective performance of those individual subtask. Integration means creating links between differentiated sub-tasks to ensure successful completion of the whole task. To understand environment, contextual variables must be identified (Donaldson, 2001).

In this paper, contingency theory serves the purpose of explaining the effects of internal structural differentiation of the MNCs due to the diversity of their contexts. Contextual variables such as strategic sourcing environment and technology that already identified by researchers in field (Schoenherr, Modi, Talluri, & Hult, 2014; Stonebraker & Afifi, 2004) are used to describe contexts.

Methodology

Case study design provides a rich understanding of the empirical world (Flyvbjerg, 2006). The case study design is considered suitable for this paper because it can provide in-depth insights on effects of internal structural complexity on purchasing function. The following section describes the cases studied for this research.

Cases

The empirical data for this research were collected from two Swedish MNCs. A brief description of each case is presented on Table 1. Table 1 reveals few important factors about cases. First, both the organization are well established, large and have existence in a number of countries of the world. Case-I is a world-leading key and lock manufacturer. Founded in 1994, it has grown from a small regional company to a large group of over 200 companies in 20 years. The organization has 43,000 employees and operates in 70 countries. The product range includes mechanical, electromechanical, and electronic products. The supply base of case-I has 8700 direct material suppliers. On average, the case organization sources 60% of its sales volume from its suppliers

Table 1: An overview of the cases

Attributes	Case 1	Case 2
Founded in the year	1994	1890
Size (no. of employees)	43,000	110,000
Operates in	70 countries	180 countries
Industry	Key and lock manufacturer	Network solutions for the telecom industry
Sector	Manufacturing	Service
Typical categories	Lock cases, electronics, aluminium, machining, casting, etc.	Patent, electronic components, real estate, power, etc.

Sales to sourcing percentage	60%	60%
No of suppliers	8700 (only direct material suppliers)	28000 (direct and indirect material suppliers)

Case II is the largest supplier of mobile telecom systems in the world. Founded in 1876, the organization currently employs approximately 110,000 people in more than 180 countries. The key product of the organization is mobile networks representing 55% of sales value. However, it is also a strong player in providing services (40% of sales value) to the telecom industry and in developing support solutions for TV and media. The organization has 28,000 suppliers. Depending on the product category, the value of sourcing ranges from 50% to 90% of the sales value. On average, the organization sources 60% of its sales value from suppliers.

Data collection

The data collection efforts in the two cases are presented in Table 2. The primary method of data collected was semi-structure interview. The aim of the interview was to understand their roles and contexts of operation. Eighteen (18) sourcing professionals of case-I who are positioned all over the world are interviewed over a period of 8 months. Phone interviews were conducted for respondents located outside Sweden and for respondents located within Sweden face to face interviews were performed.

Table 2: Overview of data collection in the cases

Attributes	Case-I	Case-II
Duration of attachment	8 months	3 months
Number of respondents	18	18
Respondent profiles	Supply management professionals, sustainability managers, category managers, sourcing directors, purchasing managers	Head of network sourcing, supplier relationship managers, category managers, category leads, category heads
Documents	88 (internal and external: presentation, risk reports, sustainability reports, annual reports)	20 (external: annual reports, presentations available on the website, masters' theses)

For case-II, similar questions are repeated among eighteen 8 sourcing professionals to gains insights into their roles and contexts. As for case II, all the sourcing professionals were located in Sweden, the interviews are contacted face to face. Average duration of interviews for both cases were one and half hours. With the exception of one or two respondents from each case, all the interviews are recorded.

The secondary source of data was internal and external organization documents that were collected during and after the interviews. For case-I, 88 of such documents were collected from the website and the respondents. For case-II, the number of documents collected was 20.

Data analysis

Because of the qualitative nature of the gathered data it was subjected to content analysis (Dooley, 2016). Recorded materials were transcribed verbatim. The transcribed interviews as well as the documents were thoroughly read by the authors. The principle concern was to

understand the effects of internal structural complexity based on the theoretical underpinnings of bounded rationality and contingency.

Findings

Internal structural complexity

For Case-I, the horizontal complexity is embodied in the five divisions at the same level. The vertical complexity is embodied in the three hierarchical levels, i.e., the group, divisional, and entity levels (e.g., manufacturing units and company). The spatial complexity is characterized by the geographical spread of the organization in different regions. Regional divisions A, B, and C operate in the geographical areas of the Americas, Europe, and Asia Pacific, while product divisions E and F operate globally.

In comparison, the horizontal complexity for case II results from 120 product categories. Similar to case-I, the vertical complexity is embodied in three organizational levels, i.e., corporate, divisional, and regional levels. The spatial complexity is embodied by 10 regions across the globe that manages site offices in 180 countries.

Purchasing organizations

The purchasing function is referred in case-I as supply management which is a corporate-level function. The chief technology officer (CTO) is positioned at the top of the purchasing organization. The group supply chain director (GSCD) is next in the line of command. These two top managers are positioned at the corporate headquarters. The next responsible managers in the purchasing organization are positioned in the five divisions spread across the world. These five divisions are decentralized and have divisional sourcing directors as head of these divisions. These managers are responsible coordinating purchasing function within the divisions. The next line of command who reports to these divisional managers are the category managers. Category managers are reported by the purchasing managers who are positioned at individual entities such as a manufacturing plants or service offices. Figure 1 depicts the purchasing organization for case-I.

Figure 2, depicts purchasing organization for case-II. Similar to case-I, Purchasing is a corporate-level function for case-II. However, the function of purchasing is referred in the organization as sourcing. In contrast to case-I, purchasing organization is centralized for case -II. Vice president of network sourcing is positioned at the top of purchasing organization. Head of network sourcing is next to follow. This level is regarded as corporate headquarters level.

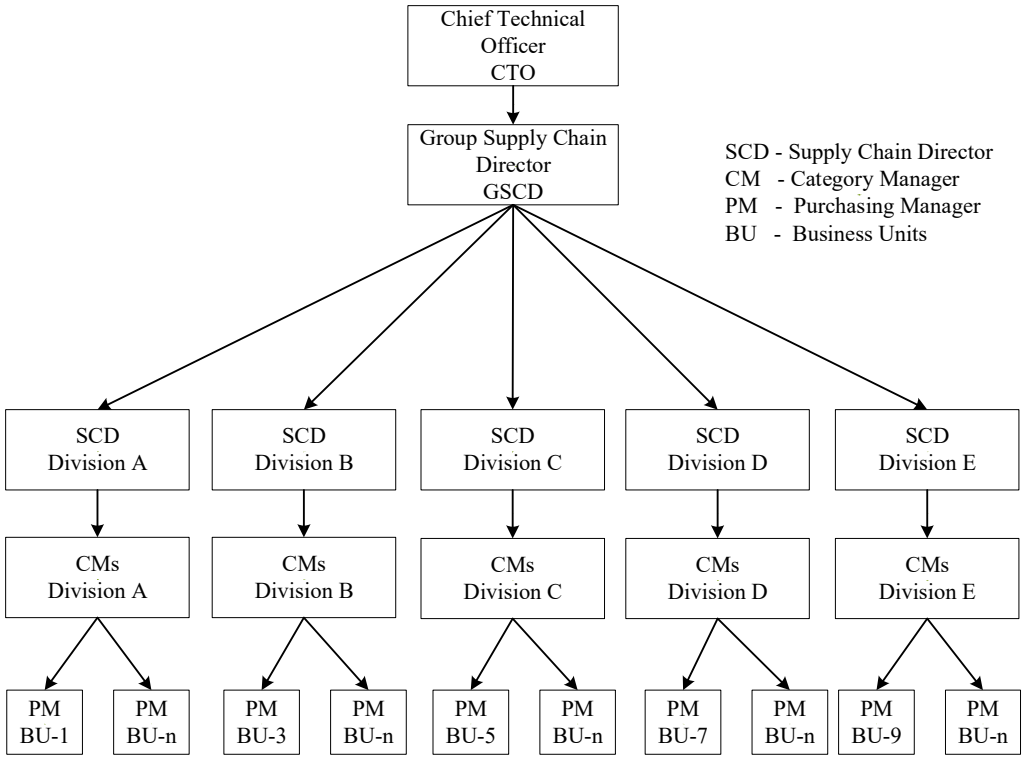

Figure 1: Purchasing Organization of Case-I

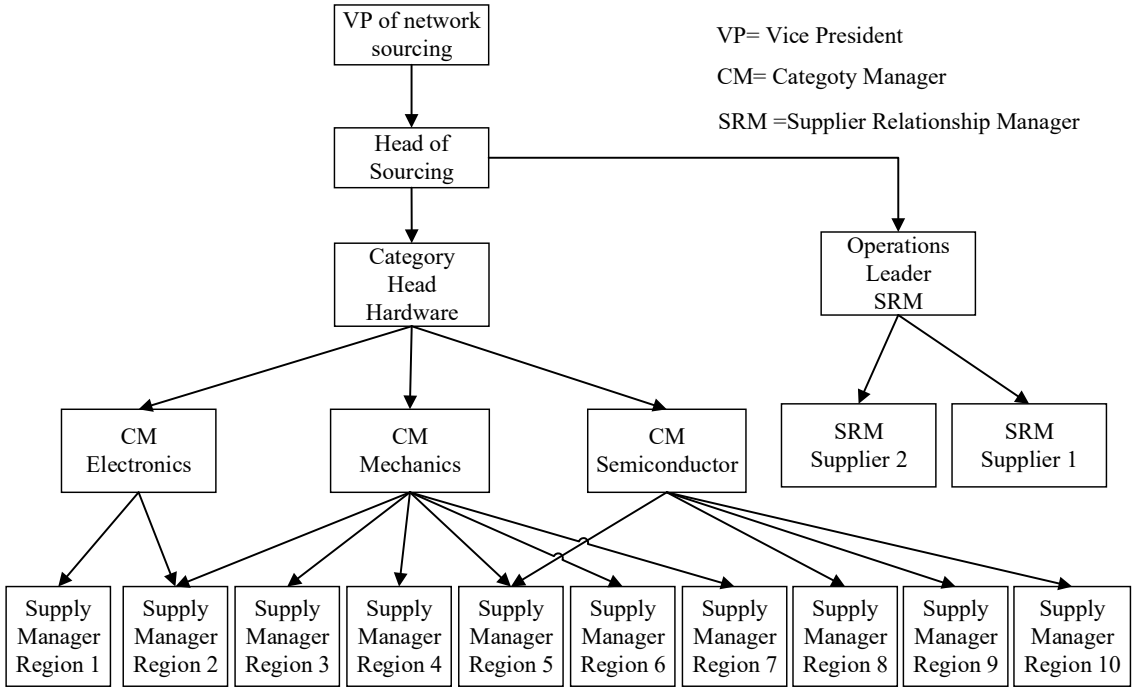

Figure 2: Purchasing Organization of Case-I

The next responsible managers in the purchasing organization are positioned at the level where categories are managed. Several managers are positioned at this level, for instance, the head of network sourcing, category leaders, category managers, operational leader for supplier

relationships, supplier relationship managers, and sourcing managers. Category leads, category managers, and sourcing managers works in a team and updated by the supply managers who are positioned at 10 regions around the world.

Roles in the purchasing organization

Table 3 and Table 4 describe different roles of purchasing professionals in case-I and case-II respectively.

Table 3: Roles of supply management professionals in case-I

Levels	Roles	Description of the role
Group level	Chief technology officer (CTO)	To lead supply management function of the group
	Group supply chain director (GSCD)	To align supply management functions of five divisions
	Group supplier quality and sustainability manager	Is responsible for carrying out sustainability audits in manufacturing units
Divisional level	Sourcing directors	Developing long term sourcing strategies
	Category managers	Developing category strategies
Entity level	Purchasing managers	Source items, raise request for quotation, issue purchase order

Table 4: Roles of sourcing professionals in case-II

Levels	Roles	Description of the role
Group Level	VP network sourcing	Responsible for the long-term development of Strategic Sourcing
	Head of network sourcing	Responsible for leading the sourcing organization
Category level	Category lead	Developing category strategy and aligning it to Supplier Relationship Management House
	Global category manager	Develop best strategies for the category and have a supplier list that fulfils organization's needs for three to five years
	Category manger	Define category strategy and decide on supply base for the category
	Operations leader- supplier relationship management	Manage and lead the supplier relationship management function
	Supplier relationship manager	Manage suppliers important large suppliers for a particular category
Regional Level	Supply manager	Creating request for quotation, checking quality and delivery of incoming materials.

Table 3 depicts that for case-I, roles are different and hierarchical i.e. GSCD reports to CTO and group supplier quality and sustainability manager reports to GSCD in the group level. In, the divisional level, two prominent roles of purchasing organization of case-I are sourcing director and category manager which is same across the five divisions. Similarly, roles of purchasing managers who are positioned at a manufacturing unit are same as purchasing manager at other manufacturing units.

Table 4 depicts that for case-II, roles are again different and hierarchical i.e. head of network sourcing reports to vice president of network sourcing. For category level (similar to divisional level for case-I), there are a number of roles that are similar for different categories. All-important categories had roles such as category leads, global category managers and category managers. Important suppliers within the category had supplier relationship managers. At the regional level, supply managers are responsible for request for materials as per requirement of the regions and checking the quality and delivery of the incoming materials.

Contexts in the purchasing organization

Table 5 presents different contexts of purchasing professional of case-I at all three levels and across various divisions.

Table 5: Contexts of supply management professionals in case-I

Levels	Roles	Technology	Strategic Sourcing Environment
Group level	Chief technology officer (CTO)	Product portfolio of mechanical, electromechanical locks, electronic IDs and entrance solutions for hospitals, garage, stadiums.	Having a world class supply base that is innovative and sustainable
	Group supply chain director (GSCD)		
	Group supplier quality and sustainability manager		
Divisional level & Entity level	Sourcing and category managers of Division A	Mechanical locks, lock systems and fittings, 46 %; Electromechanical and electronic locks, 14%; Security doors and hardware, 40%	Category Lock case - Large, but extremely concentrated (2% of the suppliers' cover 80% of the spend)
	Sourcing and category managers of Division B	Mechanical locks, lock systems and fittings, 60 %, Electromechanical and electronic locks, 26 % Security doors and hardware, 14 %	Category Lock set - Large considering the spend, but concentrated (15% of the suppliers' cover 80% of the spend)
	Sourcing and category managers of Division C	Mechanical locks, lock systems and fittings, 53 % Electromechanical and electronic locks, 9 % Security doors and hardware, 38 %	Category Stamping - Large, but concentrated (13% of the suppliers' cover 80% of the spend)
	Sourcing and category managers of Division D	Automatic doors, industrial doors and docking systems product 65%, Services 35%	Category - Electronics High supplier power, low buying power, due to competition from other industry sector
	Sourcing and category managers of Division E	Access control, 48% Identification technology, 29%	Category stainless steel : 80% are generic having large number of sources, 20% are tailored having one source

Following Schoenherr et al. (2014) and Stonebraker & Afifi (2004), contextual factors are presented in table 5 on two regards: strategic sourcing environment and technology. At the group level, contextual factors are created by nature of product i.e. mechanical, electro-mechanical locks and corporate strategies such as innovation and sustainability. At the divisional levels contexts varied across division as well as within a division. Variation of contexts among division was either due to different types of product/ technology or due to different categories. For instance, for divisions A, B and C, products were similar. However, purchasing situations were very different for different categories (e.g. lock set, lock case and stamping). For divisions D and E, the products (e.g. electronic ids and entrance solutions) are different than that of division A, B, and C. The categories are also different for division D and E from other three divisions.

Table 6 depicts various contexts of sourcing professionals for case II. Again, the contexts are presented on two regards: technology and strategic sourcing environment.

Table 6: Contexts of supply management professionals within the organization

Levels	Roles	Technology	Strategic sourcing environment
Group Level	Head of group sourcing	Industry growth only 2% A downward economy Cut through competition	Creating the highest value from supplier by balancing risk, cost and flexibility
	VP Sourcing		
Category level	Category lead	Patent	Slow category Suppliers are law firms with lots of local regulations.
	Global Category Manager	Electronics	Differs significantly for different countries Many single source suppliers
	Global Category Manager -	Site installation material	Powerful suppliers with factories all over the world Suppliers are buying out each other
	Category manger	Site sourcing	Long tail of suppliers
	Category manager	Temporary works	White collar consultants spreading over 90 countries
	Supplier relationship manager	Logistic	An important category spend in one supplier is 2 billion dollars
	Supplier relationship manger	Electronics manufacturing services	Outsourced manufacturing to a third supplier
	Supplier relationship manager	Consultancy	Lots of non-critical suppliers
	Supplier relationship manger	Software & systems	Critical supplier, difficult to swicht

Due to product nature of case II, at the group level, the contexts entailed slow industry growth and high competition as well as corporate strategy of creating value through suppliers. For category level, contexts varied with different categories as well as nature of supplier within a category. For instance, category of patent was a slow category with local law firms of a particular country as the supplier. In comparison, category of logistics had big suppliers with a global presence. Category of consultancy was significantly different than that of software &

systems with regards to criticality of suppliers. In table 6, regional level is missing because they were not purchasing anything rather just raising request for quotation for manufacturing units within the region.

Discussion

This paper sets out to understand the effects of internal structural complexity (e.g. vertical, horizontal, and spatial) on purchasing organization. In order to understand the effects purchasing organizations of two MNCs were studied. This section discusses the effect of each complexity on purchasing organization through the lens of bounded rationality and contingency theory and put forward the implications of such effects.

Table 7 synthesize the effects of internal structural complexity according to the guidance of bounded rationality and contingency theory.

Table 7: Effects of structural complexities as explained by bounded rationality and contingency theory

Theories	**Structural Complexities**		
	Horizontal	Vertical	Spatial
Bounded rationality	Horizontally roles of purchasing/ sourcing/ procurement professionals are similar. For instance, category managers for different categories perform the same responsibilities such as driving a category to reduce cost or source wisely.	Vertically roles of purchasing professionals can be different. For instance, Chief Technology Officer has a different role than that of a purchasing manager.	Spatially roles purchasing/ sourcing/ procurement professionals can be different because of the difference in purchasing authority in headquarters, in regional hubs and in small site offices.
Contingency theory	Horizontal bounds on purchasing professionals' rationality is created by different contexts. These contexts can be a result of sourcing environment of various categories.	Vertically the contexts can be different when different hierarchical levels of the purchasing organization are positioned at different locations of the world.	Contexts vary significantly with spatial complexity of purchasing organization. For instance, contexts of east Europe are not same as contexts of Asia.

The effects of vertical complexity are mostly visible by changing roles across different hierarchical levels of the organization. For case-I, various roles at the group level were group chief technology officer and group supply chain director. These were the top managers at the corporate headquarters in Stockholm who were responsible for setting the mission and vision for the entire purchasing organization. Because case-I was a decentralized organization, the divisions of the organization that were spread across the world had created another level of hierarchy for the purchasing organization. The key roles of purchasing professionals at these levels were sourcing directors and category managers. There was one sourcing director for each division who was responsible for creating sourcing long term sourcing strategies for the divisions. Category managers on the other hand had the responsibility to create category strategies for their respective categories. The next level of hierarchy was the manufacturing

units managed by each division for which category managers aggregated purchases across the category. The role of purchasing managers in charge of checking quality and delivery of the incoming materials were positioned at the entity level.

Purchasing organization for case-II was centralized compared to decentralized nature of purchasing organization of case-I. As a result, even though the purchasing organization for case-II was complex because of three vertical levels, those were different than that of case-I. At the group level, the top management roles (e.g. VP network sourcing, head of network sourcing) were again to set the strategies for the purchasing organization. At the category level, a number of roles such as category leads, global category heads, category managers, supplier relationship managers were created. While category leads were responsible for one or more similar categories (e.g. category of consultancy and temporary works), global category heads were responsible for categories that were spread across the world. Category managers were responsible for one particular category which had much spend (e.g. category of logistics). At the regional level, the supply manager only created purchase request and ensured that they had received the materials according to the requirements.

It is evident from both case I and case II that the vertical complexity has created different roles for purchasing professional at different hierarchical levels for both de-centralized and centralized purchasing organizations. Because of the large nature of multinationals, these roles in purchasing organizations are performed in different time zones with distinct authorities at different levels. According to the underpinnings of the bounded rationality paradigm (Simon 1955), these roles performed at different will create different information bounds on the purchasing professionals. As a result, their rationality for making purchasing decisions will be bounded by the roles these professionals are performing in the organization i.e. the top management such as chief technology officer or vice president sourcing and will have a different rationality bound than that of a middle manager such as sourcing director or category leads responsible for a division or a particular category. Sarker et al. (2016) have demonstrated that such rationality bounds create visibility issues of internal supplier risk among purchasing professionals. Thus, first proposition that can be put forward is:

Proposition 1: vertical complexity of MNCs creates rationality bounds among purchasing professionals due to division of authorities at different hierarchical level in the purchasing organization.

In comparison, horizontal complexity does not result in role changes in purchasing organizations but a change in context. Difference in context can be due to change of technology such as in case-I, different divisions at the same horizontal level produced different types of product. For instance, in case-I, division A, B, and C produced mechanical and electrotechnical products in different ratios. In contrast, division D had a different technical product i.e. electronic id. Division E had another kind of product i.e. entrance solutions. Therefore, even the roles of sourcing directors and category managers were similar at different divisions, they were exposed to different sourcing environment because of the nature of the product at a particular division. Within one single division, horizontal complexity can vary due to difference in sourcing environment of various categories. In case-II, such differentiation is evident in different categories such as logistics, temporary works, patent.

According to the foundations of contingency theory (Fiedler, 1967) such exposures to different contexts will require the purchasing organization to fit its structure to the particular context it is exposed to. As a result, the rationality of purchasing individuals at different contexts will be different. Therefore, the effect of horizontal complexity on purchasing organization can be described by the following proposition:

Proposition 2: horizontal complexity of MNCs creates rationality bounds among purchasing professionals by exposing them to different contexts.

The effect of spatial complexity on purchasing organization is same as that of horizontal complexity i.e. it too exposes purchasing professionals working at different hierarchical level of purchasing organization to different contexts. The difference is now the contextual variations are due to the practices at a particular country or regions. For instance, division A, B and C in case-I though had similar products but they were at different context of America, Europe and Asia Pacific. Even though the categories were similar among these divisions, the purchasing professionals needed to act different to cater to the need of a particular region. For case-II, the category patent had to pertain to the rules and regulations of a particular country. Where patent rules and regulations were strict, the protection of intellectual properties were easy compare to the regions where rule were not that strict. In such cases, for the same category of patent, the context of a northern European county (e.g. sweden) will not be same as a context of a firm in South America (e.g. Brazil). Therefore, the effect of spatial complexity on purchasing organization can be illustrated by the following proposition:

Proposition 3: Spatial complexity of MNCs creates rationality bounds among purchasing professionals by exposing them to different spatial contexts.

The common effects of all three complexities on purchasing organization are emergence of vertical, horizontal or spatial silos. These silos are created either by different roles of purchasing professionals at different hierarchical levels or exposure of purchasing professional to different contexts. The consequences of such siloed purchasing organization due to internal structural complexity can be two folds. First, the internal visibility of purchasing professionals will be according to their roles or the type of contexts they are exposed to (Sarker et al., 2016). Second, the structural complexity would raise similar integration issues (Lawrence & Lorsch, 1967) in purchasing organization as discussed by the organization theorists for having disintegrated business units around the globe. It means purchasing units working in differentiated silos (either by context or by roles) will require mechanisms for integration in order to perform better. Thus, a final proposition can be added as follows:

Proposition 4: Internal structural complexity of MNCs facilitates emergence of purchasing silos which in turn require integration mechanisms.

In sum, due to internal structural complexity, purchasing organization are divided into roles and responsibilities as well as exposed to different contexts. The conventional form of centralized purchasing organization will fit where integration is needed between differentiated purchasing units. Decentralized form will work best if certain contexts are very unique and centralization is impossible to achieve due to intricacies of the contexts. Because a mixture of centralized and decentralized purchasing strategies have to be practiced in any multinational corporation because of their inherent internal complexity, the purchasing organizations in MNCs will always be hybrid.

Conclusion

MNCs are intricate organizations. The effects of these intricacies also translate into the purchasing organization of MNCs. As a result, a multitude of roles and contexts are created within the organization. This siloed purchasing organization is problematic for a number of reasons. First, it will create various bounds of rationalities among the purchasing professionals (Sarker et al., 2016). It means communications between silos may become an issue. Second,

these differentiated purchasing units will require a mechanism for integration which will be very difficult to attain (Lawrence & Lorsch, 1967). Third, centralization of purchasing function will also difficult to achieve for many categories of these global giants (Sarker et al., 2017). understanding each other will be difficult. Therefore, understanding these effects are not only elemental for academician researching on purchasing organizations but also critical for practitioners working in these MNCs.

The key contribution of the paper is the four propositions that explain the effects of internal structural complexity of MNCs on their purchasing organizations. The effects give the reasons why purchasing organization of MNCs may require to take either a centralize form or a decentralize form, or a combination of both forms. The other contribution of the paper includes use of bounded rationality as an independent lens to explain the effects of internal structural complexity. This is because, bounded rationality has rarely been used as an independent theoretical lens in purchasing and supply chain management literature. The propositions developed in the paper can be tested in other industries in order to address the generalizability issue. Therefore, future research can be directed to understand the effects of internal structural complexity in a wider spectrum of industries.

Abstract
This study investigates which supply chain characteristics contribute to supplier relationship value and if such contributions are moderated by the intensity of the supplier-customer relationship. The results of a survey of 109 respondents, gathered from Finnish e-commerce companies, suggest that one of the dimensions of supply chain characteristics (i.e. service delivery characteristics) positively contributes to the supplier relationship value, whereas the other two dimensions (i.e. product characteristics and customer operations) do not. Further, as the intensity of the supplier-customer relationship increases, the substantiality of the connections between product characteristics and supplier relationship value and between customer operations and supplier relationship value increases.

Keywords: Relationship value, Supply chain, Service

Introduction

Supply chain management is under significant pressure to increase its contribution in changing business environments (Weele and Raaij, 2014; Bals et al., 2017). The traditional focus of the purchasing and supply domain has strongly been on cost savings, quality and technology development, and the research in the field has largely been concerned with determining how to run supply chain operations efficiently (i.e. doing things right) rather than effectively (i.e. doing the right things) (Weele and Raaij, 2014). The most recent studies, however, have also shed light on how to mobilize and manage capabilities, fairness and commitment in supply chain relationships (Weele and Raaij, 2014; Jokela and Söderman, 2017).

Among the biggest categorical changes that create pressure on supply chain and purchasing management in the 21st century are service integration and digitalization. In their study, Immonen et al. (2016) explain that the theory of service integration is based on creating value in industrial services and customer-supplier relationships in supply chains. Brito and Nogueira (2009) in turn argue that it is no longer a novelty that digitalization and Information Technology (IT) is changing the ways companies perform and that the importance of understanding the results of IT implementation is demonstrated by a number of studies dedicated to the subject of supply chain management. An example of a digital service supply chain is the acquisition of a web shop, where the purchasing process of the shop, the shop itself and delivering the service to the end customer mainly take place in digital form. Rao et al. (2011) and Griffis et al. (2012) showed that as the use of the Internet as a channel for distributing and selling solutions and goods from businesses to consumers (as well as businesses to businesses) has expanded, so has interest among different scholars, such as those in supply chain management, logistics, and operations. Rao et al. (2011) and Tsai et al. (2013) further argued that the e-retail industry has

grown rapidly during the last five years and the growth trend would continue in the future. Griffis et al. (2012) stated two reasons for the rapid growth: People's access to the Internet has increased substantially during the last decade, and the percent of Internet users who make purchases online has grown considerably.

In digitalized business environments, it is crucial to consider how relationships with suppliers are developed and maintained. This is also known as supplier relationship management, which is a critical business process for developing closer relationships with key suppliers in order to create value (Autry and Golicic, 2010; Bals et al., 2017; Bals and Turkulainen, 2017). It also demonstrates the importance of supply chain characteristics as part of the co-operation activities. For example, sharing of information can promote the integration with suppliers (So and Sun, 2010). However, while better management of supplier relationships increases company performance (Lambert and Schwieterman, 2012), few studies aim to understand the role of key supply chain characteristics in influencing supplier relationship value in digital service supply chains. In addition, the moderating influence of supplier-customer relationship intensity requires further investigation. In this paper, we aim to contribute to this research gap by studying the links between supply chain characteristics, supplier-customer relationship intensity and supplier relationship value.

The paper starts by summarizing the existing literature on supplier relationship management and then describes how the hypotheses of the current study were developed. Section 4 describes the study's methodology, and Section 5 presents the main results of the survey. In Section 6, the main results of the study are discussed and summarized. The final section discusses the study's conclusions, implications and limitations. As digitalization is rapidly expanding in different phases of supply chains and purchasing operations, we believe that the findings of the study can be relevant for many different operators dealing under domain, including digital service suppliers and customers. The implications of the study may also be relevant to digital service and solution providers. In addition to having implications for practitioners, the study's results also have implications for academic scholars.

Supplier relationships management in a digital context

Companies are increasingly interested and dependent on their suppliers' inputs and contributions, and the importance of supply chain management of these inputs and contributions has been increasingly emphasized (Weele and Van Raaij, 2014; Bals et al. (2017). Researchers have begun to reexamine the purposes, processes and functions of supply chains and how to characterize them in global business environments (Lusch, 2011). Thus, supply chain management has received a key strategic role in many contemporary businesses and among different researchers (Lusch, 2011; Bals and Turkulainen, 2017). In today's turbulent and digitizing business environments, supply chain management is under growing pressure to discover additional value generation beyond efficiency seeking behavior and to search for effectiveness by, for example, bringing in supplier product or process innovations and participating in product innovation activities (cf. Turkulainen and Swink, 2016; Bals and Turkulainen, 2017; Bals et al., 2017). As a part of the supply chain management, supplier relationship management is the business process that provides the structure for how these relationships with suppliers can be developed and maintained (Lambert and Schwiterman 2012). Due to changes in the business environments of companies, supplier relationship management has become a critical process for considering risk and achieving sustainability and cost efficiency. Recent studies have also shown that the integration of operations and sharing

of information with suppliers can improve companies' performance (Flynn et al., 2010; Lambert and Schwiterman, 2012) and increase the co-creation of value.

Two of the biggest changes that supplier relationship management has faced and must operate with in the near future are related to digitalization and the increase of services (cf. Lusch, 2011) in purchasing and supply chains. The increase of digitalization and technologies can be considered meta-forces that will change the society and practice of purchasing and supply chain management. Lusch (2011) also explains that among other benefits, as IT increases in companies, the ability to self-service and ability to serve others rises. In response to the increase in IT and digitalization of business environments, several studies have been conducted on the relationships between client and digital service suppliers, which include client-consultant relationships (cf. Dawes et al., 2007), IT outsourcing relationships (cf. Gonzalez et al., 2006; Goo et al., 2007) and relationships between customers and digital service suppliers (Kishore et al., 2003) (Brito and Nogueira, 2009). Although previous studies on digital service supplier relationships seem to have focused on outsourcing, which, according to Bals and Turkulainen (2017), is currently one of the fundamental managerial approaches to seek efficiency and effectiveness in different functional areas, these presented studies emphasize the importance of relationship management with suppliers to gain advantages from the adoption of digitalization. Brito and Nogueira's (2009) study provides further evidence that in the relationships between customers and digital service suppliers, IT resources from both parties are exchanged and combined, thus enhancing their related capabilities. Although the studies emphasize the importance of relationship management, the appropriate level of supplier integration will depend on the relationship, and an effort should be made to identify strategies for different types of relationships (cf. Das et al., 2006; Lambert and Schwiterman, 2012).

Hypothesis development

Supply chain characteristics as antecedents of relationship value

In today's information age, digital business has become one of the most important ways of selling, buying and offering both products and services for companies (c.f., Zeithaml. et al., 2002; Gotzamani and Tzavlopoulos, 2009; Oliveira and Roth, 2012). However, only a few of these companies can earn substantial profit or create more value from these digital product-service-combination businesses. In order to be successful in digital business, there is a need to identify which characteristics made successful digital business companies different from other e-shops (Gotzamani and Tzavlopoulos, 2009).

Researchers have developed various quality models that identify what is important for value creation in e-commerce. Schubert and Dettling (2002) classified the elements of e-commerce according to three dimensions, including ease of use, usefulness and trust; the authors also discussed the use of the extend web assessment method as a tool. In the context of e-commerce, Su and his collogues (2008) classified quality factors into six different dimensions, including outcome quality, consumer service, process controllability, ease of use, information quality and website design. Parasuraman et al. (2005) consider that the product characteristics that contribute to the perceived quality of the service include efficiency, fulfillment, system availability and privacy. Similarly, Huang et al. (2015) refer to the product characteristics relating to mobile service quality as efficiency, functionalities of the content and system availability. According to Gotzamani and Tzavlopoulos (2009), e-commerce quality constitutes a variety of factors that are co-related and interact with each other. Product characteristics include factors such as attractiveness, serviceability and product/service differentiation and

customization, reputation and assurance. Currently, e-commerce companies constantly seek new ways to enhance the customer experience by updating their virtual stores with new features and capabilities, such as mobile commerce, dynamic imaging, social networking, and customization (Tsai et al., 2013). As variety of product characteristics have been found to provide value to the customer, and these characteristics are likely to enhance the perceived supplier value. Therefore, it is hypothesized that product characteristics have a direct impact on supplier relationship value. Consequently, the following hypothesis was developed regarding e-commerce in the B2B context:

H1: Product characteristics have a positive effect on supplier relationship value.

The vast number of studies have mentioned the huge role of customers during the process of service delivery in creating value (Zeithaml. et al., 2002; Gotzamani and Tzavlopoulos, 2009; Oliveira and Roth, 2012). In B2B companies, customers enable value creation by providing accurate and updated information during the service delivery process for other suppliers (Fliess and Kleinaltenkamp, 2004). According to Ovalle and Marques (2003), supply chain managers experience issues such as misinformation and mistrust in case of time delays, distorted demand signals and lack of knowledge about the status of the products or services. Consequently, sharing accurate information at right time and in the right context are important characteristics for improving companies' supply chain performance (Ovalle and Marques, 2003). In addition, several studies have considered the integration of information systems as a must for companies (e.g., Ellram, 1991; Gunasekaran and Ngai, 2004). On the other hand, according to Zhang and Chen (2008), there is a positive relationship between supplier relationship and customization (Zhang and Chen, 2008).

An increase in the number of relationships between suppliers and other parties in business enhanced the importance of fairness, trust, equity and commitment, as well as the application of these characteristics in the context of business relationships (Emberson and Storey, 2006; Gotzamani and Tzavlopoulos, 2009; Oliveira and Roth, 2012). Based on previous research, fairness refers to the fair treatment of business partners, and this fair treatment encompasses a wide range of activities, such as sharing financial benefits (Cox, 2001), decision making (Duffy et al., 2013; Griffith et al., 2006) and cultivating fair relationships among companies (Luo, 2009; Jokela and Söderman, 2017); these activities generate customer value (Liu et al., 2012; Luo, 2009). The existence of fairness is a vital characteristic for continuing business relationships (Luo, 2006; 2009), while the lack of fairness in a relationship results in the dissolution of the relationship (Duffy et al., 2013).

In the context of e-commerce, different models have been proposed, and some relevant characteristics for value creation have been measured. Therefore, characteristics such as richness of information sharing, integrated cooperation and processes and trust among the companies are important for e-commerce, while delay in information sharing, out-of-date information about products and service and poor data translates are among the activities that lead to huge costs, missed revenue and dissatisfaction (Ovalle and Marques, 2003). Parasuraman and his collogues (1985) have proposed the SERVQUAL model and measured reliability, responsiveness, assurance, empathy and tangibles as the factors of service quality. Additionally, satisfying delivery promised in terms of time and quality, contact customer service, tracking of the status of the orders from the time of ordering until delivery, and high-quality websites are among the crucial operations components that can make or break satisfaction for customers (Boyer et al., 2002). A variety of service delivery characteristics were

found to provide value to the customer. These characteristics are likely to enhance the perceived supplier value. Therefore, in the B2B context, we hypothesize the following:

H2: Service delivery characteristics have a positive effect on supplier relationship value.

In digital businesses, it is necessary to satisfy the needs of e-shoppers (c.f., Zeithaml. et al., 2002; Gotzamani and Tzavlopoulos, 2009). In addition to this, digital companies rely heavily on the number of people who visit their website, purchase their products or services and become permanent customers (Smith and Merchant, 2001). As quality is one element that contributes to business growth, several studies have considered the quality of websites and customer services as the elements that boost profitability in business (cf., Gotzamani and Tzavlopoulos, 2009).

E-commerce makes it possible to shorten the time it takes to get products/services to the market; allows for growth in market share, sale, service processes and customer operation; and allows for a fast response to customer preferences. These features lead to value creation and better supply chain performance. Different quality models have been defined for value creation in the context of e-commerce. Proposed by Loiacono (2002), the TM model refers to the quality of the website and identified information fit-to-task, interactivity, trust, visual appeal, innovativeness, flow/emotional appeal, design appeal, intuitiveness, response time, integrated communication, business process and viable substitute as the 12 factors that must be considered in e-commerce (Loiacono, 2002). Barnes and Vidgen (2003) explain that consumers expect e-shops to be usable and informative and that consumers expect their relationship with the website to be good. Gotzamani and Tzavlopoulos (2009) refer to the website characteristics that have replaced the value provided by a physical store, such as system quality and information quality, as well as the aesthetics, structure and features of the website. Delone and McLean (1992) concentrated on the quality of information systems. They considered system quality, information quality, use, user satisfaction, individual impact and organizational impact as the main dimensions for the quality of the e-commerce. Based on the studies conducted by Lee and Lin (2005), website design, reliability, responsiveness, trust and personalization are among the elements in the e-service process. Based on Yoo and Donthu's (2001) studies, different characteristics, including esthetic competitive value, ease of use, design, ease of ordering, corporate and brand equity, processing speed, security, product uniqueness and product quality assurance have been mentioned in the SITEQUAL model as elements that are related to the experience of online purchasing. Additionally, different studies have mentioned information quality, user interface quality and security as three important items for customers during their online purchasing (Park and Kim, 2003; Oliveira and Roth, 2012). According to Yoon et al. (2008), e-commerce companies continuously face the challenge of enhancing customer trust and building relationships with customers. Due to this, they must understand what determines customer operations in the e-commerce environment. A variety of customer operations related to digital services have been considered to provide value to the end user. These operations are likely to enhance the value that the supplier has produced when supplying the digital service. Based on previous research, the following hypothesis was formed:

H3: Customer operations have a positive effect on supplier relationship value.

Supplier-customer relationship intensity as a moderator

One way to understand the changes in the development of customer value propositions is the recognition that it becomes easier for companies to look further down their supply chains to see

changes emerging multiple links away, thus providing additional lead time for operational and strategic planning and adjustments (Cheung et al., 2010). According to Cheung et al. (2010), this can also be considered as viewing the "supplier as a customer." Prior research in the operations and supply chain management have presented a variety of factors for *supplier-customer cooperation*, whose existence can be associated with relationship performances (e.g. Cheung et al., 2010; Li et al., 2010; Liu et al., 2009; Prahinksi and Benton, 2004). From the supplier-customer relationship point of view, Tsai et al. (2013) presented in a study of e-retailers' technology sourcing strategies that a well-designed IT infrastructure is an essential part of generating a tightly integrated value chain and delivering high-quality service. Cocreation between e-retailers and suppliers represents a critical component of service delivery processes through which e-retailers have direct input in the development of e-services (Ngo and O'Cass, 2009). The exchange of information, joint sense making and knowledge integration have been documented as important factors for the supplier-customer relationship, especially from a learning perspective (Cheung et al., 2010). These factors are also connected to the *responsiveness towards the supplier* in terms of the effectiveness with which problems are handled, the willingness to help the supplier and the speed with which a response to a problem or question is made (Huang et al., 2015; Parasuraman et al., 2005; Gotzamani and Tzavlopoulos, 2009). Prior literature often presents the length of cooperation as a proxy for the closeness of social relations between partners (Dyer and Chu, 2000; Li et al., 2010). Dyer and Chu (2000) suggest that long-term interactions between partners would be helpful to gain an in-depth understanding of each other. Lengthy cooperation also enables partners to share private information, decrease information asymmetries and facilitate the *development of trust* (Poppo et al., 2008). Trust can be defined as one party's confidence that the other party in the exchange relationship will not exploit its vulnerabilities (e.g., Li et al., 2010). Trust can also be defined as the confidence or belief that the exchange partner possesses about the honesty and benevolence of other partners (Kumar et al., 1995). The corporate image and reputation of supplier are also associated with the development of trust (Huang et al., 2015; Parasuraman et al., 2005). It is documented that when trust and behavioral norms are developed, partners are more effective in improving communication, information flow, knowledge sharing and solidarity (Hult et al., 2004), and if the company seeks to improve relationship performance only, inter-company trust and relational norms become an even more important means for this end (Liu et al., 2009). Based on the current understanding, we believe that the intensity of the supplier-customer relationship enhances the connection between product characteristics and supplier relationship value, service delivery characteristics and supplier relationship value and customer operations and supplier relationship value. In line with this, the following hypotheses were developed:

H4: Relationship intensity moderates the connection between supply chain characteristics and supplier relationship value.

H4a Relationship intensity moderates the connection between product characteristics and supplier relationship value.

H4b Relationship intensity moderates the connection between service delivery characteristics and supplier relationship value.

H4c Relationship intensity moderates the connection between customer operations and supplier relationship value.

Research model

The theoretical review discussed in previous sections led to the development of the research model, which is presented in Figure 1. The research model indicates that supply chain

characteristics, as a three-dimensional construct with the dimensions of product characteristics, service delivery characteristics and customer operations, are relevant for improving supplier relationship value. Further, it is argued that supply chain characteristics and supplier-customer relationship intensity interact with each other to maximize supplier relationship value.

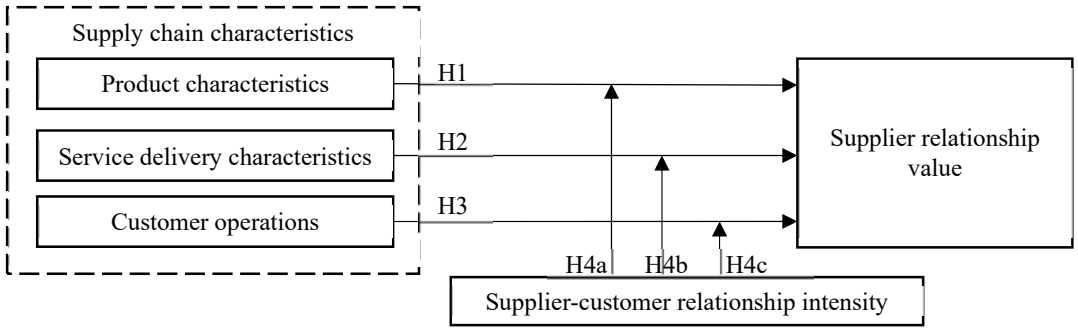

Figure 1. Research model and hypotheses.

Methodology

Construct operationalization

A survey-based approach was utilized to test the hypotheses. A literature review helped to identify relevant constructs and previously operationalized scale items. Measurement items related to supply chain characteristics and supplier-customer relationship intensity were adapted from the literature, but they were modified in order ensure contextual consistency. The measure of supplier relationship value was developed specifically for this study. To ensure validity, the measure was developed based on existing research. All of the scales were refined in collaboration with experienced researchers, and the scales underwent formal pretests to assure content validity. Table 1 presents the measurement items.

Value gained from the relationship	1	

The independent variables of the survey were the supply chain characteristics. The supply chain characteristics were operationalized as a three-dimensional construct, with the dimensions of product characteristics, service delivery characteristics and customer operations. Product characteristics reflect the characteristics of the digital product-service-combination that the supplier produced for the B2B customer company. Service delivery characteristics reflect the characteristics of the service that the supplier has offered during the digital product-service-combination delivery process. Finally, customer operations reflect the routines of the B2B customer company related to the supplied digital product-service-combination. The moderator variable was the supplier-customer relationship intensity. The six items of this variable estimate the depth of the relationship between the supplier and the customer of a digital product-service-combination. The dependent variable was the supplier relationship value. It was measured with a single-item measure. Single item measures can be used when the research setting includes singular concrete objects and attributes (Bergkvist and Rossiter, 2007) that are homogenous (Loo, 2002) and unambiguous to the respondent (Sackett and Larson, 1990). This is the case in this study. The survey also included controls for contextual variables that may have potentially confound the results. Controls included company size (measured by the number of employees), sales (measured by the portion of sales through digital channel) and the age of digital service (measured by the number of years the shop had been in existence).

Sample and data gathering

The survey was conducted in Finnish e-commerce companies. The companies had supplied a web shop and they were asked to evaluate the purchasing process of the shop as an example of a digital service supply chain. Respondents were responsible for business and customer service tasks related to e-commerce and digital business. The respondents were also managerial-level employees, as managers were expected to have adequate knowledge to answer the items concerning their company's supply chain operations. Thus, the respondents had good capability to respond to a survey that mapped the current state of their companies' digital service supply chain. The unit of analysis in the study is the individual respondent's perceptions of the supply chain characteristics and supplier-customer relationship intensity as well as the value of their company's supplier-customer relationship. Thus, the respondents provided their personal evaluations of the constructs in their company.

Initially, 2541 respondents were invited to participate in the study. 229 contacts were invalid, and the survey reached 2312 respondents. After eliminating incomplete surveys, our final sample consisted of 109 (response rate about 4.7%) responses from 107 B2B customer companies. The response rate is not always the best measure for assessing the accuracy of the results, as it ignores the compounding effect of sampling and coverage errors. The target population of this study was e-commerce companies operating in Finland that had a web shop in operation. The directive number of such companies was 7500. Besides the response rate, the accuracy of survey results should be assessed by the representativeness of the respondents. The initial sample was randomly selected among these companies and contained about 30% of the total amount of Finnish companies that had a web shop. Overall, the sample was representative

of a large amount of the entire target population. Further, the number of responses exceed the minimum returned sample size for given population size (Barlett et al., 2001). Sample size is considered appropriate.

Non-response bias

To determine whether there was non-response bias, an analysis of the variance test was performed. Early respondents were compared to later respondents on the key variables: product characteristics, service delivery characteristics, customer operations, supplier-customer relationship intensity, and supplier relationship value. Early respondents were those individuals who completed the questionnaire within the deadline after receiving the first e-mail. Respondents who responded to the subsequent e-mails were classified as late respondents. Those who were among the last to respond most closely resembled non-respondents (Armstrong and Overton, 1977). If there are no differences between early respondents and late respondents, it is likely that there are no differences between respondents and non-respondents. The results indicated no significant differences between the early and late respondents regarding key variables. Therefore, it was confirmed that non-response bias did not cause problems, and the responses were well representative of the entire sample.

Results

Measurement model

Before testing the hypotheses, the level of reliability and validity was assessed. As Table 1 shows, Cronbach´s α values are greater than 0.8, indicating that the measurements are reliable. High Cronbach´s α values also support internal consistency, which was further investigated by performing factor analysis using principal components with no rotation separately for each construct. All the items of one variable loaded to one factor, which supports internal consistency. Next, correlation analyses (Table 2) were conducted in order to investigate if the constructs behave in a credible manner. In some cases, the correlations were high, which may mean that multicollinearity can cause problems. For multicollinearity, the variance inflation factors (VIF) were calculated for each predictor by conducting a linear regression of that predictor on all the other predictors. All the VIFs were considerably lower (less than 2.0) than the recommended threshold of 5–10, suggesting that multicollinearity was not a problem (Kleinbaum and Kupper, 1988). The normal distribution of each variable was assessed via a measure of skewness. Each variable appeared to have an approximately normal distribution.

Table 2. Descriptive statistics and correlations of the variables.

	Mean	**St.Dev.**	**1**	**2**	**3**	**4**
1 Product characteristics	3.88	0.569	1.000			
2 Service delivery characteristics	3.45	0.775	0.503***	1.000		
3 Customer operations	3.86	0.567	0.532***	0.379***	1.000	
4 Supplier-customer relationship intensity	3.58	0.718	0.486***	0.669***	0.337**	1.000
5 Supplier relationship value	2.93	0.799	0.400***	0.707***	0.234*	0.568***

Sign. *** ≤ 0.001, ** 0.001 < p ≤ 0.01, * 0.01 < p ≤ 0.05

The possibility of common method bias was checked, as a single respondent from a company was used. During the data gathering process, multiple procedural remedies were used to minimize the potential of such bias (see Podsakoff et al., 2003). The respondents were encouraged to answer the items as truthfully as possible and were allowed to answer anonymously. These actions decreased the respondents' likelihood of editing their responses to

be more socially desirable. Common method biases were also reduced by paying attention to the construction of the items. Also, methodological separation was used to reduce the risk of common method bias (Craighead et al., 2011). Thus, different variations of Likert-type scales were employed, such as "weak/excellent" and "strongly disagree/strongly agree." In addition, Harman's single-factor test (Podsakoff et al., 2003) was performed. All the variables were loaded into an exploratory factor analysis, and the unrotated factor solution was analyzed. In this case, the main factor explained only 30.3% of the total variance, and no significant common method variance existed (Podsakoff et al., 2003).

Hypothesis testing

A main effects model was used to test hypotheses 1–3. Table 3 shows that the direct effects of product characteristics on supplier relationship value ($\beta = 0.156$; $p = 0.189$), customer operations on supplier relationship value ($\beta = -0.145$; $p = 0.155$) and supplier-customer relationship intensity on supplier relationship value ($\beta = 0.045$; $p = 0.708$) were not significant. However, the direct effect of service delivery characteristics on supplier relationship value ($\beta = 0.697$; $p = 0.000$) was significant. Thus, the results provided support for Hypothesis 2.

The full model, which is presented in Table 3, was used to test hypotheses 4a–4c. The full model included the interaction terms, and comparison with the previous model allowed for estimating the effect caused by the interaction term. The results suggest that supplier-customer relationship intensity has a significant interaction effect on the path from customer operations to supplier relationship value ($\beta = 1.261$; $p = 0.097$). Hence, we can interpret from these observations that the influence of customer operations on supplier relationship value increases with an increase in the depth of the supplier-customer relationship. However, the interaction effect of supplier-customer relationship intensity on the path from product characteristics to supplier relationship value was significant, but the impact of product characteristics on supplier relationship value decreased when the depth of the supplier-customer relationship was greater ($\beta = -1.994$; $p = 0.047$). The interaction effect of supplier-customer relationship intensity on the path from service delivery characteristics on supplier relationship value was not significant ($\beta = 0.696$; $p = 0.346$).

Discussion

This study examined the direct impacts of supply chain characteristics, namely product characteristics, service delivery characteristics and customer operations, on supplier relationship value, and examined the moderation effects of supplier-customer relationship intensity on that connection. Thus, our research contributes to prior research on the impact of supply chain characteristics on supplier relationship value (e.g. Ovalle and Marques, 2003; Brito and Nogueira, 2009; Autry and Golicic, 2010; Jokela and Söderman, 2017). Considering the direct effects of the main effect model (Table 3), the relationship between service delivery characteristics and supplier relationship value was highly significant, while no other direct and significant effects could be found. Regarding the value creation in the supplier-customer relationship in a B2B environment, it seems that the influence of the characteristics of service delivery outcome overrides that of the product characteristics and the customers' own operations. This highlights that different characteristics of service delivery, such as sharing accurate, updated and timely information during the service delivery process (Fliess and Kleinaltenkamp, 2004; Ovalle and Marques, 2003), together with different characteristics of quality elements, such as reliability, responsiveness, assurance, empathy and tangibles (Parasuraman et al., 1985; 2005), can be considered value drivers for the supplier-customer

relationship. However, there may be a need to integrate these service delivery characteristics as a comprehensive solution to facilitate the relational perspective for value creation, as suggested by Immonen et al. (2016). Additionally, the integration and quality of the information system (e.g. Delone and McLean, 1992; Ellram, 1991) as well as decision making process (Duffy et al., 2013; Griffith et al., 2006) have been considered value drivers for service delivery in the supplier-customer relationship and can thus be reviewed in future research. Where Lambert and Schwiterman (2012) present supplier relationship management as a business process that provides the structure for how these relationships with suppliers can be developed and maintained, the current study suggests that these procedures can be targeted to the service delivery characteristics in value creation in the supplier-customer relationship.

Another contribution relates to the prior research on supplier-customer relationship intensity (e.g. Liu et al., 2009; Cheung et al., 2010; Li et al., 2010). Considering the interaction effects in the full model (Table 3), the results indicates that the supplier-customer relationship positively moderates the relationship between customer operations and supplier relationship value. This means that the high intensity in the supplier-customer relationship, for example, in terms of supplier-customer cooperation and the development of trust is connected to customer operations with the delivered service in a way that affect the value of the supplier relationship. This may indicate that considering the "supplier as a customer" together with the relationship learning in terms of exchange of information, joint sense making and knowledge integration (Cheung et al., 2010) is associated with customers' operations with the delivered digital service (Barnes and Vidgen, 2003; Park and Kim, 2003; Yoo and Donthu, 2001), and generates a higher supplier relationship value. The cooperation that is based on the relationship learning provides better knowledge and skills for the customers to address the issues described above. The study thus strongly supports the importance of relationship learning in creating relationship value, as presented by Cheung et al. (2010). The responsiveness towards the supplier in terms of the effectiveness with which problems are handled, willingness to help the supplier and quick response to a problem (Huang et al., 2015; Parasuraman et al., 2005) is also connected to the relationship learning and considering the "supplier as a customer", thus improving the knowledge and skills that customers need in their operations. Furthermore, relationship learning, together with the willingness to have a long-term relationship are characteristics that facilitate the development of trust and further positively affect the relationship between customer operations and supplier relationship value. The study thus highlights the development of trust as an integral part of the supplier-customer relationship and an essential element in supply chain value creation, as presented by Poppo et al. (2008). The findings also suggest that the supplier-customer relationship negatively moderates the relationship between product characteristics and supplier relationship value. This may indicate that the more intensive the supplier-customer relationship is, the more irrelevant the product characteristics themselves are. In an intensive supplier-customer relationship, the supplier relationship value is created through the customer's own actions with the delivered digital service.

Where some previous studies on digital service supplier relationships focused on outsourcing in order to find efficiency and effectiveness in different functional areas (e.g. Bals and Turkulainen, 2017) or called for the exchange and combination of resources to enhance IT capabilities, the findings of the current study suggest that focusing on the service delivery characteristics that are connected to the customers' operations, especially the intensity of the supplier-customer relationship, generate supplier relationship value in an e-commerce delivery process. This can also be kept in mind when identifying strategies for supplier-customer relationships in digital services, especially in e-commerce adoption (e.g. Das et al., 2006; Lambert and Schwiterman, 2012).

Conclusions

The results contribute to our understanding of the links between supply chain characteristics, supplier-customer relationship intensity and supplier relationship value. Specifically, we examined the impacts of supply chain characteristics on supplier relationship value by identifying the moderating impacts of supplier-customer relationship intensity. The supply chain characteristics were assessed on three dimensions: product characteristics service delivery characteristics and customer operations.

The current study enriches research on supplier relationship management by lending support to the interaction effect of the supplier-customer relationship intensity on supplier relationship value. Our study argues that one dimension of supply chain characteristics, service delivery characteristics, is positively related to the supplier relationship value. Also, supplier-customer relationship intensity enhances the connection between customer operations and supplier relationship value. As a practical implication, the study provides empirically-proven guidance to understand the role of supplier-customer relationships in the connection between supply chain characteristics and supplier relationship value. The findings of our study could provide useful insights for managerial decision making by informing suppliers about which supply chain characteristics are likely to influence supplier relationship value so that suppliers can improve these characteristics.

The study has limitations that provide opportunities for further studies. First, the data is cross-sectional in nature. Longitudinal data would assist in providing an in-depth understanding of how supplier-customer relationships affect value creation. Second, the demographics may limit the generalizability of our findings, as the data was gathered from Finland. Also, a common method bias can cause problems when the key informant approach is utilized. Fourth, supplier relationship value was the only dependent variable and thus the only performance measure. Thus, the theoretical model of this study can be further studied by using other performance measures, such as financial performance and market performance, as dependent variables. Further research could address these limitations and build on the findings of this study.

SUMMARY
Team dynamics can be an influential determinant for team performance. While research in this area has been done in general management, insight is lacking in the domain of sourcing. This research fills this gap by reporting the results of a survey that was designed to offer insights into sourcing team dynamics that enable or hinder the team's success. Dimensions theorized to explain differential performance outcomes include cooperative norms, task and emotional conflict, group cohesion, psychological safety and goal similarity. The hypotheses are tested in two culturally diverse contexts—the U.S. and Japan—expected to yield differential outcomes based on their cultural characteristics.

Keywords: sourcing teams; team performance; group dynamics; survey

Increased global competition, shorter clock-speeds, and greater customer demands have become the order of the day, demanding organizations to change how they do business (Gunasekaran et al., 2008). While companies have made great strides to integrate with external stakeholders, particularly suppliers (Petersen et al., 2005), the internal integration link has often been noted as not being as well developed. However, the internal perspective cannot be neglected, and plays an important part in accomplishing the best results for the organization. Specifically, the needed internal capability pertains to cross-functional sourcing teams (Johnson et al., 2002), integrating different internal perspectives to help the organization propel its differentiation and competitive advantage in this fast-changing environment (Hardt et al., 2007).

While the use of cross-functional teams in sourcing makes sense (Luzzini and Ronchi, 2011), it is easier said than done (Majchrzak et al., 2012). Impediments to greater team performance can include a lack of understanding of each other's perspectives, unwillingness to compromise, misalignment of performance measures, and the reluctance to give up control. Recent research in cross-functional sourcing teams has identified teamwork training and team processes as instrumental in enabling team success (Driedonks et al., 2010). While team processes pertain more to infrastructural aspects that may be addressed by putting appropriate procedures in place, a more challenging dimension may be to train individuals to effectively work in teams (teamwork training). This calls attention to the behavioral aspects that need to be considered in team formation and management.

While general management researchers have been studying behavioral issues for decades (e.g., Deckop et al., 2005; Ng and Van Dyne, 2005), only recently have scholars in

supply chain management devoted attention to organizational behavior. Much of the work has been done in the area of operations management, bringing insight into behavioral issues coming into play in managing a production environment (e.g., Bendoly et al., 2010; Schoenherr et al., 2017). However, an area that has still largely been neglected is organizational behavior in cross-functional sourcing teams (Driedonks et al., 2010). It is the objective of the present research to offer insight into this emerging domain via cross-cultural empirical study.

Relying on group dynamics theory (Lewin, 1947), we develop hypotheses pertaining to the influence of cross-functional team characteristics on team performance. Specifically, we theorize about the influential roles played by the dimensions of cooperative norms of the team, task and emotional conflict, group cohesion, psychological safety and goal similarity. Cooperative norms refer to the degree to which individuals in teams are expected to help each other (Ng and Van Dyne, 2005). Task conflict can be defined as "disagreements among group members about the content of the tasks being performed, including differences in viewpoints, ideas, and opinions" (Jehn, 1995, p. 258), while emotional conflict derives from interpersonal disagreements that are independent of the task (Jehn, 1995). Group cohesion refers to aspects that make teams stay together (Festinger, 1950), which are often related to interpersonal dimensions (Ng and Van Dyne, 2005). Psychological safety assesses how team members perceive the team environment to be safe for expressing their—potentially dissenting—thoughts and opinions (Edmondson, 1999). Goal similarity refers to the degree to which all team members agree on what is important for the team (Jehn, 1995). The dependent variable, team performance, is conceptualized as the extent to which the team accomplished the desired objectives in an effective manner (Linderman et al., 2006). In addition, taking a contingency perspective, we theorize about the moderating role of task characteristics inherent to the project at hand. Task interdependence has been shown to be a significant dimension shaping the context (Sharma and Yetton, 2003), substantiating it as a relevant contributor, especially within our setting considered.

To test the hypotheses, a survey was conducted among U.S. manufacturers. A single-response format was used, asking a key contact about team dynamics and behavior in a recent cross-functional team engagement. While this limits our ability to comprehensively assess the team dynamics (by merely focusing on one respondent describing the team), this made the study more manageable. We note this aspect though as a limitation. Measurement items for the multi-item constructs were based on established scales, which were adapted to our context of sourcing teams. Since the questionnaire was targeted at very specific individuals within organizations, a professional survey research firm was hired to collect the data (Schoenherr et al., 2015). Requirements for participation included the respondent to be within the purchasing function, and for them to having been involved in a sourcing team during the last year. The respondent could be either involved as a team leader or as a team member. A merit of this type of data collection is that responses are collected only from individuals that perfectly match the criteria. A total of 166 valid and complete responses were received for the U.S. sample, and a total of 227 valid and complete responses for the Japanese sample.

We have just started analyzing the data and their psychometric properties, including reliability and validity of the constructs. Once the sound measurement is confirmed, we will proceed with the testing of the hypotheses. This will be done through moderated multi-group regression analysis. Results will be presented at the conference.

Abstract
For a mature purchasing organization, developing and integrating the technological capabilities of suppliers into the company offer creation process is increasingly a key task. In this matter, one practical question that arises for a CPO is the organization of a systematic and fair consideration of supplier offers during the selection phases of each New Product Development (NPD) process. However, the more the specifications are functional, so as to encourage innovation from suppliers, the more difficult it is to compare offers. In this article we will start by picking up the different pitfalls inherent to this innovation sourcing process and afterwards we will present a method base on a bid comparison model based on the notion of *value in use* of the possible combinations of characteristics of the purchased product. Combined with a *reservation price,* we propose a preference curve and a feasibility curve. This process creates a space of solutions for supplier innovations that can be located below and above a given target price.

Key words: Innovation sourcing, Offers selection, ESI, EPI.

Introduction:

Innovation is driven by ideas. Ideas are generated by individuals or companies. If individuals or companies want to sell their innovations, they need to find a market that wants to buy the innovation. This requires that the product attributes of the innovation are explained to potential customers. In situations where the innovating body exactly meets the technical customer demand, the price will decide if the transaction will happen. In cases where the technical customer demand does not exactly match with the offered product, the specific characteristics of the different product attributes have to be changed to match with possible or acceptable solutions for the customer. When a product has more than one defining attribute, each difference results in differentiable product stimuli. Such stimuli can be ranked by the customer in order to indicate preferences of one product solution over another one. By the method of conjoint analysis (Green and al., 1981) following the weighting of product attributes in importance for the customer, the technical utility value of each attribute characteristics can be calculated. The customer can after indicate his payment willingness in form of a *reservation price* for each product stimulus. The resulting curve

out of this activity is a customer preference curve that contains the two dimensions price and technical utility value.

If one now takes the customer perspective instead of the perspective of the single innovating body, the customer or buying firm can ask several innovating bodies to submit offers in form of utility-price combinations for a functionally specified product. Each innovating body or potential supplier can offer for him feasible utility-price combinations. If one or more innovating bodies would like to offer new or unforeseen product characteristics within given attributes or even new exclusive attributes, the customer has to take a decision to update the attribute catalogue or in other words his preference curve. Following, a negotiation over price and technical utility can take place. To prevent from the temptation to use technical innovation from one supplier by updating the customer specification and to renegotiate only over price with the risk that the true innovating body will lose his innovative idea to a competitor, the negotiation in such case should run in parallel over technical utility and price.

This short description introduces the scenery of our purpose. Our research question *is How a purchasing function can introduce a systematic method in order to compare and select supplier offers including some innovating characteristics in order to maximize both the overall utility for the final user and the benefits for the buying company?*

The following article will explain first why product innovation by suppliers should be element of the scope of purchasing. After describing the main pitfalls connected to the management of innovation coming from suppliers, a purchasing model is developed that allows fast measurement and valuation of technical and functional supplier ideas. With this model, the technology dimension can be integrated to the supplier sourcing decision in addition to the price which helps ensures and even to enhance competition

Why supplier innovation should be in the scope of purchasing?

Several researchers discuss the assimilation of external knowledge as a necessity to minimum accelerate or to reinforce internal innovation (Chesborough 2003). Regarding the innovation target itself, it was shown by Simon (2007) that if a company wants to reach market leadership, innovation and technological advantage are the key success factors. A similar finding was concluded in a study of the Fraunhofer Institute for Systems and Innovation Research about the structure and drivers of innovation success in the German machine building industry. The two elements innovation and technology and concurrent quality leadership were found to be the decisive points for the companies' success (Kinkel and Som 2007). Looking into the buyer supplier relationship, after intense studies on the question of identifying and pulling innovation from supplier to customer (Dyer and Singh 1998) also the inverse direction of pushing innovation from supplier to customer was researched (Monczka et al. 2010).

The necessity of supplier innovation integration to the customer product and process development is seen especially true in turbulent economic environment and rapid changes in the development of new products (Brem and Tidd, 2012; Johnsen et al. 2006). In an environment where the available product development time and own development resources decrease and the pressure on robust innovation increases at the same time, a significant contribution of innovation by suppliers is a necessary element for success

(Ragatz et al. 1997). Le Dain, Calvi and Cheriti (2011) explain in addition, that suppliers play a more important role in new product development with an increasing share of component outsourcing. Schiele (2010) shows that successful companies from an innovation standpoint intensively work with more than double the number of innovative suppliers than unsuccessful companies do. A prerequisite for successful innovation contribution from suppliers thereby is the early supplier involvement during the development activity on the one hand and the collaboration between purchasing and R&D department of the buying firm on the other hand. An additional aspect in this context was brought in by Rogers et al (2007), saying that new techniques in the buyer supplier management especially with regards to supplier development should be accompanied by e.g. supplier development workshops in order to mitigate institutional pressure on the buyer side and to achieve an effective and positive innovation result consistent with the buyer's institutional expectation. Another important question raised by academics was how to identify an innovative supplier (Schiele 2006). A "good" innovative supplier must first be motivated by the buyer looking at him as a preferred customer (Schiele 2012). The supplier must also have some potential resources in order to contribute in the development process. There is less unanimity about the origin of a potential innovative supplier. For Schiele (2006) the innovative must have a long history of collaboration with the buyer so implicitly he must be a part of the actual supply base of the buying firm. This most suits when the client is seeking for some incremental innovation (Azadegan 2011) but for Philipps et al. (2006), in a more discontinuous innovation context, an innovative supplier must be found mainly out of the supplier base outside the existing supply network by means of strategic dalliances in order to introduce some real novelties in the product.
If a lot of researches are trying to define the key managerial skills to successfully involve suppliers in these development activities (Wynstra 2003; Johnsen 2009), there is nothing said about how to practically compare offers received in order to select the more valuable one? If you really involve early suppliers in the NPD process the question is absolutely not trivial because the earlier you involve them, the less comparable should be their offers. Independent of the question how a supplier offering should be valued under the aspect of innovation in an early stage, early supplier involvement reduces the likelihood of supply disruptions in the future and hence reduces the perceptions of supply risk at the buying company (Zsidisin G.A., Smith, M.E. 2005)

To understand de construction of the comparative model describe in this paper we have to introduce you our perception of the main pitfalls inherent to the management supplier innovation.

Pitfalls in innovation management with suppliers

The target of the authors is to create a model that allows practical application, e.g. in an industrial environment. In this regard, the practical pitfalls and respective countermeasures have to be addressed as well when pursuing innovation management with suppliers.

The first practical pitfall for the purchaser when he is expecting innovation contribution from suppliers is that the suppliers normally have to be selected in an early project phase. As the supplier hardly can be changed in a later project phase, competition needs to be ensured before the collaboration phase between the selected supplier and the customer. As during that decision time the final product design logically is not fixed yet, the

technological dimension needs to be added to the sourcing concept of the buying firm (Schupp 2004).

This aspect needs to be emphasized as many purchasing organizations look for lowest possible product prices, good quality and high delivery reliability first, but they do not explicitly include technology or supplier innovation contribution to their primary target matrix (Schumacher et al. 2008). In this context Glantschnig (1995) asked member companies of the German Association of Materials Management, Purchasing and Logistics what are their main purchasing targets. The answers were lowest possible price, a good quality and a high level of delivery reliability. Grochla et al. in addition introduced the target of cost reduction (Grochla and Schönbohm 1981). Dobler et al. (1995) list similar targets of the Purchasing and Logistics function. This target focus shows, that purchasing organizations do not primarily strive for supplier contributed optimized designs and technological fit with the needs of the buying firm or the end customer. The purchasing organizations also do not necessarily work towards an optimized product-price allocation for items that they buy.

Schumacher et al. (2008) however, show in their study about the main leverages in purchasing that the product optimization has the biggest leverage on the bottom line of a company. Compared to this technical leverage, pooling of demand, global sourcing and process improvement have significantly less contribution. A good relationship between customer and supplier however results in significant improvements to the bottom-line as well. As a result, the study suggests that the target of product optimization should be added as one important element to the targets of a purchasing organization.

Therefore, the authors of this chapter conclude that the technology dimension itself needs to be added to the sourcing concept of the buying firm.

A second pitfall is the wrong or missing determination of functional preferences related to respective reservation prices of the customer or target prices of the customer's customer**.** In a business-to-business environment, hereby the target price of a supply chain transaction primarily is determined by the customer of the buying firm.
The competition phase of a sourcing process can have one or multiple winners that in many cases will start with the product development process after the awarding. If the market rules do not allow significant re-negotiations with the customer of the buying firm after project awarding, especially in cases where a high degree of innovation is required, the probability for a single source supplier is high. At the same time the risk for future financial loss incurred by the winning supplier is equally high. The latter is widely described under the phenomenon of the winner's curse. Here the winning bidder in a First-Price-Sealed-Bid auction tends to overestimate the unknown value of the auction object or underestimates the cost and consequently bids too optimistically. As a consequence the winner of the sourcing risks ending up with systematically limited margins or even with losses. Of course this phenomenon only occurs with bidders that act irrationally, but in business practice this situation happens from time to time. Literature analyses two main influencing factors (Engel et al. 2006). The first one states that the higher the number of bidders, the higher the risk for the occurrence of the winners curse. This aspect is widely accepted to be true. The second factor is the degree of uncertainty. Uncertainty for the supplier can arise from unclear technical aspects, from an undefined business volume or business environment or from changing expectations with regards to technological requirements.

As a recommendation for the buying firms' purchasing organization this means that in case of absence of post-sourcing re-negotiation possibilities with the buying firm's customer, the determination of functional preferences together with different reservation prices for respective functional product characteristics is necessary in order to eliminate the risk of financial loss by wrong product-price allocations.

A third pitfall in innovation management with suppliers is to close the design at a too early stage. To reduce the risk of product failure, the buying firm tends to wanting to specify product parameters in a very precise way from beginning of the project. If the buying firm does that, three types of risk can occur. The first one is a missed chance for innovation in an unexpected area. This could for example happen if a not awarded supplier could have reached superior product-price combinations in comparison with the winning supplier, but simply could not show his capabilities because of restricted product definitions in the beginning. Another risk could be that the selected supplier turns out to have technological disadvantage or even performance problems to achieve the specified product parameters if he is out of his technological sweet spot. A further risk is a non-optimized product-price combination which could lead to an overshooting of previously defined target cost or a wrong product-price allocation. The winning supplier could have been in a position to offer a better product for the same price or a less advanced product with an over-proportionally lower price. All such risks result out of ignored or simply unused supplier core or best-cost competencies in product or process innovation. Therefore it is evident for the buying firm to keep the own design open and to start with a functional specification rather than with a finalized design both on customer product and on sourcing object level.

A forth pitfall when trying to sustainably buy innovation is the rewarding problem. As the potential suppliers have to submit new technologies, own technical solutions and innovations, they must be rewarded for innovations that are used in final designs instead of the buying firm using and internalizing the innovation and sourcing it at another competing supplier. Therefore, the sourcing process has to run simultaneously over the technology dimension and the price dimension in order to avoid that the buying firms' preference is updated with the different supplier innovation contributions before the final sourcing. Otherwise the rewarding of innovative suppliers is endangered. Therefore, it is recommended to run an innovation sourcing process as a parallel process over the two dimensions price *and* technology.

Purchasing model for sourcing of utility-price combinations

The idea behind the present purchasing model is to create a solution space of possible product-price combinations instead of focussing on a fixed set of functional product characteristics or a fixed specification. In this way, the potential suppliers have the chance to introduce different technical and functional solutions that lead to several different product-price combinations. To guide the reader through the model, a reference to a practical example is used. In the example the buying firm intends to buy a display for a rear seat entertainment system to be sold to a customer that is producing passenger cars.

The model is based on a three-step concept. In the first step the user is defining his preferences. The second step creates the possible product-price combinations offered by the potential suppliers and the feasibility curve. In the third step the feasible product-price combinations will be put in context with the preferences of the buying firm. Orientated at

the value added of the product-price combination offered in relation to the preference curve and under the condition of the customer target price, an optimal supplier decision can be taken. By definition the term ‘product’ is used in the sense of the component or service to be purchased from the suppliers.

A developer’s survey reveals most important product attributes and characteristics

The development of the preference curve starts with a survey amongst the buying firms’ key development and marketing staff identifying the relevant attributes of the targeted product or components to be purchased.

Table 1: The buying firm sets relevant attributes and characteristics

Source: own

Ranking	Attributes		Characteristics	
1.	A1	Display Size [inch]	A1.1	7
			A1.2	10
			A1.3	12
2.	A2	Display Weight [gram]	A2.1	800
			A2.2	500
			A2.3	300
3.	A3	Electricity Consumption [w att]	A3.1	10
			A3.2	6
			A3.3	4
4.	A4	Response Time [ms]	A4.1	3
			A4.2	2
			A4.3	1

For each selected attribute possible characteristics have to be defined. In the model it is suggested to use 4 attributes and 3 characteristics for each attribute. The possible number of combinations equals to the number of characteristics to the power of the number of attributes (here $3^4 = 81$ combinaisons). Of course one can choose to increase or decrease the number of attributes and characteristics, however the chosen number of 4 and 3 gives enough possibilities and at the same time limits the complexity to a practical level. Another argument for limiting the number of characteristics is, that during the evaluation of the preferred and the feasible product-price combinations, an interpolation between the different combinations will be done. In the chosen example the attributes display size, display weight, electricity consumption and response time are used to characterize the purchased product.

Ranking of the top 10 product stimuli

In the next step the buying firm is requested to rank the best 10 product stimuli. Best in the sense of the model means the preferred combinations. Each stimulus consists of one characteristic per attribute.

Table 2: Ranking of stimuli according to preference and likelihood of acceptability

Source: own

Ranking	Characteristics for Attribute A1	Attribute A2	Attribute A3	Attribute A4	Reservation Price
1.	12	300	4	1	100
2.	12	500	4	2	98
3.	12	500	4	3	93
4.	12	300	6	2	85
5.	12	500	6	2	83
6.	12	500	6	3	80
7.	10	300	4	2	79
8.	10	500	4	3	76
9.	12	800	10	3	74
10.	10	500	6	3	73

In the example the best combination is a 12 inch display with 300 grams weight, 4 watts electricity consumption and 1 ms response time. Key in this development step of the preference curve is to assign a reservation price to each stimulus. The reservation price is the maximum price that the buying firm is willing to pay for the respective stimulus. As the stimuli are ranked, the highest reservation price will be found at the top ranked stimulus. Table 1 lists 10 stimuli for good visibility. Of course theoretically all 81 stimuli would be listed, but for the purpose of easier handling only the first 10 stimuli are used in the model going forward.

The setting of attributes and characteristics and also the ranking of the stimuli in business practice is only efficient with the help of digitalization. One or more stakeholders, mostly development engineers and marketing specialists, can define attributes with characteristics and rank them via a web-based tool. Out of the product planning or controlling group of the buying firm, the respective reservation prices can be added.

Conjoint analysis of stimuli and transformation into standard utilities

Step three in the development of the preference curve is the conjoint analysis itself of the stimuli. The method of the conjoint analysis identifies the importance of each attribute and characteristic (Luce and Tukey 1964). In the conjoint analysis, each attribute will receive an importance in percent totalling to 100 percent. Within each attribute, for the defined characteristics a utility value is calculated. By normalizing the values, the least important characteristic within an attribute gets assigned to the standard utility of 0. The highest valued characteristic gets assigned to the weight of the complete corresponding attribute. It is needless to say that also this step profits from digitalization over a web-based tool.

Table 3: Calculation of the utility value by conjoint analysis

Source: own

Attributes		Importance in %	Characteristics		Standard Utility
A1	Display Size [inch]	50	A1.1	7	0.000
			A1.2	10	0.200
			A1.3	12	0.500
A2	Display Weight [gram]	25	A2.1	800	0.000
			A2.2	500	0.200
			A2.3	300	0.250
A3	Electricity Consumption [watt]	20	A3.1	10	0.000
			A3.2	6	0.050
			A3.3	4	0.200
A4	Response Time [ms]	5	A4.1	3	0.000
			A4.2	2	0.030
			A4.3	1	0.050
	∑	100%			

Ranking of the best 10 stimuli by utility and reservation price

In step four the standard utilities out of step three are used to calculate the utility of each stimulus. The calculation is simply adding the standard utilities of each characteristic within the 10 selected product stimuli. By the method of normalization the maximum value of a stimulus utility is 1. The minimum is 0.

Table 4: Referencing of reservation price and utility of 10 best stimuli

Source: own

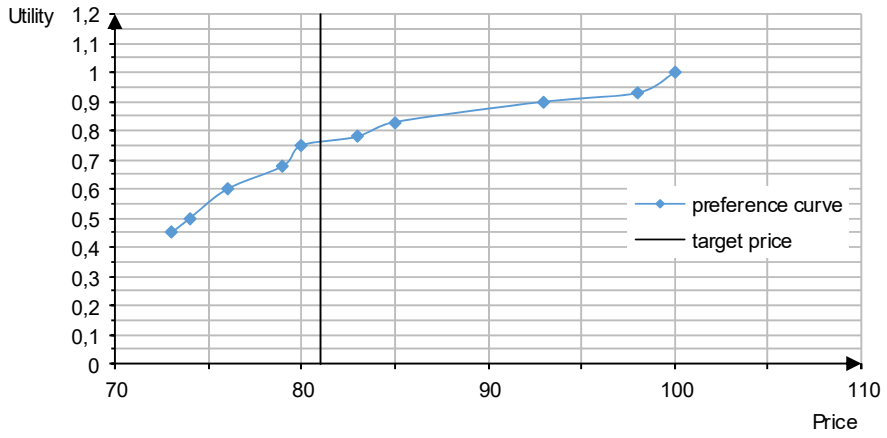
Ranking	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
Utility Stimulus	1.000	0.930	0.900	0.830	0.780	0.750	0.680	0.600	0.500	0.450
Reservation Price	100	98	93	85	83	80	79	76	74	73

In step five of the preference curve creation, the reservation price for each stimulus and the utility of the same stimulus are put in context by entering both in a graph. The reservation price is put down on the x-axis, the utility on the y-axis. The final selection for a product-price combination in business practice does not only depend on the reservation price of the buying firm, but also on the target price of the buying firms' customer. This customer target price is introduced to the model at this point.

Of course it can happen that some acceptable stimuli from a buying firms' point of view have higher reservations prices compared to the customer target price. This situation will be discussed further after the development of the feasibility curve with regards to offered product-price combinations by the potential suppliers.

Table 5: Matching of utility and reservation prices to the preference curve

Source: own



Development of the feasibility curve based on supplier innovation

Based on an open functional specification, the potential suppliers are asked to offer their product-price solutions to the buying firm. In a concept competition each potential supplier is asked to offer several possible product solutions that also can have different prices.
The first step for the development of the feasibility curve uses the utility values of the characteristics defined in the development of the customer preference curve before.

Table 6: Supplier offers translated in utility values and related offered price

Source: own

Offer	Supplier	Utility A1	Utility A2	Utility A3	Utility A4	∑ Utility	Price
1	A	0.400	0.200	0.200	0.050	0.850	105
2	C	0.400	0.150	0.200	0.030	0.780	100
3	B	0.300	0.250	0.200	0.020	0.770	94
4	A	0.550	0.200	0.000	0.000	0.750	85
5	A	0.350	0.250	0.050	0.050	0.700	83
6	B	0.400	0.150	0.100	0.030	0.680	80
7	C	0.200	0.350	0.100	0.000	0.650	79
8	B	0.500	0.100	0.000	0.000	0.600	76
9	C	0.200	0.100	0.000	0.050	0.350	75
10	B	0.100	0.100	0.000	0.030	0.230	72

If suppliers offer characteristics that do not match with the selected characteristics by the buying firm, the model will interpolate the utility values of the offered and the selected characteristics. The utility values of each characteristic are added to a sum of utilities. In addition to the utility sum of the offered stimuli by the suppliers, the corresponding offering price is included in the model. As mentioned before, suppliers might offer new product attributes that are decision relevant. If so, the steps 1 to 5 of the model have to be repeated.

Utility-price ranking of the 10 best bids

The next step of the model is the negotiation between the buying firm and the competing suppliers.
Different to conventional negotiation situations the suppliers can either offer better prices or better utilities. The latter can be done by offering better characteristics compared to the previous solution. This process can also lead to a situation where the utility value will increase and the price will increase as well. In the example this situation is shown by supplier B who is offering 100 € and a 0.930 utility in offer number 3 compared to 94 € and 0.900 utility in offer number 2. The format displayed allows three rounds of negotiation. Nevertheless more rounds are possible in real business situations.

Table 7: Three offer rounds allow price and utility changes

Source: own

	Offer 1			Offer 2			Offer 3		
Supplier	Utility	Price	Feedback	Utility	Price	Feedback	Utility	Price	Feedback
A	0.850	105	r	0.880	105	r	0.950	105	r
B	0.780	100	r	0.900	94	r	0.930	100	r
C	0.770	94	r	0.900	95	r	0.900	94	r
A	0.750	85	r	0.850	84	g	0.890	85	g
B	0.700	83	r	0.830	84	g	0.860	83	g
A	0.680	80	r	0.740	78	g	0.820	80	g
C	0.650	79	r	0.680	77	g	0.800	79	g
B	0.600	76	g	0.700	79	g	0.700	76	g
C	0.350	75	r	0.400	73	r	0.400	73	r
B	0.230	72	r	0.350	75	r	0.330	72	r

For each negotiation round a feedback is required. The feedback indicates if the offered product-price combination is above or below the preference curve of the buying firm. If the offered product-price combination is above the preference curve, the feedback is ‘g’ for green. The meaning is, the product-price point is inside the area of acceptable solutions for the buyer. The feedback ‘r’ for red indicates that the offered solution is not acceptable for the buyer as it is below his preference curve.
In this element of the model digital feedback to the suppliers allows to start immediate improvement actions by the suppliers to put themselves in a better position in the following round of negotiation.

Winner determination by comparing for preference and feasibility curve

In the following step the winning combinations are listed. Winning combinations are defined as the combinations after the final negotiation round with the feedback green.
If the result of the negotiation has more than one winning combination, another two steps to determine the best solution have to be taken.
First the offered prices of the winning combinations have to be mirrored against the buying firms’ customer target price. In general it can be assumed that an acceptable solution for the customer has to beat his target price. Nevertheless there might be situations where a customer would be willing to discuss an attractive utility-price combination that is even above his target price. Such a situation could occur if e.g. a customer has a product placing strategy for low end and high end market segments at the same time.

Secondly, the question needs to be answered which one of the winning combinations is the best combination out of the buyer's point of view.

Table 8: Identification of the utility delta between feasibility and preference curve

Source: own

Supplier	Price	required Utility	offered Utility	Δ (offered - required) Utility	above/ below Target Price
C	79	0.680	0.800	+ 0.120	below
B	76	0.600	0.700	+ 0.100	below
B	83	0.780	0.860	+ 0.080	above
A	80	0.750	0.820	+ 0.070	below
A	85	0.830	0.890	+ 0.040	above

In the example 3 winning combinations have a utility of 0.8 at a price of 79 €, a utility of 0.7 at a price of 76 € and a utility of 0.82 at a price of 80 €. If the buyer would choose the winning combination with the lowest price he would decide for a utility of 0.7 at a price of 76 €. But as the target of the model is to identify the best offer based on price *and* utility, the buyer could choose the winning combination with the highest delta utility towards the preference curve. With this argument the combination with the utility of 0.8 and the price of 79 € would be the best combination. In order to identify such kind of best utility-price combinations, all feasible solutions above the preference curve are listed and ranked by their delta utility to the preference curve. Table 8 shows which combinations are below or above the customer target price. In table 9, the presented example is aggregated into the preference curve and a feasibility curve before and after negotiation in one graph.

By the introduction of the target price line of the buying firms' customer, the user of the model can identify the relevant winning solutions. As mentioned above also the two other green utility-price combinations are element of the solution space of the model. They are above the target price line of the customer's customer, but represent high enough utilities. Therefore, the customer might offer an upgrade product to the customer's customer that he could sell to a higher end market.

Table 9: Feasibility curve of final offers in context with target price and preference curve

Conclusion and future research directions

The present model shows how to effectively include the technology dimension into sourcing decisions where a supplier contribution with regards to innovation is required. The model is created for the use in business practice. It allows systematic early supplier involvement without losing the competition phase and can be applied for innovation management with suppliers in different sectors and used for various products. A transformation from product to component level is possible as in such cases the product innovation would be gradually replaced by process innovation. In the next development step for the effective application, digital buying portals or buyer-supplier platforms have to be enhanced so the buying firm can process the technology dimension by entering attributes, characteristics to get to product stimuli and to get to calculated corresponding utilities. Invited suppliers can set their bids in form of utility-price combinations and get real-time feedback about their ranking in the negotiation. If the customer of the customer can be linked to the portal as well, the target prices of the customer's customer can be used in order to allow real-time decision making that is including even the solution space above the customer's customer target price.

Abstract: This paper investigates supplier involvement in new product development (NPD) driven by public procuring organisations. It stresses the role of small suppliers in leading the development of products that fulfil unmet public sector needs. Under high technological uncertainty, innovative SMEs can assume NPD responsibility at product level. Contracts for product development contribute to the establishment and growth of innovative small suppliers which, in many cases, would not otherwise exist. This supply network creation function is in stark contrast with supplier involvement in NPD occuring in pre-existing supply networks.

Keywords: Supplier Involvement in NPD; Pre-Commercial Procurement; R&D Contracting

Introduction

The aim of this paper is to investigate supplier involvement in new product development (NPD) that occurs in the public sector. The extant literature on supplier involvement in NPD has collectively shown that suppliers are an important source of innovation and can positively contribute to a focal firm's NPD performance (Johnsen, 2009). However, empirical research in this area has focussed on private sector buyers (typically large manufacturers) and their relationships with established suppliers of component or systems, and has ignored settings whereby the buyer is a public organisation.

Besides its focus on private sector procuring firms, the extant literature too often regards the procuring firm as the end user of the sourced innovation. Suppliers tend to contribute to well-defined specification, design and development tasks, and to be involved in specific stages of the NPD process depending on certain contingencies e.g. criticality of component and complexity of development task (Zhao et al., 2014). The depth of supplier involvement is characterised by supplier level of responsibility for development activities (e.g. 'black-box' suppliers), but such responsibility stll refers to components, sub-assemblies or systems that are integrated into the focal firm's new product (Wynstra et al., 2010).

These underpinning assumptions, which remain largely implicit, are often not appropriate in innovation-oriented public procurement settings. Public authorities also conduct sizeable R&D and invest in developing new products and technologies that have the potential to improve the delivery of public services. Internationally, a well known example is the US Defence Advanced Research Projects Agency (DARPA). Notable examples in the UK include National Health Service (NHS) England with its various related initiatives, and the Defence Science and Technology Laboratory (DSTL) operating within the UK Ministry of Defence (MoD). Similar

to developments in the private sector, such public organisations increasingly draw on industry suppliers' R&D capabilities and inputs to improve NPD performance in terms of reduced development time and costs. In such settings, the public procuring organisation may not be the end user of the new product. For instance, in UK healthcare patients are often the users of many digital medical apps that are mainly developed by industry suppliers and subsequently procured by NHS agencies. This example also suggests that suppliers may be asked to assume NPD responsibility at product level, although such products /technologies still need to be integrated into the wider service delivery system. Understanding how suppliers are integrated into public sector-oriented NPD is important, given the significant challenges in relation to the adoption of innovative products or technologies by public sector customers (Georghiou et al., 2014).

Overall, we seem to know little about supplier involvement in NPD in innovation-oriented public procurement settings. This study aims to improve our understanding by pursuing the following research question: How *does supplier involvement in NPD differ in innovation-oriented public procurement settings as compared to private sector innovation procurement?*

We address this question through a qualitative interviewing study. Our empirical focus is on the Small Business Research Initiative (SBRI), which is the UK policy instrument for public procurement of R&D. The SBRI targets private sector suppliers (especially SMEs and micro-companies) to be involved in the development of new products /services that fulfill unmet public sector needs. Our study identifies some distinguishing characteristics of supplier involvement in NPD in the context of innovation-oriented public procurement. It also identifies some novel research avenues at the intersection of research on "supplier involvement in NPD" and the "innovation-oriented public procurement".

Literature review

Supplier involvement in new product development

The literature on supplier involvement in NPD has grown considerably in the last two decades as there is recognition of the potential of suppliers as a source of product or process innovation (Johnsen, 2009). This reflects, more broadly, the wide adoption of the open innovation paradigm which suggests that a focal firm's innovation performance is increasingly dependent on interaction and collaboration with its customers, suppliers and business partners (Chesbrough, 2006). Supplier involvement in NPD refers to the integration of capabilities that suppliers can contribute to R&D projects of a focal organisation. Van Echtelt et al. (2008, p. 182) define supplier involvement in NPD as *"the resources (capabilities, investments, information, knowledge, ideas) that suppliers provide, the tasks they carry out and the responsibilities they assume regarding the development of a part, process or service for the benefit of a buyer's current or future product development projects".*

Early research on supplier involvement in NPD was biased towards the automotive industry (Johnsen, 2009), showing how Japanese auto manufacturers coordinated R&D and procurement tasks internally, and how they leveraged supplier capabilities to reduce time-to-market and improve product quality (Clark and Fujimoto, 1991). Although subsequent empirical research expanded into other industrial sectors, a common denominator of the existing literature is the focus on private sector manufacturers as the focal firms that involve, integrate and collaborate with their suppliers in NPD projects (Luzzini et al., 2015).

Existing research has emphasised a number of aspects that could be distilled into antecedents, process, and performance effects of supplier involvement in NPD. Antecedents of supplier involvement refer both to drivers of supplier integration and pre-conditions for successful

integration. Key drivers include increased market competition, rapid technological change, reduced product life cycles and the need to reduce drastically time to market. Several prerequisites of supplier involvement in NPD have been discussed in the literature, such as prior experiences with suppliers, supplier relationship quality, supply base rationalisation and supplier selection based on technical and R&D capabilities (e.g. Koufteros et al., 2007; Yeniyurt et al., 2014; Sjoerdsma and van Weele, 2015).

Process-related issues include the extent and appropriate timing of supplier involvement. Regarding the extent or depth of involvement, a distinction is typically drawn between 'black-box' and 'grey-box' supplier integration into NPD. The former refers to cases where the supplier assumes sole responsibility for developing a certain component or part, whereas the latter in circumstances where the supplier works jointly with the buyer and shares its expertise, but it does not assume sole responsibility for component development (Koufteros et al., 2007). Regarding the timing of supplier involvement in NPD, it is suggested that optimal timing depends on several factors including the criticality of component, the supplier's strategic importance and the complexity of development task (Zhao et al., 2014).

Overall, *early* supplier involvement is beneficial insofar as it helps to evaluate the technical feasibility of new concepts and to reduce the cost of changes in product design and engineering specifications. Recent studies stress the importance of focusing on supplier involvement in the "fuzzy front-end" as compared to involvement in the "execution-oriented back-end" (production to product launch) of the NPD process (Wowack et al., 2016). Supplier involvement in the fuzzy front-end is influenced by relationship characteristics (e.g. benevolence) and, when effectively managed, it can lead to significant performance benefits (Schoenherr and Wagner, 2016). Other studies stress the importance of developing a structured approach to supplier involvement and effectively managing supplier relationships (e.g. Van Echtelt et al., 2008). To this end, the positive contribution of supplier development activities has been stressed (Lawson, Krause et al., 2015). However, existing research tends to focus on dyadic (buyer-supplier) relationships and has yet to systematically consider supplier network-level effects (for a notable exception see Johnsen, 2011).

In terms of performance effects, empirical evidence collectively suggests that effective management of supplier involvement in NPD contributes to reduced development time and costs and quality enhancment (e.g. Lawson, Tyler et al., 2015; Van Echtelt et al., 2008). There are, nevertheless, several caveats to this generic conclusion depending on specific contingent factors. For instance, there is inconclusive evidence of whether involvement of existing suppliers is beneficial under high technological uncertainty and radical innovation scenarios. In such contexts, it may be more effective to involve new suppliers as a potential source of innovation (Johnsen, 2009).

Innovation-oriented public procurement

The literature on public procurement of R&D and innovation (Georghiou et al., 2014) originitates in the field of innovation policy and management and it has developed very much in parallel with research on (private sector) innovation sourcing and the more specific literature on supplier involvement in NPD. Research on innovation-oriented public procurement has focused on the enabling role of goverment procurement in stimualting innovation in supply markets (Aschhoff and Sofka, 2009). Public procurement is regarded as a distinct type of demand-oriented innovation policy instrument, which can steer the development of new products or technologies that address grand societal challenges and meet operational needs of public authorities (Edler and Georghiou, 2007). Public organisations essentially serve as lead

customers of innovative products or technologies, thus creating demand for and incentivising R&D and innovation that would not otherwise happen. The potential of goverment procurement has also been recognised in the UK, where approximately 14 per cent of GDP is spent on public procurement (HM Government, 2017).

The literature discusses two key types of innovation-oriented public procurement (Edquist et al., 2015). ”Pre-commercial procurement” concerns public procurement of R&D services that may trigger demand for yet-to-be-tested products or technologies. ”Public procurement for innovation” refers to commercial procurement of products or technologies that have already proven their benefits (Edler and Yeow, 2016). By virtue of its emphasis on early-stage, highly uncertaint R&D, pre-commerical procurement does not include commercialisation and innovation adoption tasks. Rather, private sector suppliers are awarded R&D contracts ultimately with the aim of developing and demonstrating a prototype which is to be further tested and refined. A separate procurement process is subsequently initiated to procure the final product or technology at large scale (Ribgy, 2016).

From a policy perspective, pre-commercial procurement is expected to perform three high-level functions (Selviaridis and Spring, 2017): (a) addressing market failures - of information by showcasing promising supplier products /technologies and helping suppliers (especially SMEs) to attract additional funding, and those related to positive externalities of R&D by incentivising industry effort and investment in highly uncertain NPD activity, (b) addressing system failures by facilitating connectivity of all relevant actors, promoting interactive learning and articulating and coordinating demand for innovative solutions, and (c) allowing public organisations to solve hitherto intractable problems by acting as lead customers that help create markets for new products /technologies.

A notable example of pre-commercial procurement is the US Small Business Innovation Research (SBIR) programme. This been in operation since 1982 with the purpose of developing new products or technologies that address the needs of federal departments and other public agencies. Overall, the SBIR has had a positive impact on the US economy and the growth of innovative SMEs (Mazzucato, 2015). Pre-commercial procurement policies in Europe originate in attempts to imitate the US SBIR scheme. First the UK in the early 2000s, and later the EU developed specific policies for public procurement of R&D (Rigby, 2016). The EU policy framework for pre-commercial procurement is compliant with principles of equal treatment and fair competition and avoidance of state aid. Currently, three pre-commercial procurement schemes operate in Europe: the UK SBRI, the Dutch SBIR and the Flemish Procurement of Innovation scheme designed by the Government of Flanders in Belgium (Apostol, 2014).

Research method

To develop an understanding of how suppliers are involved in public sector-driven NPD activity, and how different that is from what we already know about supplier involvement in NPD in the private sector, we have adopted a qualitative research design based on in-depth interviews (Marshall and Rossman, 1999). We have chosen to focus on the UK SBRI as that is the country’s main mechanism for involving private sector suppliers in public-sector-driven R&D activity. In addition, the UK SBRI is mainly concerned with development projects characterized by: (a) moderate-to-high technological uncertainty and, (b) potential involvement of multiple supply network tiers (SMEs and larger, first-tier suppliers to public authorities) in NPD. These characteristics make a comparison of the SBRI with supplier involvement in private sector innovation sourcing theoretically interesting.

Data collection entailed 32 semi-structured interviews with individuals who are knowledgable about the SBRI process as well as review and analysis of 80-plus documents. More specifically, we conducted interviews with 20 supplier companies /SMEs that have participated in SBRI competitions and related R&D projects, and four public organisations using the SBRI scheme to involve suppliers in NPD activity. We also conducted eight interviews with innovation /innovation procurement experts and relevant policy makers e.g. from the Department of Business, Energy and Industrial Strategy and Innovate UK. The interviews covered multiple areas such as the rationale and aims of the SBRI scheme, its implementation in practice, procurement process aspects, supplier involvement in SBRI projects, and the effectiveness of the SBRI scheme.

To complement and triangulate interview data, we collected and analysed publicly available data including SBRI review reports, Innovate UK reports, official statistics on SBRI competitions and contracts awarded, as well as policy-oriented reports produced by innovation experts and international organisations e.g. OECD. We used the ATLAS.ti software to organise, analyse and code both primary and secondary data. In parallel to assigning codes to interview transcripts and document excerpts using open and axial coding procedures (Miles and Huberman, 1994), the 'memo manager' function of ALTAS.ti was used to capture our evolving thoughts and comments during the data analysis process. Our (comparative) analysis also drew on key concepts featuring in the literature on supplier involvement in NPD. This allowed us to identify some distinguishing characteristics of supplier involvement in public procurement of innovation settings.

Findings

The Small Business Research Initiative (SBRI): scope and process

The SBRI is a horizontal (i.e. sector-neutral) policy instrument that provides opportunities for public sector organisations and innovative companies to interact and engage in collaborative R&D to solve specific challenges facing the UK public sector. Unlike the US SBIR that allows only small businesses (with maximum 500 employees) which are also at least 51% commercially owned to bid for government R&D contracts, the UK SBRI is accessible to any organisation of any size, including large firms, consultancies and even universities. This is because the UK SBRI complies with EU legislation that does not allow for preferential treatment of small suppliers, and thus it cannot prevent larger firms from taking part in pre-commercial procurement and being awarded government R&D contracts (Ribgy, 2016). The scheme's lack of exclusivity to small suppliers is also based on the expectation that SBRI contracts are not attractive to large firms because these companies can self-fund R&D activities of that scale without having to expose their innovative ideas to other organisations. According to a SBRI Account Manager from Innovate UK, approximately three quarters of all SBRI contracts have been awarded to SMEs. The SBRI employs a phased approach meaning that suppliers /SMEs effectively tender for successive R&D service contracts (see Figure 1).

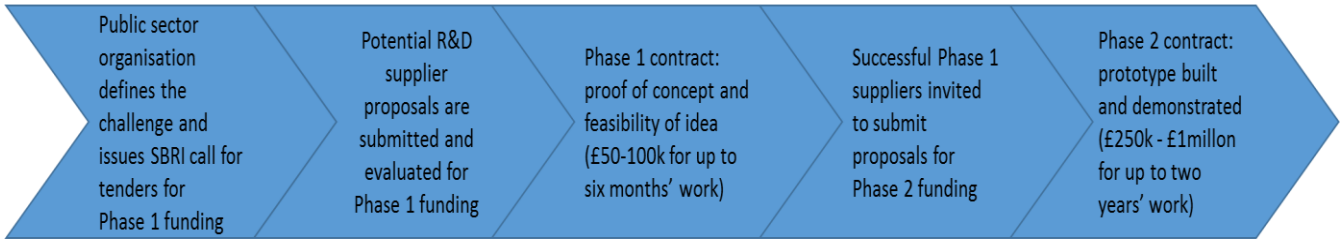

Figure 1: An overview of the SBRI process

The process starts with the identification and definition of a specific need or problem facing a public organisation, which is subsequently responsible for drafting the challenge brief and issuing the call for tenders. All tenders at that stage concern *Phase 1 contracts for 'proof of concept' research*. Supplier proposals are evaluated, and the successful ones are awarded Phase 1 contracts. These are worth £50-100k on average and last up to six months. These projects are expected to establish the scientific, technical and commercial feasibility of the innovative idea. Companies that successfully complete Phase 1 contracts can then be invited to tender for *Phase 2 contracts for prototype development*. Suppliers awarded Phase 2 contracts engage in prototyping activities and are expected to build, test and demonstrate a prototype. This work typically lasts up to two years and is worth up to £1 million. Successful Phase 2 projects may proceed to be further tested and subsequently procured and adopted by customers in the public or private sector.

Some SBRI projects (e.g. SBRI Healthcare) may informally include a third phase where the product or technology is further tested and refined in collaboration with potential customers in the public or private sector. However, this is the exception rather than the norm and there is no formal provision for a Phase 3 contract and related funding for commercialization activities.

The SBRI and supplier involvement in public sector NPD: some distinctive characteristics
This section discusses a number of seemingly distinctive characteristics of supplier involvement in public sector-driven NPD projects (see Table 1). These features result from analysis of the UK SBRI and comparison to extant literature on supplier involvement in NPD.

Table 1: Distinctive features of supplier involvement in NPD in the context of the UK SBRI

Dimensions for distinctiveness	**Distinctive characteristics**
Rationale for supplier involvement	Incentivizing supply base involvement in high-risk NPD; supporting growth of innovative small suppliers
Technological uncertainty impact	Focus on low-maturity technologies /products and involvement of new suppliers (innovative SMEs)
Supplier responsibility	Suppliers in many cases assume development responsibility at product level. They are heavily involved and usually lead fuzzy front-end NPD
Appropriation /intellectual property	Suppliers retain intellectual property even at product level
Supplier selection process	Suppliers compete on 'challenges' based on a tournament logic: evaluation of relative performance in focus
Supply network mobilization and creation	Mobilizing multiple supply network tiers in NPD; enabling creation of new suppliers
Innovation ecosystem complexity	High complexity impedes interactive learning and creates new product adoption and integration challenges

Regarding the rationale for supplier involvement, motivation extends beyond improving NPD performance in terms of reduced development time and cost. Early stage public sector R&D is highly uncertain in terms of its returns and it is prone to positive externalities and spillover effects, which discourages private sector participation and investment. Pre-commercial procurement schemes (such as the SBRI) incentivize suppliers to be involved in fuzzy front-end NPD activities by articulating demand for new products or technologies. In other words, public organisations serve as lead customers of new products that have the potential to fulfill unmet needs. In addition, there is particular emphasis on encouraging the involvement of innovative small suppliers and supporting their growth via integration into NPD that is relevant to public sector needs.

SBRI projects focus on the development of low-maturity technologies or even 'things that do not exist yet'. In this context, development risks tend to be high. Under high levels of technological uncertainty, public organisations are keen to expand their R&D supplier network and engage with agile, innovative SMEs or micro-companies that have the potential for contributing novel ideas or solutions.

An inherent requirement of the SBRI process is that suppliers are heavily involved in, and in many cases lead, early stage NPD activities. These include generating solution ideas, defining the solution concept, establishing the technical and commercial feasibility of the proposed solution, and developing and demonstrating prototypes. In most SBRI Phase 2 projects, the selected suppliers assume development responsibility at the level of the final product, rather than at component level. Public organisations monitor progress against the contracted NPD activity and typically provide feedback and expert knowledge e.g. regarding potential public-sector applications. In projects that qualify for further testing (via an informal phase 3) the supplier then works closely with all relevant public organisations (which may be other than the R&D procuring agency) to refine the solution and pilot-test it in real-life scenarios. The SBRI mechanism stipulates that suppliers retain intellectual property rights related to the novel ideas and products they develop, although public procuring authorities can have rights to access technologies as appropriate.

The majority of SBRI competitions are designed as 'challenges', making use of outcome- or problem-based specifications. The suppliers compete to be awarded R&D contracts and they are evaluated based on their relative performance (i.e. how promising and feasible a solution is as compared to others). The phased approach to awarding R&D contracts (Figure 1) suggests that the reward gap between suppliers that are able to move their product /technology ideas forward (i.e. suppliers awarded Phase 2 contracts) and those that are not (i.e. suppliers that fail to proceed beyond Phase 1) is significant enough to incentivize supplier effort and resource investment. In addition, there are substantial long-term benefits for suppliers (particularly small firms) that win such challenge-based competitions. Innovative suppliers that successfully complete Phase 2 contracts and develop promising products enjoy reputation benefits and can attract additional funding (e.g. venture capital) to further support their NPD activity.

The SBRI process also entails mobilization and involvement of multiple supply network tiers in public sector-driven NPD. Innovative SMEs or micro-companies that successfully complete R&D contracts are connected to larger, well-established suppliers (to public organisations) and work with these large suppliers to further refine a new product /technology or identify alternative applications. In addition, first-tier suppliers (e.g. prime defence contractors or pharmaceutical firms) may be working closely with public agencies to scope and specify the requirements included in SBRI challenge-based competitions, essentially proving input into needs definition. Innovative SMEs developing promising products can either become second- or third-tier suppliers or supply directly their public-sector customer. In this sense, the SBRI scheme appears to facilitate the creation and growth of innovative small suppliers, thereby supporting the development of innovation capability at the supplier network level.

The depth and impact of involvement of such small suppliers depends on many contingent factors including their positioning in the value chain, the characteristics of specific products and markets and their business model. Regarding the latter, innovative small suppliers involved in public sector R&D contracts can be classified as product-based businesses and R&D consultancies. The former are suppliers that are willing to invest resources in public sector-

relevant NPD and to build a business based on specific products or technologies derived from such NPD activity. The latter category refers to suppliers that effectively sell product /technology development services to their customers and they are not necessarily interested in building their own product-based business.

Innovation ecosystems in the public sector (e.g. in the UK healthcare and defence) are highly complex, creating structural, institutional and behavioral barriers that limit the ability of innovative small suppliers to effectively promote their innovative solutions to relevant public authorities. Systemic complexity impedes interactions and learning: both amongst relevant public organisations involved at different stages of the NPD process (R&D units, procurement units and end users of new products /technologies) as well as between small suppliers and public organisations (as potential customers and users of new products). Weak interactions and limited collaboration in many cases create challenges regarding the integration of new products /technologies (developed via SBRI projects) into existing service delivery systems. For example, the introduction of new digital technologies into health and social care systems may require partial re-design of service process, which may well be resisted by clinicians. The equal treatment and competitive tendering ethos instilled in public procurement practice may also be contributing to weaker buyer-supplier collaboration in NPD activity, despite the fact that innovation-oriented procurement processes (such as the SBRI) are in theory designed to overcome such impediments.

Discussion and conclusions

This paper seeks to understand how suppliers are involved in NPD occurring in public sector contexts, and how that may differ from supplier involvement in private sector innovation procurement settings. The research has identified several seemingly distinctive characteristics of supplier involvement in NPD in the context of pre-commercial procurement (see Table 1).

The empirical study emphasises some features that the extant literature on supplier involvement appears to have underplayed. The case of the UK SBRI stresses the role and contribution of *small suppliers* to NPD. Further, the SBRI exemplifies how, under high levels of technological uncertainty, public procuring organisations draw on the capabilities of *new suppliers* and how they deliberately expand their R&D supply network beyond their established suppliers to tap into new ideas. In many cases of SBRI projects, 'new supplier' has an additional meaning: these are suppliers (micro) companies that have been founded *because of* being awarded R&D contracts and selected to participate in public sector-relevant NPD activity. The risks related to investing effort and resources in low maturity product /technologies are mitigated via the SBRI phased approach to contracting, which resembles well-known stage-gate models of the NPD process (cf. Veryzer, 1998).

As compared to supplier involvement in private sectors, suppliers to public authorities are not only heavily involved in fuzzy front-end NPD activities (Schoenherr and Wagner, 2016), but in most cases they also lead such activities. Similar to what we already know from the extant literature, supplier selection is based on a competitive process. However, what is distinctive in the case of SBRI is that such supplier competition appears to follow a tournament logic (Wowak et al., 2016) i.e. suppliers compete for development contracts on the basis of designed innovation 'challenges' and they are being evaluated based on the relative performance of their innovative solutions.

Overall, our findings extend the literature on supplier involvement in NPD in two ways. First, we stress the role of small suppliers which can have a leadership role in fuzzy front-end

activities of developing products that fulfil unmet public sector needs. Under high level of technological uncertainty in public sector-relevant NPD, innovative SMEs can assume R&D responsibility at product level, rather than being involved in specific stages of a NPD process tightly controlled by a focal manufacturing firm (e.g. Lawson et al., 2015). The innovation locus is often external to the public procuring organisation, whose role in such cases is to facilitate interactions among SMEs, large industrial suppliers and potential end users.

Second, we show that innovation-oriented public procurement schemes (such as the SBRI) can perform a function of supply network creation. Contracts for product development are instrumental in helping to establish and grow innovative small suppliers which, in many cases, would not otherwise exist. These product-based businesses in the making can potentially fulfill the needs of public sector customers or established (first-tier) suppliers to the public sector, depending on their value chain positioning and product and market characteristics. This supply network creation function is in stark contrast with private sector innovation sourcing that happens largely in pre-existing supply networks, and entails collaboration with established suppliers and buyer influence of the supply network in a top-down fashion (Johnsen, 2011).

More broadly, our study serves as a first step towards cross-fertilising in a more systematic way two hitherto unconnected literatures: ”supplier involvement in NPD” and ”innovation-oriented public procurement”. Although our research is still in progress and it has so far focused on pre-commercial procurement settings, we can already point at some relevant avenues for future research. Potential research questions include the following: (1) What are the different pathways or models through which suppliers can be involved in NPD driven by the public sector? (2) How is supplier involvement in NPD managed when public sector customers require incremental (rather than radical) innovations? (3) What are the key success factors for increasing the adoption of supplier-enabled new products /technologies by public sector customers? (4) What is the impact of supplier involvement in NPD on the performance of public services? We hope that this working paper will stimulate intellectual debate and encourage research on some of these topics.

Abstract
The purpose of this paper is to investigate the contextual nature of reshoring drivers. This issue is examined through a multiple case study including three companies. Altogether, 49 sub drivers, categorized into 20 main drivers, were found in the case study. Among these, 40 were identified in the literature. All the main drivers, except 'government subsidies', were found in both the case study and the literature. This research proposes that the reshoring drivers are context dependent, that firm size seems to correlate to the number of drivers considered, and that Swedish reshoring seems independent of governmental subsidies.

Keywords: reshoring, drivers, manufacturing, Swedish context

Submission Category: Working Paper

Introduction

A significant movement of manufacturing from high- to low-cost environments, offshoring, has taken place in the past three decades (Ellram, 2013). This movement has created problems in the western world with regard to economic growth and employment (Wiesmann et al., 2017). The main reason for this relocation has been to reduce manufacturing cost, or more specifically the labor cost (Bunyaratavej et al., 2008). When looking in the rear-view mirror, it has become clear that many of these relocations have been unsuccessful; mainly due to the use of too simplistic calculations where the total cost was underestimated (Brown, 2010). In recent years, there has been an intensified discussion concerning the opposite movement, reshoring, that is when companies decide to move manufacturing back to their home country (Wiesmann et al., 2017). The manufacturing industry in the western world has shown an increased interest in reshoring, and more and more cases are starting to appear in both the scientific and the industry literature (Ellram et al., 2013). However, reshoring is still a young research area and has not been studied in a greater extent.

The existing literature in the reshoring field mostly focuses on investigating reshoring as the consequence of failed offshoring (Wiesmann et al., 2017). It has been argued that the manufacturing location decision often is based on vague grounds, and that managers feel that it is hard to find good support in the literature for these types of decisions (Arlbjørn & Mikkelsen, 2014). There is a need to study drivers from a locational and a supply chain perspective, including the initial offshoring decision in order to be able to explore how the location decision develops over time. The purpose of this study is to investigate the contextual nature of reshoring drivers. The research questions are as follows: (1) 'What are the reshoring drivers in a Swedish manufacturing context?' and (2) 'How do the reshoring drivers from the Swedish manufacturing industry differ from those in the existing literature?' To answer the research questions, a multiple case study was conducted including three case companies from the Swedish manufacturing industry.

Literature review

Reshoring is a relatively new concept and does not have a widely recognized definition. Several synonyms are used in the literature, including backshoring, inshoring, and back-reshoring (Wiesmann et al., 2017). Reshoring, as a concept, is also seen in different ways and have developed over time. According to Gray et al. (2013), reshoring is fundamentally a location decision, and Tate et al. (2014) state that reshoring is the relocation of manufacturing from an offshore location to a more attractive location or to the home country. In this study, reshoring is seen as a location decision, where previously offshored manufacturing is moved back to the home country. Empirical studies on reshoring drivers have been conducted in locational contexts such as Germany (Kinkel and Maloca, 2009), Spain (Martínez-Mora and Merino,

2014), Denmark (Arlbjørn and Mikkelsen, 2014), UK (Bailey and De Propris, 2014), USA (Gray et al., 2017) and Finland (Gylling et al., 2015). However, there is limited research on reshoring drivers from Sweden which motivates this research to conduct empirical studies.

Reshoring drivers found in the existing literature

The existing literature has described drivers as factors that "drives firms to make the reshoring decision despite the locational advantage of having low labor costs at the offshoring location." (Wiesmann et al., 2017, p.28). This paper focuses on drivers and distinguishes between 'main driver' and 'sub driver', where the former is built up by the latter (Table 1).

Whereas cost factors drove offshoring, reshoring is mainly driven by quality. Many authors show that 'increase quality' is the most important driver of reshoring (Arlbjørn & Mikkelsen, 2014; Bailey & De Propris, 2014; Bals et al., 2016), in particular, different aspects of quality such as: raw material, product, infrastructure in the home-country, and delivery towards the customer (Lippert & Hutzel, 2014; Martínez-Mora & Merino, 2014; Kinkel & Maloca, 2009). Also, during offshoring, goods were tied up in inventory on ships, a problem which was exacerbated due to slow steaming transportation. As such, reshoring became a way to decrease tied-up capital (Gray et al., 2013; Bailey and De Propris, 2014; Bals et al., 2015).

While there has been an expected cost advantage gained by moving to low-cost countries, scholars have considered different components of cost that have increased in offshored locations such as decreased total costs, control costs, quality control costs, coordination costs regarding quality, product development and staff, decreased differences in labor cost, raw material costs, energy costs, value exchange costs, transportation, decreased inventory and rework costs (Bals et al., 2016; Tate, 2014). Also, drawbacks with offshoring is that it is associated with increased lead-times. Therefore, research has argued that reshoring is driven by decreased lead-times (Arlbjørn & Mikkelsen, 2014; Bailey & De Propris, 2014). Research also shows that reshoring has a significant effect on increased flexibility (Kinkel, 2012) and there is a discussion focusing on flexibility with respect to production and customization (Fratocchi et al., 2016; Gylling et al., 2015).

In recent years, environmental impacts have been a great concern for global supply chains. Therefore, some authors argue that the need to decrease environmental impact drives reshoring. In the same vein, some studies discuss reshoring as a way of decreasing carbon dioxide emissions (Ashby & Hudson-Smith, 2012; Bals et al., 2016; Gray et al., 2013). Bals et al. (2015) discuss that companies want to create synergy effects by reshoring for a competitive advantage. However, recent studies also indicate that increase in innovation ability drives reshoring and different aspects have been identified in the literature such as product and process-development, and the ability to provide product-related services (Lippert & Hutzel, 2014; Pearce, 2014; Tate, 2014).

Many scholars assert that reshoring is a correction mechanism to previous location decisions (Ashby & Hudson-Smith, 2012; Bals et al., 2015; Fratocchi et al., 2016). Moreover, reshoring is driven by the need to protect intellectual assets, which has also been empirically recorded in the literature and brand counterfeiting has been identified as one such problem (Canham & Hamilton, 2013; Fratocchi et al., 2016, Gray et al., 2013). Academics have identified that reshoring is driven by increasing collaboration, which is discussed in two contexts- external collaboration (with stakeholders) and internal collaboration (with departments) (Lippert & Hutzel, 2014; Pearce, 2014; Bailey and De Propris, 2014; Arlbjørn & Mikkelsen, 2014). Some authors argue that reshoring is also driven by access (or proximity) to competence and resources such as qualified personnel, automation and raw material (Bailey, D. & De Propris, L., 2014; Kinkel, 2012; Tate et al., 2014).

Table 1. Reshoring drivers found in the existing literature

Main driver	Sub driver	References (see appendix)

	Automation	[1,3,5]
	Raw material	[22]
Government subsidies	General	[3,5,22]
Branding (Made in 'X')	General	[5,6,10,17,18,22,20]
Mitigate risks in the host-country	General	[3,4,5,10,12,16,20]
	Supply chain disruptions	[3,4,5,8,10,14,18,19,20,22]
	Political uncertainties	[8]
	Environmental issues	[8]
	Regulations	[8]
	Currency fluctuation	[10,22,23]
Increase capacity utilization	General	[5,14]
Increase control	General	[4,5,14,16,18,20]
	Supply chain control	[4]
	Production control	[16,20]
Change in company's strategy	General	[4]
Overcome geographical and cultural barriers	General	[20]
	Time-zone difference	[17]
	Cultural barriers	[5,12,14, 16, 17, 20]
	Language barriers	[4,10,12,20]
Employee loyalty	General	[6,14,16]
Patriotism	General	[2,6,17]
	Create jobs in home country	[6]
	Preserve/develop skills in homeland	[2]

Moreover, some authors discuss the role of governmental subsidies in reshoring, as policy-makers compensate companies with tax-cuts for bringing back production to the homeland (Bailey & De Propris, 2014; Bals et al., 2016; Tate et al., 2014). Some authors discuss 'made-in' branding as a marketing strategy (Bals et al., 2016; Canham & Hamilton, 2013; Lippert & Hutzel, 2014). However, other authors argue that companies reshore in order to mitigate different risks within the host-country such as supply-chain disruptions, political uncertainties, environmental issues, regulations and currency fluctuation (Ellram et al., 2013). According to Kinkel (2012), through reshoring, companies wish to increase capacity utilization.

Other benefits of reshoring are increased control over the supply chain and production (Bals et al., 2015; Kinkel & Maloca, 2009; Pearce, 2014). According to Bals et al. (2015), for some companies, reshoring is driven by change in the company's strategy. Moreover, many authors confirm that distance and cultures hinder businesses, therefore, reshoring is a suggested remedy. However, some articles consider differences such as time-zone difference, cultural and language barriers (Bals et al., 2016; Lippert & Hutzel, 2014). Some authors argue the role of intangible assets in reshoring such as employee loyalty is achieved by employing national citizens and have looked at patriotism as a driver, to save jobs in the home country and, preserve and develop skills in the homeland (Canham & Hamilton, 2013).

Research methodology

The case study research strategy was considered the most appropriate one since reshoring is a relatively unexplored research area (Fratocchi et al., 2014). A case study provides a way to develop new theory and test previously developed theory. It investigates a phenomenon in-depth, within a real-life context, in order to gain a richer understanding of the phenomenon (Edmondson & McManus, 2007; Eriksson, 2015; Yin, 2009). It is also suitable to employ a case study strategy when using 'what' and 'how' research questions (Benbasat et al., 1987).

A multiple case study was used, including three companies from the Swedish manufacturing industry. This allows for cross-case analysis, comparison and investigation of a particular phenomenon in diverse settings (Yin, 2009). The included case companies were selected based on their previous offshoring and reshoring experience. This type of selection is beneficial when seeking knowledge within a specific area (Yin, 2009). Three case companies (called Alpha, Beta and Gamma) were selected in order to capture a wider spectrum of knowledge and experience in the targeted area. All of them are located in Sweden. The case companies are from manufacturing sector and serve a global market. They have some differentiating traits, for example, they operate in different industries, and have different turnover, number of employees and ownership structure.

The main data collection was semi-structured interviews, and it was complemented with meetings, workshops and observations. To improve the quality of the collected data, voice recordings were used together with note-taking. The companies' different sizes affected the number of people involved in offshoring and reshoring decisions. Thus, the number of conducted interviews at each company varied. In total, eight interviews were conducted with a total of 13 respondents. The collected data was analyzed using both within case analysis and cross case analysis. A qualitative content analysis was conducted using a three-step process: data reduction, data display and conclusion drawing (Miles & Huberman, 1994).

Findings

Alpha is a family-owned manufacturer, with production located in Sweden and China. The company has around 50 employees in Sweden and had a revenue of 3.5 million euros in 2016. In Alpha, 21 sub drivers from 14 main drivers were identified (Table 2).

Table 2. Reshoring drivers found in Alpha

Main driver	Sub driver	Supporting quote
Increase quality	General	"Sweden has good infrastructure, power supply, as well as other factors that we take for granted" (General manager)
	Infrastructure	
Decrease total costs	General	"We wish to receive a lower total cost" (General manager)
	Energy	Sweden has good infrastructure, power supply, as well as other factors that we take for granted" (General manager)
	Quality coordination	"When offshoring, it is easy to miss that in case of quality problems, staff/ technicians might have to be sent to solve the problems. This has to be considered and budgeted, but it is rarely done" (General manager)
	Raw material	"It is possible to decrease the cost for material" (General manager)
Decrease lead time	General	"For some customers, the lead time is so important that they want production in Sweden exclusively" (General manager)
Increase flexibility	Production	"We want to increase the batch-size flexibility. Thanks to short lead times it is possible to increase or decrease the batch size according to the customer's needs" (General manager)
Decrease environmental impact	General	"The customer wants products that are environmentally well produced" (General Manager)
Increase innovation ability	Product-related services	"We wish to keep production in Sweden, and by doing so add value for our customers, we can sell security" (General manager)
Correct previous location decisions	General	"Companies have forgot to calculate and buffer for all risks which may appear" (General manager)
Increase collaboration	External collaboration	"By being close, it is easier to have good relations with the customer, we know and understand what the customer wants" (General manager)
Branding	General	"Made in Sweden is good branding, not top of the line, but pretty good" (General manager)
Mitigate risks in the host-country	Supply chain disruptions	"We want to eliminate risks with long transportation times, for when things have gone wrong." (General manager)
	In-transit damages	"Avoid damages from handling the goods, fewer moves and handlers can decrease the risk of damaged products" (General manager)
Increase control	Production control	"We want to gain increased control over the production and the changes one wishes to do. Complex products are easier to supervise if the production is close" (General manager)
	Product	"They [customers] want to have the last control so that functions, finish and everything like that is in place" (General manager)
Overcome geographical and cultural barriers	Language barriers	"It is not easy to specify quality, but having the same basic language, Swedish, makes it a lot easier" (General manager)
	Cultural barriers	"When you order a product in Sweden, you decide how it is to be produced, both agree, then you start to produce. It is not so much fuss and hassle. In China, there are a lot of hassle, among other things with payment agreements" (General manager)
Employee loyalty	General	"Swedish workers are more loyal compared the Chinese workers who often quit after the Chinese New Year" (General manager)
Patriotism	Preserve/develop skills in homeland	"We want to protect the competence and maintain it in Sweden" (General manager)

Beta is a conglomerate manufacturer with production in Sweden, Norway and the Netherlands. The company has around 150 employees in Sweden and had a revenue of 50 million euros in 2016. In Beta, 23 sub drivers from 11 main drivers were identified (Table 3).

Table 3. Reshoring drivers found in Beta

Main driver	Sub driver	Supporting quote
Increase quality	Delivery	"Secure deliveries to the customer" (Vice president, production)
Decrease total cost	General	"To find some type of saving" (Manager, supply chain management), "Can we become more cost effective?" (Vice president, production)
	Quality control	"If we have a quality problem [from supplier] we need to fix it fast. Should our supplier come to us and fix it, or should we send the products back?" (Manager, supply chain management)
	Staff coordination	"We want to avoid a lot of travelling since it is expensive and take a lot of time." (Vice president, production)
	Labor-cost difference	"Wages are changing in Lithuania, the difference in labor cost is decreasing" (Vice president, production)
	Energy	"Reassure stable processes by having a good power supply" (Manager, supply chain manager)
	Production stop	"Costs for starting production that had to be stopped could be reduced if we had the production at home instead" (Vice president, production)
Decrease lead-time	General	"By having it [production] at home you get shorter lead-times" (Production development)
	Order handling	"You get shorter delivery times, shorter order-to-delivery and so on" (Quality manager)
	Manufacturing	"If we can decrease the [internal] lead-time, we can also lower our lead-time towards our customer" (Manager, supply chain management)
Increase flexibility	Production	"If you have variations on what you previously offshored, then you're increasing your flexibility when you reshore" (Quality manager)
	Labor competence	"Flexibility in competence can be challenging when the fixed workforce is not so great. If we had larger quantities, we could have more permanent staff, thus higher flexibility in competence" (Vice president, production)
Create synergy effects	General	"Increase the proportion of products manufactured in Sweden, to get synergy effects" (Vice president, production)
	Spread overhead costs	"To have more products that can carry the overhead, which results in lower cost per product" (Production development)
Correct previous location decisions	General	"Previous offshoring decisions have not always been rational" (Production development)
Increase collaboration	External collaboration	"When customizing a lot, it's beneficial to have production close to the customer." (Production development)
Increase control	Production control	"For late annuals, it is difficult to stop an already started process" (Vice president, production)
	Product	"Decrease risks by having control over the products ourselves" (Manager, supply chain management)
Increase innovation ability	Product-related services	"The market has changed and today requires more personalized products. Companies do not want to buy 100 black chairs anymore, instead they ask their employees what they want" (Vice president, production)
Overcome geographical and cultural barriers	General	If you have problems [with quality] it's easier to handle them when you have it close and can go out and look at the problems. Compare that to explaining via email and photos" (Quality manager)
	Language barriers	"To increase customer benefits such as easier communication, problem free contracts and kept promises." (Vice president, production)
	Cultural barriers	
Patriotism	Create jobs in home country	"We feel a responsibility towards the society and wants to employ people in the region we work" (Production development)

Gamma is owned by a multinational corporation and has production placed in Sweden, Spain, Japan, China and the US. The company has around 400 employees in Sweden and had a revenue of around 130 million euros in 2016. In Gamma, 29 sub drivers from 14 main drivers were identified (Table 4).

Table 4. Reshoring drivers found in Gamma

Main driver	Sub driver	Supporting quote
Increase quality	General	"It's always easier to have quality control close to yourself" (Controller, products)
	Product	"By having the production in-house better quality of the product can be held" (Manager, manufacturing engineering)
	Delivery	"It may be that you have major delivery issues" (Manager, supplier quality)
Decreased total cost	Transport	"Logistics costs, it is becoming more and more expensive to ship things through Europe" (Vice president, manufacturing)
	Quality coordination	"One thinks that a printing is black and white, with different symbols. But the problem is that then you have different symbols and different standards and different things, so it becomes difficult" (Manager, quality engineering)
	Inventory	"We are good at compensating for [supply chain] problems and instead build a lot of inventory" (Controller, products)
	Raw material	"The supplier comes with high price increases" (Manager, supplier quality)
	Rework	"If you have quality issues on a shipment [from China], it will take 6 months before you get it corrected" (Controller, products)
	Production stop	"A stop in one of the lines costs 10,000 euros a day. Is it worth having that risk, just so we can buy a little bit cheaper from China?" (Vice president, manufacturing)
Decrease lead-time	General	"Before the company's first reshoring occurred, we had problems with lead-times" (Vice president, manufacturing)
Create synergy effects	General	"If it is possible to produce at the same price, then you reshore your production to get economies of scale" (Controller, products)
	Spread overhead costs	"If we can spread the over-head cost on more products, then we can afford to invest in equipment" (Vice president, manufacturing)
Increase innovation ability	Product development	"If you have the product internally, you can easier see opportunities to make rationalizations [improvements], change materials, make it simpler, cheaper or better" (Industrial engineer)
	Process development	"Having research and development close to the product is beneficial for process development, to maintain knowledge and activity, that it works together" (Industrial engineer)
Access to competence/resources	Raw material	"We were a small customer and got to be down-prioritized in case of problems with their supplier. We could basically only buy steel if there were any left-overs" (Controller, products).
Change in strategy	General	"Strategic decision, they said, it should be done here, adjust it so it works" (Industrial engineer)
Increase collaboration	Internal collaboration	The management wants to nail the company down in the ground, strengthen it towards our sister factory, so they want us to do as much as possible here. Closing this factory should be tough" (Industrial Engineer)
Protect intellectual assets	Brand counterfeiting	"In China, nor patent or design protection is respected. We have been told that we can send an engine from Germany, so they can copy it [and sell to us], no problem they think" (Vice president, manufacturing)
Mitigate risks in the host-country	Supply chain disruptions	"Avoid delivery issues. Storms on the Baltic sea can stop deliveries from Estonia" (Vice president, manufacturing)
	Terrorism	"I will never ask my colleague to go down and help start up a production if it is stopped because of a terrorist attack" (Manager, quality engineering)
Increase capacity utilization	General	"We have the available capacity, for example in a welding robot, which is an expensive investment. There is possibility to fill up the capacity with further details" (Manager, supplier quality)
Increase control	General	"Increased control also provides with many other benefits." (Manager, supplier quality)
	Supply chain control	"It's not just the supplier's fault, it's others involved as customs, carriers, yes everything can happen" (Manager, supplier quality)
	Product	"You want to get back control of the product" (Strategic buyer)
Overcome geographical and cultural barriers	Language barriers	"I participated in a bad telephone conference with Chinese subcontractors, they only spoke Chinese, so it was interpreted from Chinese to Japanese, then from Japanese to English. Then we held the meeting in English, but our own language is Swedish. It will not be right. Add bad telephone connection and late or early in the day" (Manager, quality engineering)
	Time-zone difference	
	Communication disruption	
	Cultural barriers	"Cultural differences, does a 'yes' mean 'yes', and what does 'we'll look at it' mean?" (Vice president, manufacturing)
Patriotism	Create jobs in home country	"If you outsource/ offshore, someone needs to lose their job." (Vice president, manufacturing)

Discussion

The reshoring drivers found in the case study, in comparison to the literature, are presented in Table 5. In total 49 unique sub drivers, combined into 20 main drivers, were found in the case study. 40 of the found sub drivers were also identified in the literature while 9 were new ones. Of the sub drivers found in the literature, 21 were not found in the case study. All, except one, main drivers were found in both the case study and the existing literature. The main driver 'government subsidies' was found only in the literature. The literature represents a much broader empirical setting than this study which covers three companies from the Swedish manufacturing industry. Moreover, it is very interesting to note that our small empirical setting revealed 9 additional sub drivers.

In the case study, the highest and the lowest number of sub drivers were found in Gamma and Alpha respectively. This is perhaps not surprising, as Gamma is a larger company with more dedicated resources. This finding could imply that the larger companies seem to consider more reshoring drivers than smaller ones.

Table 5. Reshoring drivers found in the case study and literature review

Main driver	Sub driver	Alpha	Beta	Gamma	Lit.
Increase quality	General	X		X	X
	Raw material				X
	Product			X	X
	Infrastructure	X			X
	Delivery		X	X	X
Decrease tied-up capital	General				X
Decrease total cost	General	X	X		X
	Control				X
	Quality control		X		X
	Coordination				X
	Quality coordination	X		X	X
	Product development coordination				X
	Staff coordination		X		X
	Labor-cost difference		X		X

Employee loyalty	General	X			X
Patriotism	General				X
	Create jobs in home country		X	X	X
	Preserve/develop skills in homeland	X			X

The main driver ‘government subsidies’ was not found in any of the cases. This suggests that policy-makers in Sweden have not yet drawn companies’ attention in encouraging manufacturing reshoring. The case study also revealed new sub drivers, which were not found in the existing literature such as decreased cost of production stop, decreased order-handling and manufacturing lead-times, increased flexibility in labor competence, create synergy effects by spreading overhead costs, mitigate risks of in-transit damages in host country, mitigate risks of terrorism in host country, increase control over product and overcome barriers of communication network disruptions.

Conclusion

The topic of reshoring is relatively new and unexplored. This article fulfills the purpose of investigating the contextual nature of reshoring drivers. The purpose was guided by two research questions. The first question was: ‘What are the reshoring drivers in a Swedish manufacturing context?’. The study identified 49 sub drivers within the Swedish manufacturing industry, which were grouped into 20 main drivers. The second research question was: ‘How do the reshoring drivers from the Swedish manufacturing industry differ from those in the existing literature?’. The study revealed that 40 sub drivers were found in the literature while 9 were new. All main drivers except ‘government subsidies’ were found in both the case study and the existing literature. This leads the research to propose the following:

Proposition 1: Reshoring drivers are context dependent.
Proposition 2: The number of drivers considered by a firm correlates positively with firm size.
Proposition 3: Government subsidies is not a significant driver for reshoring in Sweden.

In future research, it is necessary to find more empirical evidence of reshoring in order to strongly support these propositions. Moreover, it is interesting to incorporate the drivers into a decisions model, to help managers to make correct and rational location decisions.

ABSTRACT
Managing outsourced new product development (NPD) activities is a core issue for clients. Clients depend on supplier flexibility since NPD always takes place in a context of uncertainty, and being able to quickly respond to changes in the demands of clients, is essential for performance. In this study, we investigate the influence of organizational controls (outcome, behavior, clan) and knowledge integration mechanisms (KIMs) on supplier flexibility, and its effect on NPD project performance. Using data from 109 projects involving NPD outsourcing, this study reveals that outcome and clan controls enhance supplier flexibility, but behavior control and KIMs do not. Post hoc analyses suggest that supplier flexibility mediates the effectiveness of outcome and clan controls with outcome control acting as a double-edged sword.

knowledge integration mechanisms, new product development, organizational controls, outsourcing, supplier flexibility

Paper Category: Competitive Paper (Paper 152)

INTRODUCTION

Organizations outsource their new product development (NPD) activities to gain competitive advantage. Outsourcing helps organizations to complement their core capabilities with supplier's unique knowledge, skills, and resources (Carson, 2007; Stanko and Calantone, 2011). Access to such complementary and specialized knowledge and resources in NPD projects has been found to have a positive influence on a wide range of performance outcomes, including shorter development times, improved product quality, and lower development costs (Takeishi, 2001).

Despite the competitive advantages offered by NPD outsourcing, many organizations face challenges in effectively managing outsourced NPD activities, in particular, due to the evolving nature of NPD projects (Stanko and Calantone, 2011). NPD activities evolve over the course of a project because of various reasons, such as change in market dynamics, acquisition of new technical and product knowledge, and creation of new knowledge due to project learning (Tatikonda and Rosenthal, 2000). Therefore, the product specifications generally change in the midst of a NPD project. As a consequence, the initial agreed project requirements between clients (organizations that outsource the activities) and suppliers (organizations to whom the activities are outsourced) may no longer be adequate (Ivens, 2005; Noordewier, John, and Nevin, 1990). To cope with this problem, clients want their suppliers to incorporate the new requirements (Ivens, 2005; Narayanan and Narasimhan, 2014). Therefore, clients depend on supplier flexibility, which is the willingness of suppliers to behave in a flexible manner to the changing requirements of clients (Cannon and Homburg, 2001; Ivens, 2005).

Although clients benefit from supplier flexibility, it entails considerable costs for suppliers as they have to ensure increased availability of various resources for making adjustments (Han et al., 2014). A lack of flexibility on a supplier's part can result in problems such as developing a product that does not meet client's requirements and that can lead to lower project performance. To facilitate flexible behavior from suppliers, clients need to ensure that its suppliers are willing to align their efforts to incorporate the new requirements (Gulati, Lawrence, and Puranam, 2005; Ivens, 2005). Achieving alignment of efforts from suppliers requires both cooperation (alignment of interests) and coordination (alignment of actions) from them (Gulati et al., 2005). Therefore, clients need to know the mechanisms that they can exercise to facilitate cooperation and coordination to foster supplier flexibility.

In addition, most of the research on supplier flexibility that entails responsive behavior perspective has focused on those determinants (opportunism, market uncertainty, relationship-specific investments, and mutuality) of flexibility that do not focus on cooperation and coordination aspect of inter-organizational relationships (e.g., Han et al., 2014; Ivens, 2005). Further, this research has mostly focused on relational outcomes such as buyer satisfaction, relationship commitment, relationship quality, and trust either in industrial buyer-supplier or in channel relationships. Thus, the role of supplier flexibility in NPD outsourcing remains poorly understood.

Several previous studies have identified organizational controls and knowledge integration mechanisms (KIMs) as the mechanisms that enable cooperation and coordination respectively (e.g., Luca and Atuahene-Gima 2007; Tiwana and Keil 2009). Clients can exercise organizational controls to increase cooperation from suppliers as controls motivate suppliers to align their interests with client's interests (Das and Teng, 1998). Similarly, KIMs can help clients to improve the efficacy of their coordination efforts through effective transfer of knowledge between them and suppliers (Luca and Atuahene-Gima, 2007). Therefore, this research examines the influence of organizational controls and KIMs on supplier flexibility. In addition, increased supplier

flexibility can help clients to achieve the desired NPD project objectives in a timely manner as they can efficiently use supplier resources to respond to the changes in project requirements (Cannon and Homburg, 2001). Hence, greater supplier flexibility plays a critical role in the success of NPD projects. As such, this study investigates the relationship between supplier flexibility and NPD project performance. This research therefore aims to study the following research questions: (1) Do organizational controls and KIMs enhance supplier flexibility?, and (2) Do supplier flexibility influence the NPD project performance?

Investigation of these research questions provides fresh insights that make several contributions to the existing literature. First, by investigating the influence of controls and KIMs on supplier flexibility, clients can ascertain how to facilitate flexible behavior from its suppliers and deal with requirements that emerge over the lifecycle of a NPD project. This is important to investigate in NPD projects since these projects are inherently knowledge-intensive and involve a high degree of ambiguity and therefore organizations generally require more cooperation and coordination from their suppliers than that is required in other type of projects (Yan and Dooley, 2013). Therefore, this study contributes to NPD outsourcing literature. Understanding the mechanisms that can facilitate supplier flexibility can also contribute to effective management of relationships between buyers and suppliers in a supply chain. Second, a lack of supplier flexibility can lead to delivery of a product that does not meet the client's expectations and that can result in lower NPD project performance. By exploring supplier flexibility's influence on NPD projects, scholars can also better understand the effectiveness of organizational controls and KIMs in managing outsourced NPD activities. Further, most of the existing research on the effectiveness of organizational controls and KIMs has been limited to in-house NPD projects even though organizations quite often outsource their NPD activities (e.g., Bonner, Ruekert, and Walker, 2002; Luca and Atuahene-Gima, 2007). Therefore, this research also contributes to the literatures on the effectiveness of organizational controls and KIMs. Overall, our research provides new insights to practitioners as well as scholars and help them to better understand the various managerial mechanisms that can be exercised in complex projects encompassing development activities that span organizational boundaries.

THEORETICAL BACKGROUND

Cooperation, coordination, and supplier flexibility

Clients need to manage both cooperation and coordination problems with their suppliers to foster supplier flexibility. The problem of cooperation arises as a result of conflicts of interests between clients and suppliers (Gulati et al., 2005). Though clients outsource their development activities to suppliers due to the fact that they are not alike and have divergent skills or interests, such differences also provide sufficient grounds for conflicts of interest (Das and Teng, 2001; Johansson, Axelson, Enberg, and Tell, 2011). Due to divergent objectives, suppliers are more likely to behave in ways that favor their own interests ahead of clients' interests (Wallenburg and Schäffler, 2014) and therefore they are less likely to act flexibly. The problem of coordination occur due to inadequate shared and accurate knowledge between client and its suppliers (Gulati et al., 2005; Johansson et al., 2011). The difference in knowledge domain along with the organizational boundary between clients and its suppliers makes it difficult for them to share the accurate knowledge that is embodied in their employees and routines (Johansson et al., 2011; Puranam and Gulati, 2008). Due to lack of shared and accurate knowledge, both clients and suppliers do not fully understand each other's decision rules and how their actions are interlinked with one another (Gulati et al., 2005). Therefore, clients face difficulty in coordinating their actions

with its suppliers and making effective decisions to deal with evolving requirements. The problems of cooperation and coordination are rooted in different paradigms and clients therefore need to exercise different mechanisms to resolve both these problems. While cooperation problems arise due to divergent interests between clients and suppliers, coordination problems are caused due to poor knowledge transfer between them (Gulati et al., 2005; Yan and Dooley, 2013). Therefore, clients need to exercise mechanisms that align suppliers' interests with their interests to deal with cooperation problems, whereas they need to use mechanisms that enable knowledge transfer with suppliers to address cooperation problems.

HYPOTHESES DEVELOPMENT

Organizational controls and supplier flexibility

Organizational controls help clients to manage cooperation problems between them and suppliers as controls facilitate alignment of interests (Das and Teng, 2001). Organizational controls refer to the mechanisms used by controllers (in this case, the clients) to motivate controllees (in this case, the suppliers) to behave in a manner that is consistent with controllers' objectives (Tiwana, 2008; Turner and Makhija, 2006). Although control scholars have identified several types of organizational controls, we focus on the three most investigated organizational controls that are conceptually well elaborated in the literature: outcome, behavior, and clan (Cardinal, Kreutzer, and Miller, 2017). In this study, we postulate that a client's use of outcome, behavior, and clan controls resolve the cooperation problems with its suppliers to enhance supplier flexibility. We first discuss outcome control.

Outcome control involves controllers specifying desired quantitative performance goals evaluating controllees' performance based on the extent to which they have achieved the specified goals (Cardinal, 2001; Turner and Makhija, 2006). In the in-house NPD projects, controllers, that is, project managers generally specify performance outcomes such as project budget, cycle time, project goals, and deliverables to controllees, that is, project team members (Bonner et al., 2002). Such performance outcomes can also be specified by clients to its suppliers and therefore can be used by clients to evaluate suppliers' performance against the specified outcomes. The outcomes used by clients for development activities that span organizational boundaries are generally derived from the goals that determine the overall project performance (Gopal and Gosain, 2010; Tiwana and Keil, 2009). As a result, outcome control aligns the suppliers' goals with those of clients. According to Chen et al. (1998), one actor cooperates with another actor when their goals are positively related to each other. As such, outcome control motivates suppliers to behave more cooperatively. Therefore, suppliers are more likely to show cooperative behaviors such as responding flexibly to clients' needs as goals are associated with the motives that underlie the intended behavior (Yan and Dooley, 2013). Outcome control therefore ensures that suppliers identify with a client's requirements and respond in a manner that is in alignment with the client's requirements.

Outcome control also facilitates cooperative behavior from suppliers due to its hands off approach and that further enhances supplier flexibility. Outcome control follows a hand-off approach since it does not specify the type of process that needs to be followed for achievement of specified goals (Turner and Makhija, 2006). Once a client specifies the desired outcomes, suppliers are given substantial autonomy and independence to select and follow their own procedures for achievement of the specified outcomes (Wallenburg and Schäffler, 2014). Because of the autonomy and independence afforded by outcome control, suppliers can efficiently deal with emerging project requirements and therefore they are more likely to accommodate new

requirements from the client. Moreover, the hands-off approach of outcome control is perceived by suppliers as less obtrusive and therefore arouse less psychological reactance in them (Anderson and Oliver, 1987). Also, the use of outcome controls is perceived by suppliers as a signal that its client consider it more trustworthy and competent because outcome control does not involve close monitoring of suppliers' behaviors (Atuahene-Gima and Li, 2006; Wallenburg and Schäffler, 2014). Suppliers are therefore less likely to indulge in opportunistic behaviors. Low levels of opportunism has been shown to be associated with high levels of supplier flexibility (Han et al., 2014). Therefore, outcome control discourages opportunism and encourages flexible behavior from suppliers. Consequently, we expect outcome control to enhance supplier flexibility. Thus, we propose that:

H1: Outcome control is positively associated with supplier flexibility.

Behavior control involves controllers emphasizing procedures and rules that controllees need to follow while doing their assigned activities and evaluate controllees on the basis of their adherence to the prescribed procedures (Bonner et al., 2002; Tiwana and Keil, 2009). Behavior controls in a NPD context can include specifying development methodology, rules, and procedures (Cooper, 2001; Tatikonda and Rosenthal, 2000). Scholars and practitioners have posited that prescribing specific development methodology and procedures such as stage-gate process, quality function deployment, and design for six sigma, which are analogous to behavior controls, help in alignment of different functional perspectives and interests, and that leads to completion of development activities (e.g., Cooper, 2001, 2008). We therefore extend this reasoning to the NPD outsourcing context and expect similar effect of behavior control in facilitating cooperative behaviors between clients and suppliers. In particular, the use of standard development methodology and procedures provide a structure and flow to the development activities (Tatikonda and Rosenthal, 2000). Such a structured environment helps suppliers to better understand their role in a NPD project and the procedures that client's employ to evaluate the suppliers' performance (Aulakh and Gencturk, 2000; Carbonell and Rodriguez-Escudero, 2013). Therefore, the transparent nature of behavior control reinforces suppliers' beliefs of their integral role in the project and the perception of being treated fairly. Consequently, suppliers are more likely to take ownership of clients' interests and engage in cooperative behaviors by being flexible in allowing adjustments in project requirements.

Behavior control also requires dynamic involvement of clients as they need to actively provide inputs related to behaviors that suppliers need to follow for completion of various project activities. Such an active involvement from client signals to supplier that the client is committed to the project (Aulakh and Gencturk, 2000). The active involvement of clients in supplier's development activities also allows clients to deepen their understanding of various issues related to a project (Choudhury and Sabherwal, 2003). The gained knowledge helps clients to not only provide feedback to suppliers for corrective actions, but also helps them to make decisions regarding trade-offs that can be made to deal with changes in project requirements (Liu, 2015). As such, behavior control helps suppliers to better deal with uncertain requirements as this control allows clients to resolve various issues faced by suppliers in a timely manner (Gopal and Gosain, 2010). Thus, behavior controls are less likely to be perceived by suppliers as imposed without any understanding and foster suppliers' cooperativeness. Therefore, behavior control increases the efficacy of supplier in dealing with ambiguous and complex situations, and, in turn, engender flexibility of suppliers to accept changes in project requirements

In contrast, some scholars have argued that imposing standard development methodology and procedures constraints suppliers from using their own idiosyncratic expertise (e.g., Bonner et al., 2002; Tiwana and Keil, 2007). As noted earlier, NPD project requirements evolve over the course of the project and suppliers need their creativity and independence for quickly responding to such emerging problems (Carson, 2007). Thus, constraining their discretion to adjust the development procedures may foster inertia in suppliers and increases the likelihood that the suppliers will be less willing to readily accept the changes desired by clients (Tiwana and Keil, 2007). A client's use of standard procedures can also be perceived by its supplier as a signal that the client does not believe that the supplier can complete the outsourced development activities without its directions. Further, monitoring in behavior control can send a negative signal to a supplier that its client does not trust the supplier completely (Tiwana, 2010; Wallenburg and Schäffler, 2014). Therefore, client's use of behavior control can result in supplier feeling circumscribed and that can result in suppliers not willing to accept client's request for changes in project requirements. In summary, the aforementioned arguments suggest that behavior control can either facilitate or diminish supplier flexibility. Therefore, the following two competing hypotheses:

H2a: Behavior control is positively associated with supplier flexibility.

H2b: Behavior control is negatively associated with supplier flexibility.

In clan control, controllers employ mechanisms to motivate controllees to embrace common values, norms, and goals, and to behave in a manner that is in line with agreed-upon behaviors (Kirsch et al., 2010; Ouchi, 1979). Examples of such mechanisms in client-supplier relationships include social events, off-site meetings, and casual lunch or dinner. These socialization mechanisms facilitate transmission of beliefs, values, and cultural norms between clients and suppliers and thereby increase suppliers' cooperativeness in achievement of clients' interests (Choudhury and Sabherwal, 2003). In other words, clan control facilitate internalization of values and norms between client and suppliers making them more dedicated and committed to achievement of project objectives (Das and Teng, 2001). As such, the internalization of values and norms by suppliers enables them to respond flexibly to new requirements that emerge in the midst of the project, because the values and norms are clear to them (i.e., achievement of project objectives), even though the situation is new (Lebas and Weigenstein, 1986). Further, clan controls increase flexibility because social interactions enable parties to mutually adapt and make adjustments quickly under conditions of evolving requirements (Rijsdijk and van den Ende, 2011).

Clan control also foster generation of common understanding and language between clients and suppliers (Choudhury and Sabherwal, 2003; Tiwana, 2010). The development of common understanding and language further enhance cooperative behavior from suppliers as it provides a rich and broad implicit guide to suppliers as what is considered as an acceptable or deviant behavior by the clients without formally monitoring their compliance to acceptable behaviors (Aulakh and Gencturk, 2000; Kirsch et al., 2010). As a result, suppliers are intrinsically motivated and are committed to achievement of project objectives (Das and Teng, 2001). As suppliers are committed to project objectives, they are more likely to be willing to respond flexibly to client's requirements. As such, clan control help realizing flexible behaviors from suppliers through cooperation. Clan control also promotes mutual trust and interests through informal social interactions (Das and Teng, 1998). The increase in positive mutual expectations and interests motivates suppliers to commit to their partnerships with clients (Das and Teng, 2001). This encourages suppliers to openly identify issues and share and discuss them with clients (Gopal and

Gosain, 2010). Thus, clan control further promote cooperative behavior from supplier to respond flexibly as NPD issues are more likely to be identified, examined and resolved. Past research has also shown that mutual trust and interests between clients and suppliers lead to improved decision making and on time completion of NPD activities (e.g., Bstieler, 2006). All in all, clan control plays a pivotal role in promoting supplier flexibility by enabling cooperative behaviors from suppliers. We therefore hypothesize that:

H3: Clan control is positively associated with supplier flexibility.

KIMs and supplier flexibility

The coordination problems can be resolved by using KIMs as they facilitate knowledge transfer (Gulati et al., 2005; Luca and Atuahene-Gima, 2007). KIMs help different parties to synthesize, analyze, reconfigure and integrate different types of knowledge among them (Luca and Atuahene-Gima, 2007). Specifically, KIMs are processes and structures, such as systematic information-sharing meetings, analysis of successful and failed projects, project reviews that enable one party to capture, articulate, combine and exploit the varied knowledge and skills of other parties (Luca and Atuahene-Gima, 2007). We posit that KIMs play a pivotal role in effective coordination between clients and suppliers as they enable transfer of knowledge between them, and therefore enhance the flexibility of supplier to accept new requirements that emerge during the project.

As NPD projects are faced with new emerging requirements, the new requirements needs to be integrated into the development process for completion of development activities (Tatikonda and Rosenthal, 2000). KIMs facilitate integration of new requirements into the development activities as they allow both clients and suppliers to make better sense of emerging requirements because KIMs involve use of information processing mechanisms, such as face-to-face meetings, success and failure analysis, and project reviews, (Luca and Atuahene-Gima, 2007; Takeishi, 2001). As a result, clients and their suppliers are more likely to make timely decision related to trade-offs that can be made with regards to integration of new requirements in the development activities. Therefore, suppliers are more likely to be flexible in aligning their actions for integrating new requirements into the development activities.

NPD projects also involve transfer of both codified and tacit knowledge for effective coordination and completion of development activities. While codified knowledge can be easily articulated and transferred, tacit knowledge is not easily transferable or codifiable as it is sticky in nature and requires close observations and interactions (Johansson et al., 2011). As such, the transfer of tacit knowledge affects client's ability to coordinate the development activities and supplier's ability to responding flexibly as they don't understand the interdependencies among various development activities. KIMs facilitate transmission of tacit knowledge as they enable different parties to work together closely and exchange knowledge with each other (Luca and Atuahene-Gima, 2007). Suppliers are therefore better able to understand how client's development activities are interdependent on their development activities and this encourage suppliers to take the actions that are necessary for fulfillment of client's new requirements. Thus, the use of KIMs facilitate better coordination between clients and suppliers, and promotes supplier flexibility.

KIMs allow different parties to openly discuss the various approaches that could be followed to solve various development problems that emerge throughout the entire NPD project. They also provide common platform for one party to give feedback to another party and analyze various project problems and mistakes (Luca and Atuahene-Gima, 2007). In other words, KIMs enable involved parties to learn from past product development activities and effectively exploit the learned knowledge for carrying out the future product development activities (Luca and

Atuahene-Gima, 2007). Therefore, clients' use of KIM will enhance coordinative and flexible behaviors from suppliers because problems can be openly identified, examined, and resolved. In summary, we expect KIMs to enhance supplier flexibility. Therefore, we hypothesize that:

H4: KIMs are positively associated with supplier flexibility.

Supplier flexibility and NPD project performance

Supplier flexibility emphasizes the willingness of supplier to accommodate changes in the client's requirements (Ivens, 2005). Having a greater supplier flexibility suggests that a supplier is willing to let client use its skills and competencies for dealing with new project requirements (Narayanan and Narasimhan, 2014). A high level of supplier flexibility, in particular, suggests that a client can easily share its ideas and solve problems with its suppliers. For example, when a client wants to make change its NPD project related requirements, it is easy for a client to communicate it new requirements and explore possible solutions for the new requirements. As a result, both clients and suppliers spent less of their resources in accommodation of new requirements and instead can use those resources for better value creation such as finding more fitting solutions for the new requirements in a timely manner. In essence, a higher level of supplier flexibility helps a client to achieve the desired project performance. Past research has also shown that the increased flexibility from suppliers help in completion of NPD project activities within time and budget. For example, Narayanan and Narasimhan (2014) found that a higher level of flexibility from suppliers leads to an increased performance in terms of time, budget, and quality. This perspective is also supported by the resource-based view (RBV) of the firm. According to resource-based view (RBV), clients outsource their activities to access the rare, valuable, inimitable, and non-substitutable complementary resources for enhancing their performance (Barney, 1991). Supplier flexibility is such a complementary resource that helps clients to efficiently responding to the new requirements in outsourced NPD activities. To summarize, supplier flexibility contributes to NPD project performance as it helps clients to efficiently deal with evolving NPD requirements. Based on the above arguments, we bring forward the following hypothesis:

H5: Supplier flexibility is positively associated with NPD project performance.

RESEARCH METHODS

Sample

To test our hypotheses, we used a cross-sectional survey design for collecting our data. The sample for our study was drawn from the REACH (Review and Analysis of Companies in Holland) database. We specifically focused on research intensive industries because firms functioning in these industries generally concentrate on new product development. Using the two-digit U.S. standard industrial classification (SIC) codes, the following six industries were selected: 28 (Chemicals and Allied Products), 30 (Rubber and Miscellaneous Plastic Products), 35 (Industrial and Commercial Machinery and Computer Equipment), 36 (Electronic and Other Electrical Devices and Components, except Computer Equipment), 37 (Transportation Equipment), 38 (Measuring, Analyzing and Controlling Instruments; Photographic, Medical and Optical Goods; Watches and Clocks Manufacturing). These six industries were selected because organizations operating in them are actively involved in intensive new product development. Within these six industries, we gathered contact details of 1502 companies that had more than 50 employees. Thus, the final sample comprised of firms that are active in research intensive industries and are involved in outsourced NPD projects. The data collection effort yielded responses from 109 client firms.

Measures

The face validity of the construct items was assessed by five management scholars who served as judges. The items were further refined and finalized based on a pilot study with six product development managers to test whether all the items were understandable and clear. Finally, the questionnaire was administered to the full sample. Drawing upon the extant literature on organizational controls, we compiled various items from mature scales to measure the three organizational controls: outcome, behavior and clan. Outcome control is a seven-item measure based on Atuahene-Gima and Li (2006), Bonner et al. (2002), Kirsch (1996), and Snell (1992). The measures for behavior control are adapted from Bonner et al. (2002), Carson (2007), Snell (1992), and comprises of six items. Clan control is a six-item measure, and is adapted from Kirsch (1996) and Kirsch et al. (2002). KIMs measures are adapted from De Luca and Atuahene-Gima (2007), and consist of five-items. Supplier flexibility consists of five items adapted from Bello and Gilliland (1997) and Gulati et al. (2005). NPD project performance is measured with five measures that are consistent with measures that have been previously used for measuring the performance of NPD projects. We consider NPD project performance as a formative construct as it is a manifestation of the five measures. These perceptual measures

Control variables

Five control variables were included in this study since alternative variables can account for supplier flexibility and NPD project performance. We included a dummy variable for product component. Product component of a larger system involves more complexity and requires frequent changes that makes supplier less flexible. Prior research has shown that component change of a larger system asks for more information exchange (Tiwana, 2008). We controlled for supplier team members as a large number of supplier employees represents a large pool of dedicated resources, potentially increasing NPD project performance (Tiwana, 2008).We also controlled for geographic proximity because a supplier that is located closely to a client is more flexible (Cannon and Homburg, 2001). Geographic proximity can also influence NPD outcomes due to the strong relational exchange between clients and its suppliers. The two variables relationship duration and prior projects accounts for the relationship history between clients and its suppliers. The duration of a relationship (years) has been found to influence the various relational elements of a client-supplier relationship (e.g.,Cannon and Homburg, 2001). Consequently, relationship duration may help explain the flexible behavior of suppliers. Also, clients and suppliers with relatively longer duration of relationship are more likely to align the project related activities and therefore influence project performance (Tiwana, 2010). The number of prior projects that has been executed together by a client and supplier can also potentially influence the relationship functioning (Carson, 2007), and hence performance (Gopal and Gosain, 2010). Appendix B provides the mean, standard deviations, and correlations of all the variables in this study Appendix C presents the constructs along with their items and control variables used in this study.

Construct reliability and validity

We took several steps to assess the construct unidimensionality, reliability, and validity. Given that NPD project performance is operationalized using formative measures, we did not consider it for further analysis as traditional techniques are not suitable for assessing its reliability and validity. First, we conducted exploratory factor analysis (EFA) using maximum likelihood extraction with promax rotation. We checked if all the construct items loaded onto their designated construct factors with small cross-factor loadings. While factor loadings above 0.30 are considered

to meet the minimum standard, factor loadings in the 0.40-0.50 are preferred (Hair, Black, Babin, Anderson, and Tatham, 2006). We deleted two items each for outcome control and KIMs, and one item each for behavior control and supplier flexibility (see Appendix C). The deleted items were those that either loaded low on all the five factors as these items did not represent any of the five factors or the items that loaded high (greater than 0.40) on multiple factors as these items could not distinguish between some of the five factors (Hair et al., 2006). The latter condition is important in order to ensure that the discriminant validity of the scales is sufficient.

Second, we further assessed the unidimensionality of all the constructs using confirmatory factor analysis (CFA) (Hair et al., 2006).. The CFA results suggest overall good fitting measurement model (χ^2 /df = 1.27, RMSEA = 0.05, SRMR = 0.07, CFI = 0.96, IFI = 0.96, and TLI = 0.95).We used Cronbach's alpha (α), composite reliability (CR), and average variance extracted (AVE) values to establish the reliability and convergent validity of a construct. All the constructs have Cronbach's alpha, CR and AVE values above the desired level of 0.70 and 0.50 respectively, except for outcome control (Hair et al., 2006). While the AVE for outcome control (AVE =0.49) is below 0.50, but it is still within the acceptable level of 0.40 (Menor, Kristal, and Rosenzweig, 2007). Also, the CR value for outcome control (=0.80) is above the threshold of 0.70, we therefore kept the outcome control construct in its current form. We used the following two methods to demonstrate discriminant validity. First, we conducted chi-square difference tests for all the constructs in pairs to determine if the restricted model (i.e., correlation fixed at 1) is significantly poorer than the freely estimated model (correlation estimated freely). The chi-square differences are significant for all the 10 pairs suggesting that all constructs represent unique scales. Second, we compared the square root values of AVE with the inter-construct correlations. The square root of AVE values for each construct is greater than the corresponding correlations of each construct with other constructs as seen in. Taken together, the reliability, and convergent and discriminant validity tests indicate that the theoretical constructs exhibit acceptable psychometric properties.

Common method bias

We used CFA with single-factor technique to assess potential common method bias. The fit for single-factor model (χ^2/df = 1.82, RMSEA = 0.09, SRMR = 0.13, CFI = 0.88, IFI = 0.88, and TLI = 0.86) is considerably poorer than the five-factor model (χ^2 /df = 1.27, RMSEA = 0.05, SRMR = 0.07, CFI = 0.96, IFI = 0.96, and TLI = 0.95). Also, the chi-square difference between the single-factor and five-factor model is significant ($\Delta\chi^2$ (3) = 121.84, $p < 0.001$). We also used the CFA marker variable technique to assess the common method bias (Williams, Hartman, and Cavazotte, 2010). Using selection bias as the marker variable (see Appendix C), the analysis suggests that there is no significant improvement in the fit indices (model with only hypothesized variables vs model with both marker and hypothesized variables): χ^2/df = 269.05/212 vs 346.68/276, CFI = 0.96 vs 0.95, IFI = 0.96 vs 0.95, TLI = 0.95 vs 0.94. The difference in the chi-square values of the two measurements models is not significant ($\Delta\chi^2$ (64) = 77.63, n.s.) (Williams et al., 2010). These results provide some degree of assurance that common method bias does not seriously impact the findings in our study.

ANALYSIS AND RESULTS

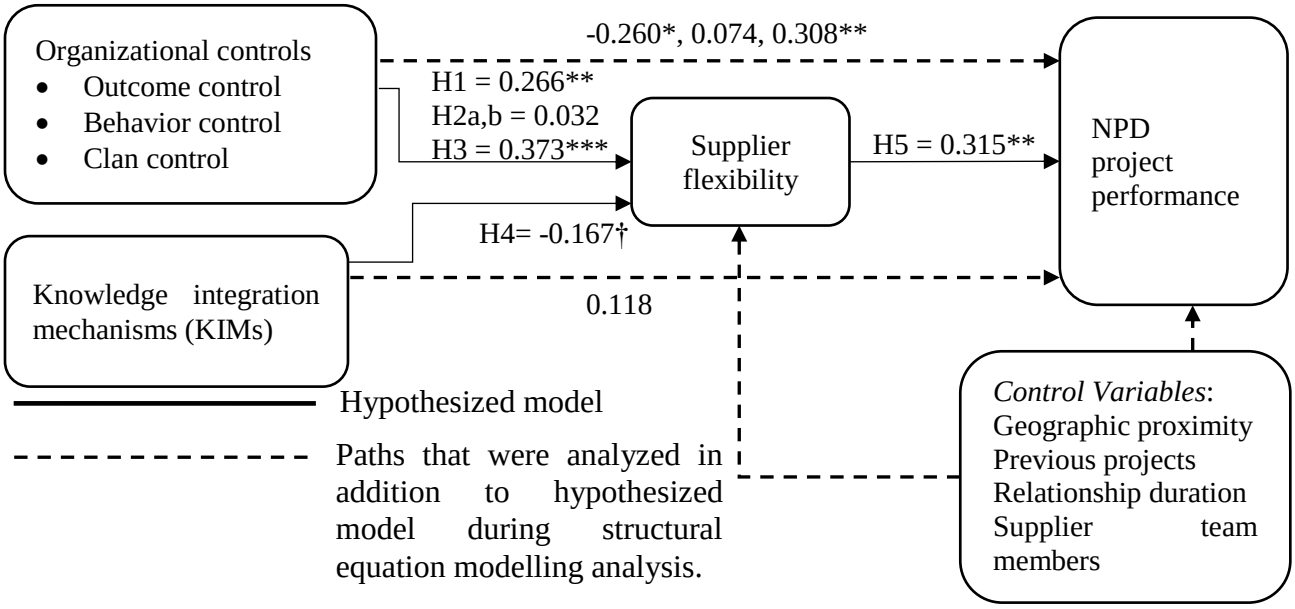
The hypothesized relationships were tested by performing structural equation modelling with bootstrapping option (Preacher and Hayes, 2004). Bootstrapping is a nonparametric statistical method that repeatedly samples from the available dataset with replacement and is particularly useful for small sample size (Preacher and Hayes, 2004). The number of resamples for the

estimation of bias corrected bootstrap intervals was set at 5000 and the level of confidence intervals was set at 95%. The fit indices values indicates that the model shown in Figure 1 Figure 1 fits the data very well: χ^2/df = 1.10; SRMR = 0.07, CFI = 0.98, IFI = 0.98, TLI = 0.97, and RMSEA = 0.03 (90% confidence interval: 0.00,0.083).

Hypothesized effects results

In Figure 1 and Table 1, we present the path estimates for the hypothesized relationships. H1 positively links outcome control with supplier flexibility. The path estimate for this path is significant ($\beta = 0.266$, $p < 0.05$). Thus, H1 is supported. Our results do not support both H2a and H2b as the estimate for the path leading to supplier flexibility from behavior control is not significant ($\beta = 0.032$, n.s.). In H3, we hypothesize that clan control is positively associated with supplier flexibility. The results show that the path estimate is positively significant ($\beta = 0.373$, $p < 0.001$), and hence supports H3. H4 predicts that KIMs is positively associated with supplier flexibility. We do not find support for H4 as the estimate for the path between KIMs and supplier flexibility path, contrary to our hypothesis, is negative and marginally significant ($\beta = -0.167$, $p < 0.10$). The estimate for the path between supplier flexibility and NPD project performance is significant and in the expected direction ($\beta = 0.315$, $p < 0.01$). Therefore, H5 is supported.

Figure 1: Results of structural equation modelling analysis with path coefficients



† Significant at $p < 0.10$, * Significant at $p < 0.05$, **Significant at $p < 0.01$, ***Significant at $p < 0.001$

Table 1 : Path analysis: standardized parameter estimates

Variance explained (R^2) NPD project Performance			0.321

Notes: †p <0.10, *p < 0.05; **p < 0.01; ***p < 0.001 (all two-tailed test). Significance levels are based on bootstrapped, bias-corrected confidence intervals.

Post hoc analyses: direct effects and mediation

To gain additional insights, we also conducted post hoc analyses in order to investigate the effectiveness of organizational controls (outcome, behavior, and clan) and KIMs along with examining the mediating effect of supplier flexibility on their effectiveness. Table 2 presents the detailed standardized coefficient estimates for total, direct and indirect effects computed for the mediation analysis. As seen in Table 2, the results suggest that the estimate for the path leading to NPD project performance from outcome control is significant but negative ($\beta = -0.260$, $p < 0.05$). Given the positive zero-order correlation between outcome control and NPD project performance (see Appendix B), a further analysis revealed that outcome control is a suppressed variable in relation to NPD project performance (see Appendix A for details). A statistical model should account for the suppression effect as it advances theoretical development because without the suppressor variable the relationship between an independent and a dependent variable may be smaller or maybe of opposite sign (Cheung and Lau, 2008; Maassen and Bakker, 2001). Therefore, one should combine the effects of both suppressor variable and suppressed variable for interpreting the results (Cheung and Lau, 2008). Since outcome control is a suppressed variable, the model without other predictors of NPD project performance underestimates the direct negative effect between outcome control and NPD project performance. Thus, by including behavior control, clan control, KIMs, and supplier flexibility in our model, we more clearly understand the opposing effects of outcome control in NPD outsourcing.

The results in Table 2 further demonstrate that the indirect effects of outcome control on NPD project performance is significant but in opposite directions, that is, positive ($\beta = 0.084$, $p < 0.01$). However, the total effect between outcome control and NPD project performance is not significant. As such, the results imply competitive mediation (or inconsistent mediation). Competitive mediation exists when both direct and indirect effects of an independent variable on a dependent variable exist but are of opposite signs and that may result in an overall non-significant effect

between the two variables (Zhao, Lynch, and Chen, 2010). Thus, supplier flexibility mediates outcome control—NPD project performance relationship.

Table 2: Standardized direct and indirect effects (Bootstrapping two-tailed test)

	NPD project performance								
Predictors	Total effects	LL 95% CI	UL 95% CI	Direct effects	LL 95% CI	UL 95% CI	Indirect effects	LL 95% CI	UL 95% CI
Outcome control	-0.171	-0.356	0.046	-0.236*	-0.450	-0.014	0.064*	0.013	0.171
Behavior control	0.057	-0.149	0.277	0.043	-0.172	0.256	0.014	-0.036	0.079
Clan control	0.369**	0.154	0.560	0.277*	0.041	0.508	0.092**	0.023	0.218
KIMs	0.093	-0.110	0.284	0.135	-0.069	0.331	-0.043	-0.135	0.007

Notes: *$p < 0.05$;**$p < 0.01$; *** $p < 0.001$ (all two-tailed test).LL= Lower Limit, UL= Upper Limit, CI=Confidence Interval.

As seen in Table 2, the direct and indirect effects of behavior control on project performance are not significant. Supplier flexibility therefore does not mediate behavior control—NPD project performance relationship. Concerning clan control, the analysis demonstrate that the path estimates for the direct ($\beta = 0.308$, $p < 0.01$) and indirect ($\beta = 0.118$, $p < 0.01$) effects of clan control on NPD project performance are positively significant. As such, supplier flexibility mediates the relationship between clan control and NPD project performance. The direct effect of KIMs on NPD project performance is not significant ($\beta = 0.118$, n.s.). In contrast, the indirect effect of KIMs on project performance through supplier flexibility is negative and significant ($\beta = -0.053$, $p < 0.05$), suggesting an indirect-only mediation (Zhao et al., 2010).

DISCUSSION

Organizations increasingly regard outsourcing of NPD activities to suppliers as a strategic medium for improving NPD project performance. The overarching objective of this study was to advance research on managing outsourced NPD activities. In this study, we investigate organizational controls and KIM as mechanisms that can be leveraged by clients to improve both coordination and cooperation with suppliers to enhance flexibility of a supplier for greater project performance. Using survey data from 109 outsourced NPD projects, we find that outcome and clan controls facilitate supplier flexibility, but the use of behavior control and KIMs do not enhance supplier flexibility. We also find that an increase in supplier flexibility results in higher NPD project performance. Our post hoc analyses also reveal that supplier flexibility mediates the relationship of outcome and clan controls with NPD project performance and KIMs have an indirect effect on NPD project performance via supplier flexibility. On the whole, this research offers significant contributions to the literature and implications for the practice.

Theoretical contributions

This study makes three important contributions to the extant literature. The first key contribution of this study is to unpack the direct effects of organizational controls on supplier flexibility in NPD

outsourcing. The results show that while outcome and clan controls are effective in increasing the willingness of suppliers to behave in a flexible manner, behavior control is not. As such, our results do not provide support for the traditional control research that has generally advocated exercising one control in a particular context (e.g., Ouchi, 1979). Further, the differences in how outcome and clan control affect supplier flexibility relative to behavior control may be explained by the fact that outcome and clan controls allow suppliers to select their own methods and procedures for completion of outsourced activities. In contrast, behavior control constraints suppliers from using their own idiosyncratic knowledge and that prevents them from responding quickly to the changes required by clients (Carbonell and Rodriguez-Escudero, 2013; Tiwana and Keil, 2007). Suppliers are therefore less willing to respond to changes in clients' requirements. However, since our results indicate that behavior control does not influence the supplier flexibility, the dysfunctional effects of behavior control are probably offset by its positive influence.

The finding that behavior control does not enhance supplier flexibility is also interesting in light of the suggestion made in the literature that a structured procedural methodology helps in dealing with unpredictable requirements (Gopal and Gosain, 2010; Tatikonda and Rosenthal, 2000). One plausible explanation for this difference could be that the use of a standard procedural framework is beneficial for alignment of interests only when it defines the boundary conditions for execution of development activities. The framework, however, can have an inconsequential role in enhancing supplier flexibility if it becomes too explicit in defining the procedures that suppliers have to follow while executing the NPD activities. Overall, we encourage future research to focus on a more detailed understanding of behavior control functioning in NPD outsourcing.

The second key contribution of our study is that it provides insights related to KIMs—supplier flexibility relationship in NPD outsourcing. Contrary to our prediction that the use of KIMs fosters supplier flexibility, we find that they do not influence supplier flexibility. The non-consequential influence of KIMs might be due to the perception differences between clients and suppliers (Chen et al., 2016). We believe that the use of KIMs is perceived differently by clients and suppliers. For example, when a client feels that the project requirements need to change and use KIMs for communicating information. However, its supplier does not see the need for the required changes. The supplier therefore perceives the use of KIMs by the client as a signal that the client does not trust the vendor and want to analyze something that has been done wrongly by the supplier. A client's use of KIMs will therefore not facilitate flexible behavior from suppliers. Previous research has also highlighted communication mechanisms overall not being effective between buyers and suppliers because of the difference in perception of buyers and suppliers related to such mechanisms in situations marked by variability (Oosterhuis et al., 2011; Yan and Dooley, 2013). However, our results do not disclaim the fact that the mechanisms that facilitate knowledge transfer between clients and suppliers are important. Rather, our results appear to call into question the claim that using knowledge transfer mechanisms will readily improve performance in inter-organizational relationships. This may or may not be the case based on how suppliers perceive the use of such mechanisms. Future research therefore needs to do an in-depth examination related to the role of knowledge transfer mechanisms in managing outsourced NPD activities.

The third key contribution of this study is that it elucidates the role of supplier flexibility in NPD outsourcing. Our results provides support for the assertion that flexible behavior from suppliers help clients to succeed in achieving higher performance (Narayanan and Narasimhan, 2014). Our post hoc analyses provide further insights related to the role of supplier flexibility in NPD outsourcing. The analyses suggest that supplier flexibility mediates the effectiveness of

outcome and clan controls, but does not mediate behavior control—NPD project performance relationship. Specifically, the analyses show that both outcome and clan control enhances NPD project performance via supplier flexibility. The post hoc analyses also demonstrate that KIMs indirectly diminishes NPD project performance via supplier flexibility. As such, supplier flexibility is one of the most important relational attribute between clients and buyers in NPD outsourcing that plays a critical role in the success of NPD projects.

Further, our post hoc analyses reveal that clan control also have direct positive performance consequences. A plausible explanation for the positive influence of clan control on NPD project performance is that they cultivate a channel of close interpersonal information sharing channels between clients and suppliers. A high level of close interpersonal information sharing channels that are bidirectional have been found to increase supplier's relationship commitment which embodies its intrinsic motivation (Anderson and Weitz, 1992). With regard to outcome control, the post hoc analyses show that it functions as a double-edged sword because the performance benefits achieved via supplier flexibility are balanced by the direct negative performance consequences of outcome control. Although the finding that outcome control diminishes NPD project performance needs further investigation because of the negative suppression effects, it provides support for the agency theory (Eisenhardt, 1989) assertion in the literature. Agency theory posits that rewarding controllees (i.e. suppliers) based on performance outcomes in settings that involve variability, such as NPD projects in this case, transfer risk to them as the achievement of outcomes is dependent on their actions (Eisenhardt, 1989). As controllees are risk-averse, they indulge in opportunistic behaviors and that leads to negative performance consequences. Collectively, this study's findings complements the contemporary work on controls that suggests that each organizational control functions distinctly (e.g., Turner and Makhija, 2006).

Managerial implications

This study provides fresh insights related to the mechanisms that can be exercised by clients to effectively manage their outsourced NPD activities. They should rely on mechanisms that emphasize specification of outcomes and development of common understanding between them and suppliers to effectively deal with emerging requirements as these mechanisms promote flexible behavior from suppliers. However, client managers should not specify those outcomes that are beyond the control of suppliers as such outcomes can transfer unnecessary risk to suppliers. Such unwanted risk can lead to suppliers indulging in opportunistic behaviors and that can decrease project performance. Therefore, they should be cautious in specifying outcomes that suppliers need to achieve and should select those outcomes that do not transfer unnecessary risk on its suppliers. Client managers should also prioritize those mechanisms that helps in development of shared values, norms, and understanding as these mechanisms not only leads to higher project performance by making supplier behave flexibly but also have other positive performance consequences. Further, client managers should be careful in setting up mechanisms that rely on specification of procedures and facilitate knowledge transfer between them and suppliers. Specifically, client managers should ensure that specification of procedures that suppliers need to follow do not constraint suppliers from using their own idiosyncratic expertise. Also, client managers should clearly explain the objective of using knowledge transfer mechanisms to suppliers so that their use are not perceived negatively by suppliers. Overall, client managers should take all the necessary steps to foster supplier flexibility, an important relational attribute in NPD outsourcing, for successful completion of their NPD projects.

LIMITATIONS

This research has several limitations. The first limitation is that the data used in this study is cross-sectional. Cross-sectional data limits the ability to make conclusions related to causality. Therefore, future studies should include alternative types of data, such as longitudinal or experimental data that allows scholars to examine the causal effect of organizational controls and KIMs on the project performance over the course of the project. The second limitation of this study is the use of self-reported data collected from single respondent within each firm. While the CFA techniques suggest that common method bias is not a serious concern, the possibility of some common method bias affecting the research findings cannot be ruled out. The third limitation of our study is the small sample size, which is similar to other studies at project level (e.g,Liu, 2015; Tiwana and Keil, 2009), as a large sample size is difficult to obtain at project level.

CONCLUSION

The goal of this study has been to broaden our understanding of the mechanisms that influence supplier flexibility, which plays a critical role in an uncertain environment that usually surrounds a NPD project. This study confirms that exercising outcome and clan controls facilitate cooperative behavior from suppliers and as such increases supplier flexibility. This study also reveals that the use of behavior control and KIMs do not foster supplier flexibility. In addition, this study reveals that supplier flexibility mediates the relationship of outcome and clan controls with NPD project performance. Our results suggest that outcome control acts as double-edged sword with regard to NPD project performance. On one hand, exercising outcome control leads to higher project performance as its use facilitate supplier flexibility, but on the other hand the use of outcome control leads to direct negative performance consequences. The results also demonstrate that that supplier flexibility helps to transform the increased cooperativeness of suppliers, due to clan controls, into higher NPD project performance. Our study therefore unbox the understanding related to distinct implications of mechanisms aimed at cooperation and coordination on supplier flexibility and its critical role in NPD outsourcing.

Appendix A

Dealing with suppression effect

Conger (1974, pg. 36) note that "a suppressor variable is defined to be a variable that increase the predictive validity of another variable (or set of variables) by its inclusion in a regression equation". To check for the suppression effect, we used the procedure suggested by Maassen and Bakker (2001). We analyzed different regression models with outcome control and each of the other four predictors of NPD project performance (i.e., behavior control, clan control, KIMs, and supplier flexibility). The analysis reveal that the negative path coefficient between outcome control and NPD project performance became larger and significant when each of the four antecedents were also included as a predictor of NPD project performance in alternative regression models. Therefore, the analysis suggests that when the variance in NPD project performance due to behavior control, clan control, KIMs, and supplier flexibility was accounted for, the remaining variance correlated with outcome control revealed a negative relationship (Cheung and Lau, 2008; Maassen and Bakker, 2001). This indicates that the other predictors played the role of suppressors for outcome control (the suppressed variable) in relation to NPD project performance.

Appendix B: Descriptive statistics and correlations

		Mean	StdDev.	1	2	3	4	5	6	7	8	9	10	11
1	Outcome control	5.11	0.94	**0.698**

Appendix C: Survey Measures

Measures	SFL
Outcome control: To what extent did you influence the external party by setting goals? *(α = 0.79 ; CR = 0.80; AVE = 0.49)*	
• We monitored the degree to which the external party achieved specific goals	0.77
• We evaluated the external party on the degree to which it achieved these specified goals	0.71
• We strongly emphasized attaining project goals	0.80
• We assessed the extent to which our organization adhered to predetermined budgets	0.52
• We set clear goals for the external party concerning the cycle time of the project	0.65
• We clarified which customer requirements the product should meet[a]	-
• We used prespecified technical specifications as a benchmark for evaluations[a]	-

Measures	SFL
Behavior control: To what extent did you control the external party project by specifying the procedures and processes to be followed? *(α = 0.92 ; CR = 0.93; AVE =0.73)*	
• We formulated detailed and comprehensive specifications for the procedures that the external party had to follow	0.78
• We specified the processes and methods by which the external party had to operate	0.96
• We monitored whether the external party operated according to prescribed methods	0.89
• Our evaluations of the external party were strongly based on how well they followed specified processes or procedures	0.86
• We strongly emphasized that the external party conducted the tasks according to our prescriptions	0.76
• We determined the actions that the external party had to take during the project[a]	-

Measures	SFL
Clan control: To what extent did you try to build a sense of unity between the members of your organization and those of the external party? *(α = 0.87 ; CR = 0.90; AVE = 0.60)*	
• We tried to achieve a sense of unity among the members of our organization and those of the external party	0.74
• We ensured that the members of the external party strongly felt part of the project	0.80
• We put considerable emphasis on achieving shared goals, values and norms between the members of our organization and those of the external party	0.64
• There was a strong sense of common spirit between our organization and the external party	0.82
• We tried hard to have good relations with the team-members of the external party	0.76
• There was a bond of trust between our organization and the external party	0.83
Relationship duration: For how many years has your organization been working together with the external party? …years	
Knowledge integration mechanisms: To what extent did the project use the following methods for capturing knowledge and information and communicating it between your organization and the external party? *(KIMs) (α = 0.77; CR = 0.80; AVE = 0.60)*	
• Regular formal reports and memos that summarize learning	0.49
• Formal analyses of problems in the project	0.98
• Formal analyses of pleasant surprises within the project	0.77
• Information sharing meetings[a]	-
• Face-to-face meetings between members of the different organizations[a]	-

Measures	SFL
NPD project performance (KIMs) (Formative construct) Please indicate the level of success of the project compared to the project goals for the following project outcomes.	
(1) Timing, (2) Budget, (3) Quality, (4) Technical Performance (5) General Satisfaction	-
Supplier flexibility: How would you describe the flexibility of the external party? *(α = 0.90; CR = 0.90; AVE = 0.70)*	
• They reacted flexibly in response to requests for changes	0.85
• They were open to revising prior agreements	0.79
• They had no problems with adapting to changes in the product requirements	0.84
• They were prepared to adjust initial agreements if this was required by the situation	0.86
• They would rather work out a new plan than hold on to the original agreements when an unexpected situation arose[a]	-
Product component: Does the 'product' under development concern a component of a larger system or an independent product? (0 = Component, 1 = Independent product)	
Previous projects: How many prior projects did you execute together with this external party? …projects	
Geographic proximity: Was the most important contact of the external party located abroad or in your own country? (0 = Abroad, 1 = Domestic)	
Selection bias (as marker variable) (a) Please indicate to what extent you agree with the following statements about yourself, (b) I generally work under high time pressure, (c) I generally work in a conscientious and accurate manner	
Supplier team members: How many employees of the external party worked on this project? … employees	

Notes: SFL = Standardized factor loading, α = Cronbach's alpha, CR = Composite reliability, AVE = Average variance extracted. All scales used seven-point Likert-type items except control variables. All scales were measured using anchors "1= strongly disagree" and "7 = strongly agree". NPD Project Performance items were measured using anchors "1 = much worse than preset goals", "4 = equal to preset goals", and 7 = "much better than present goals".
[a]This item was deleted from further analysis because of its low or cross factor loading.

Title:

Identifying partners outside existing networks

Subtitle:

How do corporate organizations search for startups?

Abstract:

Search for external knowledge has evolved to a strategic task for corporate organizations. Startups are a source for particularly novel and innovative product ideas. Our article analyzes search strategies for the identification of startups followed by corporate organizations. Therefore, we conduct a multiple-case study among eight firms within the automotive industry. Results highlight four organizational approaches, a detailed identification process and 11 search instruments. Our findings add to literature on external knowledge sourcing in the context of corporate-startup relations. Further, we contribute to purchasing literature by highlighting how organizations identify innovative partners outside their networks.

Keywords:

search strategies; corporate-startups relationships

Introduction

External sources of knowledge have become a necessary extension to internal innovation activities (Monteiro, Mol and Birkinshaw, 2017; Rosenkopf and Nerkar, 2001). Collaborations with customers, suppliers, universities or even competitors are a promising way to extend the own knowledge base in order to increase the firm´s innovativeness (Felin and Zenger, 2014; Laursen and Salter, 2006). Considering this potential set of external partners, suppliers seem to have the largest impact on product innovation (Un, Cuervo-Cazurra and Asakawa, 2010). Yet, suppliers' innovative potential is limited as described in a case study by Gassmann, Zeschky, Wolff, and Stahl (2010), which further shows how a new venture supplier, commonly referred to as "startup", has succeed at providing a truly innovative idea (a haptic feedback control device for automobiles). Therefore, startups as a specific knowledge provider have received growing attention (Weiblen and Chesbrough, 2015; Zaremba, Bode and Wagner, 2016). By collaborating with startups, corporations hope to benefit from the startups´ entrepreneurial characteristics, such as alertness, creativity, flexibility and willingness to take risks (Audretsch, Segarra and Teruel, 2014; Criscuolo, Nicolaou and Salter, 2012; Marion, Friar and Simpson, 2012).

Firms looking for innovative ideas search within distinct search spaces, which differ according to their proximity of existing knowledge (Knudsen and Srikanth, 2014). Local search builds on knowledge already in use (Stuart and Podolny, 1996), while distant search expands existing knowledge and often builds on external stimuli (Fleming and Sorenson, 2004; Rosenkopf and Nerkar, 2001). Existing literature on search for external knowledge analyzes the impact of various knowledge providers on firms´ innovation performance (Laursen and Salter, 2006; Leiponen and Helfat, 2010). More specifically, prior studies have shown that knowledge provided by startups increases the innovation performance of corporations (Dushnitsky and Lenox, 2006, Wadhwa, Phelps and Kotha, 2016).

Existing studies have also focused on how to identify specific external knowledge partners, applying search approaches like netnography for lead users (Belz & Baumbach, 2010) or competitions for suppliers in the early stages of firms' innovation processes (Langner & Seidel, 2009). In particular, scholars have so far focused on how corporations identify innovative partners within their supply base (Pulles et al., 2014; Schiele, 2006). Still, we lack understanding on how firms search for new innovation partners, such as startups, outside their networks. As startups are usually unknown partners without prior relations to the buying firm, the search for such partners is more challenging and requires much more effort compared to identifying established suppliers. Some research has focused on the identification of startups but is limited to mechanisms within external organizational structures, such as external scouting or sensing units (Gassmann and Gaso, 2004; Monteiro and Birkinshaw, 2017). As no prior study provides a holistic picture of approaches to identify startups, our research addresses the following main question: *How do corporate firms search for startups?*

To answer the research question, we conduct a multiple-case study among 8 automotive multinational corporations in Germany. Results show that established corporations set up external and internal organizational structures and use various instruments, such as pitch events and networks, to identify startups. By focusing on startups as a single source of external knowledge, we contribute to recent calls to better understand the activities necessary to search for innovative partners. Thus, we expand our knowledge mainly limited to the outcome of search activities (Monteiro and Birkinshaw, 2017). Further, we extend literature on the embedment of scouting units by showing three internal approaches. In addition, the role of purchasing in the innovation process is highlighted by explaining the involvement of purchasing managers in the search for startups (Schoenherr and Wagner, 2016; Wagner, 2012). From a managerial perspective, our results show how corporations can identify startups in order

to maintain their firm´s position in dynamic market situations (Anderson and Tushman, 1990; Bergek, Berggren, Magnusson and Hobday, 2013).
The paper is structured in the following way. First, we analyze literature on external knowledge sourcing in the context of corporate-startup relationships as well as boundary spanning literature. The following part describes the framing of the study and data. Next, we show the results of the study by illustrating organizational approaches, a search process and search instruments. The paper ends with a discussion of implications and future research directions.

Theoretical background

External knowledge sourcing and search for startups

Accessing external knowledge has evolved to an essential part of firms' overall strategies (Basu, Phelps and Kotha, 2016; Van Wijk, Jansen and Lyles, 2008). Various empirical studies show the positive impact of external knowledge on the innovation performance of the sourcing firm (Ahuja and Katila, 2001; Laursen and Salter, 2006, 2014). Corporate-startup collaborations differ in their closeness, flexibility and equity-involvement which has implications on their reversibility as well as the necessary commitment (Van de Vrande, Lemmens and Vanhaverbeke, 2006; Van de Vrande, Vanhaverbeke and Duysters, 2009). Prior research describes strategic alliances (Lavie, 2007; Stuart, 2000), corporate venture capital (CVC) investments (Dushnitsky and Lenox, 2006; Wadhwa and Basu, 2013) and mergers and acquisitions (M&A) (Ahuja and Katila, 2001) as successful ways to access external knowledge. But knowledge from distant industries and new partners, such as startups, becomes more important (Brunswicker and Hutschek, 2010; Gassmann et al., 2010). Therefore, corporations have started to create specific program-based collaborations, such as accelerators and incubators, to access this knowledge (Bergek and Norrman, 2008; Pauwels, Clarysse, Wrigth and Van Hove, 2016).
But why are startups a valuable source of external knowledge? Due to missing assets, experimentation with a large number of ideas is not possible (Burg, Podoynitsyna, Beck and Lommelen, 2012; Marion et al., 2012). Hence, startups are enforce to conduct focused and dynamic new product development (Cooper, 1981; Freeman and Engel, 2007; Rothaermel, 2002). Newly developed products increase their legitimacy and allow startups to quickly access market shares as well as early cash flows to sustain survival (Schoonhoven, Eisenhardt and Lyman, 1990). Thus, innovation capability is a critical variable for startup performance (Chrisman, Bauerschmidt and Hofer, 1998). Further, startups´ flexibility is ensured by its organizational structure, including short chains of command, due to its small firm's size (Kickul, Griffiths, Jayaram and Wagner, 2011; Rothaermel, 2002). In addition, startups have highly dynamic capabilities, a willingness to take risks, and a high growth potential, accomplishing a prime position for innovation, especially disruptive innovation (Criscuolo et al., 2012; Engel, 2011). Thus, forming ties and acquiring knowledge of startups "can be an important source for innovation and growth for the established firm" (Weiblen and Chesbrough, 2015).
In order to systematically search for external knowledge, corporations have installed processes and apply search instruments (Homfeldt, Rese, Brenner, Baier and Schäfer, 2017; Rohrbeck, Hölzle and Gemünden, 2009; Weiblen and Chesbrough, 2015). Scouting for external technologies and startups is conducted in an early phase of innovation processes and consist of identification, selection and evaluation (Rohrbeck, 2010; Salerno, De Vasconcelos Gomes, Da Silva, Bagno and Freitas, 2015). Lichtenthaler (2005) describes a six step search process to identify diversification opportunities, divided into: (1) definitions of search fields, (2) identification of business ideas, (3) validation of business ideas, (4) rough assessment of business ideas, (5) detailed analysis of business ideas, and (6) decision making. Some

instruments to identify startups are described in literature, e.g. AT&T Foundry identifies interesting startups "through the foundry's network or through a response to a call for proposals in a certain problem area - get the chance to pitch their idea at a Foundry event" (Weiblen and Chesbrough, 2015). Further, the role of (technology) scouts (Pauwels et al., 2016; Rohrbeck, 2010), scouting-units (Monteiro and Birkinshaw, 2017; Rohrbeck, 2010) or startup pitch events (Homfeldt et al., 2017; Weiblen and Chesbrough, 2015) received attention in prior research.

Boundary spanning to transfer knowledge of startups

Boundary spanning on an organizational level describes the openness of organizations towards external sources of knowledge (Dollinger, 1984; Leifer and Delbecq, 1978). Through boundary spanning, firms can access knowledge or capabilities to face current and future market needs (Rosenkopf & Nerkar, 2001). Prior research also addresses the question on how individuals collect and channel external knowledge to make it accessible for internal units (Tushman, 1977; Tushman and Scanlan, 1981). Another research stream analyzes the inter- and intra-firm interaction of teams (Ancona and Caldwell, 1988, 1992). On the one hand, boundary spanners, such as individuals, departments or business units, can be allocated close to current business practice ensuring a good link to internal experts (Hill and Birkinshaw, 2014). On the other hand, boundary spanners located outside the organization, e.g. within a specific business unit or a scouting satellite, close to external sources for knowledge (Basu et al., 2016; Keil, Maula, Schildt and Zahra, 2008). For our study we define boundary spanning units as "specialized entity that mediates the flow of information between relevant actors in the focal organization and the task environment" (Monteiro and Birkinshaw, 2017, p. 344).

3 Method

The purpose of our research is to provide a complete picture on how to identify startups as innovation partners by describing the underlying organizational structures and implementation of search. Therefore, we conducted a multiple-case study mainly based on interviews with experts within the field of startup management from an established firm's perspective (Eisenhardt, 1989; Yin, 2014).

3.1 Design and sample

Our sample consists of major firms within the German automotive industry. The automotive industry is recognized as one of the fastest changing and most innovative industries in the world economy, with corporations spending huge amounts of resources on the identification and development of innovation (Hüttinger, Schiele and Schröer, 2014; Ili, Albers and Miller, 2010). In order to establish a certain degree of variation and maintain comparability in our sample, we applied a theoretical sampling approach (Patton, 2005). All selected companies belong to the automotive industry and the selected suppliers are listed among the 100 largest automotive suppliers. We followed the assumption that larger corporations are the first to develop approaches to collaborate with startups, due to their high amount of resources available. The initial list of cases was extended by two original equipment manufacturers from the automotive industry to get further insights in their current practice. For an overview of the sample see Figure 1.

Data collection and sources

Data for this research was collected in two phases. In the first phase, based on secondary data, first insights on selected cases were obtained and served as case-specific preparation for the interviews (Eisenhardt and Graebner, 2007; Yin, 2014). Secondary data showed that several cases utilize an own corporate venture capital department, use public media to attract startups, organize startup events, and use their online appearance to address startups. Furthermore, the

cases provided information on corporations´ field of interest, possible collaboration approaches, and rough selection criteria. In the second phase, 13 in-depth semi-structured interviews were conducted. We followed a key informant approach including employees from innovation management, R&D, procurement, M&A, strategy, and corporate venture capital (John and Reve, 1982). A structured interview guideline was used. All interviews were conducted face to face or by phone. To increase the reliability, two researchers participated in the interviews (Eisenhardt, 1989). All interviews were recorded and transcribed. In total, the interviews yielded 10 hours of interview data and 196 pages of transcript.

Firm*	Product portfolio	Revenues (2016; B €)	Job title of interview partners	Duration of interviews
A	Supplier exterior components	10-50	(1) Head of strategy	52:17
B	Supplier electronics & software	> 50	(1) Investment Partner (2) Procurement manager	1:08:27 50:18
C	Supplier exterior components	10-50	(1) Senior manager M&A (2) Manager corporate strategy	51:34 45:23
D	Supplier powertrain components	10-50	(1) R&D manager (2) Head of corporate strategy	43:28 43:28
E	Supplier exterior & interior components	<10	(1) R&D manager	52:22
F	Supplier electronics	<10	(1) R&D manager	48:14
G	Car manufacturer	10-50	(1) Procurement manager (2) Director Partnering	24:01 44:32
H	Car manufacturer	> 50	(1) Manager business innovation (2) Manager Technology Scouting	52:05 22:14

*all firms are headquartered in Germany and belong to the automotive industry

Figure 1: Sample

Data coding and analysis

All data was analyzed and coded. Before coding, the initial review of data provided a first classification of results. In a next step, codes were given and redefined through the research to capture themes that emerged from the data. First, we analyzed each case individually to make sense of the data by structuring, defining, and reducing the collected information. In the following, we were able to define the corporations´ organizational structure, processes, and instruments to identify startups. After the single case analyses, the cross-case comparison followed. Here, we continuously reviewed all interview transcripts, where several patterns and themes were found. Based on detected similarities and differences qualitative statements on corporations' search approaches were abstracted. Assuming that larger corporations hold expertise in identifying startups the analysis includes best-practices form the identification of startups, triggering new research in this field and providing a foundation for hypothesis generation.

Results

Our results show that practitioners are looking for organization in their approach to identify startups, as it was described by an investment partner of corporation B: *"(the need for) more systematization, let's say, more standardized (in processes), with appropriate tool support."* In the following, corporations´ search approaches are analyzed. Addressing four different

organizational structures, one systematic process, and various instruments used to identify innovative startups.

Organizational approaches

Corporations use various organizational structures in order to identify startups (for an overview see Figure 2). The analysis of our data shows four distinct approaches which can be own organizational entities (referred to as central unit) or part of existing units (decentralized unit). Moreover, decentralized approaches can imply single or multiple business units. Further, central units can be differed regarding their distance to respective R&D experts which engage with startups in joint R&D projects by being an internal or external unit. Most of the time, setting up decentralized structures are initial steps to start searching for attractive startups. As the expert of Corporation F: *"(The corporation) decided to integrate technology and innovation management in R&D. Therefore, it is no central innovation management […] there is no separate function for technology scouting or startup monitoring."*

In contrast, centrally managed units pool demands and support trend scouting. Besides internal units, corporate venture capital or listening units exist and are examples for external units. An investment partner at Corporation B describes the role of such a unit in the following way: *"[…] everything concerning startups runs through this department […] (and we) get in direct contact with startups."* However, this organizational structure requires a strong link to internal stakeholders.

Structure	Description	Coupling to internal customers	Flexibility and speed
Decentralized – single functional	▪ Experts from one single department (such as R&D, procurement or M&A) involved ▪ Less systematic and standardized processes	Strong	Low
Decentralized – cross-functional	▪ Involvement of cross-departmental teams (including, e.g., R&D, procurement, M&A and corporate strategy) ▪ Systematic development of search field and approach based on internal demands and trends	Strong	Low
Central – internal	▪ Definition of search fields and monitoring of startup environment centrally ▪ Extensive communication among departments	Moderate	Moderate
Central – external	▪ Establishment of an external unit, such as, CVC unit, scouting satellite or listening post ▪ Extensive communication between internal and external department	Weak	High

Figure 2: Organizational approaches

Identification process

Our study shows that corporations have established distinct processes to operationalize their search for startups. The various search process are resembling and consist of the three main steps: definition of search fields, systematic search for startups and evaluation. Search processes for startups start with internal demands or external opportunities, such as described by the interviewed procurement manager of Corporation B: *"[…] technical departments, have some technical questions, problems. We then search for external knowledge providers. (Further we) derived (search fields) from mega-trends […]."* These demands result in search fields, which can be very specific as they search for solutions to specific problems. By being less specific,

firms allow broader search and enhance their chance to identify more distant knowledge (Criscuol, Laursen, Reichstein and Salter, 2017). Depending on their resources, corporations pick search instruments and decide how broad and intensive their search is designed. After applying these instruments, corporations end up with various ideas provided by different startups. These ideas are then validated and pre-selected accordingly: *"[…] the first pre-filter is of course, does it (the startup innovation) fit to our search fields."* (Corporation D, interviewee 2) Finally, depending on the type of collaboration, a thorough evaluation is conducted. Building on the identified approaches, we offer a consolidated identification process consisting of seven steps (Figure 3).

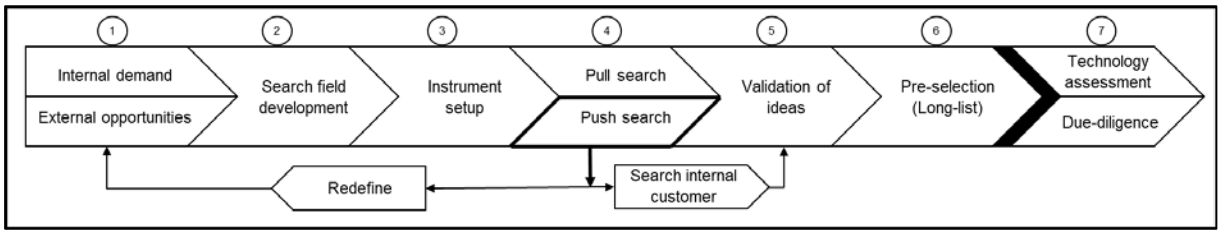

Figure 3: Identification process

Search instruments

Our analysis focuses on the design of the instruments, search approach, effort, and output as well as benefits and problems. By distinguishing in "pull" and "push instruments", we follow recent terminology for instruments within open innovation (Homfeldt et al., 2017; Wagner and Bode, 2014). While pull instruments require the initiative of corporations and active search, push instruments are rather passive, e.g., in a way that startups are introduced by external partners. The following section describes the identified instruments in detail (see Figure 4 for an overview).

The first identified pull instrument is desk-research. Most corporations start to search for startups by *"continuous screening of web-based sources"* (Corporation G, interviewee 1). An investment partner at Corporation B describes that they *"currently try to professionalize (startup scouting) by a web-crawler, which is able to scan for various search criterion within various media, especially within the internet."* Utilizing this instruments has a higher cost of implementation. Still, the yield of the instrument is a continuous screening of market deal-flows, limited to previously defined keywords. In order to enrich web-based search results, corporations buy external startup database services. Moreover, corporation uses *"scientific publications […] to spot interesting startups"* (interviewee of Corporation E). Experts within corporations visit scientific conferences to spot new technologies, talent and spin-offs. This instrument allows to spot future technology developments in an early stage. Similar are visits of trade fairs and exhibitions. This instruments requires an internal employee to visit startup fairs, conferences, and open pitch events. Often, these kind of events are organized by external service providers, as for example venture capitalists, in order to connect startups to potential industrialization partners and investors. Without preparation, the yield of this instrument for corporations is rather limited. However, by systematic structuring of these visits *"using a process, following the event catalog, […] dividing responsibilities across participants, […] and drawing up a summary of the event"* (Corporation D, interviewee 1), startup events are a good opportunity for first contacts to interesting startups and their founders. Furthermore, these events are an opportunity to build network connections and communicate the corporation's interest in collaborating with startups as new business partners. Another pull instrument are self-organized pitch. Depending on the setting of this instrument, startups and internal experts

of the corporation get in first contact and have the opportunity to discuss, for example, the commercial and technical aspects of startups innovation. In addition, our results show that corporations utilize fund of funds in order to continuously screen market deal-flow. This instrument utilizes the opportunity to invest in existing funds, referred to as "fund of funds". The usage of this instrument is described by an investment partner of Corporation B: *"We invested […] to benefit from their expertise and screen their deal-flow, this gives us the opportunity to match (startups to our search fields)."* Moreover, corporations invest in the service of external scouting partners. These partners search for innovative startups *"based on previously developed scouting request"* (Corporation C, interviewee 1). Requests are mostly based on corporations´ search fields and startups are matched by external scouting partners. External scouting services are assumed to be highly professional, yielding in high search outcome. The last pull-instrument are scouting satellites, which are external units set up within startup "hot-spots", like the Silicon Valley or Israel.

In addition to these pull instruments, we identified four push instruments. The first is networking with business partners as an instrument to identify innovative startups. Here, potentially interesting startups are communicated, e.g., through the value chain by suppliers. The R&D manager of Corporation D describes that they have a *"network with original equipment manufacturers and suppliers, exchanging information concerning a specific field of interest, where we just receive a phone call, asking for corporations´ interest into a specific startup."* Here, corporations are able to identify startups with minor efforts. However, they are dependent on the professional startup management skills of their suppliers. Other partners are venture capitalists. Furthermore, corporations use networks with non-partnering firms in order to identify innovative start-ups. This instrument describes the practice to build networks with customers, competitors or corporations form other industries to identify startups, which communicate information about relevant startups. In addition, organizations use networks to universities, public or non-profit research institutes to identify emerging startups, especially using *„direct contacts to university professors, are in continual exchange to get interesting information [about startups]"* (interviewee of Corporation E). Another passively managed push instrument to identify startups are landing- or web-pages. Within this instrument corporations are contacted by startups which are searching for new business partners. The establishment of such a contact possibility requires low effort by the corporation: *"on the webpage the startup is asked to provide general information […] (which are) automatically transferred into a database"* (Corporation H, interviewee 1). However, there is no opportunity for the corporation to filter the received applications, leading to a high effort in selecting the detected startups afterwards.

Instrument	Description	Continuous deal-flow	Effort	Output	Benefits	Drawbacks
Pull instruments						
Desk-research	Web based search, automatic web screening and external database services	Y	Low	Low	▪ Continuous screening of market deal-flow ▪ Straightforward implementation	▪ Depending on quality and breadth of database ▪ Time consuming
Scientific conferences/ publications	Visits of scientific conferences, reviewing publications	Y	Moderate	Moderate	▪ Identifying startups in an early stage ▪ Access to distant knowledge (different industries)	▪ Requires profound knowledge ▪ Time consuming
Trade fairs/ exhibitions	Visits of trade fairs and exhibitions	N	Moderate	Moderate	▪ Active search within search fields ▪ Marketing effect for corporation	▪ Preparation and post processing ▪ Time consuming
Self-organized pitch events	Organizing startup events with open registration	N	High	Moderate	▪ Intensive exchange of information between internal experts and startup members	▪ Requires high organizational effort ▪ Requires startups to be proactive
Fund of funds	Investment in VC funds managed by external venture capitalists	Y	High	High	▪ Investment in regional, industry specific, and multiple funds possible ▪ Continuous participation in deal-flow of VC	▪ Highly dependent on selected funds and investment managers ▪ High investment costs
External scouting partner	Scouting by external service provider	N	High	Very high	▪ Professional service provided by experts ▪ Breadth pool of startups	▪ High cost ▪ No direct screening of market deal-flow
Scouting satellite	Scouting department located in startup “hot-spots” managed by internal employees	Y	Very high	Very high	▪ Passive search due to local presence ▪ Active search based on search field specific scouting	▪ High implementation and maintenance cost

Push instruments

Networking with business partners	Communication of potentially interesting startups by business partners can be suppliers, consulting firms, VCs	N	Very low	Moderate	▪ Detection of startups within the industry ▪ Identification of industrialization partners	▪ Depending of profession startup management skills of suppliers
Network with universities research institutes	Potentially interesting spin-off firms are communicated by universities or research institutes	N	Low	High	▪ Early stage startups with innovative technologies ▪ Cross-industry	▪ Limited to institutes network partners
Network with non-partnering firms	Building a network with competitors, customers, and cross-industry parties	N	Low	Moderate	▪ Wide range of startups ▪ Low cost for implementation	▪ Difficult to find right partners in a unknown field
E-mail, landing-, and web-page	Online contact opportunity for startups	N	Low	Low	▪ Wide range of startups ▪ First administrative steps	▪ No filter opportunity ▪ Requires startups to be proactive

Figure 4: Search instruments

Discussion

Our study examines (1) organizational structures and (2) the implementation of search for startups. In the following we discuss our findings under the light of boundary spanning and external knowledge sourcing literature.

To start with, the four deducted approaches to organize the search for startups differ regarding the involvement of internal stakeholders and their closeness to the ordinary organization. One of the approaches describes an external, centrally organized unit, e.g., an overseas scouting (Monteiro and Birkinshaw, 2017) or corporate venture capital unit (Wadhwa and Basu, 2013). Our findings highlight difficulties in the knowledge transfer and boundary spanning for this approach due to missing links to the internal organization (Dushnitsky and Lenox, 2006; Rosenkopf and Nerkar, 2001). Further, internal centralized units also face the problem of missing intra-organizational links (Ancona and Caldwell, 1988, 1992). In contrast, internal, decentralized organizational structures limit possible constrains of not-invented here syndrome and missing absorptive capacity as project managers get to know startups and their ideas in at earlier stage (Cohen and Levinthal, 1990; Katz and Allen, 1982).

Regarding the implementation of search, the deducted process shows similarities to the identification and evaluation process for diversification opportunities deducted by Lichtenthaler (2005), which consists of search field definition, systematic search and evaluation. Our results also provide more details explaining, e.g., the definition of search fields and application of tools compared to prior research (Rohrbeck, 2010). Further, we highlight a specific search process for external knowledge which extends prior findings on, e.g., individual search for inventions (Maggitti, Smith and Katila, 2013) or general description of innovation processes on an organizational level (Salerno et al., 2015). In addition to the deducted process, we describe 7 pull and 4 push instruments to operationalize the search for startups. Several of these have already been described in prior literature on external knowledge sourcing (Laursen and Salter, 2006; Leiponen and Helfat, 2010). Searching within databases or the internet as well as attending trade fairs and exhibitions have been described as sources of external knowledge (Cruz-González, López-Sáez, Navas-López and Delgado-Verde, 2015; Leiponen & Helfat, 2010). Further, establishing networks to universities or research institutes as well as competitors (non-partnering firms) originates the same literature stream (Laursen, Masciarelli and Prencipe, 2012; Laursen and Salter, 2014). In addition, networks to business partner, such as suppliers, consulting firms or venture capitalist can offer additional deal-flow. Networks to venture capitalist can be enhanced by investments in their funds, commonly referred to as fund of funds (Dushnitsky and Lenox, 2005; Monteiro et al., 2017). Literature has also described internal and external technology scouts (Rohrbeck, 2010; Wolff, 1992). Especially, external scouting entities, e.g., listening post, are effective approaches to access knowledge provided by startups (Gassmann and Gaso, 2004; Monteiro and Birkinshaw, 2017). Innovation contests have been discussed in literature (Boudreau, Lacetera and Lakhani, 2011; Felin and Zenger, 2014). This approach to access external knowledge is very similar to self-organized pitch events as both require commitment and action of the external partner. Finally, startups can directly contact corporates via open channels, such as a corporate homepage. Thereby, startups follow a similar path as if applying for corporate engagement programs, such as accelerators (Kohler, 2016).

Theoretical contributions

Our research contributes to three major literature streams: external knowledge sourcing, boundary spanning and purchasing literature. First, our research contributes to the external innovation sourcing literature addressing startups as corporations' future innovation partners (Weiblen and Chesbrough, 2015; Zaremba, Bode and Wagner, 2017). While prior literature has mainly focused on established partners within the supply chain (Johnsen, 2009; Schiele, 2010), our study addresses the role of new venture supplier, referred to as startups, as providers of external ideas. Most scholars have focused on various external sources of knowledge, such as

suppliers, customers, universities or competitors (Criscuolo et al., 2017; Laursen and Salter, 2006). Just recently, the process to identify single sources of knowledge has been regarded in detail (Monteiro and Birkinshaw, 2017). Moreover, our findings provide 11 instruments to identify startups. As a consequence, our research adds to literature on open innovation instruments which allow firms to access external knowledge in a structured way (Homfeldt et al., 2017).

Second, we highlight four organizational structures showing how corporate organizations realize boundary spanning to access knowledge provided by startups (Rosenkopf and Almeida, 2003; Rosenkopf and Nerkar, 2001). These approaches allow corporations to link to the external knowledge providers (Basu et al., 2016; Souitaris, Zerbinati and Liu, 2012). Whereas prior studies have focused on external scouting units embedded in local startup environments (Doz, Santos and Williamson, 2001; Gassmann and Gaso, 2004), we highlight three internal approaches to organize the search for startups. Our findings, are in line with recent research emphasizing the importance of close bounds to internal organizational units (Monteiro and Birkinshaw, 2017).

Finally, our findings add to literature on the intersection of purchasing and entrepreneurship by highlighting ways to enhance supply chain relationships between established firms and startups. We thereby help to advance this understudied field (Kickul et al., 2011). By showing how purchasing departments contribute to joint search for startups, we support prior findings on the role of purchasing in the innovation process of corporate organizations (Schoenherr and Wagner, 2016; Wagner, 2012). Our findings illustrate how firms can search for innovative partners beyond established networks and extend the limitations of prior research exclusively regarding the identification of established partners (Pulles et al., 2014; Schiele, 2006). This is particularly important since the identification of startups requires a radically different approach compared to identifying established suppliers. Startups are usually unknown partners without prior relations to the buying firm and therefore a systematic search represents the basis for their identification. Existing approaches to identify established suppliers are not directly applicable to the identification of startups. Overall, this article provides adequate organizational approaches, search process and instruments to enable the search for startups.

Managerial contributions

Digitalization and sharing economy are only two trends which now even affect product-focused industries, such as the automotive industry (Richter, Kraus, Brem, Durst and Giselbrecht, 2017; Svahn, Mathiassen and Lindgren, 2017). As a consequence, existing technologies may become obsolete and the search for radical innovations with focus on digital products becomes a necessity. As startups are powerful partners to face these challenges, managers should consider them as future partners (Anderson and Tushman, 1990; Bergek et al., 2013). Our study provides four organizational structures which are used to organize innovation sourcing from startups. When selecting one of these approaches, managers should consider costs and efforts of their implementation. In order to operationalize search for startups, managers can select of a set of instruments which are highlighted in our study. Further, the described process to identify startups provides the basis for implementing structured search for startups.

Limitations and future research

Our research has limitations as findings may be specific to the automotive industry. However, “they might also be applicable to industries that have similar structural characteristics such as the aircraft, aircraft engine, semiconductor, medical device and consumer products industries” (Hüttinger et al., 2014, p. 713). Moreover, our case study is limited to a set of 8 cases and 13 interviews, abstracting data for a multiple-case study from a relatively small sample size.

As this study has explorative character, we were not able to evaluate which search approaches are most successful. Future studies could regard this from two ankles. On the one hand, an analysis of the impact of different organizational settings (internal/external and

centralized/decentralized) on the success of search for startups as well as on the innovation performance of firms would provide an important contribution. On the other hand, future research could focus on the effectiveness of search strategies. Is more intensive search and broader application of search instruments beneficial for the searching firm? Such studies would add to previous findings analyzing the effects of search breadth and depth for external knowledge (Laursen and Salter, 2006; Leiponen and Helfat, 2010).

In addition, our research is limited to the perspective of established firms. A further assessment on identification instrument could be obtained by taking the perspective of startups on how to identify future business partners. Moreover, an analysis on individual level could enhance our understanding of searching and scouting for startups, e.g., regarding the effects of "the presence of technology scouting units, and the adoption or involvement of different organizational structures in the external search process—on the success rate of development, identification, and integration of external knowledge" (Bogers et al., 2017, p.14). As identifying startups is only the first step to set up collaborations, future research could examine how corporations engage with startups to participate in their knowledge and how startups may support corporations to manage ambidexterity by balancing exploration and exploitation (Weiblen and Chesbrough, 2015; Tushman and O'Reilly, 1996).

Conclusions

Our study shows how corporate organization design their search for startups. We identify four organizational approaches and 11 search instruments. Our findings advance external knowledge sourcing literature as we identify internal approaches to organize the search for startups and instruments enabling the search for startups. By highlighting the role of purchasing in the search activities and showing how firms can identify partners outside their existing network, we advance purchasing literature as well.

Archetypes of Decision-Making - International Purchasing vs Global Sourcing

Alina Stanczyk[1], Constantin Blome[2] and Martin C. Schleper[3]
1 EBS Business School, Germany
2 University of Sussex, United Kingdom
3 Nottingham University Business School, United Kingdom

Abstract
We investigate global sourcing decision-making (GSDM) processes by answering the questions 'which archetypes of global sourcing decision-making exist?' and 'how do contextual factors determine these types of global sourcing decision-making?'. The study highlights how differences in GSDM are explained by variations in contextual factors. A multiple case study approach drawing on 19 interviews and publicly available and internal data from buying firms was applied. 3 archetypes are identified (bureaucratic-discursive, pragmatic-impartial and political-unstructured) which are mainly influenced by the contextual factors global sourcing maturity, product complexity and leadership style. These factors determine companies' GSDM when global sourcing is a viable option.

Keywords: Global sourcing; decision-making; contextual factors

Introduction

While many researchers in the field agree that global sourcing is inevitable and/or lucrative for their business (Gelderman *et al.*, 2016) several other studies have failed to show significant benefits from its implementation (Vos *et al.*, 2016).
Although prior studies show that decision-making takes a pivotal role in the success or failure of global sourcing strategies (Kaufmann and Wagner, 2017), the topic of global sourcing decision-making (GSDM) has scarcely been scrutinized. So far, only few studies provide insight on how companies actually decide in respect of global sourcing (e.g.,Smart and Dudas, 2007; Moses and Åhlström, 2008) but why they undertake a certain path is still mainly opaque. Among the exceptions are the studies of Kaufmann *et al.* (2012; 2017), Akinci and Sadler-Smith (2012), Riedl *et al.* (2013) and Stanczyk *et al.* (2015) and Kaufmann and Wagner (2017) which provide a more nuanced and deeper understanding of the phenomenon by applying an organizational buying behavior (OBB) perspective.
Given the above contributions, different GSDM patterns are observable in practice and academia and although these prior studies describe the essential character of many GSDM processes they do not investigate contextual factors responsible for their emergence. However, research indicates that the decision-maker's task environment is crucial for understanding decision-making process variance (Elbanna and Child, 2007). In fact, two studies in the sourcing literature stream focus on the impact of contextual factors on GSDM. Kaufmann *et al.* (2012) test the influence of decision environments (dynamic vs. stable) on the relationship between procedural rationality and decision effectiveness whereas Riedl *et al.* (2013) examine the impact of organizational, situational and personal antecedents on the use of procedural rationality. These studies, however, do not claim to illuminate GSDM taxonomies. An exemption in this regard presents one of the latest studies in the field, in which Kaufmann *et al.* (2017) apply hierarchical regression analyses and provide a taxonomy of decision-making modes surrounding supplier selection.

Although operations management literature frequently utters the call for more research in behavioral operations management (Kaufmann *et al.*, 2014; Stanczyk *et al.*, 2017) and for a more rigorous investigation of the influence of contextual factors on actual decision-making processes and their variance (Papadakis *et al.*, 1998), this gap is a particular shortcoming of the operations management field, as strategic decision-making literature has already offered normative models of strategic decision-making processes for a long time (Shrivastava and Grant, 1985).

This study captures these calls and contributes to a vast stream in the operations management literature. The purpose of this study is to investigate GSDM archetypes along with their respective contextual factors. In doing so, this study seeks to answer the following research questions. (1) Which archetypes of global sourcing decision-making exist and (2) how do contextual factors determine these types of global sourcing decision-making?

By identifying patterns of variation of GSDM) processes which constitute GSDM archetypes, this study investigates the extent to which differences in decision-making processes are explained by variations in environmental, organizational and decision-specific factors. In doing so, the established definition of integrated global sourcing is adopted, according to which global sourcing refers to the proactive coordination and integration of common activities, items, processes, designs and technologies across worldwide buying centers within the purchasing function and across organizational functional groups (Trent and Monczka, 2003). The study differentiates between global sourcing and international purchasing, where the latter relates to a commercial purchase transaction between a buyer and a supplier located in different countries (Trent and Monczka, 2003).

Moreover, this study rests fundamentally on Stanczyk *et al.* (2015)'s findings by applying their same variables of the GSDM process, such as procedural rationality, functional politics and intuition. Based on the investigated relationships between those variables, the decision-making types are distinguished and contextual factors affecting them are determined. Due to a strong affiliation with the Stanczyk et al. (2015) study, a term global sourcing decision-making will be used as a general term for the decision-making across all global sourcing levels.

In order to answer the aforementioned research questions, a multiple case study approach is employed. In total, five cases of GSDM processes for complex purchasing components were investigated at firms from the mechanical engineering industry in Germany and Austria. The results show that three archetypes of GSDM can be identified (i.e., bureaucratic-discursive, pragmatic-impartial and political-unstructured) which provide a first step towards a taxonomy of GSDM process models. Further, global sourcing level, product complexity and leadership style are found as contextual factors that influence the emergence of GSDM archetypes.

Theoretical background

Decision-making in global sourcing

Scholarly knowledge about GSDM is still in its development stage. Prior studies emphasize that GSDM constitutes complex decision-making problems (Nydick and Hill, 1992; Smart and Dudas, 2007; Moses and Åhlström, 2008) as multiple different actors and numerous steps are typically involved in these contexts (Van Weele, 2010). Its complexity is additionally driven by a plethora of quantitative and qualitative factors and by an intrinsic difficulty of making tradeoffs among these factors. The wide range of aspects that need to be considered has caused many firms to employ cross-functional sourcing teams, which combine the spectrum of divergent expertise and skills necessary to make global sourcing decisions (Foerstl *et al.*, 2013; Golini and Kalchschmidt, 2015).

So far, only a few researchers have approached global sourcing at the decision-making process level in order to develop GDSM frameworks, however mainly by describing how these processes work (e.g., Smart and Dudas, 2007). Cavusgil *et al.* (1993), for example, developed

a descriptive GSDM process model which includes a wide set of common decision variables and the interrelations between these. In another study, Moses and Åhlström (2008) have portrayed the procedure of cross-functional sourcing processes and have identified factors that lead to a disruption of these processes, such as misaligned functional goals, functional interdependence and strategy complications.

Other researchers have shed more light on the behavioral aspects of GSDM, concentrating primarily on the procedural rationality dimension. Kaufmann *et al.* (2009) investigated how companies support rational supply management decision-making in the context of uncertainty. They identified three debiasing strategies: expanding bounded rationality of the decision makers, reducing dynamism and reducing the complexity of the decision-making environment. Further, Kaufmann *et al.*, (2012) link decision processes based on procedural rationality positively to higher decision quality (Kaufmann *et al.*, 2012), whereas Riedl *et al.*, (2013) find them effective in reducing uncertainty in supplier selection decisions. Other studies investigate the influence of intuition in sourcing decision-making with a positive correlation of intuitive decisions (Akinci and Sadler-Smith, 2012). New advances in the sourcing literature have been made by Kaufmann *et al.* (2014), who integrated intuition into GSDM by testing the effect of rational and intuitive decision-making approaches in cross-functional sourcing teams. They found that the cost performance (of the final decision) is enhanced in sourcing teams which applied highly rational decision-making (Kaufmann *et al.*, 2014). These findings suggest that too much focus on rational processes among the team members and the neglect of experience-based intuition can limit the effectiveness of the decision-making process (Kaufmann *et al.,* 2014). Stanczyk *et al.* (2015) assert that procedural rationality cannot be comprehended without examining politics and intuition at the same time, as those notions appear simultaneously with varying intensities and in different types. The study differentiates between two types of functional politics, namely assertive and negotiating politics. Whereas assertive politics affect procedural rationality negatively, negotiating politics have a positive effect on it. Similar to the opposing repercussions of politics, they find that creative intuition has a negative impact on procedural rationality, whereas justified intuition influences procedural rationality positively (Stanczyk *et al.*, 2015). Most recently, Kaufmann *et al.* (2017) investigate decision-making in sourcing contexts and develop a taxonomy of decision modes in supplier selection by applying a cluster analysis. Although their study focuses more on individual purchasing managers than on cross-functional sourcing teams, the taxonomy bases on rational, experienced-based and emotional processing and shows the possibility of providing meaningful taxonomies which support managers and sourcing teams in analyzing GSDM situations properly.

Overall, it can be concluded that although knowledge of the conduct, structure and behavioral dimensions of GSDM have been developed recently, the patterns that companies follow and their contextual factors have only very selectively been revealed. Hence, this study strives to extend the literature by sorting the apparent patterns of GSDM processes into GSDM archetypes and by investigating their contextual factors. Building particularly upon Stanczyk *et al.* (2015), this study applies the same process dimensions, namely procedural rationality, functional politics and intuition and recognizes the previously evidenced relationships between them.

Decision-making and contextual factors

To a large extent, prior OBB literature focuses on a better understanding of industrial decision-making processes and their antecedents, as well as on the influence of varying contextual variables (Sheth, 1996). As a main antecedent, the specific task environment was found to significantly determine the behavior of the participants in the decision-making process (Wilson, 1978). The most researched contextual determinants of industrial buying behavior are

novelty, complexity and environmental uncertainty (Lilien and Wong, 1984; McQuiston, 1989; Geok-Theng *et al.*, 1999). However, most of the findings provide mixed results with respect to their impact on the decision-making process.

While some researchers have found that higher environmental uncertainty induces firms to apply flexible ways of collecting non-routine and novel information from the environment (Spekman and Stern, 1979), others have suggested that a bureaucratic approach is crucial for the decision-making process in order to facilitate the gathering and processing of information (McCabe, 1987). Further, an increased complexity of the product requires that a larger number of technical experts are involved to develop and evaluate available alternatives (Kotteaku *et al.*, 1995), due to higher information requirements (Geok-Theng *et al.*, 1999). On the contrary, McQuiston (1989) did not find a significant relationship between complexity and the amount of communication in the decision process; moreover, Johnston and Bonoma (1981) did not confirm enhanced divisional involvement with an increase of complexity. With respect to purchase familiarity, OBB researchers agree that a rise in purchase novelty causes increased communication among decision-process participants (McQuiston, 1989) and higher levels of departmental representation in the decision-making process (Johnston and Bonoma, 1981).

Prior OBB research in respect to the influence of contextual factors on the decision-making process provides mixed results. In his literature review, Sheth (1996) contended that OBB research had changed dramatically since the 1970s and that many issues touched upon in the past had become obsolete. For many years, this research stream has not been fully exploited, particularly as it relates to global sourcing. In building on the OBB tradition, however, this study scrutinizes specific aspects of global sourcing, given that global sourcing is a complex phenomenon which reflects companies' contemporary buying behavior (as opposed to locally-oriented industrial buying behavior).

Some insights into the influence of contextual factors on the decision-making process can also be found in the strategic decision-making literature. However, these studies also produced mainly contradictory results. Fredrickson and Iaquinto (1989) argued that companies operating in stable environments have rational–comprehensive decision processes. Likewise, Stein (1981) contended that firms in highly dynamic environments follow less rational decision processes.

Until recently, few authors in the sourcing literature addressed the question of how environmental, organizational and decision-specific factors impact GSDM. Kaufmann *et al.* (2012) empirically tested the impact of the task environment on the relationship between procedural rationality and decision effectiveness in the supplier selection process. Investigation revealed that both in dynamic and stable environments procedural rationality influences decision quality in a positive way. Riedl *et al.* (2013) examined organizational, situational and personal antecedents of procedural rationality in the supplier selection decision-making process. Brief and contradictory remarks have been made with respect to the potential impact of global sourcing level on GSDM. In their work, Trent and Monczka (2003) suggest that in international purchasing the decision-making is opportunistic and is driven by need rather than by strategy, whereas global sourcing means that GSDM is planned and results from a global sourcing strategy. Conversely, Gelderman *et al.* (2016) found that, irrespective of the global sourcing level, critical incidents trigger global sourcing decisions. It is thus not clear what role global sourcing level plays in relation to GSDM.

The relatively small number of studies, of which most are surveys, which have investigated the relationship between GSDM and contextual factors leaves much room for further exploration of this topic. It is therefore important to gain a deeper understanding of which contextual factors are important for the GSDM process, how they affect it and to what extent they are responsible for the emergence of GSDM archetypes.

Methodology

This study applies a multiple abductive case study approach (Ketokivi and Choi, 2014). It builds on the case study work by Stanczyk *et al.* (2015) and extends its findings on the decision-making in global sourcing in terms of the influence of contextual factors on the decision-making. Following a purposeful sampling approach, key decisions were made in order to set the boundaries for the population covered by this research (Miles and Huberman, 1984). The case selection followed a structured process to ensure the greatest richness of information and at the same time to limit the number of cases necessary to achieve comprehensive insights (Perry, 1998).

In a first step, selection criteria were established in a way which ensured that the intended participants were supportive in pursuing the study's main goal; namely to identify GSDM archetypes and their underlying contextual factors. Johnston and Bonoma (1981, p. 254) noted that "no two purchases in any given company are ever exactly alike, nor will any two companies follow exactly the same procedure in two similar purchase situations, but at the same time, there should be some general patterns of behavior (…) which will be the same across even moderately dissimilar purchase situations". Thus, in order to detect such decision-process patterns and their determinants, this study opted for similar purchase situations. It is assumed that the organizational design and the applied processes are mainly dependent on the sourcing category, i.e. a group of similar items that are required for specific business activities (e.g., Van Weele, 2010). Processes for complex components are more sophisticated, relative to the buying processes for standardized goods in a single instantaneous act. Thus, the mechanical engineering industry was selected, in order to make the purchase situations comparable and to ensure the complexity of the sourcing projects and of the components sourced by firms within the same industry.

Furthermore, to assure division of labor at the functional level and at the individual level within the functions (Papadakis *et al.*, 1998; Elbanna and Child, 2007), large organizations were the focus of GSDM investigations. A revenue threshold of 1 billion EUR was selected for two reasons. First, large firms are more complex in terms of their organizational structures and their geographic sales and production facilities and second, their procurement operations are more dispersed than those of small firms. At the same time, the sample contained firms with global and regional supply chains to ensure different levels of global sourcing maturity (Trent and Monczka, 2003).

Subsequently, the sample has been limited to private firms headquartered in Germany and Austria, as these countries are major industrialized economies and their cultural proximity permits controlling for the legal and cultural environment of the home country and in order to assure that all firms' decision-making was primarily economically driven. Table 1 compares the five strategic business units (SBUs) across selection dimensions and industry subsectors.

Data collection and analysis

Case interviews were conducted based on a semi-structured interview guideline. Out of 9 companies which were invited to participate in our study, 2 we were unable to provide complete and reliable information concerning the same sourcing project. 2 additional companies failed to contribute significant new insights about the decision processes in global sourcing. Therefore, it was determined that we achieved theoretical saturation with 5 cases (Eisenhardt, 1989; Strauss and Corbin, 1998).

The interview protocol called for multiple informants from multiple functional areas who participated in a particular global sourcing initiative. In total, 19 interviews were collected, with three to four managers per organization involved in a GSDM project representing the purchasing, logistics, R&D, quality, strategy or controlling function. Each interview lasted 60-120 minutes. The data were recorded, transcribed and forwarded to each interviewee.

Consistent with state-of-the art case-study research rigor, multiple sources of information were used for triangulation purposes and to cross-verify findings (Eisenhardt, 1989). Apart from interview data, annual reports, web pages, market reports and internal documents, such as purchasing guidelines, policies and procedures were analyzed. Further, respected and established coding techniques (Strauss and Corbin, 1998) and quality safekeeping mechanisms were employed (development of a case study database, an independent coding of data and documentation, discussion of coding discrepancies).

Following the procedures of Miles and Huberman (1994) in a first step, the within-case analysis was conducted, which allowed to understand the decision context and the GSDM on an individual-firm basis. By drawing up within-case descriptions a comprehensive summary of the GSDM process of the cross-functional team and the surrounding context was generated. With respect to GSDM process, following the work by Stanczyk *et al.* (2015) process dimensions such as procedural rationality, intuition and functional politics were utilized.

Further, open coding of the interviews was conducted and the codes were organized into categories, continued by axial coding. More specifically, the aim was to look for contextual factors, which have been identified by comparing emerging categories with concepts from OBB and the sourcing literature, outlined in the literature review section. Some of the variables required certain adjustments (e.g., environmental uncertainty has been adjusted to technological uncertainty, as it is more relevant to the mechanical engineering industry context). Due to this approach, product complexity, purchase novelty and global sourcing maturity were validated as important factors for GSDM pattern emergence (Table 2).

Cases	Alpha	Beta	Gamma	Delta	Epsilon
HQ	Germany	Germany	Austria	Germany	Germany
Ownership type	Corporate	Family-owned	Family-owned	Corporate	Family-owned
Number of employees	~45,000	~10,000	~5,000	~10,000	~15,000
BU activity	World leading supplier of automation systems and services for machine tools and production machines in various industries. Develops and produces a range of controls with integrated motion control, logic and technology functions, as well as converters, servo and linear motors.	Manufacturer of material handling equipment, warehousing and material flow engineering systems, leader in the European market.	Provider of consulting and research/testing services for automotive industry. Deals with the development of test systems, instrumentation and powertrain systems, produces also electric powertrains.	One of the world's leading suppliers of engines and propulsion systems for off-highway applications and of distributed power generation systems. Produc es engines and propulsion systems for ships, for heavy land, rail and defense vehicles and for the oil and gas industry.	A world leader in drive technology and in drive-based automation sector, producing gear motors, gear units, motors etc. as well as drive solutions for automotive, transport and logistics, beverages and filling liquids.
Global presence of operations	Connected global operations	Connected manufacturing, R&D in Germany	Four production sites located in Europe and the US	Eight production sites across Europe and Asia	15 plants worldwide, centralized R&D in US & Germany
Sourced component	Electronic circuit system for motion control system	Lithium-ion battery cell for cranes	Air handling unit for the test system unit for combustion engines	Finished machined cylinder for industrial engines	Cooling element for industrial gear motors
Industry subsector	Motion control systems	Lifting and hauling vehicles	Automotive engine testing systems	Engines and propulsion systems for ships	Industrial drive systems

Table 1 Sample company characteristic

Construct	**Definition/operationalization**
Global sourcing maturity	An internationalization of sourcing process as firms develop worldwide experience, i.e. a progression from domestic sourcing level to the global coordination and integration of common items, processes, designs, technologies, and suppliers across worldwide locations (Monczka and Trent, 2003).

Technological uncertainty	Difficulty in predicting the future of a given environment, stemming from changes in technology (Dess and Beard, 1984; Sharfman and Dean; 1991), operationalized as an average number of patents granted in the industry (field) within the last ten years (based on Sharfman and Dean, 1991).
Product complexity	Product complexity can be determined according to five dimensions: functional, manufacturing, specification, commercial and political complexity (based on Homse, 1981 and Campbell, 1985).
Purchase novelty	A lack of experience of the decision-process participants with similar purchase situations (McQuiston et al.,1989).
Procedural rationality	Extent to which the decision process involves the collection of information relevant to the decision, and the reliance upon the analysis of this information in making a choice (Dean and Sharfman, 1993).
Intuition	Mental process based on gut feeling as opposed to explicit, systematic analysis, which yields an intuitive insight or judgement that is used as a basis for decision-making (Elbanna et al., 2013)
Functional politics	Intentional acts of influence to enhance or protect the self-interest of individuals or groups, shaped by goal misalignment and power imbalance among functions involved (Allen et al., 1979; Stanczyk et al., 2015)
Participative leadership	The leader shares the problem with his subordinates as a group. Together they generate and evaluate alternatives and attempt to reach agreement (consensus) on a solution. The leader does not try to influence the group to adopt "his" solution, and is willing to accept and implement any solution which has the support of the entire group (Jago and Vroom, 1977).
Consultative leadership	The leader shares the problem with the relevant subordinates individually, getting their ideas and suggestions. Then he makes the decision, which may or may not reflect the subordinates' influence (Jago and Vroom, 1977).
Negotiating politics	A type of politics driven by a combination of high goal misalignment and low power imbalance. This constellation prevents one function from dominating the GSDM process, instead leading to negotiations between the involved representatives about the most desirable choices (Stanczyk et al., 2015)
Assertive politics	A type of politics driven by a combination of high goal misalignment and high power imbalance, which leads to power abuse by decision-making participants (Stanczyk et al., 2015).
Justified intuition	A type of intuition that identifies a usage of intuition that is more based on prior experience, which can be more easily documented, shared and discussed with others and, thus be formalized to a certain extent (Stanczyk et al., 2015).
Creative intuition	A type of intuition that denote a usage of intuition that is based strongly on the more intra-personal and difficult to communicate gut-feeling component of intuition (Stanczyk et al., 2015).

Table 2 Major constructs definitions

	Alpha	Beta	Gamma	Delta	Epsilon
GS maturity					
GS strategy	Essential part of corporate strategy	International purchasing as part of sourcing strategy	International purchasing only when needed	One of the pillars of corporate strategy	International purc only when needed
Functional coordination	Direct and indirect materials are coordinated across worldwide Bus (approx. 60% of total volume bundled); specialized components are sourced at the BU level	Functional coordination of indirect materials across BUs, early functional coordination for strategic components (recently developed global purchasing procedures as a standardized process)	Functional coordination for standardized components occurs regionally; no coordination for complex products, sourcing procedures nonexistent; Limited exchange on supplier information, processes or technologies among purchasing units.	Exchange of technologies, processes and supplier information across worldwide BUs Majority of RFQs go through the global purchasing offices, which results in globally dispersed sourcing volume outside Europe, particularly in China, India and the US	No coordination e to bundle demand across individual Sourcing procedu specified; a gener exists that purcha commodities abo annual spend requ supplier quotation compared
Cross-functional integration	Sourcing strategies are aligned across functions within BUs supported by dedicated tools for cross-functional integration and existence of cross-functional sourcing committees	Alignment of functions to develop sourcing strategy in some categories within BUs; existence of cross-functional sourcing teams with predefined goals	Weak cross-functional integration; cross-functional teams do not exist, cooperation between functions based on need	Cross-functional integration is advanced especially for technically complex components; functional strategies are aligned in global sourcing	No integration am functions in terms processes or sourc strategy, cross-fur cooperation based

GS motive					
	"The decision for Global Sourcing is naturally (around) the topics of cost, labor cost advantage, risk management, etc. It can also be local content requirement or requirements of our clients or achieving currency balance. (…) It is about taking advantage of the worldwide supply chain." *Head of Strategic Procurement*	"Eroding all possible sources from the price, logistics, customs, quality, security of supply point of view. Exploiting all possibilities and finding there the most adequate supplier. In fact, not only restricting to one country or one region but (*looking*) really globally." *Procurement Manager*	"Global sourcing is a little bit a vision from my side that it doesn't matter where the goods are coming from as long as they fulfil our specs, the quality is fine and the price is, of course, in favor of our needs. It means not only necessarily the cheapest, but the best mixture of price and quality." *BU Manager*	"Aiming at getting an optimum footprint in sourcing. This topic depends on especially where is our global production footprint, where are our customers, where is our business and then we try to find the best solution for suppliers. (…) At first, we want to have an optimum cost decision, the cost does not only relate to the price of the part but very much on the logistics. (…) And we also have to consider the exchange rates. There are several factors, not only the price." *Vice President Strategy*	"It was first, the cost and second, the know-how (i.e., technology) covered. It was a double hit." *Head of Procurement*

Table 3 Global sourcing maturity, Global sourcing motive and Leadership style

			Leadership style		
	"The final decision is a joint decision (…). The lead manager is, of course, the purchasing representative, but the decision is comprehensible for all parties involved and is of course well documented." *Vice President Strategic Procurement*	"We make the final decision together with the development department. (…) Yes, for this last filter stage, both areas are equally entitled to the weighting of the result. (…) And then we had to vote. We said however, ok both voices are equal and therefore it is quite normal the mathematical ranking." *Procurement Manager*	"The final decision in a project is made by the project manager. (…) So, in Europe it's me, but of course I rely on the local guys and I rely on the headquarter guys. And if there are (…) some questions marks, then, it is my task to figure it out (...) and then to make a final decision.." *BU Manager*	"Almost all of the decisions are much cross-functional (…). We have cross-functional meetings, where we discuss about what is needed, what is possible, what are the options. In the end, it is the final decision of the purchasing department." *Vice President Product Management, Strategy*	These four departments (production, logistics, quality, purchasing) are the partners who discuss together, (whether it) makes sense or not. In such a case, a proposal will be worked out. If it can be implemented, then it is the decision of Mr. K as the purchasing manager." *Quality Manager*

Table 4 Cross-case comparison

Results

In the following, the findings of the study are presented in form of a taxonomy based on three identified archetypes based on the work by Stanczyk *et al.* (2015) and the key characteristics of each archetype are discussed. Introducing different archetypes means that a firm's GSDM process should be understood and described as a combination of multiple dimensions

Bureaucratic-discursive decision-making archetype

Alpha and Beta represent the bureaucratic-discursive GSDM archetype. It is characterized by high to modest *global sourcing* levels in which precise guidelines for the decision-making process for complex components exist and in which standardization of purchasing processes and an overall alignment of functional strategies within global sourcing projects are present (despite Beta's modest operations infrastructure). Beta's Procurement Manager admitted: "I need clearly defined partial steps to conduct analysis on good fundaments". Thus, the sourcing procedure in this archetype is cross-functionally designed to select suppliers purposefully.

The primary *global sourcing motive* in the bureaucratic-discursive archetype can be depicted by a balanced view (i.e., including the interests of diverse departments in the longer perspective). For instance, Alpha wants to cater the purchasing volume up to 100% where its production footprints are and at the same time to fulfill a set of goals, such as access to technology, lower cost etc. Moreover, Vice President for Category Management explains "we have discovered, that so called, Low Cost Country suppliers are, by all means, capable to support global for global," as a result, emerging countries sourcing accounts for 30% of total spend. At Alpha, there are three broad types of categories - full direct material, indirect material and sector specific material. Apart from the latter one, synergies are looked for when

purchasing globally. The product in scope is part of electronic category that belongs to full direct materials. Alpha is bundling approximately 60% of its total procurement volume, to achieve economies of scale. Once a year a commodity roadmap is developed for pooled materials. Among others for different circuit boards across the sites. The roadmap is cascaded from Purchasing Unit Council to the material team of a business unit and further it cascades to the particular site for electronics.

At Beta procurement is organized by product group. All sourcing needs are structured according to a group wide product management system that encompasses 40 main product groups. Beta's purchasing volume is broken down into production material, merchandise and indirect material. More than 90 per cent of the purchasing volume was allocated in Europe. Indirect spend is centralized at headquarters while direct component purchases are decentralized. In the studied case, the product in question belongs to direct spend.

Concerning GS motive, in the studied situation, Beta wants to better understand the global supplier landscape in terms of price, technological capabilities, logistics parameters and macroeconomic data and to use this knowledge efficiently, to pursuit of economies of information and learning. Purchasing Manager explains „the background was a new technology that we wanted to bring into our vehicles and we have had little knowledge of its global procurement market so far. (We wanted) to get acquainted with the new technology, ie the different industrialization progress and cost structures." The direct trigger for Beta's GSDM was finding a supplier of lithium-ion battery cell. The GSDM procedure developed for complex components required the identification of a large number of alternatives. According to Beta's Head of Production Logistics, "at least a hundred of potential suppliers are usually globally identified in this first phase. Afterwards, they are filtered according to macro criteria and narrowed down to the number of fifty". This sourcing procedure prescribes also the conduct of the analysis and the development of the final solution. Alpha initiated a GSDM process regarding potential new suppliers following a yearly supplier evaluation of electronic components and a capability verification of the global sourcing pool. Alpha's Head of Strategic Purchasing explained: "Once a year we ask ourselves in detail, if we can use additional options because of the topic of low-cost countries and (…) opportunities that could emerge from a changed supplier landscape."

In both cases, the *product complexity* was moderate and the *purchase novelty* was either high (Beta) or modest to high (Alpha) which instigated certain conflicts of interest between the purchasing and other departments.

In Alpha's GSDM process, the quality and the purchasing department's interests collided. As a result of yearly evaluation of the suppliers of the electronic components by a cross-functional sourcing committee, a new supplier has been nominated mainly due to better performance indicators in terms of quality compared to others. Quality Manager explains "you have to imagine we have different circuit boards and there are often process steps that go well beyond 300 different process steps, so and all this knowledge that people have acquired that cannot be easily wiped off the plate."Although a fairly good amount of electronic circuit board purchase experience existed, a potential new supplier provided new product specifications which is why extensive quality tests had to be conducted. The quality department insisted on the new supplier, whereas the purchasing department preferred to stick with the previous one, who provided better cost targets.

At Beta, an innovative type of battery cell for hauling vehicles had been considered from a new supplier. As Purchasing Manager explains „ the battery consists of the cell and the electronics; the electronics we can manufacture in-house, because we have our own electronics production but the cell we have to buy." Further he continues "yes that was the lithium-ion project, where many areas were involved. In addition to the product itself, the unit price, the logistics is crucial, because it is hazardous material goods and there are certain restrictions on transport (...) Here

I need the support of the development department not only to select the supplier on the commercial side but also on the technical side, because there are different technologies, different in chemicals. Also, different voltage levels and areas of application for the individual products and that must be analysed." Extensive worldwide search for supplier of an innovative product has been conducted by the purchasing. A Korean concern was nominated by technical department for further tests, as it fulfilled all technical requirements Nonetheless not all commercial criteria were fulfilled, thus Purchasing Manager had bad gut feeling towards that supplier. Extensive trial periods were required at an external scientific institute, as the product specifications were provided by the supplier. Given the high novelty in commercial and technical aspects, tensions between Beta's purchasing and development department could be noted when it came to cost vs technical adequacy of the supplier.

In the bureaucratic-discursive archetype, such differences of interest are alleviated through fact-based discussions and negotiations (i.e., *negotiating politics*) and the development of a solution is a common effort. In both GSDM processes, the purchasing department was *the lead* department for coordinating and collecting functional inputs. The purchasing representatives assured a transparent and open discussion among the sourcing committee and argued for the development of a common solution. Alpha's Head of Strategic Purchasing explained: "To solve (this conflict of interest) means to bring data, facts and objectivity into the discussion." Beta's Development Manager stated: "We discussed and came to conclusion we need to find a common solution, as our opinions are equally important." Thus, each party contributed equally and everyone felt involved in the decision-making at Beta.

Justified intuition in the form of personal experience codified in historic data is sometimes used as a decision support tool in the bureaucratic-discursive GSDM archetype. This is particularly the case when multiple suppliers are comparable in terms of hard criteria. Beta's Purchasing Manager admits: "One tries to support his gut feeling with facts. No one would accept pure gut feeling as an argument." In this archetype, the final decision is collectively reached by a democratic vote which reflects *participative leadership*.

Pragmatic-impartial decision-making archetype

Delta represents the pragmatic-impartial GSDM archetype. This archetype is characterized by integrated *global sourcing (high level of global sourcing)*, reflected in functional coordination across worldwide locations and mature cross-functional integration. Decision-making occurs according to standardized cross-functional sourcing-process guidelines for complex components. The sourcing procedure as well as the global sourcing infrastructure enable an extensive information search. Delta's Purchasing Manager explained: "We have defined what the buyer has to do, so he has the obligation to seek suppliers from the global landscape." The standardized sourcing process requires purchasing to collect at least four offers, which are evaluated with regard to commercial and technical performance criteria.

Similar to the bureaucratic-discursive archetype, the pragmatic-impartial archetype is also defined by a balanced *global sourcing motive*. In Delta's case this means to achieve an optimal global sourcing footprint, while at the same time to secure an optimum combination of price, logistic costs and technology level. This goal is supposed to be reached through long-term planning, the development of commodity strategies every 4-5 years and a related supplier review. Such a commodity roadmap development was also the trigger for the studied GSDM context.

Head of Strategy explains "our product portfolio is structured in a way that most of our products are low volume and high complexity so we don't compare to automotive industry that can source hundreds of thousands of the same pieces." Purchasing is organized in that the direct spend is decentralized, central purchasing for indirect goods and services exists, and there is also MRO business across all sectors. In the Onsite Energy and Components business unit in

the diesel engines division, the broad categories sourced are raw parts, finished parts as second source and medium-low tech. parts from low cost countries.
The component in question is a machined cylinder head for diesel engines, it belongs to direct spend, as a mid tech part. Those parts are sourced from low cost countries to achieve economies of scale. The Purchasing Manager elaborated "at the end of the day the final motivation was the total cost (…) we always look for the landed cost, so total costs of ownership is our decision making factor. We not only look on the export price of the supplier, we look at the quality performance, how are the audit results, how is the supplier dealing with flexibility etc."
In the analyzed decision-making situation, the *purchase novelty* was not as high as in bureaucratic-discursive archetype (i.e., modestly modified rebuy) as the new aspects related mainly to commercial aspects.
The engine's machined cylinder head was previously produced in-house; therefore, technology and specifications were already familiar and the overall *product complexity* was rather low. The greatest difficulty in this regard was evoked by commercial complexity, as Delta had decided to purchase the product from Brazil for the first time. The Purchasing Manager explained: "The process that we get finished machine components including assemblies from Brazil is a new step for us. (…) Because we do also in-house machining of this part, so we did in that case also make-or-buy study for our in-house production, we quoted and made an investment plan that we compared to two suppliers, one in Mexico and one in Brazil and (…) because it was more economical we sourced it out and not do it in-house. Then it went to the supplier in Brazil." The purchase novelty required the involvement from the engineering department in terms of knowledge exchange with the new supplier to secure a stable production process. Yet, their participation in the decision-making was rather limited, presumably due to the lower product complexity.
The role of the logistics department turned out to be more important: "Our parts are very big, for example, a crank cave of an engine is almost as big as a truck. Therefore, logistic costs have to be taken into consideration" (Head of Strategy). Nonetheless, this pragmatic-impartial archetype is marked by *goal alignment* and the absence of conflict of interests and hence *functional politics* in the GSDM process. Along these lines, the Purchasing Manager stated: "Strictly speaking, purchasing decides where we source, based on inputs from logistics" (i.e., the purchasing department is *the lead*).
During the coordination of the GSDM process, the purchasing department prepares an approval sheet in which all data (functional inputs) are collected for mutual transparency. As affirmed the Purchasing Manager: "We only move forward in the process if everyone is content". As well as in the case of Alpha and Beta, *justified intuition* serves as a support tool in final decision-making in the pragmatic-impartial archetype.
Yet, although the solution is truly developed in common by all participating departments, the final decision is made by the purchasing representative in the pragmatic-impartial archetype (i.e., *consultative leadership*).

Political-unstructured decision-making archetype
Gamma and Epsilon represent the political-unstructured GSDM archetype. It is characterized by low *global sourcing level i.e. international purchasing*. Epsilon pursues an international purchasing approach only when required and conducts its purchases from far-distanced countries through a purchasing agent. Although no standardized sourcing procedures exist, a general rule requires that large purchases for important commodities are based on 2-3 comparable supplier quotations and that the purchases are accepted by the company owner. Similar, Gamma also has no standardized processes and no specified purchasing procedures in place. Thus, GSDM participants are trusted to follow their own logic. Gamma's Business Unit

Manager explained: “We rely on common sense […] and everyone basically knows what to do.”

In the political-unstructured GSDM archetype, the primary *global sourcing motive* is to achieve rather short-term goals, with a main focus on low-cost sourcing and access to technology (cost vs quality at Gamma, cost vs technology at Epsilon).

At Gamma, standardized products are purchased via headquarters, whereas customized products are purchased locally by separate business units. The product sourced in the studied case was a sophisticated air handling unit for testing engines, the economies of information and process were looked for. The trigger for Gamma’s GSDM process was an emerging client order. Yet, the search for information was limited as the team usually relies on local suppliers in these cases.

At Epsilon, the purchasing structure is decentralized. Chief Procurement Officer describes “the plants worldwide are more or less self-sufficient (…) the world of Epsilon is very large worldwide. All decisions are taken rather locally.” In Epsilon’s case, a generation of sourcing alternatives was constrained from the very beginning as the sourcing direction was imposed by the Chief Procurement Officer (CPO) (i.e., *assertive politics*), who intuitively followed the general trend of sourcing from China (i.e., *creative intuition*) to achieve the economies of scale.

In the political-unstructured archetype, the *purchase novelty* is rather low. Gamma had previously bought a similar product and the Western Europe supply base is well-known. In this light, the Purchasing Manager commented: “We have plenty of known suppliers with which we already have some experience.” However, although the air-handling unit was highly customized, the technical specifications were new. For Epsilon, the product was also a slightly modified rebuy. Attempts had already been made to purchase the cooling element from local vendors before and the Purchasing Manager stated that “German suppliers cracked their teeth” on it. Thus, due to quality and technical problems as well as cost pressure, a new supply base had to be found.

On the contrary, the *product complexity* is rather high in the political-unstructured archetype. At Gamma, the component was characterized by a high manufacturing and functional complexity. The testing unit for combustion engines at Gamma had clear limits in terms of temperature, pressure and humidity and needed to be very well integrated as it was part of a larger test system. Thus, the Business Unit Manager explained: “In fact, building and delivering building components like this one is really complex, it is always customer-specific.” At Epsilon, the production of the cooling element involved four manufacturing processes which is why it was considered to be highly complex. The CPO elaborates: “technically it is not easy to achieve, because they (suppliers) need a very intelligent tool maker who masters the process so that the aluminum casting, the material is injected into a preheated form then it also needs to be cooled down intelligently. Material formation is then crucial to the cooling capability of this heat sink. It could be that it looks quite good from the outside but unfortunately does not have the right qualities. Still our own factory, we have our own aluminum die casting foundry in France, did not manage to do it right.” Furthermore, the distance of the potential supplier in China increased the purchasing complexity.

As a result, the political-unstructured archetype can be described as prone to conflict of interests. At Epsilon, the GSDM process became a source of disagreement between the purchasing and logistics departments because the storage design, consumption pattern and forecasts did not fit with purchasing’s strategy, i.e., ordering large batches from China to achieve unit cost savings. At Gamma, due to the high degree of technological advancement, the engineering department had a strong position in the decision-making process. Thus, Gamma’s Business Unit Manager complained: “They are so much down at the technical level”, meaning that it was possible for the engineering department to manipulate the GSDM process by providing questionable recommendations to select their preferred suppliers which caused

assertive politics. Similar, the emergence of *assertive politics* was observed at Epsilon. Due to a lack of experience in purchasing from China and in interaction with Chinese suppliers, the quality and the technical department were resistant towards a cooperation with Chinese partners.
Consequently, in both cases an individual who was *the lead* in the decision-making process independently developed a solution. At Epsilon, the CPO even withheld important information from the logistics department (i.e., *assertive politics*). At Gamma, the Business Unit Manager steered the decision process and managed the work of the purchasing and development departments. However, he also admitted to influence the GSDM process significantly (i.e., *assertive politics*): "I am challenging (the engineers) and, of course, purchasing is checking this at the end, if the figure is reasonable or if the way to come up with this figure was completely (…) crystal balling (…). I sometimes need to change an engineer in the project. Otherwise it would end up in a war."
At international purchasing level in the political-unstructured archetype, a certain latitude in the preparation of the analyses and solutions is present, leading to *creative intuition* in the decision-making process, such as relying on gut feeling (as mentioned above for Epsilon).
Finally, the final decision is made by the lead individual in the in the political-unstructured archetype (i.e., *consultative leadership*). Gamma's Business Unit Manager developed a solution independently, trying to manage the interests of the technical function, the procurement function and local commercial goals. Although he discussed and reevaluated the outcome bilaterally until all parties agreed he made the final decision on his one. Stressing the role and the responsibility of the purchasing department, Epsilon's CPO emphasized: "Basically, purchasing is in the lead, because we also carry the responsibility to ensure that it all works and that's why we make final decision."

Discussion

Throughout the study, three patterns of GSDM were identified: the bureaucratic-discursive, the pragmatic-impartial and the political-unstructured GSDM archetype. Two of the analyzed cases (Alpha and Beta) can be classified as the bureaucratic-discursive type, meaning that the decision-making process is characterized by high procedural rationality and the rationality is enhanced by negotiating politics and justified intuition. Delta represents the pragmatic-impartial type, where procedural rationality is strengthened by justified intuition. The political-unstructured type (Gamma and Epsilon) has low procedural rationality and the rationality is negatively influenced by assertive politics and creative intuition.
With respect to the contextual factors that account for the emergence of archetypes, some of the factors delineated in the literature were validated, while additionally new ones, such as global sourcing level and leadership style were found throughout the data analysis.
In the following, the interplay of the contextual factors and GSDM is discussed and the findings are reflected against existing literature.

Global-sourcing decision-making and contextual factors

Overall, support was found for the claim that different GSDM occur dependent on present contextual factors. As assumed, global sourcing level matters for the conduct of the decision-making process on complex components. This factor is the main contextual factor responsible for the emergence of GSDM archetypes. In organizations with more advanced global sourcing practices, the GSDM process was rationally driven, with political and intuitive behavior strengthening procedural rationality. This can be explained by the existence of standardized sourcing procedures. These procedures improve the scrutiny of the decision process since a more exhaustive search for suppliers is conducted and usually more sourcing options are generated.

Further, these guidelines reflect mature functional coordination and cross-functional integration. Thus, they first prescribe actions and second, secure goal alignment between different functions. Consequently, through clearly prescribed roles and responsibilities that frame the behavior and set the boundaries, negotiating politics and justified intuition are fostered to enhance the comprehensiveness of the GSDM in these cases. However, negotiating politics do not always occur in complex-components decision-making contexts of high global sourcing (i.e. integrated global sourcing) (or global-sourcing organizations as in the case of Beta).

In this context, the cases show that purchase novelty and product complexity are important contextual factors. Moderate to higher levels of purchase novelty (driven by both commercial and technical factors), as in the cases of Alpha and Beta, result in certain goal misalignment (i.e., conflicting interests) which activates a negotiating politics behavior (i.e., discussion and negotiations between the departments broaden the scrutiny of the analysis). Moreover, moderate product complexity requires different expertise and transparent information exchange, which is secured by the sourcing procedure, thereby enhancing procedural rationality. The sourcing procedure also enables justified intuition to formally contribute to final decision-making, thereby likewise strengthening procedural rationality. This leads to the first proposition:

P1. *In global sourcing the decision-making is characterized by bureaucratic-discursive decision-making archetype, when product complexity and purchase novelty are rather high than low.*

On the contrary, Delta demonstrated low product complexity and moderate purchase novelty – driven mainly by commercial aspects. This means that the required cross-functional expertise and information exchange was lower and the burden of novelty in this purchase situation was handled mainly by one function (purchasing). Due to decreased cross-functional interaction and a lack of conflicting interests, functional politics did not emerge. However, justified intuition enhanced procedural rationality and supported the final supplier choice, thus:

P2. *In global sourcing the decision-making is characterized as pragmatic-impartial decision-making archetype, when product complexity and purchase novelty are rather low than high.*

It was observed that in cases with lower levels of global sourcing - the international purchasing (i.e., Gamma and Epsilon) GSDM on complex components is less rational and procedural rationality is influenced by assertive politics and creative intuition. For example, the procedural rationality is lower, as the information search is less scrupulous and yields a limited number of alternatives due to the use of an intuitive analysis (creative intuition). Moreover, international purchasing means both immature functional coordination as well as cross-functional integration, which result in a lack of standardized sourcing procedures and a reliance on rather general rules. Such general rules give discretion to the lead individuals in terms of process design, its conduct and outcome.

Against this background, the contextual factor product complexity mattered for the studied decision-making contexts. In both cases, product complexity was high. Whereas Gamma's complexity was driven by technical aspects, Epsilon's was driven by commercial arrangements. However, for both organizations this resulted in conflicting interests among involved departments. Additional escalation was caused by moderate purchase novelty; another important contextual factor, which caused additional conflict between the departments with respect to new suppliers at Epsilon and Gamma. Since no clear roles and responsibilities were prescribed, there was plenty of room for assertive political behavior. As assertive politics replace the transparent data exchange and discussion and cause a deterioration in procedural rationality, it is proposed:

P3. *In international purchasing the decision-making is characterized as political-unstructured decision-making archetype.*

A contextual factor that emerged from the data that was not considered in the literature review is the global sourcing motive. The motive that includes the interests of diverse departments in the longer perspective, is multidimensional and goes beyond the short-term technology access or cost goals.is termed "balanced global sourcing motive". This motive is related to procedurally rational GSDM. Alpha and Beta show that a balanced global sourcing motive accompanied by participative leadership is characteristic of the bureaucratic-discursive decision-making archetype. The leader facilitates information exchange and moderates the discussion in case of conflicting interests, thereby fostering negotiating politics. This leadership style also enables equal departmental contributions to developing a solution and making a final joint decision, which ensures that different functional interests are reflected in the decision-making outcome. Thus, procedural rationality is supported.

Although a balanced global sourcing motive turned out to be a prerequisite of a procedurally rational GSDM, it does not automatically lead to the bureaucratic-discursive archetype. The case of Delta shows that a consultative leadership, accompanying a balanced global sourcing motive, constitutes a different type. The leader ensures that functional inputs are contributed in the development of the solution in a transparent manner, according to a balanced global sourcing motive. Yet, after following the input of the team, he makes the decision independently. This leads us to our second proposition:

P4. *Participative leadership facilitates global sourcing decision-making in conjunction with a balanced global sourcing motive such that it is characterized as bureaucratic-discursive decision-making archetype.*

P5. *Consultative leadership facilitates global sourcing decision-making in conjunction with a balanced global sourcing motive such that it is characterized as pragmatic-impartial decision-making archetype.*

A narrow global sourcing motive which focusses on two competitive factors in a rather shorter perspective is related to less-procedurally-rational decision-making. This is the case, if at the same time another contextual factor, such as consultative leadership occurs. The leader collects the relevant analyses from the involved departments. However, he uses inputs selectively in the development of a solution and makes the final decision individually, giving priority to preferred departmental interests. In those cases, the project leader facilitates assertive politics, for example, by deploying such tactics as withholding important information. Such tactics cause personal or departmental preferences to substitute for rigorous analytical methods and thus diminish procedural rationality. Therefore, it is proposed:

P6. *A consultative leadership style leads to a political-unstructured decision-making archetype when the international purchasing motive is rather narrow.*

Scholarly contributions

This study's approach to consider global sourcing level as an important contextual factor leading to certain GSDM archetypes turned out to prove right. The findings extend the view of Trent and Monczka (2003) concerning the character of decision-making at various global sourcing levels. According to these authors, international purchasing facilitates opportunistic decision-making, while organizations at higher global sourcing level carry out GSDM in a planned manner. The findings show that decision-making types at global sourcing level are rationally driven, as opposed to those at international purchasing level, where the decision-making is less rational, more opportunistic and intuitive (i.e., more political behaviors occur).

Moreover, two out of three contextual factors identified in the OBB literature were validated. Regarding purchase novelty, the findings partially agree with prior OBB studies, which claim that higher purchase novelty instigates higher departmental participation and increases communication (McQuiston, 1989; Johnston and Bonoma, 1981), as well as with Riedl et al (2013), who claim that for moderate to high purchase novelty decision-making is more rational. The cases show that in two decision-making archetypes purchase novelty induces increased information exchange. Moreover, decision-making is more rationality-driven in the

bureaucratic-discursive archetype, whereas it is less procedurally rational in the political-unstructured archetype. This is due to the fact that higher levels of purchase novelty activate functional politics. Further, depending on the combination of purchase novelty with other contextual factors (e.g., global sourcing level), this can affect procedural rationality either positively or negatively.

The second validated contextual factor, product complexity, turns out to be linked to all GSDM archetypes and the findings confirm some of the prior contributions. In line with Hillier (1975) and Kotteaku et al. (1995), the cases show that with higher product complexity more communication and divisional involvement occurs, which can be seen by comparing the pragmatic-impartial with the bureaucratic-discursive and political-unstructured archetypes. Due to low product complexity in the pragmatic-impartial archetype, a lower requirement for data exchange exists compared to the other types. As with purchase novelty, higher levels of product complexity activate functional politics. In fact, in the political-unstructured archetype, both purchase novelty and product complexity apparently enhance assertive politics and the use of creative intuition, which causes deterioration in procedural rationality. On the contrary, in the bureaucratic-discursive archetype, both contextual factors instigate negotiating politics, which strengthens procedural rationality.

The cases show that two of the analyzed contextual factors do not turn out to be fully valid or at all. On the one hand, technological uncertainty (in the literature environmental uncertainty) does not indicate clearly towards any GSDM type (see Table 4). High technological uncertainty appears in two cases representing the political-unstructured archetype, but at the same time, extreme values are present in the bureaucratic-discursive archetype. Extant research provides mixed results when it comes to the impact of environmental uncertainty. Some researchers claim that in stable environments the decision-making is predominantly rational (e.g., Stein, 1981), other that dynamic environments yield in higher rationality levels in the decision processes (e.g., Bourgeois and Eisenhardt, 1988). Our research confirms the contribution of Kaufmann *et al.* (2012) who found that relationship between the decision-making process and environmental uncertainty is indifferent.

On the other hand, a similar situation in terms of antecedent validity is visible with the type of ownership. Whereas the political-unstructured archetype cases (Gamma, Epsilon) are both family-owned, Beta, which is also family-owned represents the bureaucratic-discursive archetype.

A new contribution in the field of global sourcing is the identification of the decision-maker's leadership style as a contextual factor for GSDM archetypes. The participative leadership type has been identified in the bureaucratic-discursive decision making archetype, whereas consultative leadership has been identified in both the political-unstructured and in pragmatic-impartial archetypes. Further research could investigate whether another GSDM archetype exists in which less rational decision-making concurs with participative leadership style.

Last, this study highlights the role of the global sourcing motive for the GSDM process. Previous research discussed the global sourcing motivation only with respect to global sourcing level. Thus, integrated global sourcing has been found to be aimed at achieving competitive and comparative advantage and from an international purchasing perspective, mainly price benefits are expected (Trent and Monczka, 2003). This paper explores the global sourcing motive in more depth and links it to GSDM archetypes, thereby also presenting the interplay with different leadership styles.

Overall, following Papadakis *et al.* (1998), it can be concluded that contextual factors in decision situation have the strongest influence on the decision-making process. The findings of this research also suggest that organizational characteristics (i.e., global sourcing level) can present another critical factor for the GSDM processes.

COLLABORATIVE WORKING CAPITAL MANAGEMENT
in automotive value chain: A longitudinal analysis

Summary
This paper examines the relationship between working capital cycles and firm performance in the automotive value chain. Recent literature suggests that industry-specific reasons may lead to different conclusions compared to conventional theory. Therefore, by using a repeated measures data-panel of 1058 firm-year observations between 2007 and 2016, we examined the relationship between firm performance and cash-conversion cycle (CCC) components. The findings indeed contradict conventional literature and suggest that increased firm performance is related to simultaneous reduction of payables and receivables cycles, while keeping longer cycles of inventories.

Keywords: Financial Supply Chain, Working Capital, Supply Chain Finance

Introduction

Supply Chain Management entails the coordination, planning and execution of inter-organizational arrangements related to the flow of cash, information and goods, from the raw material stage to the end consumer (Mentzer, 2001; Camerinelli, 2009). Significant research efforts have been undertaken from the academic community and the corporate world concerning the informational and physical flow of the goods in the supply chains, but not for cash flows (Wuttke, Blome, & Henke, 2013). Thus, when the 2008 financial crisis negatively affected credit availability, the cash flow processes of automotive corporations collapsed. The affected firms responded globally with a myopic optimization effort (Hoffman & Kotzab, 2010; Vasquez, Sartal, & Lozano, 2016), which included trade credit extensions from their suppliers in order to supplement their operations with other forms of financing. Under this environment, credit risk and capital financing costs were transferred from the dominant Original Equipment Manufacturers (OEM) firms to earlier stages in the upstream supply chain (Pohlem, Terrance, & Goldsby, 2003), increasing supply chain disruption risks. As a result, when the economy began to recover some firms were not able to finance their operations and participate in the economic recovery, leading themselves to the so called “working capital trap” (Hoffman, Maucher, Piesker, & Richter, 2011).

The questions that emerged from the aforementioned developments, caused the resurface of the financial supply chain management (FSCM) discussion. Despite the reemergence of this topic, research was fruitful only in incorporating financial flows and trade credit concepts into inventory models (Gupta, 2009; Àlvarez & Lippi, 2017). Furthermore, much of the research currently associated with this topic is still rather conceptual (Monto, 2013; Wuttke et.al., 2013). This suggests that the theoretical framework is not yet conclusive (Gelsomino, Mangiaracina, Perego, & Tumino, 2016). Thus, our first contribution is to research empirically the topic by using secondary data to validate previous conceptual research into financial supply chain management.

Furthermore, there are few comprehensive research efforts that cover this topic and even fewer to include more than first tier upstream suppliers, which contradicts what researchers propose concerning end-to-end supply chain management research (Vasquez, Sartal, & Lozano, 2016). One value chain that would benefit from such research is the global automotive industry as it was the one who reportedly neglected to manage its cash flows ((Zhao, Flynn, & Yeung, 2008) and it suffered during the credit crunch of 2008 which resulted in the bailouts of GM, Ford and Chrysler. Therefore, a second aim of our research is to implement an end-to-end value chain approach of five stages in the vertical and mature environment of automotive industry to reveal empirical trends at the value chain level.

Finally, the third contribution of our paper is the use of a longitudinal research design, which despite its ability to control for time effects (Kroes & Manikas, 2014) and its popularity among proposed future research (Weele & Raaij, 2014), is still scarce among the literature.

Consequently, the research question we aim to investigate is:

"*How do cash-conversion-cycle (CCC) components affect the firm performance of the companies which operate in the automotive value chain?*"

The structure for the rest of this paper is as follows: During the next section, the theory and the consequent proposition development is presented on the basis of working capital management (WCM), financial supply chain management (FSCM) and transaction cost economics (TCE) theory. In the third section, dataset construction and methodology are analyzed while in the fourth section the results of the research are outlined and discussed. The final section provides the conclusions, limitations and further research suggestions.

Literature Review and Propositions Development

Working Capital Management and Firm Performance

Working Capital (WC) is the amount of cash firms need to have for immediate use for their day to day operations (Mullins & Komisar, 2009). Accordingly, WCM aim is to reduce a firm's current assets portion to the lowest possible level. In other words, a firms' management must strive for the lowest account receivables while at the same time retain the right amount of cash to finance its operations without missing investment opportunities. Despite this goal, there is not a universal minimum level that fits-all situations and at the same time to maintain appropriate funding to execute business (Chen, Wang, & Lin, 2009; Popa, 2013). Thus, any miscalculation born from random variability and unpredicted circumstances could lead the firm to borrow too much money and decrease profitability or to borrow too late and reduce the ability of the company to get loans (Chen et.al. , 2009; Mullins & Komisar, 2009).

Working Capital can be approached from two perspectives. The first perspective is the more accounting one and revolves around the notion of Net Working Capital. The alternative and more related to this paper's perspective, is the process-related working capital (Monto, 2013). In WCM, this notion is directly measured from the cash-conversion-cycle(CCC) metric which represents the average days needed to convert a dollar invested in raw material into a dollar collected from a customer (Stewart, 1995).

CCC consists of three accounting based components (Table 1): First sub metric is the Days of Sales Outstanding (DSO) which resembles the average number of days between the sale of a product and the receipt of cash payment. The second sub metric, Days of Inventory Outstanding (DIO) resembles the average number of days that the stock value of raw materials, work in progress and finished goods of a company are converted into product sales. Lastly, the Days of Payables Outstanding (DPO) resembles the average number of days between the purchase from a supplier and the cash payment to that supplier (Table 1). The CCC is the sum of DSO and DIO minus the DPO.

Previous empirical research done mostly from the single-firm perspective revealed that the best strategy for increased firm performance is to maximize DPO and minimize DIO, DSO and CCC (Deloof, 2003; Garcia-Teruel & Martinez-Solano, 2007; Randall & Farris, 2009; Ebben & Johnson, 2011). This notion was consistently confirmed with alternative firm performance proxies and was recently further supported with longitudinal research which not only validated the above strategies, but uncovered a lagged effect of the CCC components in relation to firm performance (Kroes & Manikas, 2014; Huff & Rogers, 2015). More specifically it was revealed that firm performance can be affected today, by changes in DIO and DPO up to three years before.

The main criticism against this research stream is that it assumes only a single-company perspective (Losbichler, Heimo, & Rothbock, 2006; Protopapa & Seiffert, 2010; Hoffman & Kotzab, 2010; Monto, 2013; Wuttke et.al., 2013; Vasquez et.al., 2016) but when approached in a value chain setting "the gain of one is the loss of the other" (Losbichler et.al 2006). Accordingly, the empirical research and literature must also be extended to include

the fact that modern business competition occurs between supply chains and not mere firms (Rice & Hoppe, 2001; Larsen, 2007). Such extension is the proposal of the conceptual "supply chain-oriented perspective" WCM.

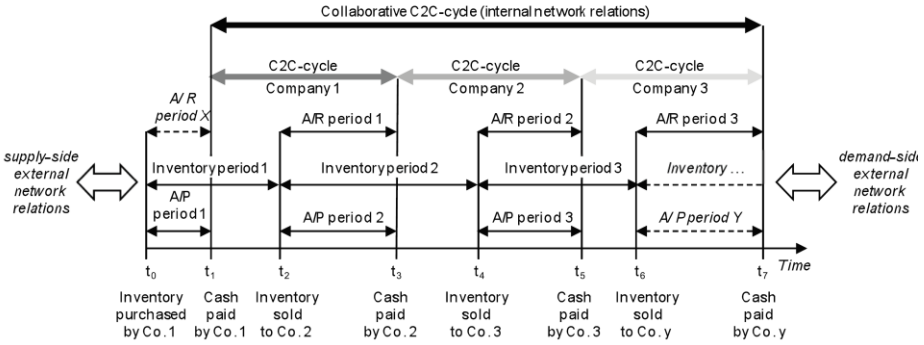

Figure 1 Supply Chain Perspective of CCC - Adopted from Hoffman Kotzab,2010

The main notion behind this theoretical perspective is that the companies which enjoy a high level of supply chain integration behave as one entity. External network relations of that "entity" follow the traditional single-firm perspective strategies as confirmed by most of working capital research so far. However, within the "entity" those traditional strategies are not applicable. As shown in Figure. 1 the A/R period (DSO) of Co.1 and A/P (DPO) of Co.2 are happening at the same time interval ($t_2 - t_3$) and cancel each other out. The natural interpretation in terms of Transaction Cost Economics, is that inner-cycle transactions costs become a bottleneck for the efficiency improvement efforts due to the unnecessary and redundant transactional costs of the "internal" payment periods. Consequently, the OEM firm (Co. y) has a strong motive to help coordinate upstream transactions.

The aforementioned concept can be observed through the effort of OEM firms to decide the payment terms with their suppliers by taking in consideration the second-tier suppliers as well. Data between 2012 and 2016, reveals a significant increase in the percentage of manufacturers who achieved total supply chain visibility (KPMG, 2012; KPMG, 2016) while at the same time senior managers have stated their preference to develop cost-to-serve structures (KPMG, 2016) in order to pinpoint cash flow and cost inefficiencies in their supply chains, especially when serving heterogenous customer profiles. These insights are evidence towards a general holistic approach and mindset from managers, something which further hints at a system level optimization like the supply chain perspective described above. Based on both theory and practice it can reasonably be assumed that the cash-conversion-cycle metric is only relevant at the value chain level of the automotive industry but not to any individual value chain stages. Proposition 1(P1): Cash-Conversion-Cycle metric is managed at the automotive value chain level

Another important implication from the "Supply Chain Perspective" collaborative approach relates to inventory. Assuming that the trade credit components are preferable to be managed at the system level, the only operation which can be available to local decisions is inventory. Modern inventory optimization efforts are closely related to the concept of lean management. Past research in lean inventory management (i.e. just-in-time etc.) produced mixed results concerning firm performance effects (Koumanakos, 2008), or even non-meaningful links between inventory leanness and firm performance. Results ambiguity caused the resurface of the discussion for industry-specific leanness (Haan & Yamamoto, 1999). More specifically it is stressed that the feasibility and desirability for leanness practices depends on specific production and supply chain conditions that relate to that industry's business model. Recent research confirmed this notion and more specifically that automotive industry related sectors experience increased firm performance when the inventory cycles increase (Eroglu & Hofer, 2010).

This seems to be confirmed in practice as well. In 2012 after the deep global recession was over, most popular challenge as voted by the CEOs in the automotive industry, was the ability of their supply chains to react in real time fluctuations of demand, while third most popular was the ability of their supplier's capacity to meet demand (KPMG, 2012). This can be attributed to their need to deal with fluctuations originating from increased market demand as the economies were recovering. Although, this notion comes in contrast with what the traditional perspective of working capital management instructs (i.e. negative DIO relationship with firm performance), it makes sense when observed

under the collaborative scope of (Hoffman & Kotzab, 2010). Therefore, it is reasonable to assume that on average, longer cycles of inventory in the automotive value chain can support firms' effort to satisfy increased yet volatile demand.

Proposition 2 (P2): Days of Inventory Outstanding in the value chain level is positively related with firm performance

Transaction Cost Economics (TCE) and Financial Supply Chain Management (FSCM)

As mentioned previously, there is not yet a conclusive theoretical framework for FSCM. To circumvent this limitation, we look for the help of TCE to complement our approach. TCE derives from the research of Coase (1937) Williamson (1981) and was used extensively as theoretical support in real world supply chain concepts such as vertical economic integrations (D'Aveni & Ravenscraft, 1994) and supplier performance and governance (Mahapatra, Narasimhan, & Barbierri, 2010). At the same time, is also applicable in the FSCM context due its association with uncertainty, opportunism and bounded rationality on transaction costs (Wuttke et.al., 2013).

The main concept to which TCE relates, is the optimization between the level of specialization (productivity) and the total amount of costs. The total amount of costs encompasses transaction costs and production Costs. Transaction costs are the sum of "all costs necessary to run a relationship" (Carr & Pearson, 1999) and along with the production costs they constitute the total cost of producing goods or services. As today the competition is between supply chains and not between companies, the Transaction Cost Economics theory becomes extremely relevant for the research at hand. From a certain point and further, a reduction of production costs comes at an exponential increase concerning transaction costs mainly due to information asymmetry and misalignment of interests (Hayek, 1945). Therefore, in TCE terms, the previously described supply chain perspective achieves the reduction of information asymmetry and misalignment of interests thus the minimization of transaction costs. In other words, the goal of FSCM can be considered to align the interests of all the implicated parties and keep the transaction costs at a manageable level but without sacrificing the level of specialization.

Indicatively, Financial Supply Chain (FSC) refers to the "holistic and comprehensive activities of planning and controlling all financial processes, which are relevant within a company and for communication with other enterprises" (Popa, 2013). One of the most cited and well-regarded concepts towards a unified FSCM theory is the dichotomy of FSCM before and after invoice release (Wuttke et.al., 2013). More specifically, a "pre-shipment" FSCM is defined as "the group of practices such planning, managing and monitoring cash flows along the supply chain, which take place before the actual delivery, quality control and invoice release". The second perspective is the "post-shipment" FSCM and encompasses "the practices that take place after the actual delivery, quality control and invoice release*"*. The latter perspective is essentially supply chain finance (SCF) practices.

More specifically, SCF solutions relate directly to trade credit components financing, like accounts receivables and accounts-payables of all the players in the value chain. The main goal is to help reduce account receivables of the suppliers but without a reduction in the accounts payables of the OEM firm (Haile & McDonald, 2012). In other words, the supply chain finance system owner, usually a financial institution, is funding the in-between period of these obligations allowing participating firms to receive payments earlier minus interest rates. This is achieved through an electronic database system which aggregates information and credit decisions on behalf of the OEM who initiates this scheme. This concept is documented to be used in automotive industry (Wuttke et.al., 2013).

Therefore, when seen under the supply-chain-perspective any effort from any supplier to extend its payables would harm the upstream tier supplier and probably would initiate an effort from that supplier to receive earlier payments from other of its customers or transfer this inefficiency to the pricing of its products (Viskari, Lind, & Karri, 2012). The result would be a domino effect to the whole supply chain and a subsequent deterioration in working capital positions. Therefore, for our third and last proposition it is reasonable to assume that on average the trade credit components, namely DSO and DPO are negatively linked with firm performance at the value chain level.

Proposition 3(P3): Trade credit components in the (DSO, DPO) value chain level are negatively related to firm performance.

Automotive Value Chain

The necessity for a holistic research led several researchers to turn to the value chain analysis. The concept of the value chain (VC) was first conceived by Michael Porter and is defined as the set of activities that a firm operates, within a specific industry, in order to deliver a valuable product or service for the market (Porter, 1985). Although the terms value chain and supply chain were not seen as the same concept in the past, due to the increased level of integration and collaboration, the two terms are currently used inter-changeably. In other words, it is not necessary for all the companies to work with all the rest in the value chain, but it suffices to add value in one way or another for the sector (Van-Weele & Rozemeijer, 1996). The automotive industry value chain was chosen for our research due to its maturity level, which allows as us to use it as template for all the problems most manufacturing industries will face sooner or later (Pirttila, Lind, Viskari, Schupp, & Karri, 2012) and because it was hit hard at the 2008 financial crisis.

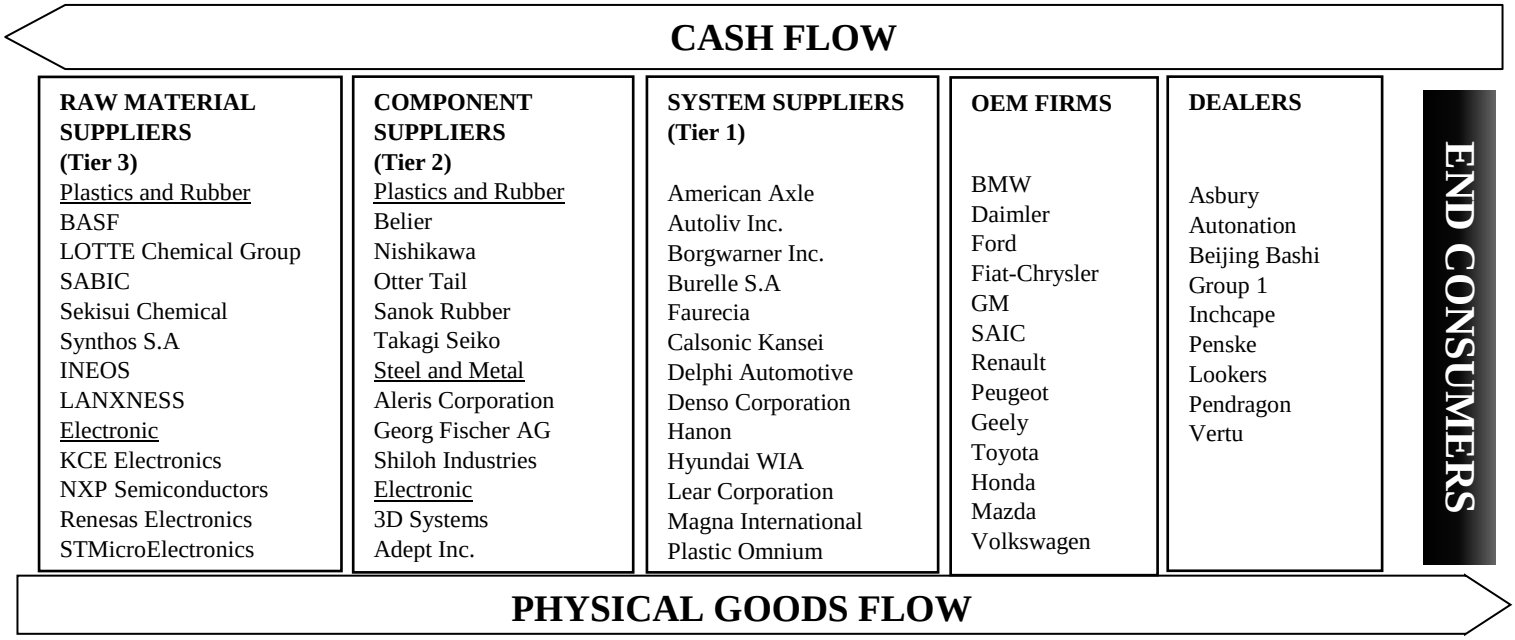

Figure 2 Value Chain Model(indicative)

Research Design and Methodology

Automotive Value Chain Model

Our research design adopts the automotive value chain model from past research (Pirttila, Lind, Viskari, Schupp, & Karri, 2012) and extends it to include data from 2007 to 2016. Our version of the automotive value chain model includes five stages (figure 2):

The first one is the refined materials components stage (tier three) which is divided to raw plastic/rubber materials and electronic component materials. In this stage components like coatings, catalysts, engineered plastics and semiconductor PCBs are produced and sold to the next stage. The second is the components stage (tier two) which includes plastic/rubber components, metal components and electronic components. In this stage plastic chassis, seat parts, metal structural components and electronic systems are supplied to the next level. The third one is the systems suppliers (tier one) which includes brake systems, full seating systems, power control units, airbags climate control systems etc. The fourth one represents the automotive original equipment manufacturers (OEM) which are responsible for the design of the car, the creation of the specifications, R&D, branding and final assembling and finally the fifth and last stage includes distributors/Retailers which include wholesalers and car dealers which buy cars and stock them to push them into the market.

Data Panel

To construct this paper's longitudinal data panel, FACTSET database was employed due the high quality of its post processing auditing services. This ensures the accuracy of this research and that the data are representative of the real world.

The value chain dataset for this research is similar to previous research (Pirttila, Lind, Viskari, Schupp, & Karri, 2012). Despite the commonalities, especially in the choice of the stages, there are some significant extensions to this paper's value chain data panel. Most important extension, is the use of the Supply Chain feature of FactSet. This feature shows the customers and suppliers for each of the firms used and solves the limitation of estimating the relationships (Pirttila et.al., 2012; Viskari et.al., 2012) or the criticism of uncritical use of databases (Moers, 2007). Therefore, the relationships in this dataset are not implied but accurately representative of the real-world supply chain relations. Furthermore, the Supply Chain feature shows the monetary value of the relationships and the percentage they represent to the total relationships of the firm. Any relationships that either did not include that percentage and/or the monetary value of a relationship, were excluded from the dataset. The rest of the relationships were ranked and the top suppliers/customers in terms of relationships and monetary volume were included. The reason for this choice is to include firms with big proven relationships which can be representative of the automotive industry. If any supplier of any stage could not be traced back to at least one supplier in the downstream tier, then the list was extended accordingly so there was at least one connection for that supplier. Finally, another significant extension of this dataset compared to its predecessor editions, is the adequate representation of all the important regions of the automotive value chain (US, France, Germany, Italy, China, Japan). In this manner, the dataset becomes more robust concerning the global developments in the industry.

Measures	**Abbr.**	**Calculation**
Days of Sales Outstanding	DSO	$\frac{\text{Receivables}}{\text{Sales}}$*(# of days in a period)
Days of Inventory Outstanding	DIO	$\frac{\text{Inventories}}{\text{COGS}}$*(# of days in a period)
Days of Payables Outstanding	DPO	$\frac{\text{Payables}}{\text{Sales}}$*(# of days in a period)
Cash Conversion Cycle	CCC	DSO+DIO-DPO
Tobin's Q	TobinsQ	$\frac{\text{Equity Value+Book value of LongTerm Debt+Net current liabilities}}{\text{Total Assets}}$
Debt to Asset Ratio	DEBT	$\frac{\text{Debt}}{\text{Total Assets}}$
Annual Sales'(in million dollars)	SALES	Sales

Table 1 Measures and Formulas

The resulting dataset includes 112 unique firms that had official public reports of their annual accounting and financial data. Since some firms reports did not include all the relevant data to this study, the sample set was reduced to 99 firms with data spanning from 2007 to 2016. The removed companies did not have full CCC components or metrics related to their balance sheet and income statements. Finally, the time span choice was based on the lack of data for a significant number of suppliers for earlier than 2007. The reason for this lack of data can be traced in different reporting regulations prior to 2007 in many regions around the world.

Dependent variable

Tobin's Q is the ratio of the market value of a firm to the replacement value of its assets (Tobin, 1969) and has been employed in a significant amount of past researches as a firm performance indicator in multiple topics (Dowell, Hart, & Yeung, 2000; Hennessy, 2004; Chen et.al., 2009). Calculating the exact value for this metric needs firms' disclosed information, so this paper utilizes the (Chung & Pruitt, 1994) approximation formula for which they showed that approximates the actual Tobin's Q measure by 95%. The formula is: Tobin's Q= (MVE+PS+DEBT)/TA where MVE is the market price per share of stocks multiplied by the number of stocks outstanding, PS represents the net current liabilities and DEBT the Book value of long-term debt. The sum of those parameters is divided by the book value of the total assets. If Tobin's Q>1 then the firm is doing an efficient job into replacing the value of its assets if <1 then not. In other words, the metric incorporates the market's view on how the companies' operations are managing their assets in the long term (Kroes & Manikas, 2014).

The reason for employing this metric instead of more traditional ones like RoA is threefold. Firstly, it has been shown that in automotive industry metrics like RoE, RoA cannot be linked directly to operational metrics because other aspects of firm management moderate and distort this relationship (Klinkenberg, Timberlake, Geurts, & J.Brown, 2013). Secondly, since inventory represents a significant portion of the assets under the control of automotive firms, this proxy is more suitable to represent the firm performance since its concept is linked to the value of assets replacement. Thirdly, Tobin's q has been linked to superior representation of firms performance (Wernerfelt & Montgomery, 1988) and in some cases to even superior representation of industrial firms' performance than other proxies like RoE, RoA etc (Lindenberg & Ross, 1981).

Control Variables

The models are controlled for four important parameters; that is debt, firm size, year and value chain stage. Firstly, controlling for debt is necessary because in the case of high-level debt, a firm could not receive any concrete contributions from cash that is freed from improved working capital position because that cash could be redirected to meet its debt payment deadlines (Capon, Farley, & Hoeniq, 1990). The formula depicting this control variable is the ratio of Total Long-term debt to Total Assets.

Secondly, the model is controlled for firm size because in the past firm size was linked to the market valuation of a corporation (King & Lenox, 2002). In other words, a company could be doing a terrible job in managing its operations but due to its sheer size of sales the financial performance metrics could show superior performance. Total Assets is omitted as a control variable due to potential multicollinearity issues (i.e. Tobin q) (Kroes & Manikas, 2014). To control for this parameter, the Annual Sales metric of the firms is used. Since in past research sales is linked to a non-linear relationship, for this model a natural logarithm transformation was applied to create the control variable. Thirdly, year parameter is included to control for any seasonal or short-term environment developments, which affected the industry that year and could distort the firm performances from year to year.

Finally, since this is a value chain analysis the value chain stages are control factors themselves. In many cases, the upstream supply chain, especially tier two and tier three suppliers, could be involved in other industries as well such as aerospace, motorcycles etc. thus their firm performance could be affected by developments found only in that stage (Pirttila et.al., 2012). Furthermore, suppliers are running on different business cycles, reduced profit margins and lower credit ratings. (The-Hackett-Company, 2012; Vasquez et.al.,2016). Therefore, a categorical variable for the value chain stage is included to control for any business parameters that are unique to each stage.

Statistical Analysis

The statistical analysis for this research paper was carried out by SPSS 24. Since the dataset panel is of repeated-measures, a General Estimating Equations (GEE) model was employed. The reason for using this technique over an OLS, is the capacity of the model to estimate the coefficients for data samples exhibiting high correlation between repeated measurements (Ballinger, 2004). This is a feature which is suited perfectly to this paper data panel. The link function used to apply the GEE for the model, is the linear one, thus the model becomes a Generalized Linear Model.

Furthermore, repeated time-series financial data like cash flow components are shown to exhibit a first order autoregressive correlation between subsequent time periods (Hui, Leung, & Huang, 1993). Therefore, the model is adjusted to control for first-order auto-regression AR (1) (Zeger & Liang, 1986).The resulting models are specified as:

CCC Components Model:

$$TobinsQ_{it}=\beta_0+\beta_1(StageNr)+\beta_2(ln\_Sales_{it})+\beta_3(Debt_{it})+\beta_4(Year)+\beta_5(DIO_{it})+\beta_6(DSO)+\beta_7(DPO_{it})+e_{it} \quad (1)$$

CCC Model:

$$TobinsQ_{it}=\beta_0+\beta_1(StageNr)+\beta_2(ln\_Sales_{it})+\beta_3(Debt_{it})+\beta_4(Year)+\beta_5(CCC_{it})+e_{it} \quad (2)$$

As this is a repeated measures data panel, *i* stands for firms and *t* represents the years. To further understand the breakdown of the results the above models are also used on each stage of the value chain separately.

Results and Discussion

Overview

Overall, the data panel even from the descriptive statistics (table 2) depicts an interesting landscape. The longest cycle of inventories can be found in Tier three (raw component stage) with the retail stage on a similar situation. For tier three suppliers, it can be attributed to the production model they follow, but also how the second tier organizes its production cycles as well. Retailers on the other hand, still show an extended inventory cycle and one can question whether the lessons of the 2008 US automotive bailout were indeed transferred to the future. The smallest cycle of Inventories can be found in the system suppliers and may be explained by the high level of integration between them and the OEM firms.

The biggest receivables cycle can be found to the OEM firms' stage. This finding confirms (Viskari et.al.,2012) research and shows that the practice of financing and leasing business of the retailers can affect when and how the car manufacturers will be paid. Moreover, CCC on average varies considerably between stages. The difference between the minimum and maximum CCC is over two months and can be found between the OEM firms and tier 1 suppliers, a fact that also may be the byproduct of integration policies. The second and third tiers are related with more days of cash conversion cycle than the value chain average (121) which poses interesting questions for the future, as to what are the factors contributing to this finding.

Finally, Tobin's q ratio is below one for this industry and by what the analysts explain, the automotive value chain players do not efficiently replace the value of its assets and their business model may not be sustainable. OEM firms have very low Tobin's q while the highest figure can be linked to the third tier. The results for Tobin Q, could be related to significant investments overall in the industry (high long-term debt).

Table 2 Data Panel Descriptive Statistics

Mean (St.dev)	**#of Firms**	**DIO days**	**DSO Days**	**DPO days**	**Debt %**	**Sales billion $**	**CCC days**	**Tobin's Q**
VC	99	53(33)	68(41)	54(23)	16(12)	22.4 (45.6)	121(53)	0.7(0.73)
Tier 3	18	70(35)	65(25)	52(17)	18(18)	10.763 (21.2)	135(43)	0.95(0.73)

Value Chain Analysis (Propositions Testing)

The results at value chain level are summarized in table 3. By the term "value chain level" this paper refers to the aggregated trends and findings of all the relationships included in this data panel. The analysis of the CCC components (Table 3) to the Tobin Q ratio shows that DSO and DPO are significantly and negatively associated with the average firm performance at the value chain level. The relationship is at an 1% significance showing that the

results for this research's scope are substantial. This means that for every additional day of DSO or DPO the average firm performance in the value chain decreases. Furthermore, DIO is also strongly significant at the 1% level and positively related to firm performance, meaning that on average, for every additional day of inventory outstanding the firm performance of the value chain will improve. These findings strongly support Propositions 2 and 3.

Our results contradict the previous findings of research between WCM and firm performance and may be interpreted with the collaborative financial supply chain management concepts described earlier in this paper. Accordingly, concerning the trade credit components (DSO, DPO) this research confirms the findings of (Viskari et.al., 2012). The practical implication of these results is that if the suppliers in the value chain begin to apply the short-term strategy of demanding payments earlier (DSO) and extending their own payment deadlines (extending DPO) they will eventually harm the value chain as a whole. On the other hand, the use of post-FSCM practices (supply chain finance) as already documented (Wuttke et.al., 2013) could interpret how the opposite result (lower DPO, DSO with higher firm performance) is achieved in the automotive industry. More specifically, post-FSCM actors take the role of the mediator and help the supply chain players of the value chain to plan better and simultaneously reduce their trade credit cycles.

In TCE terms, the simultaneous negative relationship between firm performance and DSO/DPO of the participant firms, relates to increased specialization (productivity) level but without any additional transaction costs that would result if such endeavor was to be employed without supply chain finance solutions. In other words, supply chain finance practices allow firms to avoid exerting their power to retain cash in expense of their suppliers (i.e. opportunism) and enables inter-firm cooperation (i.e. reducing environmental uncertainty and bounded rationality), thus rendering any excessive negotiations and credit collection costs etc. as redundant.

Table 3 Value Chain Level Results.

DPO	-0.001***	(0.0002)		
CCC			0.002***	(0.008)
DEBT	0.136	(0.1769)	0.146*	(0.0861)
Ln(Sales)	-0.102***	(0.0173)	-0.094***	(0.0128)
Years	0.121***	(0.0111)	0.032**	(0.135)
QIC (fit stat.)	23.848		568.934	

Table 3 shows the models as described in the methodology section. Model (1) resembles CCC components (DIO, DSO, DPO) to the firm performance (Tobin Q), (2) the Cash-to-cash cycle to the firm performance (Tobin Q) on the value chain level.
*0^a = reference stage for categorical variable , *p<0.1 (10 % significance), **p<0.05 (5% significance), ***p<0.01(1% significance)*

The second important finding concerns the positive relationship of DIO with the firm performance (proposition 2). This finding contradicts the traditional single-firm perspective literature which predicts negative relationship between the length of inventory cycles and firm performance. One plausible explanation for this finding could be the relatively long production cycles and the unique nature of automotive industrial engineering in comparison to other industries (industry-specific theory). More specifically, due to the relatively time-consuming and sensitive assembly processes that govern this industry, inventory stock (including raw materials, work in progress and finished goods) need on average longer cycles to support variations during the production cycles. A second explanation could be that the increased demand generated from the economic recovery of the last five years demanded increased capacity from all the suppliers in the value chain as a whole, but due to cash constraints there

is yet not enough infrastructure to support this additional capacity demand. This is something that the managers also stated in KPMG (2012).

The second model on table 3, concerns the CCC metric to the firm performance on the value chain level. CCC is found to be on average significantly and positively related to the firm performance of the value chain. The relationship is also substantial, at the 1% significance level. Moreover, in table 4 the multi-group analysis concerning CCC vs firm performance reveals no association for the Retailers, OEM, Tier 1 and Tier 2 stage. On the contrary the CCC metric is significant for the Tier 3 stage and positively related to firm performance individually for that stage. Under the light, of these findings, support for Proposition 1 is mixed. The practical implication of this finding is that collaborative management of all the CCC components which comprise the CCC Metric, is mostly meaningful if is done at the value chain level with aggregated information and collaborative strategies. The supply-chain perspective (Hoffman & Kotzab, 2010) is in line with this result.

CCC Components Multi-Group Analysis

In Table 5 the multi-group analysis of the separate value chain stages is presented. The (1) model was applied for each stage separately and tested the CCC components concerning that stage. According to the results, DIO is positively and significantly associated with firm performance in tier one, tier two but not the OEM firm. This is an interesting finding which suggests that maybe the tier one and two firms are having the most trouble to match inventory (production) capacity with demand. Interestingly tier three stage follows the traditional lean theory CCC-performance link and if combined with the tier three result of CCC in table four raises the question whether the supply integration (Hoffman & Kotzab, 2010) ends at tier two or if supply chain integration is even the defining parameter for it. For what is worth, managers even today strive for full supply chain visibility (>tier three) with limited success, a development that might explain why the results of tier three are connected with the single-perspective approach. Despite this ambiguity, the link between longer cycles of inventory with better performance in the automotive value chain seems to be robust.

The landscape is a bit different in the trade credit metrics (DSO, DPO). For DSO purposes, one can observe negative associations in the upstream part of the automotive value chain while positive and significant associations with firm performance can be observed for DPO for the same tiers. This could mean that DSO and DPO are very important for the upstream tier stages due to the thin profit margins that they operate with. Further evidence, towards the preferable of the collaborative WCM is that the OEM's DPO is negatively associated with firm performance as any abuse of power in that extend could harm the company itself due transfer pricing of any damage to its suppliers.

On the other hand, relationships in the last stage of the value chain (dealers) show that the only important metric to manage is the DSO. This is to be expected as at this stage, as firms are heavily involved with customer payment terms and leasing options from several enterprises. Thus, more days of sales receivables translate to more sold cars, due to better payment terms given to the customers.

Table 5 CCC Components by Value Chain Stage

Conclusion, Limitations and Future Research

This paper contributes to the literature of WCM with a comprehensive research of the automotive value chain. By using a repeated-measures data panel and General Estimating Equations, the link between the cash-conversion-cycle components and firm performance was examined. The data set robustness and representativeness were enhanced through the utilization of real documented supply chain relationships and thus an uncritical estimation of the relationships was avoided. The results were interpreted with the help of the emerging theory of financial supply chain management, the discussion for collaborative WCM practices and Transaction Cost Economics.

The theoretical conjectures of the collaborative WCM theory as described before, appear to be in-line with our findings. More specifically, the results of our research contradict previous conventional knowledge on WCM and suggest that in the automotive industry longer inventory cycles lead to better firm performance. This finding further gives credibility to the "industry-specific leanness" school of thought which has recently emerged and certainly challenge traditional literature by hinting at a deeper and more complicated relationship between the production cycles lengths and DIO. Moreover, a negative link between trade credit components (DSO, DPO) and firm performance was identified in the value chain level, suggesting that the automotive industry managers now follow a more supply chain approach and understand that single stage optimization gives short-term gains which are cancelled out from the other stages. Despite these results, conclusive judgement for collaborative WCM is premature but our findings lay the foundation for more value chain research in this topic.

A significant limitation for our research is the lack of theory to explain the variations of the CCC component coefficients between tiers. These variations hint that maybe each tier characteristics affect differently the optimal relationship between the firm performances in that tier and the respective CCC components. This notion for 'stage-specific' relationships should be explored further in future research. Moreover, it would be interesting to examine cross-tiers interaction or in other words how CCC metric changes in one tier could affect firm performance of their buyer (downstream tier) and under what conditions.

Lastly, despite the robustness of our Dataset due to the FACTSET database, the sample size and demographics is limiting the results' generalizability. An interesting future research would be the replication of this study with larger data and alternative value chain designs in order to establish the validity of the results. Finally, the use of Tobin Q poses another limitation towards conclusive results. Although, Tobin's Q is compatible with inventory replenishment operations, future research endeavors should replicate this study with an alternative firm performance metric, known for its compatibility with operation processes.

Conclusively, the findings of this paper suggest the existence of collaborative working capital practices and as the automotive industry supply chain integration gets stronger, these practices will become a necessity to reduce transaction costs.

Abstract

Buying companies increasingly need suppliers that substantially contribute to their innovation and capability resources. Customer attractiveness and the strategic fit with a supplier are likely to play an important role in new product development projects. However, no research has addressed and simultaneously investigated the interplay of strategic fit, customer attractiveness, and supplier contribution to buyer innovativeness. This study fills this gap by carrying out a quantitative survey study among 81 members of the branch organization for the Dutch fabricated metal industry. The findings largely confirm the positive relations between the core variables of this study. The results suggest that purchasing professionals should invest in customer attractiveness, rather than coerce business partners into supplier development programs.

Key Words: buyer-supplier relationships, buyer innovativeness, strategic fit, customer attractiveness

Category: competitive paper (IPSERA 2018)

1 Introduction

Increasing global market competition, fast changing customer demands and the environmental uncertainty and complexity require continuous development of products and services (Ferreira, Fernandes, Alves, & Raposo, 2015; Kibbeling, der Bij, & Weele, 2013; Revilla & Villena, 2012). Therefore, innovation is imperative for firms to gain sustainable competitive advantage (Arlbjørn & Paulraj, 2013). Innovation and innovation management have been a popular research topic for many decades. In addition, the issue of how inter-firm collaboration creates and stimulates innovation performance has become a critical research question (cf. Song et al., 2010). Gone are the days when innovations were the result of the efforts put forth within a single firm; instead, firms need to increasingly rely on the competencies of multiplicity of firms within their supply chain network in order to innovate (Arlbjørn & Paulraj, 2013). By teaming up with other firms that have complementary resources, a company can make the most of its own resource base, without having to build up other resources from scratch.

In a strategic buyer-supplier relationship, the buyer (as well as the supplier) aims to leverage the relationship to gain competitive advantage (Tanskanen & Aminoff, 2015). Inter-firm collaboration has become a crucial component in the pursuit of competitive advantage (e.g. Nielsen, 2010), although strategic buyer-supplier relationships require much effort and are complex to manage successfully. Furthermore, collaboration on open innovation in supply chains (Rosell, 2014), and a trend towards reduction of suppliers in many business-to-business markets (Schiele et al., 2012) increase the exposure to potential opportunistic behaviour. Obviously, both buyers and suppliers have become very selective in terms of with whom to engage in a strategic relationship (e.g. Tanskanen & Aminoff, 2015). From an innovation perspective, buyers need suppliers that actually contribute to their innovation resources and capabilities. Companies are advised to select suppliers with complementary resources and skills (Wilkinson et al., 2005).

Obviously, not every supplier is capable of contributing to the innovativeness of the buying company. A critical purchasing task is to identify innovative suppliers with technical expertise in combination with a collaborative attitude which distinguishes suppliers that contribute to buyer innovativeness from suppliers that do not? (Pulles et al., 2014). The scarce literature sheds little light on this crucial issue. In order for a supplier to contribute to its customers' innovation processes, the supplier needs to be innovative, technically competent, and offer high quality products (e.g. Croom, 2001). The case study research of Schiele & Krummaker (2011) suggested that the suppliers that contributed most to buyer innovativeness are the ones that consider that buyer as a 'preferred customer'. Customer attractiveness becomes more important when suppliers are considered strategic or when suppliers have many alternatives. A strategic partnership with a supplier is preferred, when the contribution of that supplier affects critical processes, components or systems of the buyer (Hsuan, Skjott-Larsen, Kinra, & Kotzab, 2015).

Mortensen and Arlbjørn (2012) concluded that the performance and efficiency of the development initiative can be positively affected by the buyer when it considers the strategic

fit with the supplier. As an outcome of this research it is expected that a strategic fit positively influences the supplier contribution to buyer innovativeness. Furthermore a strategic fit can affect a supplier's perception of customer attractiveness (Mortensen et al., 2008) therefore a positive relationship between strategic fit and customer attractiveness should be a plausible finding. Since customer value is expected to rise in joint collaboration on innovation projects (La Rocca et al., 2012), it is expected that customer attractiveness positively influences supplier contribution to customer innovativeness.

Although the concept of customer attractiveness has received increasing attention in academic literature, few empirical studies investigate the influence of customer attractiveness on the actual contributions of suppliers to the innovativeness of buyers. Most studies do not particularly focus on the purpose of ways for buyers to be attractive (cf. Schiele et al., 2012), for instance to gain access to technologies and innovation initiatives of suppliers (e.g. Ellis et al., 2012). Few have addressed and investigated the interplay of the strategic fit between buyer and supplier, customer attractiveness, and supplier contribution to the innovativeness of buying companies. This study fills this gap through a quantitative study, addressing and simultaneously investigating the interplay of strategic fit, customer attractiveness, and supplier contribution to buyer innovativeness. A conceptual model was developed and empirically validated using data from a survey among the members of the branch organization for the Dutch fabricated metal industry.

This study contributes in several ways to the existing knowledge. First, where the traditional perspective is more focused on supplier attractiveness, a supplier's perspective on customer attractiveness might help to better understand the innovative contribution of suppliers (Schiele et al., 2012; Schiele & Vos, 2015). Second, most literature about customer attractiveness is either conceptual or based on case studies. This study is survey based, aimed at investigating specific antecedents of supplier contributions to buyer innovativeness (Hüttinger et al., 2014) . Third, this study examines the influence of the strategic fit between buyer and supplier on customer attractiveness and directly on supplier contribution to buyer innovativeness.

2 Theoretical background and hypotheses

2.1 Innovativeness of the buyer

Innovativeness refers to "a firm's ability to develop and implement new ideas, processes, or products in the organization" (Inemek & Matthyssens, 2013, p. 581). Innovativeness may also imply a firm's willingness to explore and invest in new opportunities (Garcia et al., 2003). Innovativeness is a multidimensional construct and product- and process innovation are the foremost dimensions (e.g. Phan, 2013; Salomo, Talke, & Strecker, 2008; Tidd, Bessant, & Pavitt, 2005). Phan (2013) concludes that both product and process innovation emerge as interconnected issues and there exists only a blurred dividing line. Product innovativeness is considered as a measure of the potential discontinuity a product can generate in the marketing and/or technological process. In our study we will follow Garcia and Calantone (2002) who consider technological innovation as an iterative process leading to the successful production and marketing of that innovation. An innovation is only of economic value when the New Product Development (NPD) process leads to a successful market introduction (Schumpeter,

1934). The iterative aspect implies that innovation takes place at the development stage, but also at all subsequent phases in the product life cycle, including manufacturing, installation, consumption, and maintenance (Martini, Laugen, Gastaldi, & Corso, 2013).

With Cohen and Levinthal (1990), we consider the capacity to innovate as the organization's ability to successfully adopt or implement new ideas, processes or products. Buyer innovativeness appears from the fact that the buyer often leads the industry at introducing new products and adapting new technologies (e.g. Song et al., 2010). Firms with more internally developed research capabilities benefit more from collaborations, and firms with more collaborations benefit more from their internal basic research (Fabrizio, 2009). The accrual of knowledge assets that drive innovation in firms come from two primary sources: internal knowledge generation and knowledge derived from external sources (Bellamy, Ghosh, & Hora, 2014). By evaluating and finally selecting suppliers, the purchasing function has a strong influence on the innovation performance of the firm (Corsten & Felde, 2005).

2.2 Supplier contributions to buyer innovativeness

In the 90's Roberts (2001) found that the most important change in technology management over the past decade is the relentless intensification of all companies dependence upon external sources of technology. In multilevel business-to-business relationships, suppliers often have the best or the only access and comprehensive knowledge about the end users and are considered as an important resource (Brem & Tidd, 2012). The ability to protect a resource barrier and to maintain a relative position to competitors indicates a potential for high returns, since one competitor will have an advantage (Wernerfelt, 1984). Innovative suppliers can function as a first mover advantage.

Supplier contribution is not limited to product offerings but also encompasses resources such as information about the supplier's product, its product application, how to process the supplier's product, the supplier's IT and logistics services, and especially the supplier's information that will help the buyer create value in the relationship and in its other relationships such as with its own customers (Baxter, 2012). Furthermore, suppliers may contribute to firm innovation by performing R&D of its own and thus absorbing some of the R&D costs the buying firm would have to incur normally. Moreover, suppliers may have valuable knowledge of production and fulfilment processes that may influence firm performance. Finally, suppliers can transfer ideas for better products and features that could enable the buying firm to enhance products itself (Corsten & Felde, 2005).

Inter-firm collaboration has become strategically important for companies that need to strengthen their innovation capabilities (Pulles et al., 2014). A strategic mode of collaboration focuses on sharing customer requirements, basic technology exchange, new product development, new market entry and capital expenditure planning (Cousins, 2005). Although costs and quality of products remain important aspects within global competition, real competitive advantage is to be found in a firm's ability to mobilize complementary resources, adapt routines and foster competencies in order to survive (Heine & Rindfleisch, 2013; Prahalad & Hamel, 1990; Stieglitz & Heine, 2007). Suppliers should therefore contribute with

complementary capabilities such as a high level of innovativeness and fitting learning styles (Azadegan & Dooley, 2010).

Buyer-supplier collaborations are important sources of innovation (Walter et al., 2001). Supplier contributions to the innovativeness of buyers can be considered as the outcome of collaborative behaviour (Krause, Pagell, & Curkovic, 2001). The collaborative behaviour of suppliers is reflected by their pro-activeness in approaching the buyer with innovative ideas, the actual support in product development and process improvement, and the willingness to share (technological) information (Pulles, Veldman, & Schiele, 2014). Prior research suggests that collaboration in product development results in significant improvements in the product development performance of the buyer, in terms of cost, quality, cycle time, and innovation (e.g. Inemek & Matthyssens, 2013). It is proposed that greater depth of supplier involvement across the stages of the NPD cycle will lower the causal ambiguity experienced by inter-organizational NPD teams (Potter & Lawson, 2013). The supplier contribution to NPD is to a large extent influenced by the degree of attractiveness of the buyer (cf. Schiele & Vos, 2015). Therefore, we hypothesize:

H_1: *Supplier contribution to buyer innovation is positively related to buyer innovativeness.*

2.3 Customer attractiveness and supplier contributions

Attraction is a concept from the Social Exchange Theory and explains how social relationships initiate, endure and develop (e.g. Blau, 1964; Christiansen & Maltz, 2002; Ellegaard & Ritter, 2006). Business relationships can be assessed in terms of benefits and costs. This means that the relationship continues as long as the partner is sufficiently attractive and adds value to the relationship. Two broad approaches to customer attractiveness emerge from existing literature (La Rocca et al., 2012) . The first is related to the current and potential economic value of the customer to the supplier. According to Walter et al. (2001) this economic value is the result of direct monetary benefits from the customer realized through its profit, volume and safeguard function. Baxter (2012) proved that supplier's commitment to the buyer is strongly related to customer's financial performance as judged by the supplier. The second is the relational focus which encompasses factors that are related to the characteristics of the relationship and customer supplier fit. In this stream of literature, the customer attractiveness to a supplier refers to "the buyer's interaction strategy that aims to increase supplier dedication to the buyer in relation to the supplier's other customers" (Makkonen et al, 2016, p. 157). Ellegaard and Ritter (2006) argue that an attractive customer is better at mobilizing supplier resources, leading to increased added value. Walter et al. (2001) link relational aspects to indirect non-monetary benefits for the supplier. These benefits can be realized through the customer by its innovation function, its market function, its scout function and its access function. The way a customer deals with a supplier in an ongoing relationship clearly affects the willingness and opportunities of that supplier to participate in a particular development project (Wynstra, Weggeman, & Van Weele, 2003). Attractive customers collaborate with suppliers in order to leverage core competencies and acquiring knowledge of new technology (Christiansen & Maltz, 2002; Walter et al., 2001).

Customer attractiveness means that the buyer should be sufficiently attractive to the supplier, whereby the latter will not abuse its power and will provide privileged resource access (Schiele & Vos, 2015) which leads to loyalty and superior performance (La Rocca et al., 2012). The main goal of being an attractive customer is to achieve preferred customer status (Baxter, 2012) where the supplier offers the customer prioritized access to their technology and innovations (Ellis et al., 2012; Steinle & Schiele, 2008). Therefore being an attractive customer is an important condition in order to consistently receive competitive preference for scarce resources from a critical mass of suppliers (Bew, 2007). Attractive customers collaborate with suppliers to leverage core competencies and acquiring knowledge of new technology (Christiansen & Maltz, 2002; Walter et al., 2001).

H_2: Customer attractiveness is positively related to the supplier contribution to buyer innovativeness.

2.4 Strategic fit between buyer and supplier

Strategy literature discusses the concept of strategic fit on the organizational level (cf. Hong et al., 2011). Companies are advised to align the basic set-up of the firm with the characteristics of the environment (cf. De Wit & Meyer, 2010). Strategic changes are pursued to remain in harmony with external conditions. Adapting strategic fit in order to optimize organizational performance can cause a potential tension between a firm's strategy and its environmental situation vs. a fit between its strategy and its unique competencies (Zajac, Kraatz, & Bresser, 2000). This tension increases when environmental situations require adaption of strategy and affecting the traditional core competencies (Prahalad & Hamel, 1990).

Strategic fit has also been used as a key concept to investigate a variety of topics and issues, for instance supply chain management (consistencies between a product and its underlying supply chain, cf. Wager et al., 2012), project management (consistencies between project environment, project resources, and project goals, cf. Hong et al., 2011), alliances (consistencies between the motives of both partners, cf. Nielsen, 2010), and innovation management (consistencies between existing resources and new product development projects, cf. Harmancoglu et al., 2009). In addition, within the context of inter-organizational collaboration, a strategic fit refers to similarities between the supplier and buyer in terms of similar background, prior history, strategy, attitudes, complementary skills, and reputation (Mortensen & Arlbjørn, 2012). Organizations tend to prefer partners with complementary resources and skills, but who operate in similar ways in similar market positions (cf. Wilkinson et al., 2005). Buyers and suppliers with a high level of strategic fit are likely to share a common understanding of the relationship value and a common perception of attractiveness (cf. Mortensen & Arlbjørn, 2012). In general, positive benefits and outcomes are associated with a strategic fit between collaborating organizations. The strategic fit between business partners is likely to facilitate and stimulate the contributions of suppliers to the innovativeness of the buyer. We hypothesize:

H_3: The strategic fit between buyer and supplier is positively related to the supplier contribution to buyer innovativeness.

Suppliers are more likely to be responsive to buyers whose expenditure constitutes a greater rather than a smaller proportion of their total sales. Ramsay and Wagner (2009) identified several other sources of value for suppliers. Also, demand stability and forecast reliability, both aspects of strategy fit, are related to customer attractiveness. If markets are highly unstable suppliers may seek a secure stream of relatively unprofitable deals as an insurance against unforeseen demand failures (Walter et al., 2001). Especially for manufacturers which lack size or power to force suppliers to share leading edge technology, exchange of innovation and market information can be valuable sources for a supplier. Transferring knowledge, training supplier's personnel, participation in customer's processes or open information exchange systems can turn a small customer into an attractive partner (Christiansen & Maltz, 2002). Suppliers, particularly in fast changing, technologically complex product sectors, may regard early involvement in the customers R&D processes as essential for securing future orders (Ramsay & Wagner, 2009). In case of a high level of strategic fit, customers are likely to be perceived as attractive business partners. The perception of attractiveness will be affected by the strategic fit between buyers and suppliers (Mortensen & Arlbjørn, 2012). We posit:

H_4: The strategic fit between buyer and supplier is positively related to the customer attractiveness.

Figure 1 shows the conceptual model.

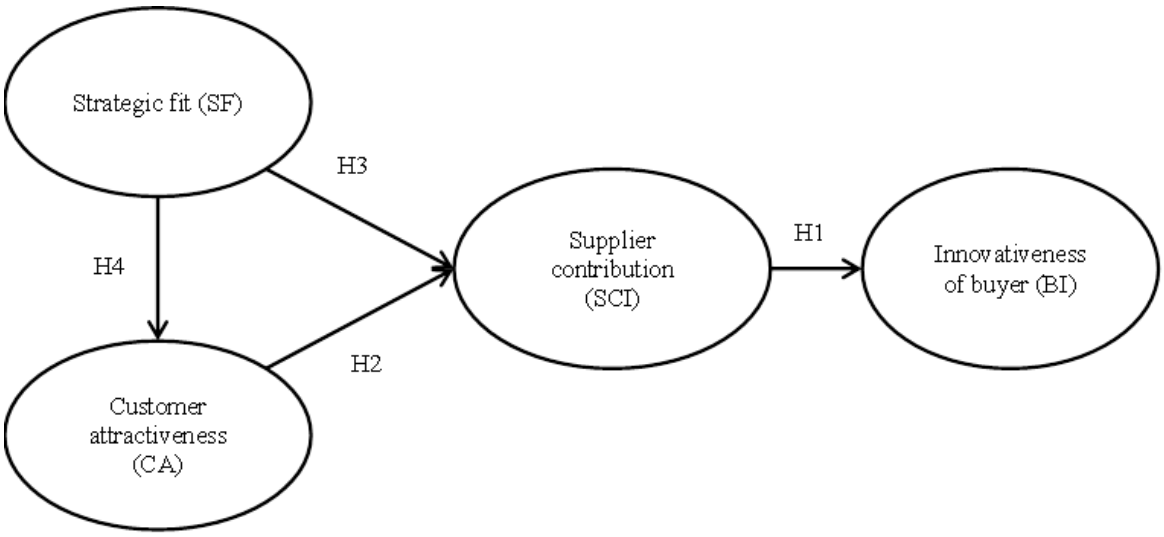

Figure 1: Conceptual model

3 Research method

The hypotheses were tested using a survey administered to the 1,600 members of the branch organization for the Dutch fabricated metal industry (northern district). Data were collected through an online questionnaire, which was brought to attention via the weekly newsletter. In

addition, members were asked to fill in the questionnaire in a meeting. An important selection criterion was that respondents should actively be involved in innovative cooperation with customers. A total number of 83 questionnaires was received, resulting in an effective response rate of 5.2%. We used structural equation modeling to test the plausibility of our causal model. The advantage of this method compared to regression is that it allows analyzing a system of variables at once. We specifically decided to use the variance-based PLS-SEM approach. This multivariate analysis is compared to the covariance-based SEM less stringent when working with non-normal data, achieves higher statistical power even with small sample sizes and is the recommended method when working with reflective constructs (Hair et al., 2017).

About 73% of the respondents have executive as their job title. The other respondents were sales manager (12%), production manager (11%), procurement manager (2%) and R&D manager (1%). Member companies of the branch organization are all small and medium sized companies (SMEs). 83% of the participating companies were industrial production companies, 4% were trading companies and 13% were service companies. 76% of the companies have fewer than 50 employees, 22% fewer than 250 employees. Looking at the areas of responsibility it can be assumed that respondents are involved in innovative cooperation with customers.

The variables in the hypotheses were measured as multiple-item constructs on 5-point Likert-scales. Operationalizations were derived from measurement scales used in other academic studies. Respondents were asked to keep in mind one of their most important customers. The *buyer innovativeness* was measured using five items drawn from Imenek & Matthyssens (2013). We adapted items that were used by Inemek & Matthysens (2013) in their operationalization of a supplier innovativeness construct. Items measure ‘adopting new technologies’ and ‘asking for new products and investments’ and ‘approaching suppliers for joint product development’. The *supplier contribution* construct was based on the operationalization of Pulles et al. (2014). The seven items reflect the willingness to share information (attitude) and the actual involvement in collaborative ventures (behavior). The items measure predominantly the collaboration with the customer in a number of areas (i.e. product quality, technical assistance, innovation workshops, information sharing, and ventures). A strategic fit between companies is likely to affect the common understanding of the relationship value and is likely to stimulate suppliers to contribute to buyer innovativeness. Buyers need suppliers with complementary resources, but prefer partners who operate in similar ways. The items to measure the *strategic fit* ask respondents to compare ‘their’ customer to other customers. Five items, adapted from Mortensen & Arlbjørn (2012), were used to measure the strategic fit construct. Customer attractiveness can help to attain preferential access to supplier resources that are important sources of innovation. The *customer attractiveness* construct is measured by five items obtained from Pulles et al. (2015). The questionnaire was pretested to improve readability, question order and to improve ambiguous questions.

4 Results

4.1 Evaluation of measurement models

- Examining Indicator Loadings

A common rule of thumb is that outer loadings below 0.70 should be considered for removal but should be deleted only when deleting the indicator leads to an increase in the composite reliability (CR) and/or average variance extracted (AVE) above the suggested threshold values of 0.70 and 0.50 respectively (Hair et al., 2017; see next sections). As a result, five out of 22 reflective items were dropped because of poor outer loadings. In the sections that follow, the results of the final model are presented and interpreted.

- Assessing Reliability

The most commonly used measure of reliability is the internal consistency reliability. Composite reliability (CR) and Cronbach's alpha are both measures of internal consistency reliability. For exploratory research, Cronbach's alpha values greater than about 0.60 are acceptable (Bagozzi, 1994). CR values from around 0.70 represent acceptable reliability, although this is not an absolute standard, and values below 0.70 are acceptable if the research is exploratory in nature (Hair et al., 1995). In our study, both Cronbach's alpha values and CR values meet the threshold values of 0.60 and 0.70 respectively, suggesting that internal consistency reliability of each reflective latent variable is acceptable.

- Assessing Validity

The dominant measure of convergent validity is the Average Variance Extracted (AVE). AVE should be 0.50 or higher (Hair et al., 2017). In our study, all AVE values are above 0.50, suggesting that convergent validity of each latent factor is acceptable. Another measure of convergent validity of the measurement models is found by computing the standardized loadings for indicators and generating Bootstrap t-statistics for their significance. "At a minimum, the outer loadings of all indicators should be statistically significant." (Hair et al., 2017: 113). In our study all standardized loadings are found significant at a significance level of 0.001, confirming convergent validity.

To determine the discriminant validity of our indicators, we checked the matrix of loadings and cross-loadings for all reflective items in the model. "The loadings of the items in this table should be greater for the latent variable to which they theoretically belong than for any other latent variable" (Lowry and Gaskin, 2014: Table A1.2). There is no presence of cross loadings that exceed the indicators' outer loadings. Thus, there is considerable indication that discriminant validity is met. Criterion for assessing discriminant validity is the Heterotrait-monotrait ratio of correlations (HTMT) (Henseler, Ringle, & Sarstedt, 2015). Gold et al. (2001) and Teo et al. (2008) suggest that if the HTMT value is below 0.90.

Table 1: Heterotrait-Monotrait Ratio (HTMT)

	Customer attractiveness (CA)	Innovativeness of buyer (BI)	Strategic Fit (SF)
Innovativeness of buyer (BI)	0.437		
Strategic fit (SF)	0.541	0.459	
Supplier contributions (SCI)	0.767	0.669	0.538

4.2 Evaluation of the structural model

Collinearity assessment

o assess collinearity, we consider variance inflation factor (VIF) values above 5 in the predictor constructs as indicative of a potential collinearity problem (Hair et al., 2011). As can be concluded from Table 2, VIF values in our study are well below the threshold value of 5, indicating that collinearity is not an issue.

Table 2: Collinearity Assessment

First set (CA)		**Second set (SCI)**		**Third set (BI)**	
Construct	VIF	Constructs	VIF	Construct	VIF
SF	1.000	SF CA	1.190 1.190	SCI	1.000

Size and significance of path coefficients

Table 3 presents the estimates of path coefficients of the proposed model and respective t-values and levels of significance. All hypothesized paths are statistically significant.

Table 3: Size and significance of the Structural Model Path Coefficients

Path	**Path Coefficients**	***t* Values**	**Sign. Levels**	***p* Values**
Customer attractiveness (CA) -> Supplier contributions (SCI)	0.449	4.491	***	0.000
Strategic fit (SF) -> Customer Attractiveness (CA)	0.400	4.089	***	0.000
Strategic fit (SF) -> Supplier contributions (SCI)	0.248	2.773	**	0.006
Supplier contributions (SCI) -> Innovativeness of buyer (BI)	0.571	8.102	***	0.000

Note: $^{**}p \leq 0.010$; $^{***}p \leq 0.001$

5 Conclusions and discussion

Innovation is imperative for many organizations to maintain competitive advantage. The critical importance of collaborative supplier relationships is well documented and sustained in literature. In New Product Development processes, where supplier and buyer work closely together, mutual trust, commitment and understanding are important relational characteristics that reduce risks and potential opportunistic behaviors. A strategic fit between buyers and suppliers is likely to have a positive impact on the buyer-supplier collaboration. A relative new topic is customer attractiveness which relates to the need for buyers to achieve preferred customer status and to gain access to scarce, often technological, sources of innovative suppliers. However, no research has addressed and investigated the interplay of the strategic fit, customer attractiveness and supplier contribution to buyer innovativeness. This study was aimed at filling this gap by analyzing data from members of the branch organization for the Dutch fabricated metal industry.

The results of our study confirm the positive relationship between buyer innovativeness and collaborative behaviors of supplier (H_1). As expected, supplier contributions are an important source of innovation for buying companies (cf. Walter et al., 2001). Valuable suppliers proactively approach their customers with new ideas and actual support in product and process improvement (cf. Pulles et al., 2014). With Ellis et al. (2012), we show that a productive supplier's involvement in a buying firm's new product development process is positively related to the supplier's perception of the buying firm as a preferred customer which, in turn, is positively associated with the willingness to share new technology with the buyer. These positive perceptions of customer attractiveness can be considered an important

antecedent for successful supplier integration into collaborative NPD projects (cf. Schiele, 2012; Schiele et al., 2012).

Although a growing number of studies includes customer attractiveness as an important concept for understanding buyer-supplier relationships, few empirical studies investigated the influence on the actual contributions of suppliers to the innovation of their customers. We find a statistically significant relationship between customer attractiveness and supplier contribution (H_2), which is in line with the results of prior research (cf. Schiele et al., 2012; Ellegaard & Ritter, 2006; Christiansen & Maltz, 2002).

The empirical results shed light on the role of the strategic fit between buyer and supplier in the supplier contribution to buyer innovativeness. Similarities between parties is likely to facilitate and stimulate buyer-supplier collaboration. However, the impact and the role of the strategic fit between buyers and suppliers appears to be an overlooked factor in buyer-supplier research, with Mortensen & Arlbjørn (2012) as a notable exception. There must be more to the business relationship than suppliers "merely" providing valuable and complementary resources and skills (Wilkingson et al., 2005). We developed hypotheses that relates the strategic fit with the supplier contributions (H_3) as well as with customer attractiveness (H_4). The empirical results provide support for theoretical expectations. This paper is the first to empirically investigate and confirm the relationships between the strategic fit, customer attractiveness, and supplier contribution to buyer innovativeness.

6 Limitations and recommendations

This study had a number of limitations, which could induce further research. The sample was restricted to supplying companies in the fabricated metal industry. To get more insights into the effects of customer attractiveness and strategic fit, future research could use a dyadic approach and include the experience and views of both buyers and suppliers. Another limiting aspect is the cross sectional nature of this study. Experimental and longitudinal studies would be more suitable for investigating cause-effect relationships, shedding light on the interplay of the various variables under study.

Suppliers can contribute to various levels and types of innovativeness such as to architectural or to component innovations (Garcia & Calantone, 2002; Lee & Veloso, 2008). The level and type of innovativeness impact the intensity of knowledge transfer, interaction and the level of interdependency between buyers and suppliers (Sobrero & Roberts, 2002). Because the level of interdependency differs with the level and type of innovativeness, future research into the role of strategic fit at the various levels and types of innovativeness could lead to better insight in collaborative NPD projects.

Another avenue of future research could be including drivers for customer attractiveness. Tanskanen & Aminoff (2015) distinguished economic-based, behavioral-based, resource-based, and bridging-based drivers of attractiveness. Different drivers could play different roles in collaborative buyer-supplier relationships in general, and in buyer innovation initiatives in particular. Similar to strategic fit, the concept of customer attractiveness too can be considered at different levels. Our study implicitly employed the meso-level: between companies. Other

levels that could be investigated are the micro-level (between individual actors) and the macro-level (entire networks and supply chains). Each level could produce other explanatory power in analyzing supplier contributions to the innovativeness of buying companies (cf. Schiele et al., 2012).

The results of our study suggest that purchasing professionals could benefit from the finding that a strategic fit with supplying companies significantly enhances the impact of supplier contribution to innovation projects. Buyers should acknowledge the need to develop and implement (marketing) strategies aimed at improving their (perceived) attractiveness for innovative suppliers. Buying companies should redesign supplier development programs which are aimed at forcing suppliers to improve their performance. A more mature and promising approach for buyers is to invest in their own customer attractiveness.

Summary
This research aims to reveal the common grounds and the cultural and structural induced differences in a set of 300 European and 300 ‘Chinese’ job advertisements (China, Hong Kong and Singapore). European and ‘Chinese’ employers require both hard and soft skills, however more soft skills than hard skills are demanded. From the about 60 skills one third is a common ground, one third is typically Chinese and one third European. Negotiation is the highest ranked common ground. The paper emphasises on the managerial implications for companies with a multicultural Chinese and European staff in PSM.

Keywords: job skills, PSM, Confucian Dynamism

Submission category: Working paper

Introduction

Purchasing and supply management (PSM) professionals are frequently working in a global business context (Horn et al., 2013). Understanding cultural differences can help professionals to communicate appropriately with people from different cultural backgrounds (Hofstede et al., 2010). Successful use of cross-cultural teams could provide different insights into the inner and outer world and avoid cultural misunderstandings to achieve the competitive position of organizations in a global setting (Dafoulas and Macaulay, 2002).

The impact of national cultures on the success of operations practices and firms’ performance in certain countries is significant (Chipulu et al., 2014; Hope and Mühlemann, 2001; Shou and Wang, 2017; Wiengarten et al., 2016). Differences in operational decision-making can be explained by deviations in the rise of cross-cultural issues (Pagell et al., 2005) and national culture is a key factor that is influencing PSM performance (Quintens et al., 2005; Shou and Wang, 2017). With the increasing economic globalisation, many Europe-based multinational companies integrated themselves into global sourcing and a majority of them are targeting the Asian market (Horn et al., 2013). The PSM functions in European firms have been

more global and interconnected in the Asian market, by offshoring to countries like China, Hong Kong and Singapore. However, not all offshoring lead to success. Partly due to cultural issues firms restored to European suppliers (Horn et al., 2013). This study aims to explore differences in PSM job advertisements between 'Europe' (Austria, Belgium & the Netherlands) and 'Confucian Chinese Society' (China, Hong Kong and Singapore).

For this research, a bi-continental approach is chosen, to compare online PSM job advertisements from 'Europe' with 'China'. The European sample was already drawn in an earlier research from online job platforms in three European countries with an alike GDP per capita, but with distinctive different cultural profiles: Austria, Belgium and the Netherlands (Hofstede et al., 2010; Kale, 1995; Kogut and Singh, 1988; Stek et al., 2017). The Chinese societies sample is an exact replication of the European set and is drawn from online job platforms in the Peoples Republic of China, Hong Kong and Singapore. To distinct the national cultural differences the four cultural dimensions of Hofstede are applied (Batenburg, 2007; Hofstede et al., 2010).

Literature sees the secondary data analysis, like requirements mentioned in online job advertisements, as an important source of state-of-the-art and practical available data that gives good understanding what employers' requirements are (Arcodia and Barker, 2003; Mathews and Redman, 2001; Rafaeli and Oliver, 1998; Shou and Wang, 2017). This research will eventually contribute to literature as the first to compare PSM (or SCM) job ads between the two continents with the aim to find common grounds and the cultural and structural induced differences.

Literature review

Affiliates of western companies in Asian countries are actively involved with the parent companies' global procurement activities and are *'duplicating the sourcing strategies with suppliers in Asia that have been used successfully by their parent company'* (Carr et al., 2000). As the technology and the nature of supply markets is fast changing, the role of the purchasing function has changed. The PSM function *'evolved from a loose affiliation among functions such as purchasing, manufacturing, and logistics to an integrated and cross-functional discipline'* (Radovilsky and Hegde, 2012). PSM professionals are more and more responsible global sourcing and have to deal with *'longer and more complex supply chains, longer time of purchasing and in essence more severe competition and challenges'* (Shou and Wang, 2017),

Firms require market, product and technical knowledge (Bruneel et al., 2010; Eriksson et al., 1997). In addition, scholars believe that value of market knowledge will be extended by providing employees and managers, who have strong entrepreneurial spirit, with training programs that enhance their ability to apply market knowledge (Ma and Huang, 2016). Additionally, the literature suggests that having the necessary skills to interpret changes in the supplier market, offer technical assistance and assist in developing suppliers are some of the necessary skills for strategic purchasing (Eltantawy et al., 2009; Knight et al., 2014; Steinle and Schiele, 2008).

The Confucian Dynamism Dimension

In his book *Culture's Consequences* Hofstede concluded his study with an extensive research of employees from culturally diverse backgrounds at the international corporation IBM (Hofstede, 1984). In addition, he divided national cultural variabilities into four dimensions, including power distance, uncertainty avoidance, individualism, and masculinity. Based on a questionnaire designed by Chinese scholars (Hofstede and Bond, 1988), scholars have argued that there is Confucian Work Dynamism, which is identified in Asian countries and strongly correlated with recent economic growth (Hofstede and Bond, 1988). Hofstede defined the fifth dimension as "Confucian Dynamism" (also known as the fifth cultural dimension 'Long-term

orientation') in his later work in 1991. In the second edition of *Culture's Consequences*, this new finding is discussed extensively. *'Values associated with long-term orientation are thrift and perseverance; values associated with short-term orientation are respect for tradition, fulfilling social obligations, and protecting one's "face"'* (Hofstede, 1994).

In general, traditional Chinese culture results mainly from the influences of Confucianism (Hofstede and Bond, 1988). From the past to the present, Confucius' thoughts can be regarded as the main core value of Chinese culture. Hofstede (2003) argues that Confucianism is not a religion but a set of pragmatic rules for daily life derived from Chinese history. Confucianism is uniquely compared with the Western dimension, the Eastern dimension is full of questions of spirit and openness (Hofstede and Bond, 1988). On the one hand, Hofstede and Bond (1988) argue that Confucius believes that to create a stable and harmonious society it is critical to understand the relationships between people and the value of each individual in society. In addition, the idea of Confucius has clarified that the family is the rudiment of all social organization (Minkov and Hofstede, 2012). Furthermore, Confucian ethics emphasize harmonious relationships within society, family, and individuals, and have influenced the business practice in Confucian Chinese society (Cheung, 2004).

Figure 1 Hofstede Culture Compass

	Power Distance	Individualism	Masculinity	Uncertainty Avoidance	Long Term Orientation
CHINA	80	20	66	30	87
HONG KONG	68	25	57	29	61
SINGAPORE	74	20	48	8	72
AUSTRIA	11	55	79	70	60
BELGIUM	65	75	54	94	82
NETHERLANDS	38	80	14	53	67

Source: Hofstede et al. (2010)

Hofstede and his research group have summed up a new dimension of his cultural dimensions theory through the study of Confucianism, i.e. *'long-term orientation'* and *'short-term orientation'*. Furthermore, in this dimension is mainly used to measure the degree to which individuals of a single culture group have an incentive to delay the attainment of its emotional and social needs (Hofstede and Bond, 1988). Moreover, the research group suggested intercultural negotiations demand an insight into the range of cultural values to be expected among partners from other countries and compared against the negotiators' own culturally determined values (Hofstede et al., 2010).

On the other hand, Hofstede's country comparison (see Figure 1) states that Confucian Chinese Society is characterized by a larger level of power distance, a high level of collectivism and a larger long-term orientation (Minkov and Hofstede, 2012). This means that people from

high power distance and collectivism cultural backgrounds are unwilling to share decision-making and lack effective communication when working in projects.

Research framework

The prior study of the European set is a part of the Purchasing Education and Research for European Competence Transfer project (PERFECT). The aim of this project is to contribute to the issue of how to design modules for an academic European PSM curriculum that meet the needs of employers for PSM personnel. The European data has investigated online PSM job advertisements in three countries from the European Union. It includes Austria, Belgium and the Netherlands. Previous European studies found common grounds and culturally and structurally induced differences. There is evidence that the common grounds can be seen as a European set of PSM requirements. The job advertisements where found at online platforms in different languages. The frequency of the requirements mentioned in the set of 100 Austrian, 100 Belgian and 100 Dutch were taken in account (Stek et al., 2017).

Based on the research methodology of the European analysis of job requirements in online PSM job advertisements from three distinct European cultural clusters represented by Austria, Belgium and the Netherlands, the study of "Confucian Chinese Society" has performed the same research methods to collect secondary data: online job advisements. Consequently, China, Hong Kong and Singapore are taken in account in this research (see Figure 2). Because in Singapore 74.3 percent of the population constitutes of citizens with a Chinese origin (Lansford, 2014). The frequency of the job requirements mentioned in the set of 100 China, 100 Hong Kong and 100 Singapore were taken in account.

A total of 300 samples will be grouped and coded as different job skills into a fixed competences matrix: KODE®X. KODE®X is an organization-specific competency model that measures personal competencies and structures of individuals and teams in organizational units. The model was developed by two German scholars, and provides externalized statements for personal management and decision makers for continuous personnel development. Following prior study, the "Confucian Chinese society" skill sets are measured using the following constructs: personality competence, activity and action competences, social-communicative competences and methods and professional competences. This is graphically represented in figure 2 below.

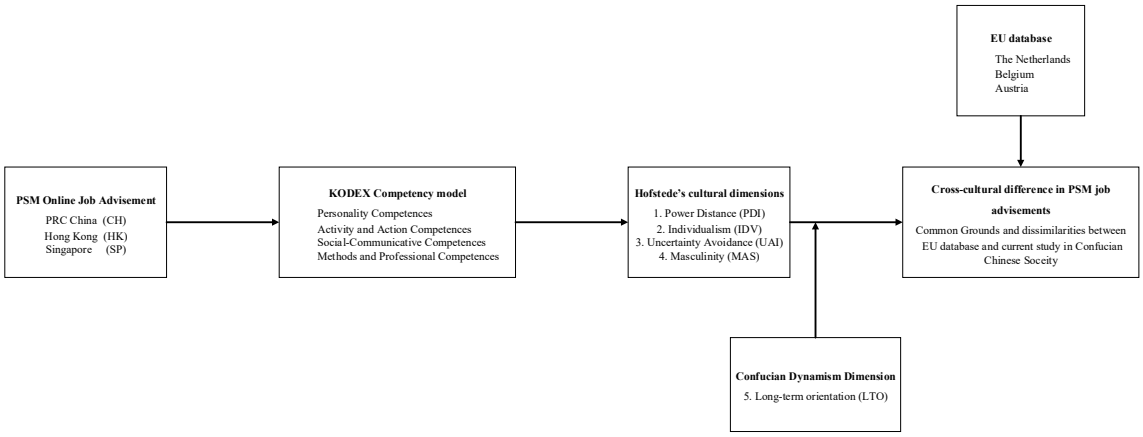

Figure 2. research framework

With the integration of Hofstede's cultural dimensions, Hofstede (1994) describes culture as *'the collective programming of the mind which distinguishes the members of one group or category of people from another'*. Hofstede's theory provides a basic knowledge framework, through the study of his theoretical knowledge, one will understand and analyse the

differences between different cultures. By comparing the collected data from the Confusion Chinese Society and the European dataset, it is possible to investigate whether there are similarities and dissimilarities in the two different cultural groups.

Analysis

In the first phase of this study, Confucian Chinese Society will be introduced. For the initial mass analysis, the study involved three countries from the Confucian Chinese group, chosen to collect and analyse data from. The three countries are China (CH), Hong Kong (HK), Singapore (SP). An initial sample pool of over 300 online job advertisements from the three different countries' job search sites will be collected, resulting in a minimum of 100 job advertisements per country, respectively. The key search terms "Purchaser", "Junior Buyer", "Buyer", "Senior Buyer", "Purchasing Manager" and "Purchasing/ Procurement Engineer" will be employed while sampling on Linkedln, a website for job search and recruitment.

The collected 300 online job advertisements will be processed and classified into different groups with the assistance of KODE®X skill matrix. For example, the keyword shown in the online job advertisements "ability to collaborate with individuals across multiple cultures and geographies" will be translated into "being a team player" and "international mind-set and intercultural sensitivity".

There are over 3,600 variables, which have been coded at this phase. With this result, it is important to better understand what the impact of the 3,600 variables will be, looking at the Confucian Chinese dataset. In addition, with the constructed Confucian Chinese dataset, it is important to further understand and investigate the difference and similarities of PSM professionals' competencies among the three Confucian Chinese Societies. As well as the difference and similarities of PSM professionals' competencies between Confucian Chinese and the dataset from the Europe study.

The data was analysed first in the different Microsoft Excel to calculate frequencies. The outcomes, the similarities and differences were analysed on the underlying details to obtain a more comprehensive picture resulting in about sixty different skills and competencies. Next, a Cell-wise Residual Contingency Table Analysis will be performed in IBM SPSS Statistics 22 by squaring the individual Adjusted Residual per cell of the Cross Tabulation. Subsequently, SPSS calculated the associated P-values per country for each competency in order to find the significant differences and similarities between the three European percentages per skill and the three Confucian Chinese percentages per skill. The null-hypothesis H_0 is: the distribution of averages per skill is equal in each set of three countries. The alternative hypothesis H_A is obviously the opposite. Alpha is set on 0.05 and divided by two: the number of observations (countries) per skill (Beasley and Schumacker, 1995; García-Pérez and Núñez-Antón, 2003). Subsequently a t-test was performed to define the (dis)similarities in the European and Confucian Chinese Society common grounds.

Results

The results of this study offer interesting insights on the job skills between the European and the Confucian Chinese Society. For example, the "*Communicative skills*" has been highly valued by the companies from Confucian Chinese Society. On average 67 percent of job advertisements required that prospective employees are able to transmit and receive messages clearly. However, the demand of people who master effective communication skills in the European job advisements is 20 percent point lower, with an average of 47 percent. The high demand of communication skills in the Confucian Chinese Society also reflects that a company wants the PSM employees to have an understanding on certain languages. Although not reported in table 2, PSM job advertisements in Hong Kong require that potential PSM practitioners are excellent in speaking Cantonese, which is a regional dialect in China.

Hofstede and Bond (1988) argue that European countries have been recognized to be more individualistic and East Asian countries are more collectivistic (see Figure 1). However, our observation indicates that "*Being a team player*" is an important personal competence, which is mentioned in both the European and the Chinese job advisements, with 47 percent and 40 percent displayed in table 1 respectively. Consequently, 12 percent of the companies from Confucian Chinese Society expect their potential PSM employees to have the ability to work in a dynamic working environment across various functions and cultures. Compared to the other five countries, China is compared to Hong Kong and Singapore the latest country on the progress on urbanization, and the PSM professionals need to deal with the uncertainty in the local market resulting from the conflicts between the state government and big corporations (Chaolin et al., 2012). An understanding of Chinese culture and the ability to work with it in the business practise is meaningful.

Following to the data shown above in Figure 1, all three countries of the Confucian Asia Society have a high score on the Confucian Dynamism Dimension (Long Term Orientation). The score indicates that people from the Confucian Chinese Society deal with things more practically and are more goal- oriented. According to the Table 2, "*Process management & Knowledge of Process*" is one of the job requirements that is asked for in the Confucian Chinese Society PSM job markets. On average, 17 percent of the job advertisements require the prospective employee to understand the specific responsibilities and to focus on the goals and reach them.

Table 1
Common grounds – general requirements for European and Confucian Chinese Society purchasers

Common grounds in European and Chinese societies				
		European (n = 300)	Chinese Society (n=300)	z-value
1	Negotiation Ability	140	120	1.6477
2	Being a Team Player	106	98	0.6894
3	Expert Knowledge	66	49	1.7632
4	Having BASc/BSc/MSc Technical study	64	83	-1.8035

13	Trustworthiness/Honesty/Reliability	39	26	1.7075
14	Computer Literacy towards ERP systems	36	24	1.6329
15	Proceed in a systematic-methodical manner	26	37	-1.4649
16	Strategic Thinking	25	37	-1.6094
17	Will to learn/Learning Ability/Curious Mindset	19	19	0.0000
18	Innovation Propensity/Innovative	14	12	0.4010
19	Stakeholder Management	10	17	-1.3785
20	Change Management Knowledge	9	8	0.2460

Given the growth in the Asian economies, it is natural to explore the driving forces behind its momentum, including that of effective leadership (McDonald, 2012). McDonald (2012) found that Confucianism offers explanation and insight into the nature of modern Chinese business leadership. With the integration of Hofstede's cultural dimensions, the characteristic of Chinese leadership is closely associated with long-term orientation and collectivism. These two characteristics can be explained as the Chinese spend more time on decision-making rather than action taking. Furthermore, the Chinese decision making is based

on ensuring that all parties can be included and the result of the decision balances advantages against disadvantages. This finding also reflects on this study, leadership skills have been taken into account in the Chinese job market (see Table 2). Employees with a better understanding of the cultural values and features of Chinese leadership in Confusion Chinese society are more effective and successful in building relationships with their co-workers and customers.

Table 2
Common grounds – general requirements for European and Confucian Chinese Society purchasers

Cultural and structural dissimilarities in European and Chinese societies				
	China > Europe	European (n = 300)	Chinese Society (n=300)	z-value
1	Communicative Skills	142	202	-4,952536

Conclusions

This research aimed to examine Hofstede's Cultural Dimension theory and attempt to identify if purchasing skills and competences are culturally determined. With the integration of Hofstede's Cultural Dimension theory, Europe has been recognized more individualistic, for

example, the Netherlands has a higher level of individualism compared to the other five countries in this study. However, while making a comparison between the *"Being a Team Player"* PSM job postings sample in Europe and in Confucian Chinese Society, this personal competence has been equally mentioned from each set of three countries. Consequently, the results suggest that there is no significant difference between Europe and Confucian Chinese Society on the purchasing skills requirements of the job postings in Table 1 above. On the other hand, the Z-values of most variables in Table 2 are greater than the critical value of 1.96, which we set as alpha is significant equals 0.025 (i.e. alpha 0.05 divided by two groups/countries). Therefore, we failed to reject the null hypothesis. The average of competencies and skills from each set of two groups/countries are significantly unequal.

This study also aimed to look for ways in which practitioners and companies can better understand the changing role of PSM job skills in the industry. The outcomes of this research will help practitioners to gain understanding and thus work more efficiently and effectively with their co-workers and customers. In practice, companies could apply the results from the study to provide a practical skills training programme for its employees.

Limitations and future research

In general, our findings lead to new insights into PSM job postings on the two different cultural clusters. Through the study between the European database and the Chinese database, we explained more than 60 personal competences that are demanded by the employers in the current PSM job market. Between the range of two databases, we identified a certain amount of dissimilarities and common grounds between the two cultural clusters.

In addition, this study contributes a large-scale dataset, which could benefit other researchers who are conducting further study on this topic. The findings have given a detailed understanding of job requirements and applicants' capabilities and in particular it gave insight in the cross-cultural differences between PSM job advertisements in Europe and Confucian Chinese Society.

The results presented, also offer a potential lead for future research on a homogeneous research. Hereby, some ideas will be briefly discuss. One of the future research possibilities could be extending the current database, and regroup, the European and Confucian Chinese Society. The new study will only assess companies from outside of Europe, which are employing PSM professionals in the EU job market. On another hand, a database can be collected of foreign companies who are recruiting PSM professionals to work in Confucian Chinese Society. As many businesses have globalized their supply chains nowadays (Carter et al., 2010), the objective of the new study will be the foreign companies who need to make the decision to hire more domestic PSM professionals, very knowledgeable on the local business culture contexts, or to hire international professionals for unique skills unlikely to be found domestically. Furthermore, the future research could be to include semi-structured interviews with a group of human resource managers from companies at both cultural groups. Through interviews with employers a deeper understanding on how intercultural sensibility has its cultural impact on the global division of labour skills at the PSM setting will be reached.

Shortly, there are some limitations to our study which deserve to be mentioned as the KODE®X competences matrix has been a part of our study. The language restriction of the KODE®X model creates some uncertainties for grouping different skill sets to further understand the association between each subject. Therefore, the development of a PSM skills and competences model in a common language for professional or academic purpose is necessary. However, this attempt will be a time-consuming project and needs to be incorporated with different functions and more academic research on relevance needs to be conducted.

Individual Innovation Sourcing Success
Combining Crucial Skills with Top Management Support

Summary: A decade ago Tassabehji and Moorhouse (2008) provided a two-by-two matrix, based on literature reviews and interviews, concluding that a higher level of skills in combination with internal support for strategic purchasing and supply management (PSM) leads to strategic elevation of PSM. Many scholars in the field of ‘purchasing skills’ have cited this article, however no empirical evidence for this assumption was found since 2008. On basis of quantitative data: a purchasing skills survey, this research found evidence that strategic elevation is reached via distinct, significant individual skills if and only if there is top management support for strategic PSM.

Keywords: purchasing skills, innovation success, polynomial

Submission Category: Working paper

Introducing the taxonomy of Tassabehji and Moorhouse (2008) and the need for empirical evidence after one decade

Innovation sourcing and implementation can be described as acquiring access to the innovative solutions of the supplier and implementing these innovations in the own products, services or processes. Since innovation is increasingly outsourced suppliers play an increasing role (Schiele, 2012). Subsequently, the innovation potential of firms is depended on suppliers, because these suppliers possess crucial technological knowledge and skills in R&D and innovation. Therefore, innovation sourcing and implementation is the firm’s most strategic and significant role assigned to the purchasing and supply management (PSM) function within firm’s (Knight et al., 2014; Luzzini and Ronchi, 2011).

Individual, strategic PSM professionals hence need skills to manage the relationship with the main supplier in order to be successful in innovation sourcing and implementation (Feisel et al., 2011; Giunipero and Pearcy, 2000; Knight et al., 2014). Tassabehji and Moorhouse (2008) state that an increased level of individual skills of strategic PSM professionals is not enough and always need to be accompanied with the top management’s support for strategic PSM: *‘(…) Before procurement can be elevated to strategic, the professional first needs to possess a strong set of these underlying skills and competencies (…).*

While skills related to processes and technology (i.e. technical and internal enterprise) are important, by themselves they are not enough to improve a company's procurement performance (…). The (…) skills (…) (are) largely cumulative where one builds on the core procurement skills, to reach the ultimate level of skills to be able to operate strategically. In order to optimise the role of procurement to achieve added value and competitive advantage for the organisation (…), the procurement professional must develop technical (including advanced procurement process skills), interpersonal, internal and external enterprise and strategic business skills coupled with a high degree of support and internal recognition' (see: figure 1) (Tassabehji and Moorhouse, 2008).

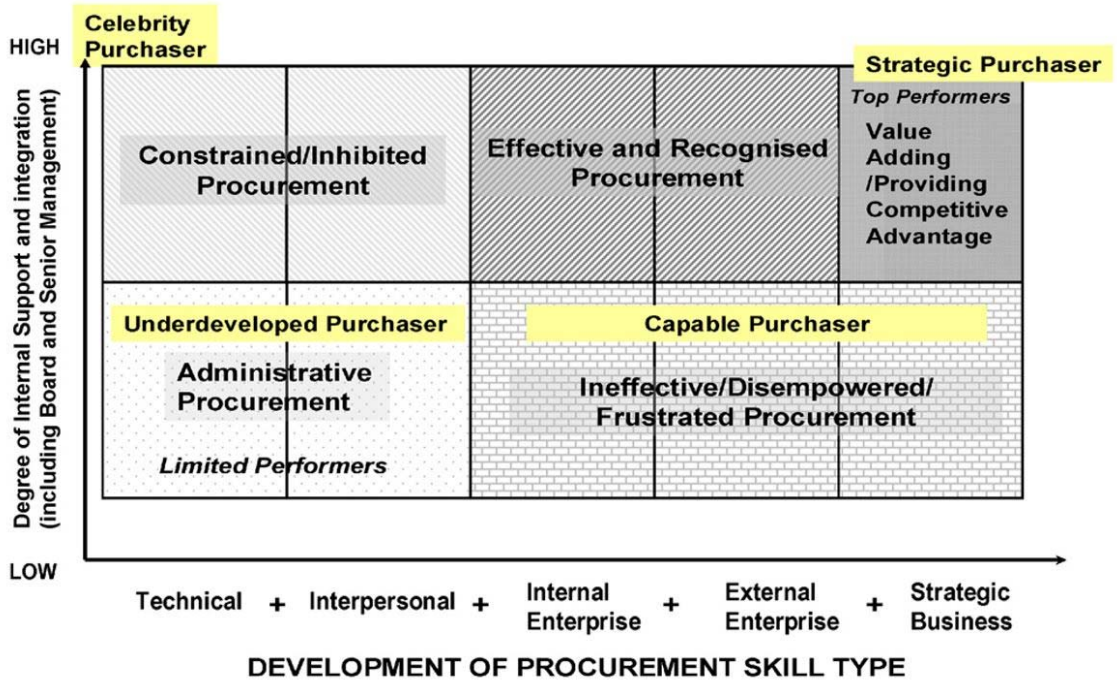

Figure 1 Procurement Effectiveness Matrix of Tassabehji and Moorhouse (2008)

The taxonomy of Tassabehji and Moorhouse (2008) appears 46 times in scopus.com (February 2018) and is therefore relatively well-cited within the field of 'purchasing skills' research. The article seems to have a function as a standard amongst other well-cited articles like Giunipero and Pearcy (2000), Carr and Smeltzer (2000), Cousins et al. (2006), Feisel et al. (2011), Kern et al. (2011) and Knight et al. (2014). When examining the most recent citations it is striking that since 2008 apparently, no empirical evidence is found for the assumptions. The most recent citation, for instance is made by Dubey et al. (2018) who state about the article of Tassabehji and Moorhouse (2008): *'The study has identified the role of organizational support and recognition on procurement skill and its impact on organizational performance'*. Tchokogué et al. (2017) conclude from Tassabehji and Moorhouse (2008) that *'the increasing professionalism of supply managers', 'have influenced greatly how supply management and its strategic contribution have evolved'*. Sinha et al. (2016) associate Tassabehji and Moorhouse (2008) with *'specialized studies of the procurement/purchasing function (that) suggest that the most important skills are "strategic thinking skills" and the purchasing manager's ability to assume "more strategic roles"'.* This small selection of recent articles is illustrative. The assumptions of Tassabehji and Moorhouse (2008) are still of importance, although empirical evidence seems to be lacking.

The Procurement Effectiveness Matrix (see: figure 1) of Tassabehji and Moorhouse (2008) consists of two axes without a clear scale, which can be interpreted as an illustrative 'two-by-two' to explain the concept that the sum of a high level of different skills and a high degree of internal governance support leads to strategic elevation. However, with the assumption that higher levels on both axis together are leading to strategic elevation, Tassabehji and Moorhouse (2008) are adding an extra dimension. In the matrix this strategic elevation is translated in success-terms: purchasing professionals with a low level of skills and a low level of support are 'underdeveloped purchasers' and those with high levels of skills and high levels of support of the top management are 'strategic purchasers' and 'top performers' that are 'effective', 'value adding' and 'providing competitive advantage'.

This study is taking the taxonomy, the matrix, and the assumptions regarding strategic elevation as a starting point and is aiming to test those empirically. The focus of this research is on PSM professionals' most strategic and significant role: innovation sourcing and implementation (Knight et al., 2014; Luzzini and Ronchi, 2011). This study aims to reveal the effect of an increased skills level combined with the level of top management's support for strategic PSM and its' internal recognition. The research questions therefore are:
RQ1: Is there empirical evidence for the taxonomy of Tassabehji and Moorhouse (2008)?
RQ2: Does 1) an increased level of significant skills of innovation focussed PSM professionals in combination with 2) an increased level of support and internal recognition of top management for innovation sourcing and implementation lead to 3) an increased level of individual innovation sourcing and implementation success of those PSM professionals?

The implications of this study are practically and theoretically of importance. Theoretically it aims to find evidence for the underlying assumption of the matrix and taxonomy of Tassabehji and Moorhouse (2008), which has on its turn manifold managerial implications, since the assumption is that both, individual skills level and top management support lead to success in the firm's most important value adding and strategic issues. It therefore contributes to management and theory in both fields: (strategic) skills development and managing a mature innovative atmosphere.

Methodology – towards a new purchasing skills taxonomy

Introduction of the methods section

To come to the answering of the research questions four steps have to be taken on which hereunder is further elaborated in this methodology section: first the PSM professionals with an innovative focus (n=102) were isolated from the results of purchasing skills survey (n=581). The second step is subject of RQ1: in order to find empirical evidence for the taxonomy of Tassabehji and Moorhouse (2008) each of the 88 survey skills was categorised into the taxonomy and subsequently confirmatory and exploratory factor analysis on that set was performed. Third, with a t-test the means on the 88 survey skills items of the purchasing professionals with an innovative focus (n=102) are compared with those of the other survey participants (n=479). The fourth stage is regarding RQ2 and aims to find the relationship between the three variables via polynomial regression with response surface analysis.

European Survey on Purchasing Skills – data collection

This study is part of the project Purchasing Education Research for European Competence Transfer (PERFECT). The main aim of this project is to align academic learning objectives with the needs of practitioners in the field of purchasing and supply management. A part of the research project is to perform an online purchasing skills survey. In summer 2017 via LinkedIn.com, about 3,200 purchasing and supply management professionals were invited personally to fill out the survey. Regarding the question, which particular PSM professional to invite, the LinkedIn-algorithm was leading. In total 581 professionals filled out the survey. The

response rate is thus over 18 percent. The sample (n=581) is Western-European, predominantly Dutch: about two third of the respondents have the Netherlands nationality, twelve percent is French and eight percent is Germanic. A quarter is working in 'service', 35-40 percent in 'industry' and 35-40 percent in the 'public sector'. The spread over the ages is normal distributed.

The survey consists of four different kinds of items. First, the participants' professional purchasing focus was determined. Participants were asked to rank their possible focus on 'costs', 'quality', 'delivery', 'innovation', and 'competitive advantage'. Second, the importance of 88 different skills were self-rated on a 5-point Likert-scale (fully disagree to fully agree). Next, statements on the perceived internal support for innovation sourcing and innovation implementation were self-rated on the same 5-point Likert-scale. Hereafter, statements on individual innovation sourcing and innovation implementation successes were self-rated on the same Likert-scale. In the next paragraph this methodologies are further elaborated on.

Participants ranked 'costs', 'quality', 'delivery', 'innovation' and 'competitive advantage' from rank 1 (most important) to rank 5 (least important). The participants who placed 'innovation' on rank 1 (n=36) and the participants who placed 'innovation' on rank 2 (n=76) are selected for this study. Outliers and incomplete surveys were discarded, which resulted eventually in a final sample of 102 observations.

Statistical methods

The second step of this study is a confirmatory factor analysis with SmartPLS (Ringle et al., 2015) to test the taxonomy of Tassabehji and Moorhouse (2008) with the 88 skills. With the substantial sample size (n=581) this analysis resulted in significant factor loadings of above 0.3 (Hair et al., 2010), Cronbach's Alpha's higher than 0.830, and strong Composite Reliability values. However, the Average Variances Extracted (AVE) are all under 0.5, which was reason to perform the factor analysis again by means of exploratory factor analysis (Varimax with Kaiser Normalisation; Eigenvalue = 1; IBM SPSS22). This analysis resulted eventually in eleven different factors, which are mostly in line with the taxonomy of Tassabehji and Moorhouse (2008): the Technical Skills (TS) are grouped together in three different factors that can respectively be titled as 'purchasing skills', 'analytical skills' and 'eProcurement skills'. The interpersonal skills are found in two factors that can be titled as: 'intrapersonal skills' and 'interpersonal & cultural awareness skills'. The internal enterprise and external enterprise skills load in six distinct factors, however they seem to overlap. Strategic business skills are found within one factor. After this exploratory factor analysis an iterative process of five confirmative factor analyses was performed in order to increase the AVE. Overall, this study seems to supports the taxonomy of Tassabehji and Moorhouse (2008) and is contributing to literature by refining it by stating subcategories and naming the associated skills. In table 3 the new taxonomy on basis of the factor analyses is shown.

RQ2 is regarding the increased level of *significant skills of innovation focussed PSM professionals.* The third step in this study is to find the significant skills of PSM professionals with an innovation focus compared with those who have a non-innovation focus. The participants who ranked 'innovation' as the number-1 or number-2 professional focus were distinguished. Next, a t-test is performed to find the significant skills, which are displayed in appendix 1. The column 'code' is referring to the taxonomy of Tassabehji and Moorhouse (2008): technical skills (TS), interpersonal skills (IS), internal and external enterprise skills (IE/EE) and strategic business skills (SB).

The fourth step in this research comes to the relation between the two predictors (increased skills and support levels) and the outcome variable (increased success rate for PSM professionals in innovation sourcing and implementation). To provide *'a nuanced view of relationships between combinations of two predictor variables and an outcome variable by*

graphing the results of polynomial regression analyses in a three-dimensional space' are applied (Shanock et al., 2010).

The three dimensions in the polynomial regression consists of three constructs. At the x-axis the *Significant Purchasing Innovation Skills' (SPINNS)* are projected. This construct is formed by the means of the 23 significant skills in appendix 1. The y-axis projects *'Internal Innovation Support and Integration' (INTSUP)*. This construct consists of the average means of the nine items regarding the role of the purchasing function in innovation purchasing and development (see: appendix 3). At the z-axis the construct *'Individual Innovation Purchasing Success' (INDINS)* is projected and consists of the average means of the three items on individual success of innovation sourcing professionals (see: appendix 2).

To perform polynomial regression with response surface analysis, a number of conditions have to be satisfied. First, there has to be 'agreement' between the variables, i.e. that the standard deviations have to be within half a standard deviation from each other. Half a standard deviation of the variable on the x-axis is 0.38044 (0.76088 / 2). All standard deviations of the different variables that separately will be projected at the y-axis are in the range 0.38044 to 1.14132, i.e. within half a standard deviation. Vice versa this is also the case (see table 1)

Table 1: standard deviations of the variables on the x- and y-axis

	N	Mean	Std. Deviation
Individual Innovation Success - INDINS	102	3.8264	.65244
Degree of Internal Support and Integration - INTSUP	102	3.3032	.76088
Significant Purchasing Innovation Skills - SPINNS	102	3.5272	.54258

The second condition is met: the variables are all measured on the same numeric scale. For both variables on the x- and y-axis a 5-point Likert-scale is used. Third, the variables share a conceptual domain and fourth the residuals are normally distributed. Figure 2 shows the linearity of the residuals of the dependent variable. Figure 3 shows the normal distribution of the residuals of the dependent variable (INDINS), however Shapiro-Wilk test appears to be significant.

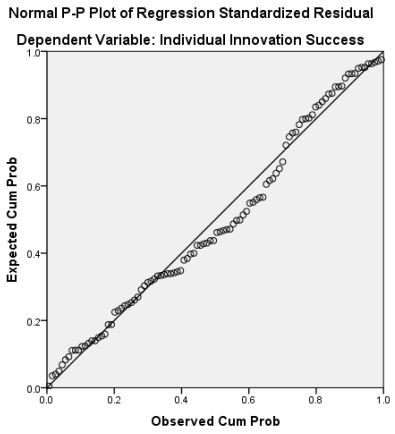

Figure 2: linearity of the residuals

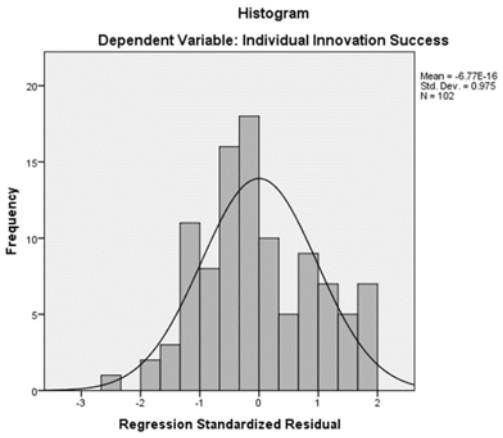

Figure 3: distribution of the residuals

Finally, the variance of inflation (VIF) of both independent variables is 1.00. which means there is no multi-collinearity detected between the independent variables INTSUP and

SPINNS. Herewith the conditions to start polynomial regression are met. *'Before conducting the polynomial regression analyses, it is important to inspect how many participants would be considered to have discrepancies between the two predictors. (…) If it turns out that very few participants have discrepant values (…) the practical value of exploring how discrepancies affect an outcome variable would be small'* (Shanock et al., 2010). Therefore, in SPSS the z-scores of the new computed y-axis variable (INTSUP) and x-axis variable are calculated (SPINNS). Both z-scores are subtracted from each other. These new groups were examined on the spread of the z-scores. Table 2 shows that the discrepant data (that is more than half a standard deviation above or below standardized score of zero; i.e. the section of < -0.5 and the section of > 0.5) is higher than 10 percent (resp. 29 and 34 present), which is a condition to perform further polynomial regressions. Polynomial regression was performed according Shanock et al. (2010).

Table 2: Level of agreement in z-value levels of the independent variables

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	< -0.5	29	28.4	**29.0**	29.0
	-0.49 to 0.49	37	36.3	37.0	66.0
	> 0.5	34	33.3	**34.0**	100.0
	Total	100	98.0	100.0	
Missing	System	2	2.0		
Total		102	100.0		

Results – a new purchasing skills taxonomy and empirical evidence for the decade-old assumptions

Regarding RQ1: on basis of the taxonomy of Tassabehji and Moorhouse (2008) table 3 is displaying the different factors and the associated skills and knowledge area's that could be derived from the iterative factor analyses. Five iterations took place. The first attempt was unsuccessful by grouping low-score loading in the factors 'basic purchasing skills' and 'internal planning & cooperation': Request for Quotation; Cooperation with Legal Department; Evaluating Offers; Forecasting of the Demand; ERP; Make-or-Buy; and Customer orientation. In the second iteration, these skills were all shared under 'basic purchasing skills', which gave a better, however not satisfying result. The third iteration consisted of the distinction between intrapersonal skills and interpersonal skill. In the fourth and fifth iteration the skills mentioned in first iteration were placed on eventually the factor that table 3 is showing. All factors have significant loadings higher than .55 (n=102) (Hair et al., 2010), except Commodity Knowledge (.50); Cooperation with Legal Department (.50); Contract Development (.53); Customer orientation (.40); Developing Specifications for Supplies (.43); Forecasting of the Demand (.44); Request for Quotation (.54); and Stakeholder Relationship Management (.53).

Regarding RQ2: the polynomial regression leads to a three-dimensional image as displayed in figure 5. Table 4 shows that (only) the slope on the diagonal x equals y is significant. The slope is ascending from (-2, -2, -0.13) to (2, 2, 4.02) (table 5). This means that the assumption of Tassabehji and Moorhouse (2008) is supported: a higher level of significant purchasing innovation skills, if and only if combined with a higher degree of internal support and integration, leads to an increase of individual innovation success. This means there seems to exist additive effects and no complementary. Neither one of the predicting variables can be replaced by the other, e.g. and increased level of *Significant Purchasing Innovation Skills* (SPINNS) only leads to a higher level of individual innovation purchasing success (INDINS) when there is an increased level of *'Internal Innovation Support and Integration' (INTSUP).*

Table 3: new purchasing skills taxonomy based on Tassabehji and Moorhouse (2008) and on empirical evidence

TS	basic purchasing	Claims management; Commodity Knowledge; Contract Development; Contract Management; Cost Analysis; Developing Specifications for Supplies; Global Sourcing; ERP; Make-or-Buy Decisions; Negotiation.
	analytical	Big Data analysis; Cost Reduction Techniques (Act of cutting costs to improve profitability; e.g. by analysis and statistics); Set key performance indicators (KPI's); Performance Measurement and Follow-up; Portfolio Analysis; Statistical Analysis.
	eProcurement	Procurement IT Systems / eProcurement applications; Automation of Purchasing
IS	intrapersonal traits	Complexity understanding; Conscientiousness; Creativity; Holistic thinking; Honesty; Inventiveness; Learning ability; Loyalty; Problem-solving; Personality Development; Poise; Proactivity; Self-Assurance; Risk-taking, Result-driven;
	interpersonal & cross-cultural	Advice skills; Communication; Conflict-solving; Cross-cultural awareness; Customer-orientation; Empathy; Networking; Persuasion; Salesmanship; Social Manners; Stakeholder Relationship Management; Team-ability.
IE	human resource & leadership	Change management; Cooperation with HRM department; Employer Development; Employer Performance Measurement; Defining Roles & Profiles; Leadership; Personnel Selection; Project Management; Training Personnel.

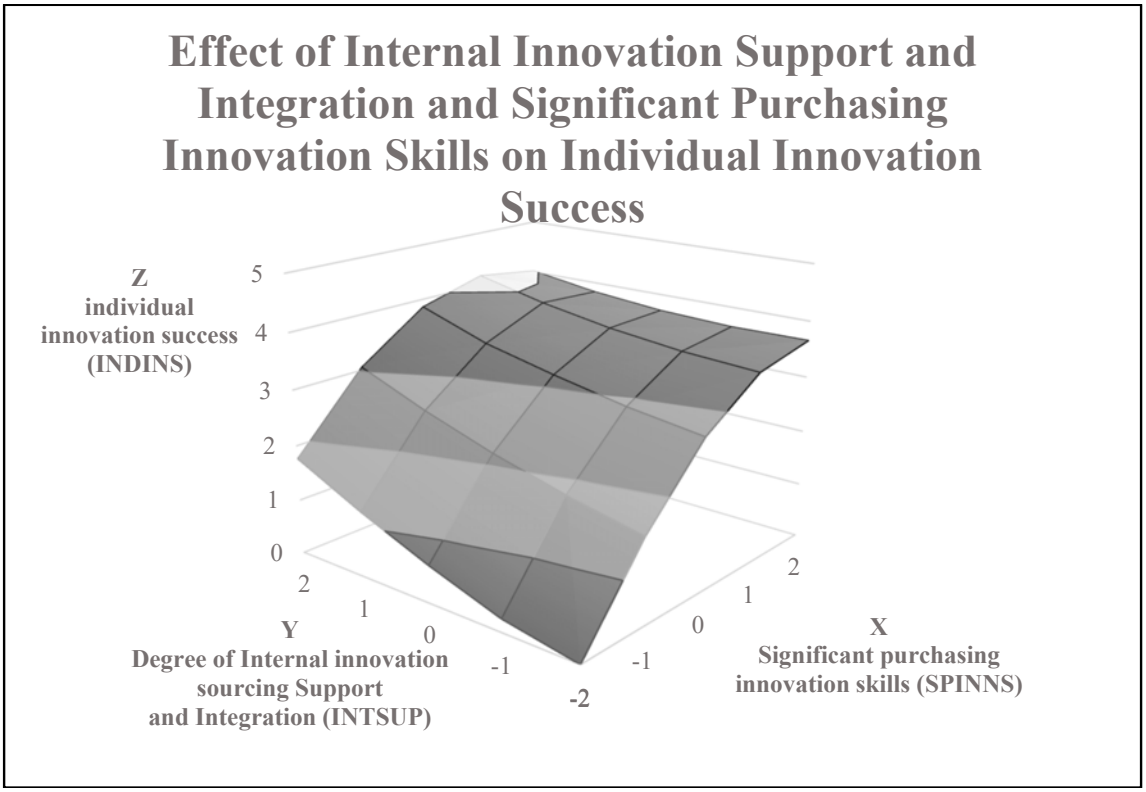

Figure 5: Effect of Internal Innovation Sourcing Support & Integration and Significant Purchasing Innovation Skills on the level of Individual Innovation Success

Discussion – Innovation-sourcing success has two sides of a coin: purchasing innovation skills development and internal purchasing innovation support

As mentioned, there is evidence that the assumptions of Tassabehji and Moorhouse (2008) are supported (RQ2). A higher level of skills significantly belonging to innovation sourcing professionals, if and only if there is a higher level of support from top management for innovation sourcing, is leading to a higher level of success of individual purchasing professionals in the field of innovation sourcing and innovation implementation. Next, this study provides empirical evidence for the taxonomy of Tassabehji and Moorhouse (2008) (RQ1). It is extending the skills list of the taxonomy with its 88 skills and is categorizing them accordingly. Moreover, this study refines the taxonomy and divides the original five groups up into eleven factors, with substantial factor loadings and a high to reasonable AVE.

This study therefore contributes not only to literature but also to management practice: the outcome is most likely to be disappointing for dedicated, well-skilled innovation sourcing agents with no top management support. Tassabehji and Moorhouse (2008) in their paper referred to those strategic professionals as: '*ineffective, disempowered and frustrated*'. There is no reason to assume that these characterisations have to be adjusted on basis of this research.

This study has taken innovation-focussed professionals in consideration: hailing from industry, service and public procurement and contributes to the knowledge on innovation-related skills of purchasing professionals. Appendix 1 is displaying the skills that significantly belong to these professionals. The main take-away for managerial use is that innovation-sourcing success is reached via distinct, significant individual skills (appendix 1) but only when there is also top management support. i.e. a mature innovative atmosphere (appendix 3).

The sample sizes are considerable; however, the limitation of this research is that the sample is predominantly from one country: over two third of the respondents are from the Netherlands. As mentioned, some factor loadings or not significant and it is doubtful if these

items can be maintained under the specific factor. The Shapiro-Wilk test for the spread of the residuals of the dependent variable is significant; there is no normal distribution.

Within this study the sample (n=102) could be enlarged when the participants with a focus on innovation and/or competitive advantage on rank #1 and/or #2 (n=207). This would probably affect the Shapiro-Wilk test in a positive way. Further research could be performed on replicating this study outside the Netherlands to test first the groupings that are presented in table 3. Secondly, a replication could test the finding that a higher level of skills only in combination with top managements' support is leading to a higher level of success of individual purchasing professionals.

Summary: Purchasing agents from industry, service and public procurement (n=581) took part in a survey on 88 purchasing skills and were asked about their focus and success. Success skills depend on the sector. Per sector significant skills of successful purchasing agents (with a strategic focus) appear, however a clear profile could not be made; some success skills in some sectors seem to be in hands of a higher educated, slightly older, male-dominated group. Practitioners, recruiters and educators have the task to bridge the gap by acquiring these skills and adopting them in learning objectives and curricula.

Keywords: Purchasing skills, focus, industry, success.

Submission Category: Working paper

Introduction – gap in the PSM skills literature on success factors

The level of the individual competencies and performances of PSM professionals relates positively to the success of purchasing and supply management (PSM) in firms (Carr and Smeltzer, 2000; Giunipero et al., 1999; Kaufmann and Carter, 2006; Mulder et al., 2005; Schiele, 2007; Shou and Wang, 2015; Tate and Ellram, 2012).

Although there is a vast range of PSM literature on skills and knowledge (hereafter: ‘skills’) which are needed in PSM in general (e.g. Cousins et al., 2006; Faes et al., 2001; Giunipero and Pearcy, 2000; Knight et al., 2014; Tassabehji and Moorhouse, 2008), there is limited knowledge on which skills in particular are needed by PSM professionals (Bahouth et al., 2014); let alone what specific skills lead to success. Moreover, the question is how applicable ‘general needs’ are for professionals in the field of PSM? And do these skills lead to success in ‘industry’, ‘services’ and ‘public procurement’? Knowledge on specific skills of highly effective or successful PSM professionals seems to be missing in scientific literature. In their novel work Knight et al. (2014) did find three clusters (routine, tactical and strategic buying) of skills and projected them on the Kraljic purchasing portfolio matrix (Kraljic, 1983). However, the research of Knight et al. (2014) did not reveal the skills of the most successful or effective PSM professionals.

PSM professionals can have different focuses. Literature distinguishes firstly a PSM focus on lowest cost, i.e. buying supplies to the lowest possible costs or total cost of ownership. The focus on quality means buying supplies with an appropriate quality. A focus on delivery is ensuring safe, timely and sufficient supply with suppliers who have the capacity to deliver the

desired volumes. The PSM function may also focus on ensuring access to the suppliers' innovations: the purchasing of innovative solutions or facilitating innovations from and with suppliers (Foerstl et al., 2013; Hesping and Schiele, 2015; Krause et al., 2009). PSM can have an important role in achieving the firms long-term or sustained competitive advantage strategy, which leads to exclusive access to sources of suppliers; taking the resource-based-view of Barney (1991). The aim of this paper is to reveal the significant skills of successful and effective PSM professionals. For this reason PSM professionals with a transactional role, i.e. having a focus on lowering costs, improving quality and ensuring safe supplies are left out of this research. This research aims on PSM professionals that are involved in achieving sustained competitive advantage (Barney, 1991, 2012) and in acquiring access to the suppliers' innovations and implementation in the own product or process. *'Innovation is by far one of the most important competitive priorities in the current business context. Companies increasingly rely on their supply base to support their innovation potential. As a consequence, the purchasing department might dramatically affect the firm's innovation capability'* (Luzzini and Ronchi, 2011). The research questions of this paper therefore is:

- Which PSM skills are significantly associated with strategic PSM professionals per sector?

Literature on PSM skills and competencies seems to fall short when it comes to describing what PSM skills lead to success. This study fills this gap with the analyses of the outcomes of a large European online PSM skills survey that took place in the summer of 2017 (n=581). The subsample of strategic PSM professionals is 207.

Methodology – deriving of purchasing skills that lead to success

This study is done in the framework of the project Purchasing Education Research for European Competence Transfer (PERFECT). The main objective of this project is the alignment of academic learning objectives with the PSM needs in firm and organisations. An online purchasing skills survey is part of the research project. About 3,200 PSM professionals were personally invited to fill out the PSM skills survey via LinkedIn.com in summer 2017 (n=581 / response: >18%). The sample is Western-European, predominantly Dutch: about two third of the respondents have the Netherlands nationality, eleven percent is French and eight percent is Germanic. A quarter of the population is working in 'service', 38 percent in 'industry' and 37 percent in the 'public sector'. The spread over the ages is normal distributed.

The design of the survey consists of four different kinds of items. First, the professional PSM focus was determined. Participants were asked to rank their possible focus on 'costs', 'quality', 'delivery', 'innovation', and 'competitive advantage'. Second, the importance of 88 different skills were self-rated on a 5-point Likert-scale (fully disagree to fully agree). The descriptions of the survey and the 88 skills are published online (PERFECT, 2017). The participants were further questioned about their individually success rates in costs, quality, delivery, innovation, and long-term competitive advantage.

First, the sector in which the participant is employed ('industry', 'service', or 'public') is combined with the focus (rank #1 and/or rank #2: 'innovation', and 'competitive advantage'). This lead to a sample of 207 subjects in six groups (three sectors and two focuses; see: table 1). Second, a set of constructs of the individual and department's success-items on 'innovation' and 'competitive advantage' were made. Next, the 'successful' participants were determined and were distinguished from the 'unsuccessful' participants in SPSS22 by means of a dummy variable. To be 'successful', for this study the participant has to have an average score equal to 4 or higher on a 5-point-Likert-scale ('agree' and 'fully agree') on the construct. With a one-way analysis of covariance (ANCOVA) per sector and focus, the 88 skills importance levels of

the both ‘successful’ and the ‘unsuccessful’ were compared. The results of the one-tailed tests are subsequently combined in table 2.

Table 1. Focus on 'innovation' and/or 'competitive advantage' ranked at #1 and #2	innovation	competitive advantage	innovation AND competitive advantage	Total
secondary sector - industry / construction / manufacturing / mining	17	33	15	65
tertiary sector - service / trade / transport / finance	22	36	6	64
quaternary sector - public procurement / public health / public education	42	26	10	129
	81	95	31	207

Results – success depends on sector and focus

In table 2 the results of the ANCOVA are displayed. These significant skills are categorized according the taxonomy of Tassabehji and Moorhouse (2008). These can be seen as advanced skills that belong to successful PSM professionals with a focus on innovation sourcing and sustained competitive advantage. The successful PSM professionals in industry, service and public procurement have significant skills in common, like: contract management;

developing specifications for supplies; self-assurance; cross-cultural awareness; social manners; innovation implementation; cooperation with colleagues in different departments; technical planning (internal scan); and HRM-related subjects like employee performance measurement.

Some significant differences appear between the sample 'non-successful' and the 'successful'. The successful agents that are focussed at 'sustained competitive advantage' are compared to the unsuccessful (slightly) older (43.5 and 44.6 y/o with .011 significance) and more often male (sign. .001). The successful professionals focused on 'innovation sourcing' are higher educated (sign. .001). The differences ('unsuccessful'/'successful') are for PhD's 1.2 vs. 5.1 percent and MSc's 40.4 vs. 54.4 percent. No significant difference between study disciplines or between nationalities are found. Unfortunately, the successful PSM professional could not be profiled.

Conclusions - significant 'success' skills ratio differs over the sectors

In literature not much is known about PSM skills in association with success factors. Knight et al. (2014) may be an exemption and distinguish three clusters with types of PSM professionals: a 'routine product type', a 'tactical purchasing type' and a 'strategic purchase type'. Knight et al. (2014) state that: *'The strategic purchase profile fits well with the supply management quadrant'* of the matrix of Kraljic (1983). The tactical purchase profile '*fits well with Kraljic (1983) 'leverage item'*' (Knight et al., 2014). The survey items of Knight et al. (2014) are not identical with the items of the survey of this study and also the focus of the research is not in accordance; Knight et al. (2014) is clustering the most important skills in the framework of the portfolio matrix of Kraljic (1983) and this study's approach is to distinct the advanced skills of successful PSM professionals. Nevertheless, the outcomes of this research seem to be in line with the outcomes and especially the categorisation of Knight et al. (2014). Skills in both studies are matching at the strategic profile.

As mentioned, similarities are shown, but also differences between the sectors appear. Successful PSM-professionals in the service-sector seem to be equipped with the largest number of significant skills. Or in other words: the 'unsuccessful' PSM professionals lack these significant 'success'-skills. In industry the differences between the 'unsuccessful' and 'successful' are smaller than in the service sector and public procurement. The conclusion is that the professionally level in the purchasing function in industry is higher than in the other two sectors.

In public procurement the results under the category 'external enterprise skills' are remarkable. Successful public procurement agents have skills and perform apparently activities that at the first glance not seem to fit with the rules and regulations for tenders in public procurement: supplier development and early supplier involvement, which are activities that have to be seen within the context of a rather close relationship with the supplier.

Managerial implications

There seems to be a watershed between professional who have or do not have 'purchasing skills leading to success'. Moreover, it depends on what sector the practitioner is employed. Significant skills are in some cases possessed by a slightly older, higher educated, male-dominated group, however this does not count for all focuses and sectors. On basis of this study it is difficult to define the profile of a successful PSM professional. Nevertheless, there are distinct PSM agents who possess skills that are associated with success. These skills sets are of value for individual PSM professionals, their employers and educators.

Practitioners and recruiters as well as educators in PSM first have to ensure that the 'basic' skills are acquired and covered in academic learning programs to bridge the gap between the 'successful' and 'unsuccessful' in order to increase the level of the individual competencies

and performances of PSM professionals, which relates positively to the success of PSM in firms (Carr and Smeltzer, 2000; Giunipero et al., 1999; Kaufmann and Carter, 2006; Mulder et al., 2005; Schiele, 2007; Shou and Wang, 2015; Tate and Ellram, 2012).

Limitations and further research

Two-third of the subjects have the Dutch nationality. The Netherlands' economy is mostly focused on service and (international) trade, which might affect the outcomes. It is worthwhile to find out why successful public procurement agents are involved in supplier development and early supplier involvement.

Despite the broad range of items, this research was not able to profile the successful professionals. Further research could concentrate on finding distinct profiles.

Summary
This paper adopts a systematic review of abstracts to provide an overview of the concepts associated with open innovation, sustainability and the supply chain literatures. This overview is then followed with a systematic analysis of selected research. Ultimately, this systematic review will lead to a conceptual framework to depict the underlying approach to developing a sustainable competitive advantage through innovation within the supply chain network.

Keywords: Open Innovation, Sustainability, Sustainable Supply Chain Management; Systematic Literature Review

Introduction

Exploiting proprietary innovation has been a firm's business model practice which has produced great success for organizations. Yet, markets that have seen decreased and more limited access to resources have challenged firms' practice of internal innovation. In other words, it is no longer enough to create value, a firm must also capture value to ensure a more sustained development and competitive advantage. Capturing value is dependent greatly upon the organization's ability to innovate; a capability which is no longer the domain of a single firm. Instead, innovation ability relies increasingly on gathering and incorporating knowledge and innovation from other firms which may form part of the focal firm's supply chain network (von Hippel, 1988). Indeed, a growing awareness is that the reliance upon internal development is less productive and may even be less attractive as a means to realize sustainable competitive advantage or sustainable development. These circumstances are prompting some organizations to extend their innovation efforts outside of their firm's boundaries to capture opportunities (Chesborough, 2003; Laursen and Salter, 2006). Hence, companies are more reliant upon their supply chain networks to obtain and leverage resources which could also be used to enhance their ability to develop innovative capabilities.

Yet, the way in which firms actually manage innovation within their network to ensure sustainable development is not understood well (Isaksson, Johansson, Fischer, 2010; Pagell and Shevchenko, 2014). Consequently, the primary motivation for this paper is the realization that an internal focus on proprietary innovation poses particular risks in a market of reduced access to resources. As companies confront these risks, collaboration with supply chain partners with

innovation as one of its main goals, becomes increasingly important to compete efficiently (Adner and Kapoor, 2009). Indeed, interfirm collaboration highlights innovation as a basis for sustained efficiency and effectiveness and thus, an increasing practice within the supply chain (e.g., Chesborough, 2003; Chesborough, 2006; Dahlander and Gann, 2010).

Leveraging innovation may not be enough. The process of innovation suggests that the firm is adopting a long-term outlook; companies still seek a strong guarantee of maintaining access to knowledge and scarce resources through innovation approaches and processes. The benefits of extending resources through collaborative efforts among supply chain partners in the form of knowledge exploration and exploitation addresses the question of *why* companies leverage innovation. Moreover, collaboration through knowledge and innovation within the supply chain suggests *what* companies receive by adopting open innovation practices. A quick assessment of these questions indicates that companies gain a degree of knowledge which contributes to not only immediate or short-term performance, but also knowledge that increases the potential for long-term, sustainable development.

The proposition follows that leveraging innovation within the supply chain network can and should contribute to a firm's sustainability. The concept of open innovation as a firm's practice and influence on value creation and capture sustainability within the supply chain requires an assessment of the current conceptual frameworks to help provide some coherence to the different perspectives reflected in the research. To address this shortcoming, a systematic review is timely and relevant. It is also an important means to build upon the literature's foundation to help advance the area's research and in particular, to bring more concentration to theory development. Consequently, middle-range theory over a meta-theory approach is the more appropriate. The middle-range theory addresses theoretical development based upon improving conceptualizations, measures and relationships among concepts identified by the macro thread. Middle range theory advances the macro conceptualization by integrating high-level theory with empirical testing and analysis. The present review highlights several dimensions and provides some direction to focus upon an analytical framework that drives closer to addressing the question of how firms achieve sustainability through open innovation within the supply chain network.

The present paper analyses how research has examined organizations' application of open innovation within the supply chain network and whether the extant research explores open innovation as a supply chain phenomenon that advances supply chain sustainability. Accordingly, the paper makes two key contributions; from an extensive literature review it identifies, and ties together the business model approach of open innovation to supply chain sustainability theoretical development. This first contribution outlines open innovation as the bridging literature between supply chain management and sustainable supply chain management literature bases. Highlighting this addresses the question of *how* open innovation can be used to develop sustainability in the supply chain. The second contribution identifies research opportunities by outlining the 'common' concepts and relationships from the separate literatures utilizing the middle range theory approach.

This paper begins with overviews of open innovation, supply chain management network and sustainable supply chain management literatures to support the open innovation concept which links supply chain network and sustainable supply chain management literatures. Ultimately, the paper argues for the relevance of open innovation to sustainability within the supply chain network. This overview is followed by the methodology, an analysis of the systematic review and a discussion of how the review informs the development of a conceptual framework from a middle-range theoretical approach. The paper also includes suggestions for a research agenda and some recommendations for how to employ open innovation practices to increase the opportunity for sustainable development.

Innovation to open innovation network

Innovation reflects interactive learning and knowledge dissemination to create value. Innovation as is practiced internally is largely a closed process predicated on the idea that the firm gains competitive advantage from innovation and the control of innovation it produces in the market. Currently, innovation research from this perspective examines *intra*firm phenomenon. However, internal innovation may be based on knowledge assets outside the company and introduced into the company through cooperation or collaboration with other firms in the supply chain network (Chesborough, 2003). Exploiting knowledge 'sourced' from beyond the firm's boundaries may be a good means to generate new ideas and take them quickly to market without expending a lot of investment in resources. It is also a way to extend an organization's resources and ultimately, market reach.

Open innovation has emerged as a concept for understanding the nature of innovation among supply chain partners and how organizations manage the innovation process to achieve success. The practice of exploration is the foundation of open innovation; a business model oriented to purposeful and reciprocal flow of innovation outflow extending beyond a firm's contractual boundaries (Chesborough, 2003; Chesborough, 2006; Almirall and Casadesus-Masanell, 2010). The concept is grounded in the realization that some form of collaboration is crucial as knowledge becomes more distributed. The fundamental idea of open innovation is that the firm potentially builds upon internal innovation by incorporating enhancements to innovations that other companies produce. In this context, an organization enhances its innovation efforts by utilizing assets In short, innovation can reflect a firm's approach to create and capture value, but increasingly, it is becoming more challenging to create and capture value independently given the circumstances of diminishing resource access. Consequently, innovation has evolved into a more interdependent endeavor that acknowledges the need and the benefits from firm partnerships. Understanding this interaction to create and capture value is the impetus behind open innovation.

There is a well-defined and growing body of literature within the management literature that investigates open innovation from the perspective of a business model (e.g. Chesborough, 2003; Chesborough, 2006; West and Bogers 2014). Yet, the open innovation research has primarily been conducted from a meta-theory view with little covering how open innovation within the supply chain network influences a firm's ability to sustain a competitive advantage. Interestingly however, some open innovation literature has presented sustainability as an outcome of open innovation (business model) practices that provide a path to competitive advantage (Hall and Wagner, 2012). In fact, Unilever's Sustainable Living Plan outlines key areas for innovation with outside partners that would help reduce environmental impact while inducing continual business growth. The company states that:

"We have a vision of a better future for our world and our business – and we want partners to share it. If you have a new design or technology that could help us grow our business and solve the challenges we've set ourselves, we'd like to work with you though Open Innovation." (www.unilever.co.uk/about/innovation/open-innovation)

Open innovation and sustainability

An organization's objective of long-term competitiveness invokes the concept of sustainability (Carter and Rogers, 2008). Pagell and Shevchenko (2014) build upon earlier conceptualizations of sustainable supply chain management by defining it as "designing, organizing, coordinating, and controlling of supply chains to become truly sustainable with the minimum expectation …to maintain economic viability, while doing no harm to social or environmental systems" (p. 45). This definition is based on the Bruntland Commission's concept of economic, social and environmental performance over time (Brundtland Commission, 1987). In general, this paper

refers to sustainability in supply chains as research that goes beyond economic performance to include social and environmental.

The opportunity to be sustainable is enhanced with increased access to resources enabled by extended knowledge exploration and exploitation. When faced with reduced access to resources or scarce resources, open innovation is a means to extend the resource base while still providing the opportunity to create valuable returns to the firm. A firm's adoption of open innovation indicates that the firm is not just inwardly-focused but also recognizes the external market and is receptive to collaboration with partners in the supply chain network as a means to maintain access to resources. A premise of the current study follows that supply chains have a great potential and capacity for sustainability through employing open innovation. This is supported by supply chain management practices of integration, which involve crossing functional and organizational boundaries. Firms have recognized and built upon this foundational practice to become more open to sharing knowledge in order to create and capture value (Almirall and Casadesus-Masanell, 2010). Value capture, especially, is an important element of sustainability. In fact, companies across several industries increasingly have identified sustainability as a desired and necessary part of their strategic outlook. Nike, Best Buy and Yahoo, among others, collectively established GreenX, an Intellectual Property (IP) portal, to share, develop and promote innovation throughout their supply chains.

Many scholars (e.g. MacGregor, Espinach, Fontrodona, 2007; Nidumolu, Prahalad, Rangaswami, 2009; Carter and Easton, 2011) propose that companies espousing sustainability as part of their strategic direction will be in a better position to achieve competitive advantage. A high percentage of these companies also claim that innovation contributes to competitive advantage because it allows the company to better position itself for the dynamics of the market by combining technology and society needs continuously (Hall and Wagner, 2012). In fact, innovation has been recognized and explored extensively as a key component of a firm's ability to establish and to sustain competitive advantage (Boons and Lüdeke-Freund, 2013). For example, Nestlé's dairy supplier program RISE (Response-Inducing Sustainability Evaluation (RISE), is part of a more encompassing Supplier Code applied to the global based company. RISE is an assessment tool designed to encourage suppliers (primarily farmers) to continually identify potential areas of strengths and weaknesses associated with the social, economic and environmental dimensions of sustainability. One of the outcomes of the program has been increased innovation among the suppliers leading to greater social quality as well as economic and environmental. This topic has undoubtedly generated a range of important papers that explore the relationship between innovation and sustainability (e.g. Schaltegger et al., 2012; Carnovale and Yeniyurt, 2015).

Research design

This research applies a systematic review approach to identify the dimensions and antecedents of innovation and sustainable supply chain networks (especially in light of open innovation) (Tranfield, Denyer, Smart, 2003). In order to reduce bias in the research, the following steps were taken: the study searches two databases, builds on feedback from open discussion with experts at an academic conference, and initially avoided limiting itself to specific publications. The steps in the systematic review process are outlined in detail below.

Locating Articles

A systematic literature search of databases should result in a complete list as possible of relevant literature while keeping the irrelevant hits low (Duff, 1996). In order to limit bias, an initial unrestricted search was conducted on two databases: Web of Science and Google Scholar. These databases were selected as both Web of Science and Google Scholar allow researchers to search many sources, including peer-reviewed papers, theses, books, abstracts, and articles

from both academic and professional organizations and publishers. These databases thus have some of the largest repositories of business research and have been previously used in literature reviews.

The development of key word searches was an iterative process. The researchers first employed a brain storming technique and then used a snowballing process to add keywords to the search as they were discovered in the literature. These additional keywords were added until a point of saturation was reached, where no new keywords or articles were identified. The final list of keywords used is identified in Table 1.

Table 1 - Search strings for database search

Web of Science Key word strings	*TS = "open innovation" OR "sustainable supply chain" OR "green supply chain" "networks" OR "sustainability" TI="Supply chain" AND "Innovation"*
Google Scholar Key word strings	*"open innovation" OR "sustainable supply chain" OR "green supply chain" "networks" OR "sustainability" AND "Supply chain" AND "Innovation"*
Journal strings	*"Industrial Marketing Management" OR "R and D Management" OR "International Journal of Operations and Production Management" OR "International Small Business Journal" OR "Journal of Business Research" OR "International Journal of Management Reviews" OR "California Management Review" OR "Decision Sciences" OR "Journal of Small Business Management" OR "Journal of Supply Chain Management" OR "Journal of Business Logistics" OR "Management Science" OR "Organization Science" OR "Business and Society" OR "Transportation Journal" OR "Academy of Management Perspectives" OR "Academy of Management Review" OR "Journal of Business Venturing" OR "European Management Review" OR "Organization Studies" OR "Strategic Organization" OR "Journal of Operations Management"*
Notes:	*TI: Title Search, TS: Topic Search*

Articles selection and evaluation

The electronic search process resulted in the identification of 2,825 articles from Web of Science and 36,800 articles from Google Scholar, 39.625 articles total. In spite of the different approaches and vast difference in articles located, there was considerable overlap between the two sources – an indication for consistency across the search strings. However, due to the vast amount of journals pooled, a list of scholarly journals that routinely publish sustainable supply chain and innovation related articles was generated through discussions with experts in the field at an academic conference in order to further narrow the scope of the search. Further, the review panel felt that the articles needed to be limited to relevant journals in order to provide a better pool of peer-reviewed "good studies" (Tranfield et al. 2003) before moving to data abstraction for final analysis.

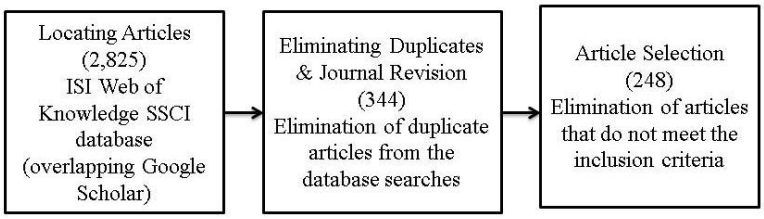

Figure 1 - Article Selection Process

Inclusion criteria were built based on discussions among the authors. Based on a review of extended abstracts collected from the articles, the authors determined one main inclusion criterion and one minor one. First, the authors contended that all the articles must demonstrate either a focus on sustainability or innovation (the inclusion of the keyword supply chain was

already a search criteria). Second, the authors excluded any articles not in English.

Analysis and Synthesis of Articles

For the analysis, all 248 article abstracts were entered into an Excel spreadsheet and then were uploaded into QDA (Qualitative Data Analysis Software). They were then coded and analyzed based on titles and abstracts with no reference to their publication outlets. Coding categories were developed to code for keywords, theories and methodologies. Eight methodologies, including structural equation modeling, regression, modeling, literature review, business model, qualitative, case study, and experimental emerged. Further, ten key words emerged including: innovation, open innovation, sustainability, supply chain, sustainable supply chain, networks, service, sustainable entrepreneurship, green, and entrepreneur. Coded keywords were then synthesized in order to elevate the abstraction of the framework (Durach, Wieland, Machuca, 2015). Because the reviewed literature did not overlap between sustainability and open innovation topics, it was more amenable to an interpretive synthesis to build higher order constructs and relationships between those constructs conceptually (Rousseau, Manning, Denyer, 2008).

Results

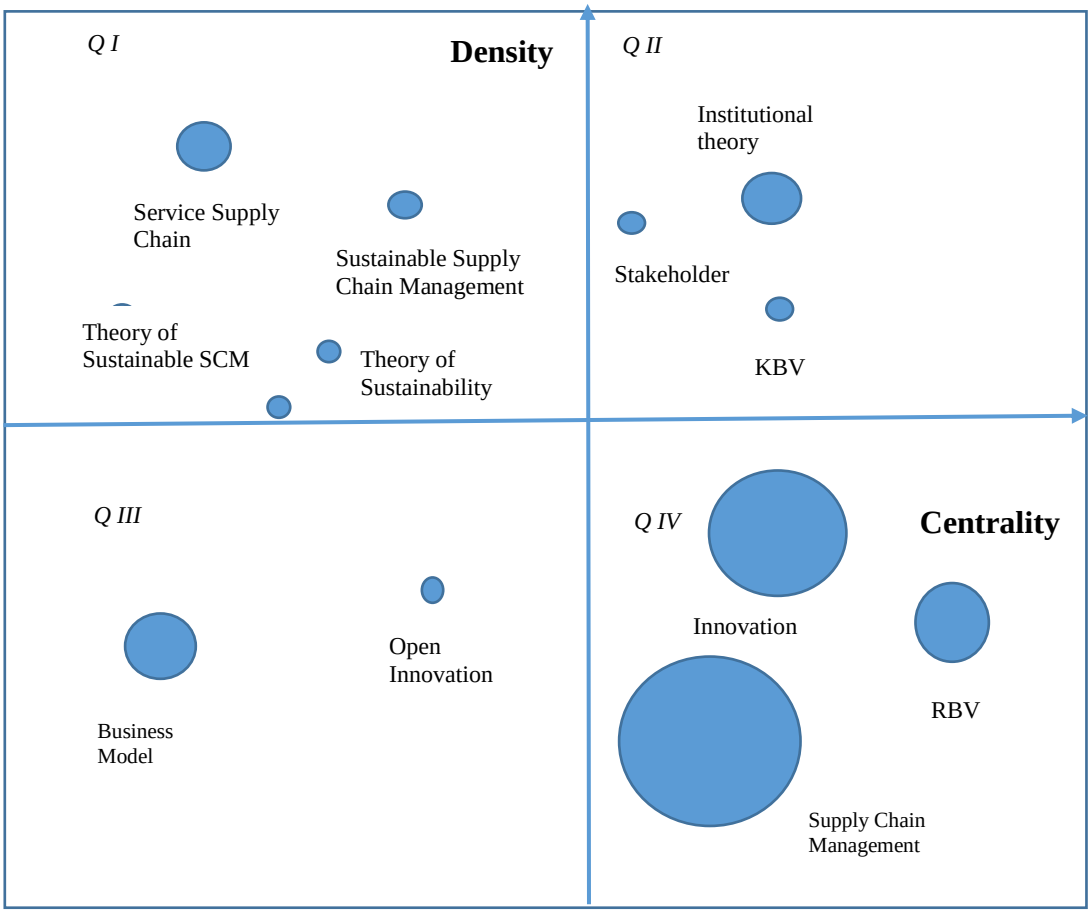
Using the code co-occurrence tool, information about the proximity of codes within the abstracts was analysis to explore potential relationships among abstracts as well as between abstracts. The themes are mapped in Figure 2. The keywords with high frequency represent particular research topics while a cluster of keywords that form a pattern is a research area. In addition, the size of the circles represents the frequency of the concept in the abstracts and a proxy measure of the strength of the respective concept in research.

A further mapping of the major themes is highlighted in Figure 2. For the preliminary analysis, only a few representative concepts are mapped to provide an overview of the different research areas and potential for further study. These are mapped into quadrants outlined in Figure 2. Figure 2 highlights *density* and *centrality* on the x- and y-axis, respectively. Density is the strength of the links that tie the keywords together. Density is the measure of the theme's development. The higher the density, the more coherent is the thematic cluster. Therefore, the y-axis (Density) represents the strength of development of the particular theme.

Centrality is the degree of interaction of a theme with other themes within the network of the keywords. Essentially, centrality represents the interaction and strength of the interaction to each other. The higher the number and proximity of a theme to other themes, the more central the theme or the more important is the theme to the development of the research field. This approach is adapted from Liu, Goncalves, Ferreira, Xiao, Hosio, Kostakos (2014). A description of the keywords and placement within the four quadrants follows:

- *Quadrant I* (top-left): These themes are not very well developed; they may have little interest to the research field outside of their particular area currently. In fact, they may represent emerging themes (e.g. theory of sustainable supply chain management).
- *Quadrant II* (top-right): These themes are internally well structured and indicate high activity research (e.g. institutional theory). However, their connections to other areas are relatively specialized and may not be valuable to the overall research field (e.g. stakeholder theory).
- *Quadrant III* (bottom-left): The main research in these is not well developed. However, they have considerable significance to the research area if a solid link is established (e.g. open innovation).
- *Quadrant IV* (bottom-right): These are themes that are well represented and core to the research field (e.g. RBV, supply chain management).

Figure 2: Quadrants (Adapted from: Liu et al., 2014)



Discussion

This abstract review points to some areas for a subsequent literature review. The ultimate objective is to contribute to academia and practice by synthesising extant literature which examines whether and how firms within a supply network leverage innovation to enhance their sustainability. A subsequent descriptive and thematic analysis offered deeper insights into the varying concepts and perceptions of the evolving nature of collaboration among organizations within the supply chain network. Given the concept of open innovation and the business model it imposes upon supply chain management, the nature of integration and collaboration may change thereby provoking new conceptual development. A discussion will also prompt the exploration of supply chain theory, which would include sustainability.

Open Innovation for Sustainable Supply Chain Management: A Research Agenda

There is abundant research on sustainable supply chain management and innovation independently, but very little which investigates how open innovation is implemented as a practice within supply chain management. Further, the abstracts and papers reviewed indicate the firm perspective and do not address the different levels associated with the *interfirm* approach associated with open innovation supply chain management. There could be, for example, different innovation incentives or characteristics at the different positions in the supply chain. Upstream may be more oriented towards product development, cost issues and IP. The downstream – closer to customer – may be associated with crowd sourcing and more into the customer domain. Accordingly, the interaction among the differences may affect the overall ability to achieve competitive advantage for a singular firm depending upon their

respective position. Arguably, a majority of companies would place the responsibility in the procurement/sourcing functions, which would have a cross-functional approach of coordinated strategy, governance and some collaboration across partners (still an economic-dominated model). A more integrated approach would combine the supply chain functions with pricing, marketing, quality and innovation. Sustainability in this sense may be defined by the customers or buyers. While many general theories provide insights into the thematic overlaps in the systematic literature review, it is possible that a mid-range approach within the scope of the popular general theories that would provide more explorative support for the adoption of open innovation in sustainable supply chain networks.

Open Innovation for Sustainable Supply Chain Management - Sustainability Theory Lens

There are some attempts to develop a theory of sustainable supply chain management from previous studies of 'green' supply chains (e.g. Carter and Rogers, 2008; Seuring and Müller, 2008; Pagell and Wu, 2009) but these developments are not consistent or they have not been taken up consistently. This inconsistency may be indicative of theory development in the initial stages but is also a result of a lack of defined concepts and measures associated with sustainability in the supply chain.

Moreover, theory development at this point is at the macro level in terms of examining identifying the general issues and relationships of concepts. Very few, studies examine the relationship between open innovation and sustainability within the supply chain network and *how* one may influence the other in enhancing competitive advantage. SCM and open innovation, however, are represented in the research to some degree, but not necessarily as conceptual or theoretical issues (Inauen and Schenker-Wicki, 2012). Open innovation provides the opportunity for a firm to outsource sustainability innovations to a third-party provider, Pagell and Wu (2009) theory of supply chain management indicates that supplier continuity is a differentiator for sustainable supply chain growth with third party providers. The abstracts and papers reviewed point to a more managerial focus providing opportunities to explore open innovation for sustainable supply chain management from a mid-range theoretical perspective to explore the following research question:

RQ: "How does a 3rd party open innovation provider align with the focal firm for sustainable supply chain management innovation?"

Open Innovation for Sustainable Supply Chain Management – A Network View

While innovation has been predominantly explored through a green and sustainable supply chain management has only begun to adopt a network view of environmental innovation activities (Dai, Cantor, Montabon, 2015). Carter and Rogers (2008) indicate the need to integrate population ecology, resource dependence, transaction cost economics, and a resource-based view of the firm, but fail to recognize the network of organizations that are necessary to implement environmental innovation. However, later exploratory research indicated the need to utilize network theory to explore the inter-firm, inter-functional approach necessary for environmental innovations to be extended throughout the supply chain. The diffusion of innovation has been a network phenomenon since the phrase was coined by Rogers (2008), this networked action of innovation diffusion and adoption is not only necessary for incremental innovations but also for radical environmental innovations that will be adopted throughout a supply chain. The radical environmental innovations that get adopted in a supply chain network are dependent on supply chain integration (with both suppliers and customers) in order to drive a competitive advantage (Dai et al. 2015). Open innovation provides a third party the opportunity to more quickly test and assimilate environmental innovations into slow moving and often slow to change larger organizations. If explored in a sustainable supply chain context, the adoption of both incremental and radical innovations has potential to function differently

within an open innovation context where third party integration is already in place. Thus, a research questions at the intersection open innovation and sustainable supply chain networks is as follows:
RQ: "How does open innovation impact the adoption and diffusion of environmental innovations in a sustainable supply chain network?"

Conclusion
This paper makes two key contributions: from an extensive literature review it identifies and ties together the business model approach of open innovation to supply chain sustainability theoretical development. This addresses the question of *how* open innovation can be used to develop sustainability in the supply chain. Second, it identifies research opportunities by outlining the 'common' concepts and relationships from the literature.

The sense and non-sense of (early) supplier involvement in NPD: a meta-analysis

Abstract

In this paper, we study supplier involvement in New Product Development (NPD). Prior research presents mixed empirical outcomes of supplier involvement and, in general, does not differentiate between NPD efficiency and NPD effectiveness. We aim to reconcile these issues by reconceptualizing the phenomenon along the dimensions of extensive and early supplier involvement and by meta-analytically assessing their effects on NPD efficiency and effectiveness, respectively. We conduct a systematic review and meta-analysis of the empirical literature from more than 4,315 unique projects to understand to what extent and when suppliers should be involved to achieve better NPD performance. Our findings show that more extensive supplier involvement, through delegation of design labor and tasks, contributes to both NPD efficiency and NPD effectiveness. On the other hand, earlier involvement of suppliers as such, for example in idea generation or concept development, does not contribute to product effectiveness but improves project efficiency somewhat. Hence, under constrained resources, managers can design more effective product development strategies by unraveling supplier involvement into the extent and the moment of the supplier's participation and selecting the most optimal strategy for achieving higher efficiency or effectiveness. In conclusion, this paper advances theorization on supplier involvement in NPD by carefully unraveling the construct into its constituent dimensions and analyzing their effects on NPD efficiency and effectiveness.

Keywords: Supplier Involvement, Meta-Analysis, Innovation

Competitive Paper

Introduction

Product innovation no longer takes place within the boundaries of the firm, but increasingly relies on others as external sources of knowledge (Un et al., 2010; von Hippel, 2007). Prominently featured among these external knowledge sources are a firm's suppliers. For example, automotive companies have increasingly turned to their first-tier suppliers to develop parts and components for new car models (Clark, 1989; Clark and Fujimoto, 1991; Johnsen, 2009). This idea of integrating upstream supply chain partners in product development has become known as 'Early Supplier Involvement'—which refers to buyer-supplier collaborations in developing new product ideas and concepts and to suppliers' execution of product development tasks (Monczka et al., 2000; Van Echtelt et al., 2008). For example, Boeing is collaborating with car seat manufacturer Adient to develop and manufacture seats for airlines, in order to cut delays in airplane delivery times (Hepher, 2018).

However, there are some puzzling issues in the literature that we aim to reconcile in this paper. Supplier involvement does not always lead to its intended effects (Eisenhardt and Tabrizi, 1995; Hartley et al., 1997; Hong et al., 2009). For example, Eisenhardt and Tabrizi (1995) show that early supplier involvement only contributes to project speed in mature industries. Furthermore, the extant literature uses a wide variety of terminology to describe the phenomenon of supplier involvement and it is not always easy to distinguish precisely between various aspects of supplier involvement and NPD performance. For example, Johnsen (2009, p. 187) writes that: "early and extensive supplier involvement in NPD projects has the potential to improve NPD effectiveness and efficiency". So which is it? We submit that supplier involvement and its effect on NPD performance can be more accurately understood by carefully unraveling the multidimensional nature of both constructs.

First, supplier involvement has been studied as the *extensive* (Clark, 1989; Wynstra et al., 2012) and as the *early* (LaBahn and Krapfel, 2000; McIvor and Humphreys, 2004; O'Neal, 1993) involvement of suppliers in developing new products (Johnsen, 2009). These two

dimensions of supplier involvement—as we will review next—have different historical and theoretical roots and may lead to different NPD outcomes.

Second, early research on supplier involvement mainly analyzed the impact on NPD efficiency, such as time-to-market and development cost (Brown and Eisenhardt, 1995; Clark, 1989) but later research also examined the effects on NPD effectiveness, such as product quality and market share (Hoegl and Wagner, 2005; Petersen et al., 2003; Swink, 1999). The extant literature treats the effects of supplier involvement on NPD efficiency and effectiveness as essentially the same (Hoegl and Wagner, 2005; Johnsen, 2009; Primo and Amundson, 2002). However, different streams of research on product development focus on NPD efficiency or effectiveness, respectively, and certain product development practices, such as supplier involvement, may affect just one aspect of NPD performance (Brown and Eisenhardt, 1995; Eisenhardt and Tabrizi, 1995).

In this paper, we employ meta-analysis to pool empirical evidence from prior research and to provide an integrative perspective on the relationship between supplier involvement and NPD performance. With the current empirical evidence painting a blurred image (Johnsen, 2009) and case studies showing that achieving successful supplier involvement is difficult (Bonaccorsi and Lipparini, 1994; Wynstra and Ten Pierick, 2000), managerial practice cannot be properly advised. With this study, we advance a more complete conceptualization of supplier involvement to inform scholarly theorization and managerial understanding.

Theory

Starting with the work of Clark (and others), the phenomenon of supplier involvement was sparked by the observation that Japanese automotive companies outperform their Western counterparts in time-to-market and development cost (Clark, 1989; Clark and Fujimoto, 1991; Iansiti and Clark, 1994). The explanation for this observed difference was found in the extensive use of supplier engineers on OEM's product development projects. That is, the managerial practice of supplier involvement was discovered by academia due to a performance gap in New Product Development (NPD) performance. Many other comparative studies were conducted in the early years (e.g., Liker et al., 1996). Later studies started to differentiate between *extensive* and *early* supplier involvement (Bidault et al., 1998a; Hartley et al., 1997; see also Johnsen, 2009). Rather than the extensive use of supplier engineers and the outsourcing of design tasks to suppliers, involvement of suppliers in (very) early phases of new product development allows ideas and new product concepts to flow freely between the buyer and its suppliers (Handfield et al., 1999; Parker et al., 2008). The terminology Early Supplier Involvement has become ubiquitous, as evidenced by book (chapter) titles and many articles (Dowlatshahi, 1998; LaBahn and Krapfel, 2000; McIvor and Humphreys, 2004; O'Neal, 1993; Zsidisin and Smith, 2005). The two dimensions of involvement —extensive and early—have been used interchangeably, are discussed using varying terminology, and are often not hypothesized to differentially affect NPD performance (Dowlatshahi, 1998; Hartley et al., 1997; Koufteros et al., 2010, 2007).

In the next sections, we therefore disentangle the two dimensions of supplier involvement—extent and moment—and develop hypotheses for their relationships to NPD performance. For present purposes, we differentiate between NPD performance as the success of the project and the success of the product, which are naturally related but not quite the same. (Brown and Eisenhardt, 1995; Hoegl and Wagner, 2005). NPD efficiency refers to the adherence to project targets and the use of fewer project resources such as financial resources and time (Hoegl and Wagner, 2005). In contrast, NPD effectiveness refers to the resulting product's quality and economic success (Hoegl and Wagner, 2005; Olson et al., 1995).

Extent of Supplier Involvement

Extent of supplier involvement refers to the division of labor and tasks between the buyer and suppliers as measured by supplier design responsibility (Azadegan and Dooley, 2010; Hartley et al., 1997; Van Echtelt et al., 2008; Wynstra et al., 2012). Outsourcing part of the design and development work to suppliers, presuming they already perform manufacturing tasks for similar components/products, increases efficiency because OEM's can save on development cost by reducing (in-house) expenditure of man-hours and can reach faster time-to-market by concurrent engineering (Eisenhardt and Tabrizi, 1995; Eppinger et al., 1994). In particular, involving suppliers in this way allows the buyer to leverage their development capabilities to its advantage.

The expected effect of extent of supplier involvement on NPD performance is highly grounded in practical observations rather than hypothesized from a (grand) theoretical foundation. For example, the observed gap in NPD efficiency between Japanese and US automakers sparked a large stream of research on supplier involvement (Clark, 1989; Clark and Fujimoto, 1991; Liker et al., 1996). The phenomenon of supplier involvement therefore represents a 'theory-in-use' or 'technological rule' (Argyris and Schon, 1974; van Aken, 2004). In particular, the theory accepted in practice, derived from the outperforming Japanese automotive companies, reads something like: 'if you want to achieve faster time-to-market and lower development cost in NPD, you should involve your suppliers extensively by delegating development labor and tasks'.

By relying on suppliers for the development of new parts, components, or (sub-)systems, buyers can leverage their suppliers' knowledge, technology, and development capabilities. Delegating design and development of core components to suppliers is in part about outsourcing the design work itself, which is more efficient than conducting it in-house, in particular with highly specialized and (technologically) capable suppliers (Clark, 1989; Iansiti and Clark, 1994). Furthermore, the buying firm is typically not interested in acquiring knowledge, but rather in applying it for the specific purpose of developing a new product (Grant and Baden-Fuller, 2004). A higher extent of supplier involvement, with substantial supplier responsibility for developing detailed specifications for a component, allows the buyer to leverage supplier development capabilities and efficiently translate the supplier's knowledge and expertise into product specifications and component blueprints (Koufteros et al., 2007; LaBahn and Krapfel, 2000).

Note that many empirical studies on extent of supplier involvement—and more importantly, their theoretical argumentation—find effects on NPD efficiency: faster time-to-market (Callahan and Moretton, 2001; Clark, 1989), lower development cost (Hoegl and Wagner, 2005), and fewer in-house man-hours spent on development (Clark, 1989). All early studies from the 1980s and 1990s on supplier involvement focus on NPD efficiency (see Johnsen, 2009, p. 188–189, Tables 1 and 2). As delegating design and development to suppliers reduces in-house expenditures on development and leverages the supplier's development capabilities, we develop the following hypothesis:

H1: *A higher extent of supplier involvement is positively related to NPD efficiency.*

Moment of Supplier Involvement

Another stream of literature has focused instead on what has become known as 'Early Supplier Involvement'. While this terminology has a broad connotation and has been used to refer to a range of supplier involvement practices (Bidault et al., 1998b; Dowlatshahi, 1998; LaBahn and Krapfel, 2000; McIvor and Humphreys, 2004; O'Neal, 1993), it is operationalized in the empirical literature by one specific measure. The *moment of supplier involvement* is the earliest of the five phases of product development, initially proposed by Handfield et al. (1999),

in which a supplier is involved. In studies on the *timing* of supplier integration (Hartley et al., 1997; Parker et al., 2008) or simply *early* supplier involvement (Dowlatshahi, 1998; LaBahn and Krapfel, 2000; Zsidisin and Smith, 2005), the exact same or highly similar conceptualization of phases of product development is employed.

Early involvement allows buyers to have informal and social interaction with their suppliers during idea generation and product concept development. The transfer of (organizational) knowledge from suppliers to buyers for the specific purpose of developing a new product is strengthened by social interaction between individuals (Fey and Birkinshaw, 2005; Nonaka, 1994). Upstream supply chain partners are recognized as a valuable external source of knowledge (Un et al., 2010) and involving them early allows the buyer to tap into suppliers' ideas, product concepts, and technologies.

Hence, buyer's product ideas and concepts may benefit from the early involvement of suppliers, ultimately leading to better commercialized products (Koufteros et al., 2010), higher product quality (Yan and Kull, 2015), and lower product costs or better profit margins (Chien and Chen, 2010). An earlier moment of supplier involvement is therefore expected to contribute to NPD effectiveness—rather than efficiency. Supplier's ideas and suggestions may result in better product concepts and designs that ultimately proof valuable in the market. Again, the theoretical foundation for expecting this relationship is deeply grounded in practical observations and is analogous to a theory-in-use or technological rule: 'if you want to achieve better products, you should involve your suppliers in earlier stages of new product development'. Based on the perspective of social interaction in knowledge transfer (Fey and Birkinshaw, 2005; Nonaka, 1994), this can also be effectively translated into the following hypothesis:

H2*: An earlier moment of supplier involvement is positively related to NPD effectiveness.*

Conceptual Model

Based on the hypotheses introduced above, we can now derive the following conceptual model, see Figure 1. The model depicts the expected effects of more extensive and earlier involvement of suppliers on NPD efficiency and effectiveness, respectively. The model also depicts that, as some of the literature suggest, the dimensions can affect both NPD efficiency and effectiveness, which we discuss in detail next to derive further hypotheses. Furthermore, the model shows that the dimensions of involvement are interrelated, which we discuss thereafter.

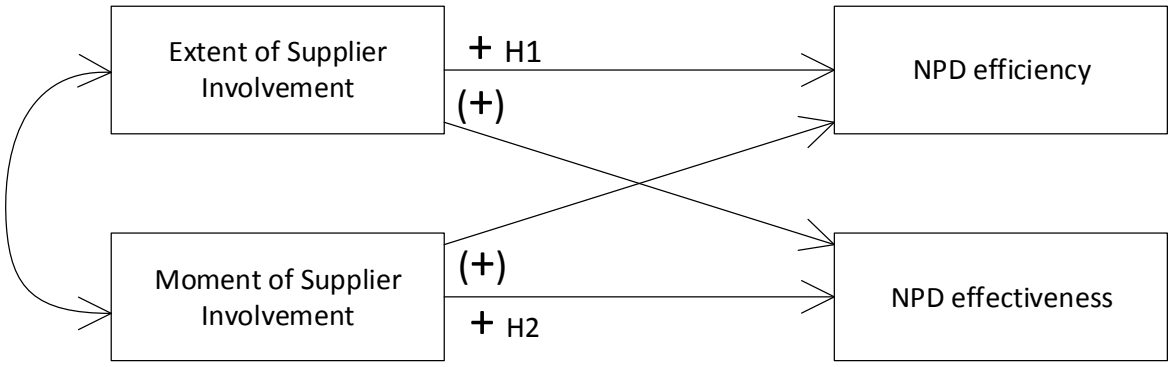

Figure 1. Conceptual Model.

NPD Efficiency and Effectiveness

First, as already briefly highlighted, a number of studies also examine the effect of delegating design and development responsibility to suppliers on product quality, market

success, and other aspects of NPD effectiveness. Most of these studies invoke the same argumentation for expecting positive effects of supplier involvement on NPD efficiency as effectiveness (Hoegl and Wagner, 2005; Johnsen, 2009; Primo and Amundson, 2002; Ragatz et al., 2002). When the manufacturing of critical product components is already outsourced to suppliers, an equally large role of suppliers in developing new components leads to the more effective integration of their (operational) knowledge in the component specifications. However, it is not exactly clear how well developed components lead to better products. In fact, coordinating disconnected sub-projects and integrating these effectively into new products can be quite challenging (Hong and Hartley, 2011; Lakemond et al., 2006). Still, in buyer-supplier collaborations for the development of new components, knowledge may also spill-over to the development of the overall product through social interaction (Nonaka, 1994) between buyer and supplier engineers. Therefore, we expect the extent of supplier involvement to also positively impact NPD effectiveness, though this effect can be smaller than its effect on NPD efficiency.

H3a: *The extent of supplier involvement is positively related to NPD effectiveness but* ***b)*** *this relationship is smaller than its effect on NPD efficiency.*

Second, several studies examine the effect of the moment of supplier involvement on NPD efficiency (e.g., Eisenhardt and Tabrizi, 1995; Koufteros et al., 2010; Laseter and Ramdas, 2002; Yan and Kull, 2015). If suppliers are involved earlier, technical and manufacturability issues can be discovered sooner, which makes them easier to fix (Eisenhardt and Tabrizi, 1995; Swink, 1999). Early discovery of potential problems with product concepts or their technical execution potentially prevents late—hence costly and difficult—changes to the product specifications or delays in operations ramp-up (Swink, 1999). On the other hand, involving suppliers early to discuss new product ideas and concepts may add substantially to project duration and can be costly to manage (Hartley et al., 1997; Wynstra et al., 2012). Thus, to the extent that late discovery of problems can be prevented, earlier supplier involvement may also positively contribute to NPD efficiency, but most likely less than to NPD effectiveness.

H4.a: *The moment of supplier involvement is positively related to NPD efficiency but* ***b)*** *this effect is smaller than its effect on NPD effectiveness.*

Interrelationship between Extent and Moment of Supplier Involvement

So far, we have discussed the extent and the moment of supplier involvement separately. However, despite the different theoretical and historical roots of these dimensions, some scholars have treated them as interrelated or have not precisely distinguished between the two (Jayaram, 2008; Jean et al., 2014). Some studies have argued that the timing of a supplier's involvement should be based on the level of design responsibility it receives (Bidault et al., 1998a; Monczka et al., 2000). In particular, when a supplier assumes a large role in developing components, it should also be involved in relatively earlier stages of the project, for example using a project integration approach (Lakemond et al., 2006). This suggests a perfect correlation between the extent and the moment of supplier involvement.

However, not all suppliers should be involved extensively ánd early per se. Given the aim of this review to develop a more complete understanding of the supplier involvement phenomenon, we aim to analyze this interrelationship empirically. Based on the discussion above, we expect that there will be a positive interrelationship between the extent and the moment of supplier involvement ($r \neq 0$), but that this relationship will not be perfect ($r < 1$).

Methods

We employ meta-analysis as an empirical research method to test our hypotheses. Meta-analysis is a research methodology and statistical technique for integrating previous empirical findings, pooling the data, and summarizing and exploring the evidence. Thus, by relying on previous research for the data, meta-analysis can achieve a large number of observations, much larger than any single study in the sample achieves. For the sake of brevity, we present the methodology for sampling and selecting studies in Figure 2.

We conducted a key-word search in major databases to discover a wide range of studies on supplier involvement and added studies from a few other sources. We then filtered these studies based on titles and abstracts and excluded irrelevant studies (not about supplier involvement) and all qualitative inquiries (case studies, etc). Finally, based on an analysis of the full text of the remaining papers, we included 27 studies, with 29 independent samples, in the meta-analysis. These studies were selected because they include constructs and measures that match our definitions—see Appendix A—and present the results using effect sizes.

Data extraction

The main parameter of interest from the primary studies is the effect sizes. As most empirical evidence in this field is gathered using survey research, typical effect sizes are the correlation coefficient r and the regression coefficient β (Lipsey and Wilson, 2001). Along with the correlation coefficient, the sample size of each study was extracted, which is used to estimate sampling error and weigh the effect sizes accordingly. Based on the information available from the primary studies, we also coded the research methods and data collection. Specifically, we used dummy variables to code whether zero-order correlations or regression coefficients were reported and whether a single or multiple sources (informants) were used to gather data. Furthermore, we coded the data collection year or publication year. We use these control variables to examine whether research characteristics explain the observed heterogeneity in effect sizes.

Data analysis

We employ meta-analysis and meta-regression (MARA) to statistically analyze the effects of supplier involvement on NPD performance (Hedges and Olkin, 1985). First, we conduct random-effects meta-analysis to estimate the average effect of each dimension of supplier involvement on NPD performance and on NPD efficiency and effectiveness respectively. When multiple effect sizes are available from a single sample, the interdependency between these effects are modelled in specifying the random effects models. Hence, effects from the same sample are clustered first into a composite, before including the cluster as a unit in the meta-analysis (Viechtbauer, 2010). However, they may be decomposed into separate effect sizes when they represent different relations in the model, e.g., different NPD outcomes.

If the average effects are heterogeneously distributed, meaning that the individual effects are estimates of different underlying true effects, a search for moderators can be conducted using meta-regression. To conduct meta-regression, we employ a weighted least squares (WLS) regression using mixed effect modelling (Geyskens et al., 2008; Lipsey and Wilson, 2001) of the reported effect size on a number of moderating variables, for example the research methodology control variables identified above. These moderators are thus operationalized to vary across studies and we use meta-regression to explore the between-study variance in effect sizes.

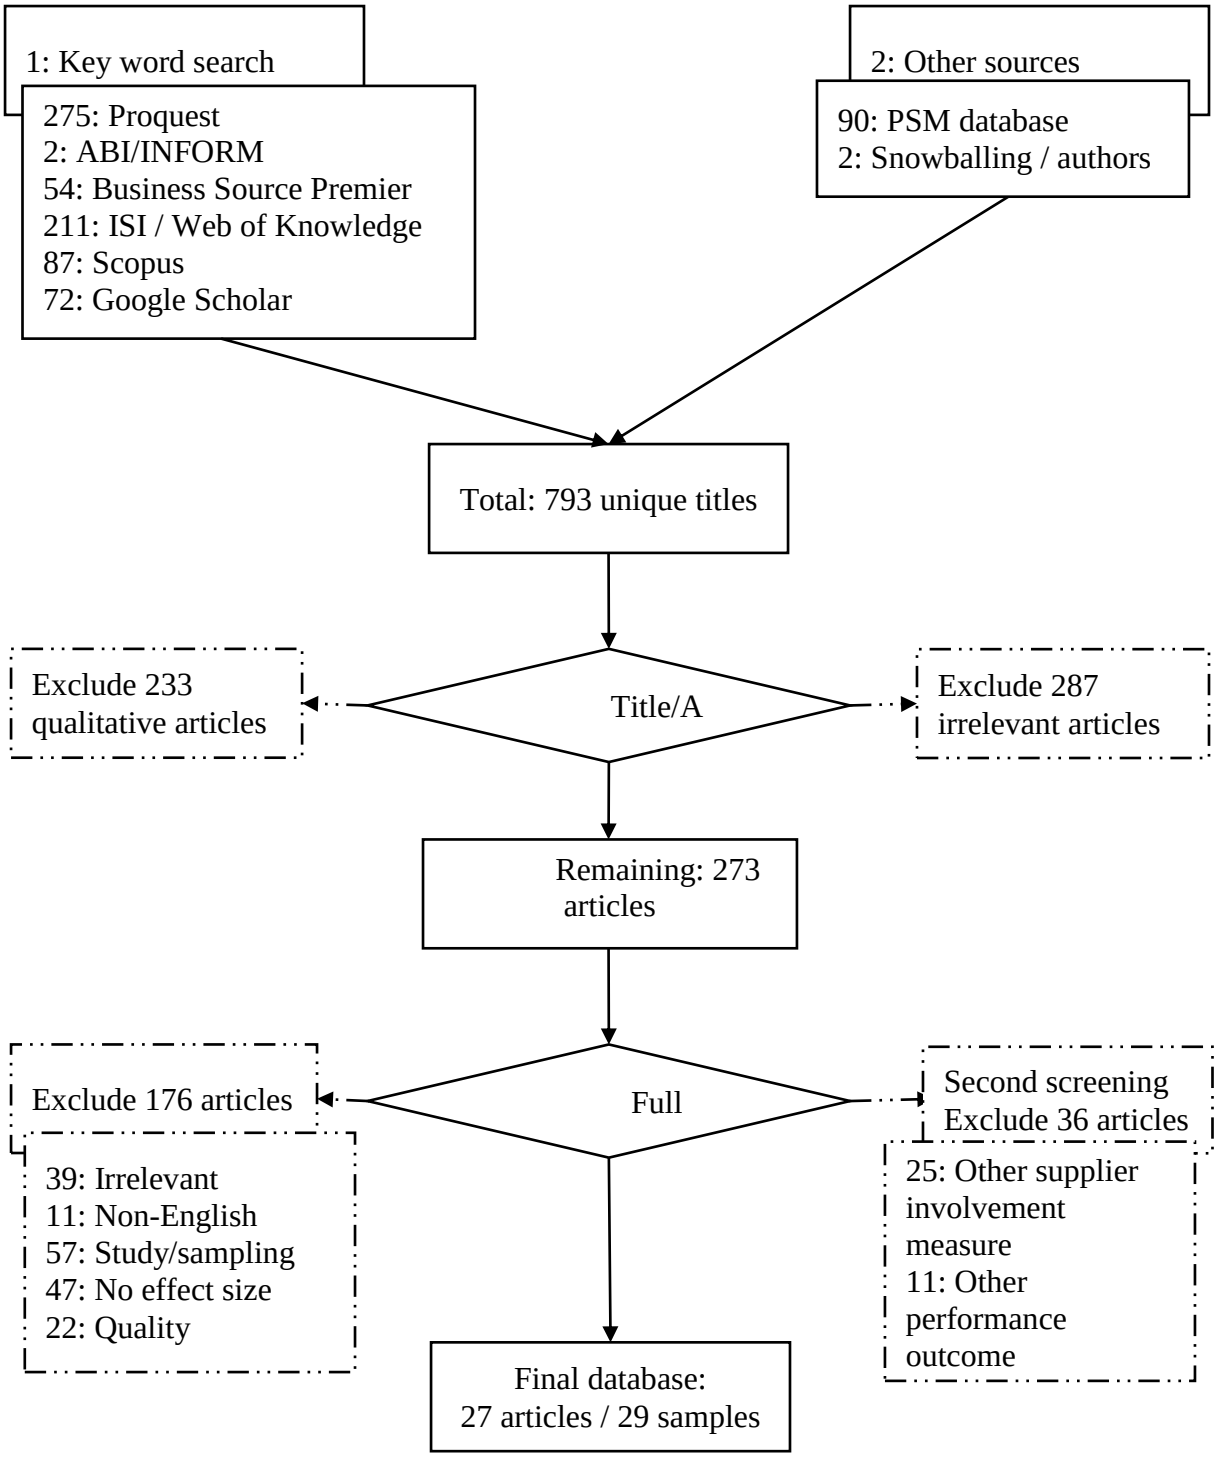

Figure 2. Sampling and selection of the literature.

Results

In this meta-analysis, we study the effect of the extent and the moment of supplier involvement on NPD efficiency and effectiveness. Therefore, we run a random effects model on the correlation coefficients between the two dimensions of supplier involvement and the two facets of NPD performance. The correlation coefficients originate from 27 primary studies (29 independent samples) and are based on a total sample size of 4,315 projects, with over 10,000 observed relations. The results from the main meta-analysis are presented in Table 1, which shows the findings of this meta-analysis for different subgroups—as in the model.

Table 1. Meta-analytical correlation coefficients

	k	N	r	95% CI	Cred Int	Q	Fn
Relationship with NPD performance							
Supplier Involvement	58 (29)	4,315	0.155	0.100; 0.209	-0.131; 0.441	183.26 *	5455
Extent of Involvement	41 (22)	3,691	0.190 [a]	0.121; 0.258	-0.107; 0.457	131.11 *	3496
Moment of Involvement	17 (10)	1,343	0.132 [a]	0.048; 0.214	-0.087; 0.339	46.07 *	202
Relationship with NPD efficiency							
Supplier Involvement	21 (18)	2,877	0.161	0.088; 0.233	-0.092; 0.395	51.72 *	563
Extent of Involvement (H1)	13 (12)	2,203	0.204 [b]	0.115; 0.290	-0.057; 0.439	33.81 *	321
Moment of Involvement (H4a)	8 (8)	976	0.114 [c]	0.010; 0.217	-0.095; 0.314	13.56	27
Relationship with NPD effectiveness							
Supplier Involvement	32 (20)	3,775	0.140	0.080; 0.200	-0.091; 0.358	94.99 *	1419
Extent of Involvement (H3a)	24 (16)	3,223	0.156 [b]	0.088; 0.223	-0.087; 0.381	66.91 *	972
Moment of Involvement (H2)	8 (6)	994	0.095 [c]	-0.015; 0.203	-0.130; 0.311	25.70 *	NA

*Note. k: number of effect sizes (number of independent samples). N: total number of observations. r: meta-analytical average correlation coefficient. 95% CI: 95% confidence interval. Cred Int: 80% credibility interval. Q: observed heterogeneity; the asterisk * indicates significant heterogeneity with p < 0.01. Fn = Rosenthal's failsafe N. a: difference between these correlation coefficients is significant at α = 0.10: $t_{(52)} = 1.865$, p = 0.069. b: difference between these correlation coefficients (H3b) is insignificant: $t_{(36)} = -1.224$, p = 0.229. c: difference between these correlation coefficients (H4b) is insignificant: $t_{(15)} = -1.214$, p = 0.245.*

Our findings show that extent of supplier involvement is positively related to NPD efficiency, in support of Hypothesis 1. As expected, delegating more responsibility for design and development tasks to suppliers is positively related to higher levels of efficiency in the NPD project, such as faster time-to-market and lower development cost.

Surprisingly, the results of the meta-analysis do not support Hypothesis 2: there is no positive relationship between earlier moment of supplier involvement and NPD effectiveness. That is, involving suppliers in earlier phases of the project, such as idea generation and concept development, does not lead to higher quality products or higher market shares.

The results additionally provide support for Hypothesis 3a: the extent of supplier involvement is also positively related to NPD effectiveness. That is, for projects in which a larger share of development responsibilities were delegated to suppliers, we observe higher product quality and market shares. We do not find support for H3b because extent of supplier involvement does not have a significantly higher effect on efficiency than on effectiveness, see Table 1 note b, while the difference is in the expected direction.

Our findings also provide support for Hypothesis 4a: the moment of supplier involvement is positively related to NPD efficiency. In other words, involving suppliers in earlier phases is related to faster time-to-market and lower development cost. We do not find support for H4b because moment of supplier involvement does not have a significantly higher effect on effectiveness than on efficiency, see Table 1 note c. In fact, the difference is in the

opposite direction and, as H2 is rejected, there is no positive contribution to effectiveness at all.

Meta-regression analysis

The results are confirmed by the meta-regression results presented in Table 2. In this analysis, all correlations between supplier involvement and NPD performance are included—as in the top line of Table 1—except the 'mixed' NPD performance category. We then perform a regression of these effects on several moderators. The moderators include a dummy variable for the dimensions of involvement (extent, moment) and a dummy variable for the facets of NPD performance (efficiency, effectiveness). Table 2 provides unstandardized regression coefficients with their 95% confidence intervals for each of the moderators.

The results in Table 2 shows that the extent of supplier involvement is more positively related to NPD performance than moment of supplier involvement. The two dimensions of supplier involvement have a differential effect on performance, because the effect of extent of involvement is typically larger and because moment of involvement does not affect NPD effectiveness. We furthermore find that effect sizes derived from partial correlations—hence, controlled for other variables—are typically smaller than zero-order correlations. The other moderators included in the model are not significant. Overall, we find that the heterogeneity in effect sizes, which is the cause of the reported mixed findings in the literature, can be explained—in part—by unraveling supplier involvement and its effects on NPD performance.

Table 2. Meta-regression: Relationship between supplier involvement and NPD performance

Moderator	Coefficient (95% CI)
Intercept	0.079 (-0.187; 0.345)
Extent of involvement (vs Moment)	*0.064 (-0.005; 0.134)†*
NPD effectiveness (vs. efficiency)	-0.036 (-0.103; 0.030)
Control variables	
Multiple sources	-0.004 (-0.113; 0.106)
Partial correlations	*-0.138 (-0.281; -0.004)†*
Year (1987 = 0)	0.003 (-0.008; 0.015)
Number of effect sizes (samples)	k = 53 (26)
Residual heterogeneity	$QE_{(df = 45)} = 122.104$, $p<0.001$
Test of moderators	$F_{(5, 47)} = 1.877$, $p = 0.116$

Note. † indicates significant moderation at α = 0.10.

Interrelationship between extent and moment of supplier involvement

We also collected data from three studies that report results for both dimensions of supplier involvement and additionally also include information for the relationship between the two dimensions (e.g., Koufteros et al., 2010). These studies, in summary, find that the two dimensions of involvement are positively related (r=0.415, $p<0.001$). The 95% confidence interval for this effect ranges from $r = 0.34$ to $r = 0.48$. This means that, on average, suppliers that are involved more extensively by partaking in design and development tasks are also involved in earlier stages. On the other hand, the correlation is only medium-sized (Cohen, 1977), so at least some suppliers assume significant development responsibility without necessarily being involved in the earliest stages of the overall project, or vice versa.

Discussion

In this study, we examined the effect of supplier involvement on New Product Development (NPD) performance through a meta-analysis. We systematically collected and reviewed the body of literature on this topic to create a better understanding of the concept of supplier involvement and the ways in which supplier involvement can improve NPD performance. While this research is not the first, or the last, to study supplier involvement in new product development, we provide new impetus for advancing scholarly theorization based on a careful examination of extensive and early supplier involvement and their effects on NPD efficiency and NPD effectiveness.

Theoretical implications

In this study, we unravel the two dimensions of supplier involvement and their effects on NPD efficiency and NPD effectiveness. Extant research under the 'Early Supplier Involvement' terminology has examined the effects of both extensive and early involvement of suppliers in developing new products (Bidault et al., 1998b; Hartley et al., 1997; Johnsen, 2009; Monczka et al., 2000). Our analyses show that the two dimensions affect NPD performance in different ways.

Extensive supplier involvement, in which responsibility for component design and development is delegated to suppliers, is related to higher levels of NPD efficiency and effectiveness. That is, projects in which suppliers contribute with engineering hours benefit with faster time-to-market and lower development cost (e.g., Clark, 1989), as well as higher quality and market advantage of the resulting product (e.g., Salvador and Villena, 2013). The effect on efficiency can be understood from the perspective of leveraging development capabilities and concurrent engineering (Clark, 1989; Eppinger et al., 1994; Koufteros et al., 2007): supplier knowledge and expertise is most efficiently translated into component specifications by allowing suppliers to co-develop these specifications. On the other hand, we also find that the end product itself can be improved through supplier integration in component development. First, superior components in itself may positively impact product quality and advantage. Secondly, supplier knowledge may spill-over to the development of the overall product specifications, which is strengthened by the collaborative nature of specification development, and ultimately results in better performing products (Hong and Hartley, 2011; Nonaka, 1994).

On the other hand, early supplier involvement, in which suppliers can contribute to product ideas and concepts, contributes to NPD efficiency but not effectiveness. That is, projects in which suppliers are involved earlier reach faster time-to-market and lower development cost, but do not ultimately produce better products. Suppliers' feedback on the buyer's initial idea and concept can quickly solve any technical issues that are costly to solve later in the project (Koufteros et al., 2010; Swink, 1999). Hence, when development risk is high, early supplier involvement—irrespective of the extensiveness—may lead to faster development time and lower cost (Wynstra and Ten Pierick, 2000).

We expected earlier supplier involvement to lead to better products because suppliers may have creative ideas and technical solutions, which, by integrating them early on in the buyer's idea generation and concept development stages, should produce higher quality products that are more attractive to consumers. There are some potential explanations for not finding this effect that future research may examine in more detail. First, suppliers may act opportunistically when buyers ask them to contribute ideas and concepts (Yan and Kull, 2015). For example, they may submit off-the-shelf solutions that appear innovative, but which are not technically superior to the buyer's current product. Second, it is possible that early involvement of component suppliers leads to better components, but that the overall system quality depends critically on the buyer's management of the difficult multi-party development project (Hong

and Hartley, 2011). For example, suppliers may propose suggestions for the buyer's product that enable higher performance of their components, but which are difficult to integrate into the overall product. If separate development tasks are relatively interdependent, earlier supplier involvement may contribute to the more efficient development of each of these tasks, but may hurt the integrated product's quality. Finally, suppliers may not have the relevant market intelligence to propose worthwhile ideas—after all, their business is selling components to business customers and not assembling or producing or marketing (consumer) end products.

Finally, we examined the interrelationship between the extent and the moment of supplier involvement. This relationship is positive, meaning that suppliers which assume responsibility for design and development are also involved earlier in the project, on average. However, the two dimensions of involvement are not correlated perfectly and should therefore be treated as two different aspects. For example, with the observed meta-analytic correlation coefficient ($r = 0.415$), the two dimensions of involvement should not be included in the same latent construct in a measurement model (Anderson and Gerbing, 1988). The extant research, on the other hand, has sometimes used the dimensions as interchangeable labels (Eisenhardt and Tabrizi, 1995; Jean et al., 2014; Primo and Amundson, 2002). As our findings show, distinguishing supplier involvement into extent and moment of involvement provides a more precise understanding of its effects on NPD efficiency and effectiveness. Thereby, it provides a more precise theorization of the phenomenon, resolving the apparent inconsistencies in the findings of empirical studies so far.

Practical implications

Building on the results from this review of the extant literature, we can derive the following practical recommendations. First, our findings allow us to develop more specific recommendations based on two distinct practices of supplier involvement. Managers that delegate design and development responsibility to suppliers achieve more efficient and effective product development. Managers that (only) involve suppliers early, may be able to achieve higher efficiency, but not better products. Secondly, if it is important to realize a fast time-to-market, both more extensive and earlier supplier involvement can help. However, if product quality or market performance are top priority, only delegating development responsibility to suppliers reaches the desired goals. This means that managers can strategically manage their supplier involvement: per component, per supplier, and per project.

Limitations

In this meta-analysis, the empirical evidence for testing the hypotheses comes from the underlying primary studies. This means that the limitations of these studies also affect the quality and validity of our findings (Bergh et al., 2016). In particular, concerns can be raised regarding endogeneity and common method bias (Ketchen et al., 2017; Roberts and Whited, 2013), as most of the data originates from cross-sectional studies with self-administered questionnaires and a single respondent for each case. Despite these weaknesses, there is some theoretical and empirical support to ground the conclusions. In particular, there is a (albeit conceptual) temporal difference between the decision to involve suppliers in NPD and the outcomes of the NPD effort, which suggests that causality cannot run in the opposite direction. Furthermore, there are no significant differences between single versus multiple informants per case, see Table 2.

The narrow focus of this meta-analysis allows us to reconceptualize supplier involvement at a detailed level. However, this also means that the set of available studies that capture either or both dimensions of supplier involvement as well as a relevant NPD outcome is more limited and somewhat smaller than in a typical meta-analysis (e.g., Zimmermann and Foerstl, 2014). Nonetheless, the amount of studies *per relationship* is somewhat comparable to

other recent meta-analyses in the field (Leuschner et al., 2014, 2013) and the total sample size in terms of development projects is much larger than primary empirical studies.

Future research

Beyond the direct suggestions from our findings as discussed in the theoretical implications, our review also allows us to describe some gaps in the literature. First, future research is required to understand how multiple suppliers can effectively be integrated in product development and how their interaction and interdependencies should be managed, as only a few studies have looked at this issue (e.g., Azadegan and Dooley, 2010; Hong and Hartley, 2011; Petersen et al., 2005). Other research has suggested that supplier capabilities or the prior history with the supplier are antecedents of supplier involvement, which is another promising avenue for research that is yet to be more fully explored (Carson, 2007; Hoegl and Wagner, 2005). Finally, most research on supplier involvement focusses on the effects on the buyer's NPD project and the final product, but it may be fruitful to also examine organizational level effects (e.g., Koufteros et al., 2007) or the effects on the supplier's and the component's performance (e.g., Jean et al., 2014; Takeishi, 2002).

Appendix A: Concepts, Definitions and Exemplary Measurement Items.

Concept and definition	Exemplary measurement item(s)
Moment of supplier involvement: The phase of the buyer's NPD project in which the supplier(s) is/are first consulted.	**Timing**: *The earliest phase at which the supplier became involved in the NPD effort* (Parker et al., 2008, p. 76). **Timing**: *How much earlier than the start of production a supplier is involved in product development* (Laseter and Ramdas, 2002, p. 110).
Extent of supplier involvement: The degree to which the design and development tasks of the NPD project are delegated to suppliers.	**Supplier development responsibility**: *This supplier's level of design responsibility during the early/middle/late stages of the final product* (Azadegan and Dooley, 2010, p. 502). **Degree of outsourcing NPD**: *Percentage of total labor provided by outside suppliers/partners. The degree to which outsourcing design activities was used on the project* (Swink 1999, p. 700).
NPD Efficiency: the adherence to project targets and the use of fewer project resources such as financial resources and time	**Speed to market**: *Slower than industry norm/faster than industry norm. Much slower than we expected/much faster than we expected. Far behind our time goals/far ahead of our time goals. Slower than our typical product development time/faster than our typical product development time* (Zhao et al., 2014, p. 1062). **Development budget**: *For measuring project performance, we collected data .. from company records in terms of [among others] development budget: the percentage above/below budgeted development cost* (Hoegl & Wagner, 2005, p. 537). **Project performance:** *assessed using four commonly used items reflecting time-to-market, technical performance, unit manufacturing cost, and R&D budget as measured relative to goals* (Misha & Shah, 2009, p. 330).
NPD Effectiveness: the resulting product's quality and economic success	**Product Technical Performance** *was measured based on two items. We asked the NPD member to rate the durability and functionality of the new product compared with products designed by competitors* (Salvador and Villena, 2013, p. 95). **Market Success** *(compared to the industry, our product): Fit target customers better. Has more loyal customers. Generated more new customers. Was more successful in the marketplace.* (Koufteros et al., 2010, p. 66). **New Product Advantage:** Offered unique features or attributes to the customer. Was clearly superior in terms of meeting customers' needs. Offered higher quality—tighter specs, stronger, lasted longer, or more reliable. Had superior technical performance. (Potter and Lawson, 2013, p. 808)

Buyer-supplier co-development of business service specifications in the sourcing process

Buyer-supplier co-development of business service specifications in the sourcing process

Abstract

In this paper, we study the process of buying business services and the role that suppliers play in the specification and definition. Previous research argues that buyers of business services should involve (potential) suppliers in the sourcing process due to their superior knowledge and expertise. When buyers have routinely outsourced the production and delivery of important supporting services to external suppliers, they may also have lost the organizational capabilities and knowledge required for properly developing the service specifications to be procured. Hence, in order to benefit from the suppliers' experience, suppliers should be involved early and extensively in the development of service specifications. In this project, we collect data on specific buyer-supplier relationships for facility services (indirect, business-to-business services) with the help of an industry organization in The Netherlands. We study the effect of supplier involvement on business service quality as experienced by the buying firm. Results show that both earlier and more extensive involvement of suppliers in the sourcing process has a positive effect on business service quality. This study contributes to advancing our collective understanding of the role supplier involvement can play in buying business-to-business services.

Competitive Paper

Keywords: Supplier Involvement, Business-to-Business Services, Quality.

Introduction

Buying business services has been recognized as a difficult sourcing process, in part because buyers experience high levels of uncertainty (Wynstra et al., 2017), lack the required sourcing capabilities (Selviaridis et al., 2013), and may develop specifications over the course of the process (Selviaridis et al., 2011). Scholars have long argued that services differ from goods, because the former are characterized by intangibility, heterogeneity, inseparability, and perishability (IHIP, see e.g., Zeithaml Parasuraman, A. and Berry, L L., 1985). After substantial criticism, the service marketing literature has abandoned this old adagio and focused instead on the similarities between goods and services, in essence arguing that all 'products' fulfil a use value (Sampson and Froehle, 2009; Vargo and Lusch, 2004). Some maintain that services are produced and consumed simultaneously and in interaction with the customer (Grönroos, 2000) and that therefore, buying services is both more complex and important (Axelsson and Wynstra, 2002).

In this paper, we study a particular issue in buying business services that has received some attention in recent years: the development of service specifications in the sourcing process (Axelsson and Wynstra, 2002; Selviaridis et al., 2013, 2011). Determining the desired quality is increasingly difficult for services and requires specific (operational) service knowledge and expertise (Jackson et al., 1995). Since buyers rely increasingly on supplier capabilities for managing service operations, they lack specific know-how to define the service a priori. Hence, supplier involvement in this process may be required. Indeed, studies show that proper and clear business service specification is important and requires early involvement of providers in the purchasing process (Tate and Ellram, 2012; van der Valk and Rozemeijer, 2009).

In this research project, we study the effects of (early) supplier involvement in co-developing service specifications with the buyer on business service quality. We present empirical evidence from a sample of outsourced facility services, collected using a questionnaire among facility managers (buyers) in The Netherlands. This preliminary examination is part of a larger program to collect data from multiple sources on both sides of the dyads and for a larger sample.

In this paper, we first review the literature on business services and in particular on the specific characteristics of the sourcing process. Based on the knowledge based and capability views, we then develop theoretical hypotheses for testing. Next, we introduce the research design, data collection, measurement, and data analysis techniques. Finally, we present the initial findings from the research and discuss the results in light of the literature.

Theory

The literature on services has greatly expanded in recent years, with the promotion of new theories, views, and logics (Lindberg and Nordin, 2008; Lusch, 2011; Sampson and Froehle, 2009; Vargo and Lusch, 2004) and the increasing reputation of academic and professional journals (e.g., Journal of Service Research). Nonetheless, while services contribute the majority of value to the economy as measured by GDP and most employees effectively work in service businesses (The World Bank, 2015; Wynstra et al., 2017), research has not yet followed suit and is underrepresented in the scholarly literature. In this study, we focus on business services, which are delivered by organizations and purchased by other organizations (Axelsson and Wynstra, 2002), hence, we study services which are exchanged between organizations and—following Grönroos (2000)—are produced and consumed simultaneously in interaction between producer and (business) customer.

The sourcing process for business services is complex because purchasers may lack the 'sourcing capabilities' required for effective management (Axelsson et al., 2005) and may "know less than they buy" (Flowers, 2007; Hendry, 2002). As a result, identifying the business needs that drive sourcing request and translating that into purchasing specifications have been identified as challenges for the procurement function (Selviaridis et al., 2013). This points to potentially conflicting objectives. On the one hand, the success of business services depends critically on the development of proper and clear purchasing specifications (Tate and Ellram, 2012; van der Valk and Rozemeijer, 2009). On the other hand, the nature of business services and the potential lack of sourcing capabilities make developing specifications much more difficult (Lindberg and Nordin, 2008; Selviaridis et al., 2011).

When companies do not possess the required knowledge, expertise, or capabilities to effectively develop service specifications, they can leverage their network of partners (Un et al., 2010). In particular, research on the process of service specification development calls for the early involvement of suppliers and an extended role of (potential) suppliers in the definition of needs and specifications (Cho and Menor, 2010; Ellram and Tate, 2015; Selviaridis et al., 2013; van der Valk and Rozemeijer, 2009). In the regular purchasing process (e.g., van Weele, 2010), organizations first develop specifications for the required product or service, and afterwards select and contract an appropriate supplier. In the context of business services, as some of the literature suggests, this process may not be effective and suppliers may need to be involved in the (re)definition of needs and specifications over the course of the sourcing process.

The early and extensive involvement of suppliers in the sourcing process allows the buyer to leverage the suppliers' knowledge and capabilities (Clark, 1989; van der Valk and Rozemeijer, 2009). By leveraging the suppliers' knowledge, a buyer firm can tap into external sources of know-how related to the effective management of a business service. Knowledge in this context relates primarily to the deep understanding of the service (operations) management process and experience with running similar types of service systems (Grant, 1996). Furthermore, by leveraging the suppliers' capabilities, a buyer firm can also use the suppliers' expertise in managing the process of (re)defining business service specifications. Capabilities refer to the set(s) of resources and practices that enable firms to develop, sell, and implement service solutions that address the buyer's needs (Flowers, 2007).

Both leveraging knowledge and leveraging capabilities therefore contribute to the buyer's ability to design and develop business services in the sourcing process.

Two dimensions of supplier involvement in the early stages of the sourcing process play a role (Johnsen, 2009; Suurmond et al., 2018). Hence, we build on the literature on new product development to study supplier involvement (Clark, 1989; Handfield et al., 1999; Johnsen, 2009; Van Echtelt et al., 2008). First, the moment of supplier involvement refers to buyer-supplier collaborations in earlier phases of the sourcing process (Handfield et al., 1999; van der Valk and Rozemeijer, 2009). Second, the extent of supplier involvement refers to the degree of supplier contributions to and execution of sourcing tasks, in particular developing service specifications (Lichtenthaler and Lichtenthaler, 2009; Van Echtelt et al., 2008). These two dimensions of supplier involvement are quite distinct managerial processes for leveraging supplier knowledge and capabilities—which we will examine in closer detail in the development of our hypotheses.

As emphasized before, service is produced and consumed in interaction between provider and customer, so the quality of the business service is the customer's judgement of a provider's overall superiority or excellence (Parasuraman, et al., 1988). While product quality can sometimes be measured more objectively as the fit between the specifications and the delivered product, service quality is more elusive and captured by the match between customer expectations and customer experience of performance (for a review of this and other differences between conceptualizations of quality, see Golder et al., 2012). In particular, business service quality is examined as related to the potential quality, the hard and soft process quality, and the output quality (Gounaris, 2005). Other research shows that there is a link between higher levels of service quality and business performance, customer satisfaction, customer loyalty and retention and other relevant organizational outcomes (Cronin and Taylor, 1992; Parasuraman et al., 1988).

Table 1 and Figure 1 summarize our constructs, definitions, and relations.

Table 1. Key constructs and their definition.

CONSTRUCT	DEFINITION	REFERENCES
MOMENT OF SUPPLIER INVOLVEMENT	The first phase of the buyer's service sourcing process in which the supplier is involved	Handfield et al., (2000); Van der Valk and Rozemeijer, (2009)
EXTENT OF SUPPLIER INVOLVEMENT	The degree of the supplier's contribution to and execution of sourcing tasks	Van Echtelt et al., (2008); Lichtenthaler and Lichtenthaler (2009)
BUSINESS SERVICE QUALITY	The customer's judgement of a provider's overall excellence related to the aspects of potential quality, hard and soft process quality, and output quality.	Golder et al., (2012) Gounaris (2005) Parasuraman, et al. (1988)

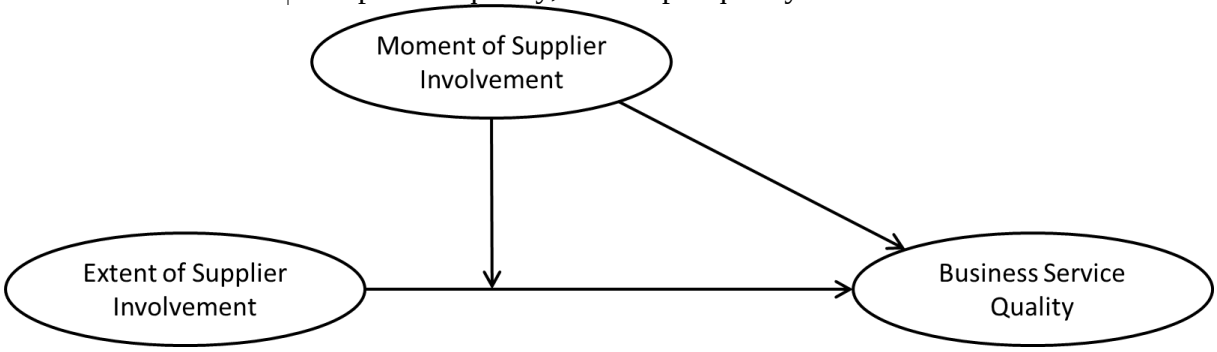

Figure 1. Conceptual model

Hypotheses development

The early involvement of suppliers in the sourcing process, i.e., before the specifications are frozen, allows a buyer to access knowledge and apply this in the shared 'service specification process'. As the success of business services is "primarily determined" during the development of service specifications (van der Valk and Rozemeijer, 2009, p. 6), early involvement of suppliers allows them to submit ideas and concepts for the business service that the buyer may not have thought about. As purchasers are not fully knowledgeable about the business needs (Flowers, 2007), involving suppliers which regularly fulfill said needs for other customers can improve buyer's ability to appropriately specify the service. An earlier moment of supplier involvement therefore provides the buyer with access to more know-how, which can be used to design and develop a better service. We expect that buyers are better able to set the appropriate specifications if they involve suppliers earlier in the sourcing process:

H1. *An earlier moment of supplier involvement has a positive effect on business service quality*

However, this still requires the buyer to leverage internal capabilities for the effective translation of supplier knowledge into purchasing requirements. Defining service quality cannot be done by the service buyer independently but should, instead, be guided by suppliers' superior knowledge of the possible solutions and expertise in how they have been used in similar contexts (van der Valk and Rozemeijer, 2009). Using a 'connecting capacity' or 'indirect capability' (Lichtenthaler and Lichtenthaler, 2009; Loasby, 1998), buyers can also leverage their suppliers capabilities themselves and integrate the supplier into the actual service sourcing process. This allows the buyer to use the suppliers' understanding of the service sourcing process and potentially make the supplier work in conjunction on some of the sourcing tasks. Hence, a higher extent of supplier involvement in the sourcing process enables buyers to more appropriately specify the business needs and specifications. We expect that the service will reach a higher quality if buyers co-develop the specifications of the service with their suppliers.

H2. *A higher extent of supplier involvement has a positive effect on business service quality*

Extensive supplier involvement, however, can only positively affect the performance of new services if the supplier is provided sufficient time to contribute with its relevant knowledge (Bidault et al., 1998; Handfield et al., 1999). Service specifications are becoming more firmly set over the course of the development project, with less to influence by the supplier in later stages. Leveraging the supplier's capability for developing service solutions is not immediate, but takes time. Therefore, we posit that the joint effect of extent of involvement and moment of involvement is larger the sum of their individual effects. Alternatively, we can also hypothesize this relationship as a necessary condition effect (Dul, 2016) following other examinations of such effects in the buyer-supplier literature (Sousa and da Silveira, 2017; van der Valk et al., 2016).

H3. a. *The effect of a higher extent of supplier involvement on business service quality is positively moderated by the moment of supplier involvement, such that this effect is larger when the supplier is involved earlier.*
H3. b. *An earlier moment of supplier involvement is a necessary condition for a higher extent of supplier involvement.*

Methodology

Data collection

To test the hypotheses, data is currently being collected on both sides of the dyad in a cross-sectional study design. The unit of analysis is a single specific service, that has recently been contracted to an external provider and for which operations have started. In particular, the services in the sample are 'facility services' which support the primary activities of a firm by organizing and executing services on 'facilities', which include all tangible assets of a firm, including buildings, infrastructure, workplaces, and people. Examples include cleaning, maintenance, providing furniture, and gardening.

Our sampling frame consists of approximately 1,000 members of Facility Management Netherlands (FMN), an industry organization for facility services. This research was announced on the organizations' website and through a mailing to all the members. The study is co-sponsored by this organization, which presumably helps to achieve a good response rate. Membership is individual and members include both buyers and suppliers of facility services. We use both groups to collect data, but for the current paper we only use the sample of buyers (546 FMN members) and have not yet collected data from their specific counterparts (suppliers) for this service.

We contacted FMN members by phone and asked for their participation in the joint study. The questionnaire, described hereafter, focusses on one particular service and asks for the contact details of the relevant person in the particular supplier's organization. Email reminders, after one and two weeks, and telephone follow-up, after four-six weeks, were applied when needed (Dillman et al., 2014). A shorter telephone follow-up questionnaire will be conducted with the identified supplier. Therefore, the results in this working paper are based on data from a single informant.

For this sample, we contacted 546 individuals, from which 171 were not qualified to answer our questions, hence, our effective sample was 375 FMN members. Another 103 were not willing to participate and 174 could not be reached by telephone—the latter were invited by email to participate later. Finally, 98 members agreed to participate and 71 actually participated to some extent. Due to missing data, the current analysis relies on the full information available from 48 respondents, an effective full response rate of 12.8%.

Measurement

All constructs as identified in the conceptual model have previously been used in the literature and have gone through extensive validation procedures. To ensure that the constructs, items, and scales were also valid in this context, we pretested the questionnaire with the help of two academic experts and four practitioners. These outside experts filled in the questionnaire while simultaneously listing any difficulty they came across and any suggestions for improvement. This helped to resolve any ambiguity in the questions and the wording of some items. No structural changes were made to the constructs or items.

Dependent variable

As a measure of service quality, a previously developed and extensively tested scale by Gounaris (2005) was employed. This scale, INDSERV, is a second-order construct to measure service quality in business-to-business services. Gounaris (2005) shows that INDSERV has better and sufficient psychometric properties than the commonly used SERVQUAL scale, in particular, for measuring business rather than consumer service quality. SERVQUAL suffers from low discriminant validity (the first-order constructs are not very distinct) and methodological complexity (it measures both expectations and perceptions, which is hard to differentiate between for respondents) (Cronin and Taylor, 1992; Dyke et al., 1999; see also: Ladhari, 2008). In contrast, INDSERV has adequate discriminant validity, a

high level of predictive validity, excellent convergent validity and internal consistency (Gounaris, 2005; Ladhari, 2008). This scale was translated and slightly adapted for the context of this study, see Table 2.

Business Service Quality is conceptualized as a second-order formative construct consisting of four first order constructs: potential quality, hard (process) quality), soft (process) quality), and output quality. This way of modelling a multidimensional construct is uncommon in the literature, but, following Jarvis et al. (2003) it makes more sense to say that service quality is the combination of the first-order constructs. In contrast, positing the first-order constructs as reflective of business service quality implies that the latter cause the former and that when business service quality increases, the level of all four first-order constructs is supposed to increase (Diamantopoulos and Winklhofer, 2001; Jarvis et al., 2003). Gounaris originally proposed service quality as a reflective construct at both levels, but also writes: "The *combination* of all these four dimensions *constitutes* a customer's overall perception of the quality of service." (Gounaris, 2005, p. 430, *emphasis added*). To make this type of modelling possible in structural equation modelling, we use all indicators of quality as reflective items of business service quality for secondary loadings, while making business service quality a second-order formative construct of its subdimensions simultaneously. This is known as the repeated measures approach in partial least squares (Sanchez, 2013; Wetzels et al., 2009).

Independent variables

As a measure of the moment of supplier involvement, we use two items similar to previous research (Handfield et al., 1999; Laseter and Ramdas, 2002): in which phase of the process and how long before operational start the supplier was first involved. For the service context of this study, and in consultation with the involved practitioners, the 'phases' were adapted, see Table 2. As a measure of the extent of supplier involvement, we use a multi-item reflective scale previously used in Wynstra et al. (2012) and building on others (Hartley et al., 1997; Petersen et al., 2005). Again, small adjustments were made to the wording of some items, such as 'project' into '(sourcing) process'.

Other measures

We also included measures for several control variables. First, we included a measure of project length, as one could argue that better service quality can be achieved simply through better preparation, which is then likely to also be reflected in more supplier involvement. Secondly, we include a control for firm size, as it is often related to success. Third, we include a dummy variable to measure public/private firms. Fourth, we measure service innovativeness, building on Ali et al., (1995) but adapted for the context of services. Highly innovative services may require supplier involvement more and lead to better service quality compared to more incremental or marginal improvements. Finally, we include controls for prior buyer-supplier relationship and its length, as again, this may relate to both (service) quality and higher levels of supplier involvement (Parker et al., 2008). Due to space limitations, the exact operationalization and measurement items for these controls are omitted from the paper.

Table 2. Constructs, items, and scales.

CONSTRUCT	ITEMS/QUESTIONS	SCALE
Moment of Supplier Involvement (MSI)	1. In which phase of the project did you first involve the supplier? Choose one:	While generating new ideas and concepts; While developing the concept and testing it; Immediately before supplier selection; After the supplier was selected and contracted; Not at all.
	2. How much earlier than the start date of the contract did you first involve the supplier	<1 month; 1-3 months; 3-6 months; 6-12 months; >12 months; Not at all.
Extent of Supplier Involvement (ESI)	1. The supplier was in charge of a considerable number of design, development, and operational tasks in the process. 2. The supplier was responsible for proposing solutions for the design and development for the service. 3. The supplier put in significant labor/time into the process. 4. The supplier served as an extension of our sourcing team (i.e., purchasing, facility management).	A six point semantic difference scale was used for each item (disagree-agree)
Business Service Quality (BSQ) Sub-dimensions		Sum of dimension scores
Potential Quality (PQ)	1. Offers full service 2. Has required personnel 3. Has required facilities 4. Has requires management philosophy 5. Has a low personnel turn-over 6. Uses a network of partners/associates*	A seven point semantic difference scale for each item (completely disagree-completely agree)
Hard Process Quality (HQ)	1. Keeps time schedules 2. Honors financial agreements / stays in budgets 3. Meets deadlines 4. Looks at details 5. Understands our needs	idem
Soft Process Quality (SQ)	1. Accepted enthusiastically* 2. Listens to our problems 3. Open to suggestions/ideas 4. Pleasant personality 5. Argues if necessary 6. Looks after our interests	idem
Output Quality (OQ)	1. Reaches objectives 2. Has a notable effect 3. Contributes to our sales/image 4. Is creative in terms of its offering 5. Is consistent with our strategy	idem

Results

To estimate the conceptual model as posited in Figure 1, we conducted path analysis using Partial Least Squares in plspm (in R 3.4.3) (R Core Team, 2017; Sanchez, 2013). The inner weighting scheme was 'centroid', measurement items were not scaled, tolerance was set to 1e-6, maximum iterations set to 100, and bootstrapping with 10,000 bootstrap samples. The complete measurement and structural model is displayed in Appendix A.

Both moment of supplier involvement and extent of supplier involvement are constructs with reflective items (2 and 4, respectively). Each of the dimensions of business service quality is constructed using their reflective items. Note that based on low factor loadings (<0.3) and significant cross-construct loadings, one item was dropped from the potential quality (PQ6) and soft process quality (SQ1) each. Finally, to approximate our conceptual model as closely as possible in PLS, we construct business service quality with all 20 reflective items for the quality scales as secondary loadings, i.e., the repeated indicators approach (Sanchez, 2013; Wetzels et al., 2009).

Table 3. Measurement model (full details available from the author – see also Appendix A)

	# items	Cronbach's alpha	Dillon-Goldstein rho	1st Eigenvalue	2nd Eigenvalue	Average Variance Extracted
MSI	2	0.454	0.786	1.29	0.706	0.647
ESI	4	0.902	0.932	3.1	0.426	0.755
BSQ	20	0.962	0.966	11.84	1.773	0.592
PQ	5	0.909	0.934	3.71	0.613	0.742
HQ	5	0.912	0.934	3.70	0.424	0.740
SQ	5	0.895	0.925	3.57	0.723	0.714
OQ	5	0.882	0.915	3.43	0.692	0.684

We first examined the measurement model in detail to assess the reliability and validity of each of the scales—we follow recommended thresholds (Hair et al., 2014; Sanchez, 2013). Chronbach's Alpha and Dillon–Goldstein's Rho's are well above 0.7 for most variables, indicative of high composite reliability. For moment of supplier involvement, Chronbach's alpha is a bit lower, because only two items were used; Dillon-Goldstein's Rho is a more appropriate measure for reliability with fewer items. The scales also exhibit unidimensionality, with first eigenvalues above 1 and second eigenvalues below 1. All scales have discriminant validity, with Average Variance Extracted always larger than the interconstruct correlations (see Table 4), except between the formative dimensions of BSQ. The scales show convergent validity with AVE's always above .5.

Table 4. Correlation matrix.

	MSI	ESI	PQ	HQ	SQ	OQ	BSQ
MSI	1						
ESI	0.246	1					
PQ	0.410	0.300	1				
HQ	0.346	0.268	0.754	1			
SQ	0.348	0.195	0.717	0.838	1		
OQ	0.225	0.366	0.660	0.848	0.783	1	
BSQ	0.373	0.313	0.865	0.949	0.918	0.901	1

Based on the feasibility of the measurement model, we then proceeded to examine the structural model. In particular, we related the two dimensions of involvement to business service quality, which itself is related to its four subdimensions, again, see Appendix A. The structural model has a very high goodness-of-fit of 0.81, to be interpreted roughly as the predictive power of the model. Path estimates provide further support for the predictive capabilities of our model.

Table 5. Structural model estimates.

Path	Estimate	SE	Hypothesis	
MSI→BSQ	0.006	0.005	H1 (+)	Supported
ESI→BSQ	0.004	0.004	H2 (+)	Supported
PQ→BSQ	*0.275*	0.022		
HQ→BSQ	*0.292*	0.018		
SQ→BSQ	*0.273*	0.020		
OQ→BSQ	*0.258*	0.030		

Notes. Significant estimates ($p<0.05$) are in italics. Based on 10,000 bootstrap replications.

The interconstruct correlation (Table 4) and the direction of the effect in the structural model (Table 5) provide support for Hypothesis 1, meaning that an earlier moment of supplier involvement is positively related to business service quality. Similarly, support is found in the data for Hypothesis 2, which means that a higher extent of supplier involvement is positively related to business service quality. Both hypotheses are also supported for the various sub-dimensions of quality, although not always at statistically significant levels.

Next, we examine the interrelationship between the two dimensions of supplier involvement and find a significant correlation. That is, a supplier with a higher extent of supplier involvement also tends to be involved in relatively earlier phases of the sourcing process. This provides initial support for Hypothesis 3a, while further testing of the interaction effect (as posited) cannot be implemented due to time constraints and modeling difficulties.

Based on the available literature, we also posited that the moment of supplier involvement is a necessary condition for the extent of supplier involvement, see H3b, such that a higher extent of involvement is only possible when the supplier is also involved in earlier phases. This approach requires additional testing using necessary condition analysis rather than regression-based techniques (Dul, 2016; Dul et al., 2010). Figure 2 presents a scatterplot of the two dimensions of involvement. This Figure shows that the two dimensions are not only related, but that the highest extent of involvement is not possible with very late involvement (lowest scores). Indeed, the necessary condition effect (Ceiling Envelopment-Free Disposal Hull) is 0.129, which is considered a small necessary condition effect, in support of Hypothesis 3b. However, as the plot shows, extent of involvement is only limited by involvement in the latest phase, in any earlier phase, all extent of involvement is possible.

For the sake of comparison, we also examined whether early and/or extensive involvement are necessary for higher levels of business service quality. In other words, we tested the equivalent necessary condition effects for Hypotheses 1 and 2. Our results show that both dimensions of supplier involvement in the sourcing process are necessary for business service quality, with effect sizes of 0.218 and 0.116, respectively. The highest levels of business service quality only occur with earlier than average involvement and with a higher extent of involvement than average. Plots omitted due to space considerations.

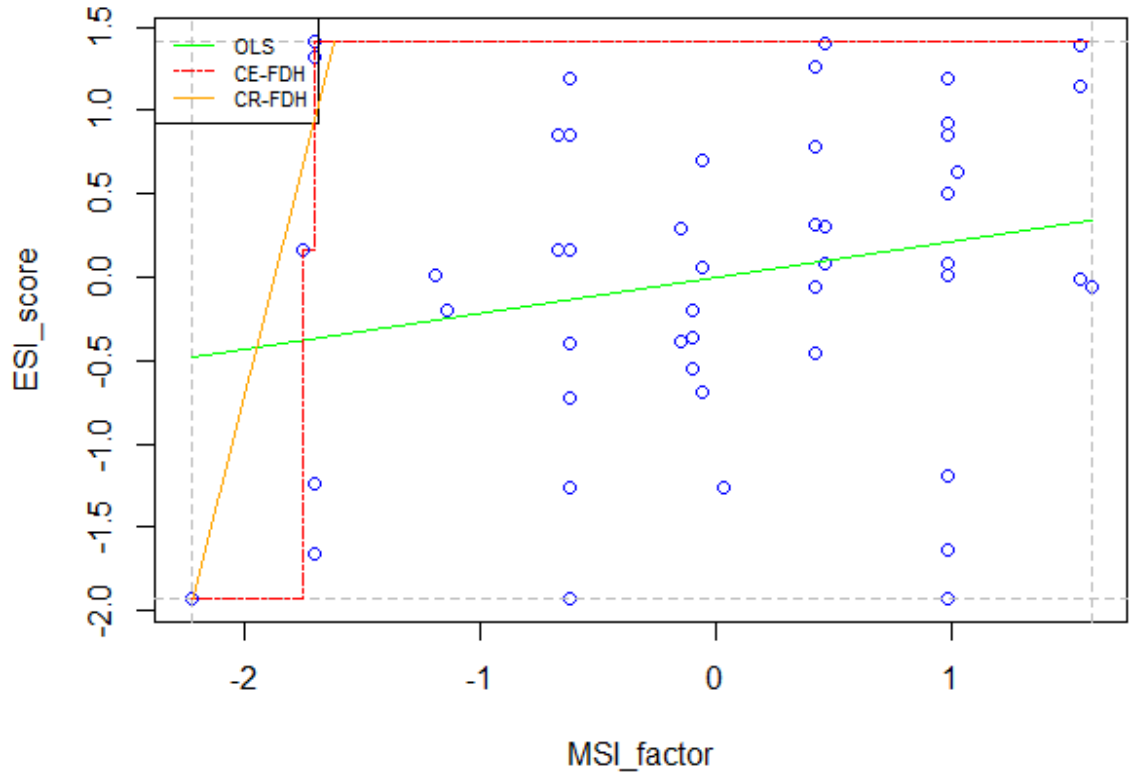

Figure 2. A scatter plot of the moment (MSI, x-axis; early is higher) and the extent (ESI, y-axis) of supplier involvement.

Discussion

In this paper, we have empirically examined the link between early and extensive supplier involvement in the sourcing process for business services and the resulting service quality. We have developed a more robust understanding of the role that suppliers play during the process of developing service specifications. Some of the literature suggests that suppliers should play an extended role in order to properly or clearly specify the desired services (Ellram and Tate, 2015; Tate and Ellram, 2012; van der Valk and Rozemeijer, 2009). Service specifications are developed over the course of the process (Selviaridis et al., 2011) and buyers often lack relevant service capabilities (Flowers, 2007; Selviaridis et al., 2013). Furthermore, since the quality of business services can only be determined after production, operation, and delivery (Gounaris, 2005; Grönroos, 2000), the business customer's satisfaction depends critically on the proper and clear specification of business needs and purchasing requirements up front. Hence, while buyers are typically not in the best position to develop such specifications properly (Selviaridis et al., 2013, 2011), the success of the service depends critically on the proper specification of the purchasing needs (Tate and Ellram, 2012; van der Valk and Rozemeijer, 2009). In conclusion, the sourcing process of business services requires buyers to leverage their suppliers' knowledge and capabilities (Flowers, 2007; Grant and Baden-Fuller, 2004; Wynstra et al., 2017).

To date, very few empirical studies have examined this process of co-developing service specifications in detail and this study provides a first attempt at clarifying the effects of involving suppliers in the sourcing process for business services. In this paper, we report research as part of a larger ongoing research program into buyer supplier collaborations in the sourcing process, and in particular, into the co-development of service specifications. We collected data from buyers of facility services on the moment and the extent of their

suppliers' involvement in the sourcing process and their satisfaction—measured by business service quality—during service operations.

We find, firstly, that involvement of suppliers in earlier phases of the sourcing process has a positive impact on the buyer's satisfaction with the service. By involving suppliers early, buyers leverage their suppliers' knowledge and expertise with similar types of services, which, due to increased outsourcing of these services, they lack themselves. Hence, earlier involvement of suppliers is an efficient methodology for knowledge integration and application (Grant and Baden-Fuller, 2004). In fact, preliminary analyses also support that earlier involvement of supplier is a necessary condition for higher levels of quality.

Secondly, we find that more extensive involvement of suppliers in the sourcing process also has a positive impact on business service quality. By involving suppliers extensively, buyers can leverage their suppliers' service capabilities in the development, implementation, and operation of business services (Flowers, 2007). Hence, more extensive involvement of suppliers in the sourcing process allows buyers to leverage a 'connecting capacity' or 'indirect capability' for using their suppliers resources and practices to their advantage (Lichtenthaler and Lichtenthaler, 2009; Loasby, 1998). Our findings show that involving suppliers more extensively is a necessary condition for achieving high levels of quality.

Thirdly, we find that the two dimensions of involvement are related (Bidault et al., 1998; Monczka et al., 2000) and that an earlier moment of supplier involvement is necessary for a higher extent of supplier involvement. In particular, we find that suppliers with the highest extent of involvement are also involved in relatively earlier stages of the sourcing process.

Limitations and Future Research

In this paper, we present the first findings on the effects of supplier involvement in sourcing business services, as part of a larger research program into this phenomenon. Therefore, a number of limitations of the current study are addressed as part of the larger program. In particular, the data presented in this paper stems from a single respondent on one side of the dyad (buyer) and endogeneity and common method bias may therefore become a threat to the validity of the findings (Craighead et al., 2011; Ketchen et al., 2017; Roberts and Whited, 2013). In the larger program, we are also collecting data from the buyer's supplier counterpart for the specific service, which will allow us to use data from multiple sources and from both sides of the dyad. Furthermore, the sample size is relatively low, which perhaps explains why some of the relationships are not statistically significant. Another limitations of this study is the relatively limited amount of questions that could be asked—in order to ensure response. Therefore, the conceptual model is straightforward and contains just three main concepts. Other research is needed to address issues such as supplier selection for involvement (Schiele, 2006) and continuous contract management (Nullmeier et al., 2016).

Abstract

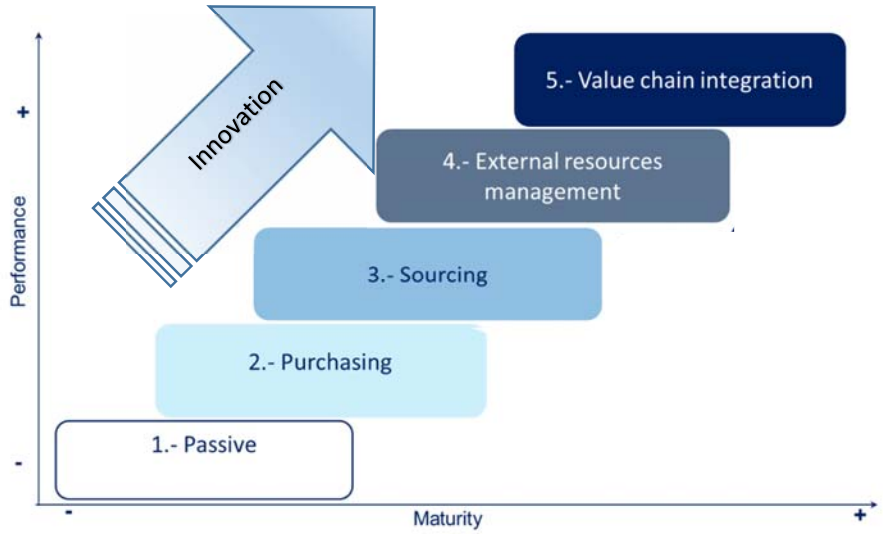
Procurement departments worldwide strive to become more relevant to the business, actively demonstrating the added value they can deliver by expanding their scope and activity beyond the boundaries that outlined Procurement's role so far. The authors consider that procurement can position itself as a **key business enabler**, maximizing the return on investment not only by securing fit-for-purpose services at a reasonable value**,** but also by offering competitive advantage to the business through **supplier-enabled innovation.** Two different case studies are presented herewith, demonstrating how procurement can go beyond traditions and deliver value in ways that were formerly unexpected.

Keywords: Procurement Added-Value; Supplier-Enabled Innovation; Crowdsourcing

Procurement evolution path

As organizations grow more sophisticated in the way they purchase goods and services, they adjust the procurement function accordingly. From simple **purchasing** all the way to **Value Chain Integration,** procurement maturity is linked to the level of dependency of the organization on its suppliers.

In more advanced phases, procurement is expected to **enable competitive advantage** for organizations through **access to innovation**. The ability to **spot, attract** and **integrate** innovation quickly and effectively, becomes a matter of vital importance. This is particularly true in industries such as FMCG, automotive sector, electronics, etc. where innovation is quite often coming from the networks of suppliers.



Spotting, Attracting, and Integrating Innovation

Socrates, the famous ancient Greek philosopher, once stated that "*True knowledge exists in knowing that you know nothing"*. Indeed, the more we learn and grow through professional experience, self-improvement, etc. the more conscious we become of the countless options that exist out there, most of which we will never discover that they ever existed. Inevitably, professionals tend to resort to **accessible sources**, when elaborating on a certain problem. This would range from their narrow professional surrounding to a few trusted suppliers or maybe certain academic sources when applicable.

Graphical representation of the range of possible options to problem-solving.

Technological advancements, however, have unlocked other options as well, as people from around the world can now connect through virtual platforms or social media. This enables access to an unprecedented width and variety of resources that could contribute to resolving a problem – what is referred to as **Crowdsourcing**.

We present two case studies which demonstrate the differing paths of accessing innovation.

Case Study 1: Attracting Market Innovation - Supplier Innovation Workshop

The basis for success in this approach is the close collaboration with selected suppliers, which is further enhanced by formally integrating innovation discussions into it. While a Procurement department can hardly *generate* innovation, they are well positioned to *scout* for it; indeed, suppliers may offer solutions to problems *known* or sometimes *unknown* to the organization. All suppliers are seeking business development opportunities, which they can achieve either by **selling more** of the same products / services, or **selling diverse** products / services. Our interest, for the scope of this paper, lies with suppliers pursuing the latter.

Human beings, by nature, are inclined to pursue **meaningful**, but also **achievable** goals. Therefore, a company that becomes established in the market as a customer that **welcomes innovation**, is likely to attract suppliers able to offer it.

The market could be alerted of such a positioning through an "innovation event", addressed to key suppliers. The event may involve suppliers across industries, if the scope of the day is simply to broadcast certain messages to the market, and have generic discussions on innovation (followed at a later stage by more specific meetings / workshops). Alternatively, if the intention is to condense more work in the same day, sector-specific innovation events would be advisable, including plenary sessions followed by actual workshops. In this case, the suppliers should come well prepared beforehand.

Event Prerequisites:

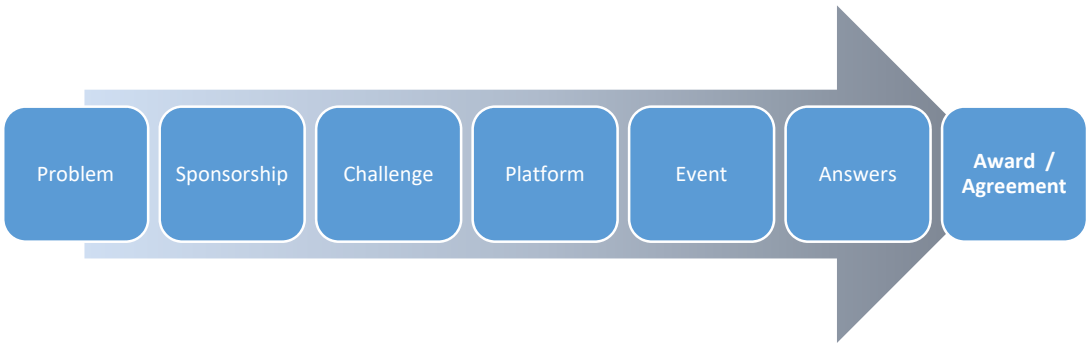
Ensure team Commitment	The procurement team needs to commit upfront to this initiative, in order to devote adequate time for aligning with suppliers, internal customers, following up on progress, etc.
Internal Stakeholders' alignment & engagement	Start with internal mapping to identify open-minded stakeholders with a drive to test new things in the given period. Invite key internal stakeholders to present to the suppliers and convey their messages, showing their commitment to collaborate.
Suppliers' Selection	It is advisable to develop clear invitee selection criteria, certainly including suppliers with demonstrated capability to bring novelty to the table. This also serves to address queries from non-invited suppliers.
Hospitality	Hospitality to invitees is important, clearly setting an "inviting tone" to strengthen the partnership and adopt new approaches. This includes mindfulness of any confidential info they might want to share, possibly calling for separate / supplier-specific sessions.
Detailed Agenda	Agenda to be distributed upfront, with a clear logic and references to covered topics. It is important to allow enough time for breaks and socializing, which will enable vivid discussions among invitees (internal and external), perhaps even triggering the first opportunities.
Clear Messaging	All attendees should leave with a clear and common understanding (key takeaways) and buy-in to return with their value-added proposals.
Follow up	It is vital to close the loop by inviting all suppliers to submit their ideas, which should then be evaluated and short-listed together with the business. All suppliers should receive feedback on their ideas.

Materialization	For this initiative to gain credibility, tangible results need to emerge in the end. This will call for additional meetings, possibly workshops, and engagement from procurement and relevant internal stakeholders
Communication	Success stories should be communicated internally and externally afterwards. Other suppliers should also be informed to keep our company as "top of mind" client when novelty comes to the table.

Novartis Hellas hosted such an event in the past, with participation of **50 suppliers** across **11 sectors.** Within three months, the event produced **28 ideas,** of which **11 eventually materialized**, with positive impact in diverse business areas (ranging from document management, car fleet and telecoms to virtual congresses and patient support programs).

Case Study 2: Bringing the Outside in - Innovation through Crowdsourcing

Crowdsourcing can simply be explained as a business challenge posted to a specific internet platform, where it can be accessed by various groups of professionals, academics, etc. (usually referred to as "solvers") trying to offer solutions, in return for a monetary return to the winner. The success of this approach lies on the wide variety of new suppliers, and the diversity of possible solutions that all this collection of mental power can bring. The sequence of actions to conduct a Crowdsourcing event could be outlined as follows:



Problem: Identify, in collaboration with the business, a **clear problem to solve**. It is important to stress that Procurement is merely offering a service provision that *may* lead to a solution. This helps the business overcome the initial reluctance or surprise. Close collaboration with the business and deep understanding of their needs and priorities is of course essential.

Sponsorship: After the problem has been defined, a sponsor to support this approach is needed. It would be advisable to assign a steering committee and a project team, involving all relevant parties. In addition, Legal and Finance need to be advised upfront for any potential implications, as Crowdsourcing sets new sourcing patterns for the company,

Challenge: The formation of the actual challenge to be posted for the potential solvers, will take some time to digest and be able to properly reproduce in the future. Among others, one will need to define: the **type of event** to set up (to specific experts vs. totally open); the **type of challenge** (public or anonymous); any **constraints** relevant to confidentiality / intellectual property aspects (ensure that no confidential info is shared, also ensuring that solvers' submissions become intellectual property of the company); the **award** for the winner(s); the **supplier selection criteria**

Platform: Several platforms are already available in the internet, and all of them follow more or less the same logic, perhaps with some differentiation in the provided services, fields of specialization and costs. What is really important is to see their **crowd** and how they manage it. In some cases we might have to recruit and register participants to our Crowdsourcing event.

Event: Apart from posting the challenge, we also need to let potential solvers know of the award for the winner(s). As expected, the further we expand our reach to external resources, the more irrelevant solutions are likely to flow in. This happens because the remoteness of potential solvers from the topic could generate misinterpretations. Therefore, a key success factor is to describe the problem as **clearly and accurately** as possible, incorporating any relevant side-information, while also maintaining an open line to handle solvers' queries.

Answers: Once the event is closed, we need to review and prioritize the answers. Defining clear and correct selection criteria is important, but not always easy. The submitted answers need to be reviewed in collaboration with the business, to short-list solvers for final review and eventual selection.

Award: Having completed all above steps, we are now ready to award and close positively the event. We could qualify more than one proposals if it makes sense.

Three examples of such projects at Novartis are outlined below:

1st example: Crowdsourcing was selected instead of the traditional bidding process for the production of a video for a contact lens ad. Instead of the usual creative agencies, the request was addressed to 67,000 solvers with great capabilities, ideas, and extreme motivation to compete. The process lasted less than 3 months and 2 great videos were selected and awarded, with 96% savings! (Winners' award vs. normal creative agency fees for this work)

2nd example: This concerns the development of a patient mobile app, which would normally include a standard RFQ with suppliers, a process that usually takes several months to agree on the specifications, negotiate prices, have the contract signed, develop and test the app, etc. Crowdsourcing returned **33** already developed apps, more or less working under test environment. Those were short listed down to 10, the final winner being a silicon-valley start-up who quickly provided a great product, with more than 50% savings (award vs normal price for a similar piece of work). Moreover, Novartis got introduced to many suppliers and acquired a much better view of the potential supply base, while the suppliers learnt a lot on customer needs while developing the app for submission, which helped them improve their proposals going forward.

3rd example: A production plant had problems in weighing small quantities of powder for a production line. The engineering departments had been looking for solutions for some time without success, so they agreed to make a crowdsourcing event for this. A few months later, 30 potential solutions were received, 9 of which were awarded! The best proposal came from a Chinese scientist working on a completely different subject, but with a similar problem, which led him to develop his home-made weighing system! The initial problem was now simplified to the industrialization of an existing small-scale solution.

Additional Considerations

Crowdsourcing, by design, brings our organization in contact and possible collaboration with totally unknown suppliers. For this reason, it is advisable to involve Legal department from the very beginning, to ensure that any legal considerations, including –but not limited to-

confidentiality of what we share publicly, Intellectual Property rights, lack of ink-signed contractual engagement, etc. are adequately and timely addressed.

Conclusion

Innovation is highly valued by the business, as it is linked with competitive advantage, but it is not an easy goal to achieve. This paper presented different approaches that procurement departments can employ to **spot**, **attract** and **integrate** innovation. None of these approaches is a panacea careful evaluation of the method selected each time is needed. What is certain, procurement can only achieve sustainable results in this area by staying close to the business, ensuring that internal customers come proactively with their issues, allowing time for new approaches. Last, but not least, success stories always need to be broadcasted, to keep attracting interest on innovation.

Acknowledgements

Much of the information captured here is based on the work of **Robert Zimmer**, Novartis Global Category Manager, Digital Services, who has been really active in the field of supplier-enabled innovation for many years now, with exceptional results. Lots of credit also goes to **Stephane Morel**, Novartis Global Head of Procurement Capabilities Development, whose support, guidance and provision of valuable insights were decisive in putting together this piece of work.

"The ideas which are here expressed so laboriously are extremely simple and should be obvious. The difficulty lies, not in the new ideas, but in escaping from the old ones, which ramify, for those brought up as most of us have been, into every corner of our minds" J.M. Keynes, 1973, preface

Summary

There are many examples from nature and natural systems that can provide inspiration (referred to as biomimicry) for the structural aspects of complex business systems using, reusing, and repurposing materials and components in a way that is sustainable. Biological networks provide inspiration regarding how business networks can communicate more quickly and effectively via information transmission to reuse materials/resources in continuous cycles. An in-depth case study was performed to support and further develop the idea of biomimicry in a business setting, showing that business can learn how to be more sustainable from the processes defined by natural networks.

Circular economy; theory; supply; value; chain; network; system; biomimicry; biomimetic; mycorrhiza; cycle

Submission category: Working paper

Introduction

New ways of thinking about how to manage resources are required to address growing resource depletion and the rising threat of global climate change. This is reflected in the current movement of corporate sustainability, where both environmental and social issues are increasingly forcing more and more companies to assume a decisive stance in developing a sustainable and efficient economy for the future. To be effective in this future environment requires new perspectives and

innovative ideas to reconfigure current business practices in ways that help mitigate corporate and consumer impact on the planet.

The greatest challenge is to create an economy which aims to eliminate waste altogether as is the case in natural ecosystems. The natural environment is characterized by a continuous cycle of salvage and reuse, where waste from one process can move as input to another, completely unrelated process. The realization of this challenge has led to efforts to establish and promote a circular economy. The European Commission has defined this as an economy in which "…the value of products and materials is maintained for as long as possible; waste and resource use are minimized, and resources are kept within the economy when a product has reached the end of its life, to be used again and again to create further value" (EC, 2015, p. 1).

The goal of operating in a circular environment stands in stark contrast to current business reality. For instance, waste from electric and electronic devices (e-waste) is on the increase. Baldé, Forti, Gray, Kuehr, & Stegmann (2017, 4ff) state that: "All the countries in the world combined generated a staggering 44.7 million metric tonnes (Mt), or an equivalent of 6.1 kilogram per inhabitant (kg/inh), of e-waste annually in 2016 […]. Globally, only 8.9 Mt of e-waste are documented to be collected and recycled, which corresponds to 20% of all the e-waste generated. The total value of all raw materials present in e-waste is estimated at approximately 55 Billion Euros in 2016 […]. Circular economy models need to be adopted to encourage closing the loop of materials through better design of components, recycling, reusing, etc., while mitigating the environmental pollution. Therefore, the circular economy concept offers huge economic and employment opportunities for e-waste management; the presented 55 Billion Euros of secondary materials is an underestimate of those economic opportunities."

In line with circular economy aspirations, the need to consider both closed and open material loops in both technical and biological cycles has recently been emphasized (De Angelis, Howard & Miemczyk, 2017). Rapid industrialization and urbanization in some developing economies has increased the need for effective and efficient use of resources (Guan & Chen, 2012). When realized, the circular economy, using principles learned from nature, would transform the function of resource utilization. Waste from factories would become valuable inputs to other processes and even across industries as products are repaired, reused or upgraded or individual materials are repurposed instead of being thrown away (Preston, 2012). Understanding the shift of perspective from a closed, mechanistic business ecosystem, to a circular value system is the overarching premise of this paper.

Companies are starting to realize the importance of looking toward natural systems and trying to emulate the more organic or fluid ecosystems (Winn & Pogutz, 2013). The lens they are looking through is referred to as biomimicry or biomimetics, a method imitating techniques and processes of nature to achieve effectiveness, efficiency and sustainability (Benyus, 1997). Biomimicry has been seen in new product development research and practice, such as, self-cleaning façade paints based on the water and dust-repellent properties of the lotus leaf (Sivakumar, Balasubramanya, & Sundaresan, 2012). However, biomimicry reaches beyond products and includes management and organizational insights from nature: "Biomimicry is an approach to innovation that seeks sustainable solutions to human challenges by emulating nature's time-tested patterns and strategies. The goal is to create products, processes, and policies—new ways of living—that are well-adapted to life on earth over the long haul" (Biomimicry Institute, 2017). The benefit of using biomimetic principles is that they are proven over 3.8 billion years, as this earth thrives and is governed by balance (Kennedy, 2013).

For the purpose of this research, advancing understanding of the preconditions for a circular economy, the biomimetic focus is placed on networks of fungi that support forest ecosystems by

distributing nutrients and information, an area which has been studied in biology for decades (Simard, Beiler, Bingham, Deslippe, Philip, & Teste, 2012). Within these ecosystems, the fungi networks play a central role in carbon, water and nutrient cycling and redistribution of resources (Warren, Brooks, Meinzer, & Eberhart, 2008; Allen, 2007; Treseder, 2004; Eason, Newman & Chuba, 1991), which is needed to keep the system circular. A comparable mechanism is missing in the current business ecosystem.

The overarching purpose of this research is to integrate the concepts of systems thinking with biomimicry for business ecosystem design. The business ecosystem should waste nothing through closed and open-loop reuse and redistribution of productive resources. The specific research question in focus here is: *"How can biomimetic principles be utilized to transition from the current mechanistic business ecosystem to a circular value system?"* To answer this question, a review of literature on the processes and operations of the fungi network in forests was first performed. The concepts discovered from this assessment allowed for the design of an in-depth case study which was conducted with an innovative organization that recognizes the importance of circular systems and works to facilitate an interconnected system that reuses and redistributes productive resources.

This paper is organized as follows. The primary tenets from biomimicry and the fungi network are assessed first, followed by complex adaptive systems and network theory. Next, the research methods are described. Based on reflection and elaboration of case study findings in relation to the biomimetic setting of fungi networks, five biomimetic principles are developed that lead the way to future research avenues. Before concluding the paper, contributions to management theory, practice and education as well as future research suggestions are discussed.

Focusing on Biomimicry

The resilience of an organization is interdependent on the resilience of its business ecosystem. The more centralized and hierarchical information flows (and subsequent material flows) become, the more vulnerable they are to disruption. In contrast, nature constructs webs or systems in which there are built-in redundancies and countermeasures. As Kharrazi, Kraines, Rovenskaya, Avtar, Iwata and Yarime (2015, 806) summarize: "High levels of efficiency tend to weaken the system's ability to respond to shocks or disruptions to its internal flows, whereas high levels of redundancy are costly to maintain and thereby tend to weaken the system's internal development and its ability to distribute flows in an orderly way. Therefore, from the perspective of the ecological information-based approach, sustainability is achieved when the system maintains robust delivery (i.e., the intensive dimension) while also achieving a reduction in the total usage of resource (i.e., the extensive dimension)."

Both dimensions aim at eliminating the trade-off between redundancies and increasing resilience. In line with circular economy aspirations, the need to consider both closed and open material loops in both technical and biological cycles has recently been emphasized (De Angelis, Howard and Miemczyk, 2017). Rapid industrialization and urbanization in some developing economies has increased the need for effective and efficient use of resources (Guan and Chen, 2012). The circular economy, using principles learned through biomimicry, would transform the function of resource utilization. Waste from factories would become valuable inputs to other processes and even across industries as products are repaired, reused or upgraded or individual materials are repurposed instead of being thrown away (Preston, 2012). This type of thinking aligns with the processes that occur in nature. Some companies are starting to realize the importance of looking toward natural systems and trying to emulate the more organic or fluid ecosystems (Winn and Pogutz, 2013). This lens is referred to as biomimicry or biomimetics, a method imitating techniques and processes of nature

to achieve effectiveness, efficiency and sustainability (Benyus, 1997). Biomimicry has been seen primarily in new product development research and practice, such as, self-cleaning façade paints based on the water- and dust-repellent properties of the lotus leaf (Sivakumar, Balasubramanya and Sundaresan, 2012). But biomimicry reaches beyond products and includes management and organizational insights from nature: "Biomimicry is an approach to innovation that seeks sustainable solutions to human challenges by emulating nature's time-tested patterns and strategies. The goal is to create products, processes, and policies—new ways of living—that are well-adapted to life on earth over the long haul" (Biomimicry Institute, 2017). The potential benefit of using biomimetic and natures principles is that they are abundant and proven over 3.8 billion years, as this earth thrives and is governed by balance (Kennedy, 2013).

For the purpose of this research, the biomimetic focus is placed on networks of fungi that support forest ecosystems by distributing nutrients and information, an area which has been studied in biology for decades (Simard, Beiler, Bingham, Deslippe, Philip and Teste, 2012). Within these ecosystems, the fungi networks play a central role in carbon, water and nutrient cycling (Warren, Brooks., Meinzer and Eberhart, 2008; Allen, 2007; Treseder, 2004; Simard, Perry, Jones, Myrold, Durall and Molina, 1997; Eason, Newman and Chuba, 1991).

Methodology

The goal of this paper is to elaborate on theory that integrates the concepts of systems thinking with biomimicry for business system design. The business system should waste nothing through closed- and open-loop reuse and redistribution of productive resources while being resilient in the face of disruptions. The specific research question in focus here is: *"How can biomimetic principles be utilized to transition from the current mechanistic business ecosystem to a circular value system?"* To answer this question, extensive review on the processes and operations of the fungi network was performed. The concepts discovered from this assessment allowed for the design of an in-depth case study which was conducted with an innovative organization that recognizes the importance of circular systems and works to facilitate an interconnected system that reuses and redistributes productive resources.

Preliminary findings and outlook

The five biomimetic principles derived from the analysis are shown in Table 1.

Main Ecosystem Variables	**Corresponding Biomimetic Principle**	**Theoretical Implications**
Roles of Agents/Actors	**Principle 1:** The ecosystem has enough scavengers and decomposers	Move beyond analyzing ecosystem producers and consumers, deliberately including the two roles of scavengers and decomposers.
Structural Characteristics (Decentralized vs. Centralized) (Interdependent vs. Independent)	**Principle 2:** The ecosystem has reliable, decentralized information storage **Principle 3:** The ecosystem has products designed for reverse material flows	Move beyond the focus of linear flows of either materials and/or information and/or financial flows, to a simultaneous perspective. Also, deliberately include reverse flows for materials.

		Challenge assumptions of centrality by reflecting on latest technological developments in terms of decentralized information storage and processing.
Co-Evolution (of Actors and the System)	**Principle 4:** The ecosystem members collaborate, joining varied capabilities toward co-evolution	Study ecosystem members with a synergistic lens, looking beyond "traditional" large firm actors, to deliberately include start-ups, intrinsically motivated individuals or NGOs, and how they co-evolve.
Internal Mechanisms (Emerging and self-organizing vs. hierarchically governed); (Reciprocity and circularity vs. Causal and deterministic); (Openness vs. separation); (Connective vs. encapsulated)	**Principle 5:** The ecosystem members see the forest and not the trees, acting in line with the other principles	Move beyond basic assumptions of short-term focus and narrow economic objectives of actors. Move beyond hierarchical governance to how ecosystem members collaborate self-organized toward a common, emergent goal (e.g. circular economy).

Table 1 – The biomimetic principles' main relation to specific ecosystem variables from literature and their summary of theoretical implications for network and complex adaptive systems research

As a broad outlook, in a way, the coordination in fungal networks in forest systems is still incredibly superior to human systems, even if we emulate the ubiquitous information and reverse material flows. One of the reasons is that the resource-sink coordination in our economic system is done primarily by price/willingness to pay. Whether that transfer is actually (most) beneficial to the overall system is not taken into account, which is actually factored in the natural ecosystem. If 10 tons of secondary material steel are going on the secondary market and a producer of luxury barbecue grills has the highest willingness to pay, that is where the material goes, even if there is an orphanage bidding for it that wants to build a new roof. That would not happen in nature. Nevertheless, improving resource efficiency and eliminating waste in mimicking fungal networks will already take us a long way compared to the current, wasteful economic system we operate.

The case study research in this paper relies mostly on interviews and materials related to two organizations. For future research, widening the scope of companies and also following a longitudinal approach holds further potential. Nevertheless, the innovative company studied provided a unique opportunity to study an early emergence of a fungi-like network element toward a circular economy.

For future research, such insights from biomimicry might also have explanatory power for the rise of the gig economy and sharing economy phenomena, currently visible. An example from nature related to resource allocation and sharing is illustrated by hermit crabs. They form a line of different-size shell searchers when one crab has found a shell too large for itself and then engage in the following process: "Synchronous vacancy chains occur after several crabs adjacent to an available vacant shell have queued in decreasing size order; as soon as the largest crab switches

into the vacant shell, a rapid series of sequential shell switches takes place" (Rotjan, Chabot & Lewis, 2010: 639).

In addition, the idea of ''meta-networks'' from research on forests also provides another interesting avenue for future research. Such meta-networks are a series of hierarchical, interacting networks and have been found to play an important role in forest resilience, when disturbance thresholds are crossed (Simard, 2009). "The interactions among these three networks: mycorrhizal, plant community, and nest networks; reinforce each other. […] I propose that these three networks function as a hierarchical ''meta-network'', where (a) each network is classified as a network guild according to the manner in which it acquires limiting resources (i.e., fixed carbon for ECM fungi, soil water and nutrients for establishing trees, and canopies and cavities for small mammals) (after Martin & Eadie, 1999), and (b) the networks interact with and stabilize each other, from which emerges complex structures and functions that stabilize the whole forest" (Simard, 2009: 103).

Another aspect for further consideration is that fungi networks combine information and material flows within one ubiquitous network. Or, as it has been said: "Perhaps the single most compelling attribute of MNs [mycorrhiza networks] is their potential to act as below ground avenues for the transfer of C [carbon] and nutrients among plants within a community" (Simard et al., 2012: 43). The area of "physical internet" could, therefore, strongly benefit from a biomimetic perspective that combines the information and physical material flows in an internet-like hub and spoke system (Sternberg & Norrman, 2017). The fungi networks, as a result of natures tried and tested evolution, might also be of avail to design those.

This research concurs with the conclusion by Murray, Skene & Haynes (2017: 377), who state: "A sustainable future for the human race will demand systems-based thinking that involves, in equal measure, society, environment and economics. It is the re-knitting together of these pillars of sustainability that must happen if we are to rediscover a balanced existence with the rest of the biosphere. […] A circular economy involves entire networks of production, and there is a diffusion of responsibility throughout these networks, with the producer and consumer not remaining ethically neutral. Future research should begin to incorporate the latest ecological knowledge into our understanding of naturalistic economical models and systems, without silencing the social and human dimension." The biomimetic principles presented in this research will hopefully serve as stepping stones to facilitate the shifts in perspective necessary to develop circular value systems.

Abstract

This paper addresses the issue of how a purchasing department develops legitimacy within an organization. Legitimacy corresponds to the actions of an entity – in this case the purchasing department – which are desirable, proper, and appropriate. Based on an extensive literature review, the main characteristics of a purchasing department's internal legitimization strategies (pragmatic, moral and cognitive legitimacy) and of the factors influencing their implementation are identified. The objective of this paper is to discuss how a purchasing department's internal legitimacy could be a crucial driver of purchasing practices and to suggest how the concept of legitimacy contributes to PSM theory.

Key words: Image, Legitimacy, Purchasing department, Reputation, Recognition

Topic: Purchasing organization, skills and competences

Category: Working Paper

Introduction

In an article focused on the "made in France" champions, Letessier (2013) discusses about the family-owned Clarins, a European luxury cosmetics leader. Since it could count on French suppliers of high-quality components, Clarins' top management decided not to outsource to foreign suppliers. Therefore, it would be easy to conclude that it is the partnerships developed with its suppliers – or *inter*-organizational relationships – which contributed to its success. However, upon closer examination, the main success factor was rather the alignment of its purchasing, logistics and marketing strategies – and, therefore, the *intra*-organizational relationships (Hochrein et al., 2017). For instance, the logistical operations have been developed to satisfy the high-end positioning of the products, while the two-month inventories of key components in the plant located near Paris eliminate stockouts. Clearly, this is an excellent example of a well-integrated strategy, which emphasizes a high level of intra-organizational collaboration. However, such a context has to be created, with all departments involved moving in a common direction. After all, isn't it what a strategy is supposed to be about?

In practice and despite the abundance of management literature on the topic, a situation like Clarins' is not as typical as one would expect; conflicts between purchasing and the other departments are common. For instance, in the new product development (NPD) process, the purchasing department faces engineering's requirements leading into a sole supplier situation, while the purchasing manager might have developed an excellent relationship with a long-term supplier with the intent that the organization becomes a preferred customer (Schiele, 2012). With the marketing department, conflicts are more likely to arise in issues such as product customization: it then becomes customization vs. standardization, or said differently, seeing customization as a trade-off between making the customer loyal and savings through larger quantities; actually, mass customization creates a spare parts variety which might well be incompatible with the objectives associated to global purchasing (Ferguson et al., 2014). Finally, with the operations department, the purchasing department is often confronted to very different perceptions about the importance of costs, and this leads to opposite prioritizations, founded on non-congruent functional measures and goals (Pagell, 2004).

In fact, the existence of tense relationships between the supply department and the other departments have existed for a long time. From a supply department's perspective, the other departments' objectives often seem contradictory with its own with respect to low costs, high quality, and fast turnaround times. Consequently, it appears nearly impossible to meet all objectives concurrently; then, it is not surprising that the other departments might consider that the supply department's legitimacy is low. So the challenge becomes: how can a supply department improve its internal legitimacy, considering that a high level of internal legitimacy increases a supply department's power, as well within as outside the organization (Cousins et al., 2006)? In fact, a supply department's legitimacy will be considered "high" if it can align its results with the objectives set by top management so that the organization can be in a sustainable competitive position; for instance, if an organization pursues a cost leadership strategy, the supply department must absolutely prioritize cost reductions over quality improvement and innovation (Baier et al., 2008; Hochrein et al., 2017). However, how can legitimacy be developed?

Much research has been performed on legitimacy in the fields of sociology, political sciences and business administration (for instance, see Tilling, 2004; Bitektine, 2011; Rogowski, 2015). One of the interesting findings coming out of the research in those fields is that it is possible for managers to increase their department's legitimacy through appropriate legitimization strategies. This question touches upon seminal works in organizational theory sociology, such as Weber's (1922); according to this author, legitimacy comes under three categories: (1) "charismatic", which is based on a leader's personal authority or a person's heroic stance; (2) "traditional", which relies on an immemorial or uncontestable tradition; and (3) "legal",

which is established based on the adherence to impersonal and universal laws. By applying this reasoning to a purchasing department, we can equate it to (1) the charisma of the purchasing manager or vice-president in charge; (2) the purchasing department being perceived as a core competence; and (3) when it is acknowledged that due to the costs of all goods and services acquired, those numbers by themselves justify the department's legitimacy.

The concept of legitimacy has been discussed in the field of organizational theory (Deephouse and Suchman, 2008). However, research on this topic has been rather limited in the field of PSM. It is mostly in the 1980s and 1990s that most articles dealing with legitimacy and associated concepts (image, reputation) were published, when purchasing departments were becoming more autonomous (van Weele, 2014). The emphasis was often to demonstrate how critical purchasing departments were to competitive advantage and that they should be recognized for this contribution as much as the other "important" departments were. As underlined by Schoenherr et al. (2012), although purchasing departments have evolved from routine and mechanical decisions to the delivery of a true competitive advantage, that literature of a few decades ago provides a good basis for further developments on the topic of "legitimacy". This paper first clarifies the concept of legitimacy; then, it identifies the dimensions of a purchasing department's internal legitimacy; finally, it provides perspectives for PSM theory[1].

Conceptual clarification

Until now, little has been published on the issue of "purchasing legitimacy"; in fact, it is mostly through concepts such as "status", "reputation", "image", and "recognition" that some authors have discussed this topic. However, these words do not have the same meaning, although they all carry an important social dimension:

- "Reputation" is based on the assessment made by individuals about other individuals or about an organization; it also depends on a person's ability to develop socially-desirable behaviors;
- "Recognition" refers to two main dimensions: one which corresponds to recognizing someone, and the other, to an effort to be recognized for one's abilities and skills (Ricoeur, 2005);
- The "image" results from an individual's perception of many tangible and intangible characteristics and attributes associated to another individual or to an organization (Dowling, 1986).

More specifically, for PSM theory, "status" describes how a purchasing department is viewed and treated by top management and other departments (Carr and Smeltzer, 1997; Paulraj et al., 2006; Tassabehji and Moorhouse, 2008; Luzzini and Ronchi, 2011), and acts "*as a precursor for many of the characteristics of purchasing that the literature considers being 'strategic'*" (Cousins et al., 2006, p. 778), while "reputation" stems from the perceived ability of this department to create value (Cavinato, 1987; Goebel et al., 2003; Chen et al., 2004). However, it appears that what some authors call "reputation" (Haynes and Helms, 1991; Eisenhardt and Schoonhoven, 1996; Goebel et al., 2003; Eltantawy et al., 2009) is called "image" by others (Carter and Narasimhan, 1996; Luzzini et al., 2012). As for "recognition", it corresponds to how other departments and top management view both the actual and the formal purchasing department's strategic roles within the organization (Carter and Narasimhan, 1996; Luzzini and Ronchi, 2011).

[1] This paper is an extension of an analysis based on a research which initially lead to an article published in the *Journal of Purchasing & Supply Management* (Tchokogué *et al.*, 2017b). It indeed makes a different contribution than does the article.

Eisenhardt and Schoonhoven (1996), as well as Chen et al. (2004), are the only authors to have discussed "purchasing legitimacy" directly, although they don't differentiate between external and internal legitimacy. Eisenhardt and Schoonhoven (1996) have specifically pointed out that when a purchasing department enters into strategic partnerships either to gain access to or to acquire unique and valuable resources, it can leverage its reputation, its status, and its legitimacy. As for Chen et al. (2004), they note that internal customer responsiveness may be considered as an "output-based competency" that indicates how well a purchasing department delivers value to internal customers, a reality which, in turn, enhances the purchasing department's reputation and its legitimacy. For these two groups of authors, "legitimacy" thus differs from reputation, and status; however, the authors provide neither a definition of legitimacy nor the factors influencing it.

Referring to authors in the field of management, it is clear that the concept of legitimacy has received significant attention from researchers in institutional theory (Suddaby and Greenwood, 2005; Golant and Sillince, 2007), and resource dependence theory (Zimmerman and Zeitz, 2002; Drees and Pursey, 2013). By adopting the resource dependence perspective, some authors have already noted that legitimacy, reputation, and status are three different – albeit important and related – dimensions of an organization's identity, and as such, are considered as key concepts in organizational theory (Bitektine, 2011). Specifically, from the resource dependence theory perspective, "*legitimacy can be considered as similar in nature to an asset, perhaps somewhat like a money, a resource an organization requires in order to operate*."(Tilling, 2004, p. 4). Since a purchasing department is a structure within an organization, we can say that the reasoning and the studies above likely apply to it as well as for an organization. Now that we have shed some light on the concepts associated to "legitimacy", we will discuss more specifically about "internal legitimacy" and its important dimensions.

Dimensions of a purchasing department's internal legitimacy

According to Suchman (1995, p. 574), who refers to organizational legitimacy: "*Legitimacy is a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions.*" This definition could refer both to internal and external legitimacy, depending on whose constructed system of norms one refers to. Therefore, we could say that a purchasing department's *internal legitimacy level* corresponds to how significant the purchasing department's contribution is perceived to be by the other departments' managers and by top management. Legitimacy is multidimensional (Low and Johnston, 2010; Crespin-Mazet and Dontenwill, 2012); while some authors suggest two dimensions, *managerial legitimacy* (which is based on efficiency logic) and *technical legitimacy* (based on technology, quality, and qualification) (Ruef and Scott, 1998), others believe that there are rather three dimensions: pragmatic legitimacy, moral legitimacy, and cognitive legitimacy (Johnson and Holub, 2003; Zyglidopoulos, 2003; Tchokogué et al., 2017b). It is this second perspective that we are using in our research. As mentioned at the end of the previous sub-section, since a department is also a structure which is part of an organization, this reality makes it possible to apply those three dimensions to a purchasing department. Therefore, in the following paragraphs, we discuss about what these dimensions could correspond to for a purchasing department:

- *Pragmatic* legitimacy relies on the self-interest of conferring entities (Suchman, 1995; Díez-Martín et al., 2013). For instance, if other departments consider that the actions taken by the purchasing department benefit them, the purchasing department's legitimacy would be higher than if the opposite is true. Pragmatic legitimacy may result from actions taken by the purchasing department, for instance involving other departments early in the supplier selection process, ensuring continuity of supply, and partnering with key suppliers.

- Internal legitimacy could also be based on *moral* considerations, when the actions taken benefit an organization's well-being, since any system is built on social values. It also appears that a "moral orientation" reduces opportunistic behavior (Cheng and Chen, 2016). Therefore, moral legitimacy could be studied through the results obtained and the managerial procedures implemented (Bitektine, 2011). From this standpoint, some authors believe that legitimacy is a "*fit with normative values and beliefs*" (Rindova et al., 2006, p. 54). A purchasing department's moral legitimacy would then correspond to its ability to do the "right things", for instance being guided by socially-responsible purchasing (Zorzini et al., 2015), and paying higher prices in order to support local suppliers.
- As for *cognitive* legitimacy, it is related to the relationships between an organization and its partners. Cognitive legitimacy opens the door to new business opportunities and to internal as well as to external resources, something which would have been more difficult otherwise (Cruz-Suarez et al., 2014). There is also clearly a societal dimension, since cognitive legitimacy comes from the fact that judgments from others – and mostly from external stakeholders – is so important that the individuals within an organization are not even tempted to bend the rules (Palazzo and Scherer, 2006). It would then translate into the stakeholders' perception of purchasing personnel's knowledge about the environment, regulations, and legislation, as well at its ability to use those in a value-creation process. Thus, based on Eisenhardt and Schoonhoven (1996), a purchasing department's internal legitimacy is an intangible resource that can help improve the department's strategic position; legitimacy itself has no material form (Hybels, 1995; Tilling, 2004).

Therefore, as an intangible resource, internal legitimacy can be associated to the resource-based view, which has been widely developed since the 1980s, due to the seminal contribution by Penrose (1959), who ponders as to how organizations grow, based on a *reservoir* of productive resources. A resource is an essential component under an organization's control; it can be tangible (raw materials, financial, etc.) or intangible (know-how, organizational culture, etc.). Barney (1991) suggests that it is the characteristics of the resources which make it possible for organizations to build, develop, and maintain a sustainable competitive advantage; there are four characteristics which are critical to gain that advantage: its value, its rarity, its non-substitutability, and its difficulty to be duplicated. Subsequently, many articles have been published in PSM where the resource-based view was the main theory used for the research (for instance, Hult et al., 2003; Hunt and Davis, 2008; Barney, 2012; Hitt et al., 2016; Yu et al., 2017). Resources should be created and developed, not only managed; a higher level of internal legitimacy should normally result from such an approach.

There are a few studies showing a relationship between a purchasing department's contribution and value creation and/or the perception of its importance in the organization (Pearson et al., 1996; Zsidisin et al., 2003; Luzzini and Ronchi, 2011; Tchokogué et al., 2017a). While some authors consider only the other departments' perception (Pearson et al., 1996), others consider many variables (Zsidisin et al., 2003; Eltantawy, 2008). For instance, Zsidisin et al. (2003, p. 130) suggest that the perceived importance of a purchasing department within an organization rests on three main variables: "*(1) the perceived importance of purchasing and supply management by top management and peer corporate functional areas; (2) the degree to which purchasing and supply management is accountable for achieving specific, measurable goals; and (3) the strategic integration of purchasing and supply management within its own firm*". Those three variables, which correspond to the three dimensions of the purchasing department's internal legitimacy (pragmatic, moral and cognitive), allow for a clear identification of the factors used in legitimization strategies. Other studies show that the purchasing department's status, purchasers' knowledge, and collaboration with key suppliers influence purchasing maturity seen as the level of professionalism within the purchasing

department (Rozemeijer et al., 2003; Axelsson et al., 2006; Foerstl et al., 2013; Schweiger, 2016).

Clearly, a purchasing department can be considered more mature than others, based on factors such as data consolidation, performance measures, and partnering with key suppliers. These practices are a sign that a purchasing department's professionalism is increasing its professionalism, while becoming more sophisticated in operationalizing effective supplier selection, purchasing procedures, and appropriate information systems. There are also examples of purchasing departments playing a strategic role upstream from production processes, for instance by collaborating with the R&D department in new product development; in such cases, the purchasing department's maturity level would be considered "high." Similarly, based on Pearson and Gritzmacher (1990), it can be more or less sophisticated, based on the following two characteristics: (1) the organizational structure (as a proxy for the purchasing department's status), and (2) the organizational perception. Those characteristics correspond to the *purchasing department's internal legitimacy* in our study. Therefore, status and legitimacy influence each other and should be analyzed together; Table 1 summarizes the main constructs associated to these two concepts.

Through its three dimensions, a purchasing department's internal legitimacy is both part of the context for exchange and a by-product of exchanges within the organization. A low legitimacy level could ultimately lead to the outsourcing of the department's operations. Considering that internal legitimacy is so important for a purchasing department, for instance when security of supply constitutes an important contribution to the firm's competitive advantage – a key component, based on the resource-based view (Penrose, 1959; Barney, 1991) – or when the purchasing department supports business strategy by improving lead time in integrating highly-reactive suppliers (Hesping and Schiele, 2015), one could wonder which of the three dimensions (pragmatic, moral, or cognitive) a purchasing manager should emphasize, unless it's better to make efforts on all three.

Table 1 A purchasing department's status and legitimacy: concepts and constructs

Concept	Constructs	References	Definition
Purchasing department's status	Recognition	Cavinato (1987); Eisenhardt and Schoonhoven (1996); Smeltzer (1997); Goebel et al. (2003); Chen et al. (2004); Cousins *et al.* (2006); Eltantawy et al. (2009); Czinkota et al. (2014); Luzzini and Ronchi (2016)	The actual and formal recognition of the purchasing department's strategic role within the organization
	Report level	Mol (2003); Paulraj et al. (2006); Luzzini and Ronchi (2016)	Number of direct-report levels between the highest ranking member of purchasing department and the CEO
Purchasing department's internal legitimacy	Pragmatic	Tchokogué et al. (2017b)	The extent to which the purchasing's practices and results correspond to what is expected
	Moral		The extent to which supply does the "right thing", with regards to sustainability principles.
	Cognitive		Purchasing personnel's knowledge and their ability to use it in creating value

Perspectives for PSM theory

According to the vision of Penrose (1959) and Barney (1991), legitimacy can be considered an intangible resource for any organization; therefore, this is the case for a purchasing department, and our research can then be viewed from the perspective of a *resource-based view of PSM within the firm*. Based on a concept developed by Dowling and Pfeffer (1975, p. 271), we could say that a purchasing department's internal legitimacy is an organizational "*social resource.*" This approach to analyze the purchasing department's internal legitimacy has two main perspectives for PSM theory: (1) to take into consideration to a larger extent the potential impact that this department's internal legitimacy has on the activities performed within the purchasing department and on its performance; and (2) to integrate legitimization strategies within the purchasing strategy.

Impact of a purchasing department's internal legitimacy

Considering a purchasing department's internal legitimacy as an intangible resource helps to realize that the legitimization strategies should be in line with that department's identity, e.g. its development level and its personnel's abilities and knowledge. In addition, the development of a strong organizational identity as explained by Scott and Lane (2000) appears to contribute significantly to the development of individual departments. Therefore, it is important for purchasing managers to manage their department strategically, *including* in the selection and the operationalization of appropriate legitimization strategies. For instance, if the purchasing strategy is focused on global sourcing to reduce purchasing costs, it would be illogical to emphasize the moral dimension of internal legitimacy by purchasing from local suppliers who would, ultimately, represent only a small percentage of the total purchases.

Through appropriate legitimization strategies, the purchasing manager builds, step by step, a social capital based on the recognition by the other departments' managers of the appropriateness of the actions taken to increase value; this social capital is made of resources associated to detaining a lasting network of interpersonal relationships which will facilitate the purchasing manager's efforts in implementing appropriate legitimization strategies. The economic capital that it develops through managerial competencies and the expertise in selecting supplier is clearly important; however, according to the vision of Penrose (1959) and Barney (1991), it is emphasized by the ability to find supporters in the other departments, thereby contributing to an extended influence network. There is a virtuous circle for internal legitimacy: when the purchasing department is viewed as strategic, it is included in the firm's strategic planning process; then, through its practices, it can increase both its pragmatic, moral and cognitive legitimacy. However, the reverse is also true. Referring to Rowley and Moldoveanu (2003), we can say that a purchasing department builds its social identity by operationalizing its legitimization strategies with the objective of making its actions – for instance those creating value, improving customer service or being focused on sustainability – known.

Legitimization strategies within the purchasing strategy

The strategies used by purchasing managers either to gain, maintain or extend a purchasing department's internal legitimacy take different forms depending on which legitimacy dimension they are trying to influence. According to Tilling (2004), a specific legitimization strategy can be in one of four categories: (1) establishing; (2) defending; (3) extending; or (4) maintaining legitimacy. Therefore, since purchasing managers also use legitimization strategies, the same categories could apply with regard to the purchasing department. In *establishing legitimacy*, purchasing managers should: (1) develop internal competencies, including at the relational level; and (2) ensure that the decisions and actions are in accordance with accepted standards of professionalism. In other words, legitimacy relies on an organizational isomorphism process

whereby purchasing managers rely on current norms, for instance selecting low cost suppliers in order to support a cost strategy in industries where the recognized strategy is based on cost competition. At the other end of the spectrum are purchasing departments associated to a high level of professional and relational competencies; such characteristics help create a sustainable organizational competitive advantage. In order to *maintain legitimacy* at a high level, purchasing managers then use strategies aimed at anticipating, preventing, or forestalling potential challenges.

It also seems that in many purchasing departments, the competencies do exist, but the potential contribution to providing a competitive advantage is not recognized within the organization, whether because the other departments believe that the purchasing department does not demonstrate enough moral considerations in the way it acts (*moral internal legitimacy*), or because they are not aware of that department's competencies and know-how (*cognitive internal legitimacy*). In order to change this perception (*extending legitimacy*), purchasing managers should demonstrate appropriate results more clearly, but also the purchasing department's competencies and know-how. The situation where purchasing managers have to *defend legitimacy* is quite different: the legitimacy level is high, but often due to the purchasing manager's personality or to a few persons in that department being particularly appreciated in terms of their competencies and/or collaboration. Since these people have a lot of influence, their legitimacy is confounded with the department's legitimacy. In such situations, purchasing managers should: (1) attract more high-caliber individuals in order to develop a strategic approach; (2) ensure that departmental actions are in accordance with accepted standards of professionalism.

Legitimization strategies can be grouped according to the three dimensions of internal legitimacy; as illustrated in Table 2, the operationalization of each of those dimensions is activated through different levers. Based on the resource-based view, tangible resources are mainly the purchasing department's personnel, as well as the available tools. Intangible resources are the accumulated knowledge and know-how of the purchasing team, but also their relational competencies when dealing with various stakeholders, including internal clients. Insofar as legitimacy is a resource (Suchman, 1995), the operationalization of legitimization strategies can be considered a process by which a purchasing department increases an organization's intangible resources. This is why a purchasing department's internal legitimacy should be well managed, notably by identifying the most appropriate legitimization strategies, considering which internal legitimacy level a purchasing department is already at. Since a purchasing department's legitimacy level is often associated to how much involvement its manager has in the strategic management decision making process, it should be remembered that more involvement results in a higher purchasing maturity and increases overall organizational performance (Bemelmans et al., 2013).

Table 2 Examples of legitimization strategies and the levers used for their operationalization

	Pragmatic internal legitimacy	**Moral internal legitimacy**	**Cognitive internal legitimacy**
Legitimization strategies	- Strong cost reduction orientation - Research of new raw material sources	- Development of corporate social responsibility (CSR) programs - Increase of purchases from local suppliers	- High contribution to value creation - Centralization of supply activities in the purchasing department
Levers used	- Strong managerial competencies - Recognized professional expertise	- Construction of a positive relation with suppliers - Environmentally-friendly image	- Highly-qualified personnel - Clear reporting of the department's performance

Conclusion

Although the link between "performance" and "PSM maturity" has been studied previously (Schiele, 2007; Batenburg and Versendaal, 2008; Kerfeld and Hartmann, 2010; Raschke and Ingraham, 2010; Úbeda et al., 2015; Johnsen, 2018), no detailed study exists on the steps leading to the progressive recognition of the purchasing department's contribution. One plausible explanation for this situation rests with the multidimensional character of internal legitimacy, which makes it difficult to find an appropriate approach for a solid analysis. Another possible reason for the absence of any in-depth study about a purchasing department's internal legitimacy might have to do with the fact that "internal legitimacy" is mostly associated to more general studies about tensions among functions, often in terms of intra-organizational conflicts. Actually it is Thompson (1967) who discussed about this reality, boosting knowledge in organization theory, but no researcher in the PSM field really tried to apply these concepts to the supply field.

This paper has clarified the concepts of internal legitimacy, status and reputation. In addition, we have identified that there appears to be a link between a purchasing department's development level and its internal legitimacy level. Also, we found that the achieved or expected results depend on a few important factors: (1) where the purchasing department stands at a given time in terms of the contribution perceived, similar to a "balance sheet" evaluation; (2) how quickly it evolves; and (3) the goals pursued and the efforts already made to achieve those goals. The combination of these three factors help to understand not only where a purchasing department stands at that time, but also where it will likely be in the future; actually, it might even be possible to get an impression as to how quickly the purchasing manager will get the department where he/she wants it to be. From this standpoint, our research shows that any attempt to take steps based on coherent legitimization strategies could help to improve both a purchasing department's legitimacy level and its development level.

A purchasing department, which is not considered by top management and the other departments as being strategically-oriented, has to develop legitimization strategies in order to do so and become more effective. And this brings the second major contribution which shows that by using the theoretical framework initially developed by Suchman (1995), pragmatic internal legitimacy appears to be a prerequisite to moral legitimacy; and both carry more weight than cognitive legitimacy. However, since cognitive legitimacy is not controlled by purchasing managers, it is more difficult to make the appropriate efforts to reach a higher level; actually, cognitive legitimacy can be considered as the coronation of the efforts made toward improving internal legitimacy by using multiple levers appropriately. Therefore, purchasing managers should first demonstrate concrete results, and then improve relationships with external parties such as suppliers. There is no need to spend too much time on trying to convince top management about how good the purchasing department is or can be: prove it first by acting properly on the first two dimensions; then it will be easier to achieve cognitive internal legitimacy.

When a supplier "liberating" its organization! Consequences for the purchasing firm and the supplier-customer relationship

Abstract
In recent years, the concept of "freedom form" ("F-form") organization, proposed by Getz (2009) has been deployed timidly in firms. This approach questions intra-organizational management. According to our knowledge, no research has been conducted with a supply chain management perspective on the consequences of this "liberating" process with an inter-organizational vision. In this exploratory paper, the impacts of "liberating" a supplier on the relationship with its customer are questioned. A single case study is analysed, with the focus on the buyer's perception. Results indicate the relationship has not changed, although potential benefits could be identified.

Key words: "F-form" organization, supplier-customer relationship, transport procurement.
Topic: "supplier relationship management"
Working paper

Introduction

In recent years, the concept of “freedom form” or “F-form” organization has been deployed timidly in firms. Beyond the philosophy of the concept proposed by Getz (2009), this approach questions intra-organizational management. The proposition is to end Taylorism, pyramidal and hierarchical firms, although it particularly hurts the intermediate levels of management by proposing the sharing of objectives and responsibilities. According to Bismuth (2015), seven points differentiate the F-form company from a "traditional" company: combining well-being at work and productivity, having a shared vision given by a charismatic, exemplary and humble leader, having shared values, ending with long control loops, making actors autonomous, adopting the principle of subsidiarity and reversing the managerial pyramid. The importance of self-governance should strengthen employee involvement (Laloux, 2014). Criticisms of the model are numerous, especially related to the place accorded to employees in this approach and the consequences of a stronger empowerment. One of the major criticism is the full power that seems to be given to the charismatic leader who carries the project, Geuze (2015) going as far as to mention this approach as a "communication strategy and imposture".

Beyond conflicts and positions taken by the authors in favour of or in opposition to the concept, research is done on the impact of this approach in an intra-organizational vision. For example, the construction of new collective skills within organizations is questioned (Dufresne, 2017). However, according to our knowledge, no research has been conducted with a supply chain management perspective on the consequences of this "liberating" process with an inter-organizational vision. We propose to answer the following research question: which are the impacts of "liberating" a supplier on the relationship with its customer, taking into account the perception of the purchasing firm?

The methodology is a single case study with primary data collection (semi-structured interviews) and secondary data collection (data resulting in particular from the communication made by the supplier company in media). The results focus on the buyer's perception of the relationship with its supplier. In the first part, we discuss the concept of F-form organization. Then, the methodology and the results from the case study are presented. The conclusion allows us to make managerial recommendations as well as to identify limits and research proposals.

The “freedom-form” or “F-form” organization and the “liberating” process

The concept of “F-form” company, defined in Carney and Getz's book, *Freedom, Inc.*, published in 2009 and which quickly became a best-seller in management, has been the subject of dozens of press articles, TV reports and has generated a real buzz on social networks (Dortier, 2016). However, the dimensions of the concept are not new in themselves, and Mayo, as early as the 1930s, highlights the importance of the human factor in industrial success, thus counterbalancing the Taylorism model (Mayo, 1949). In the same view, other approaches can be mentioned, such as Theory X by Mc Gregor (1960), the H firm (Western firm with a vertical model) and J firm (Japanese firm with a horizontal model) by Oaki (1986) or the approach that appeared in the 1980s on participatory management, in line with another bestseller, written by Peters and Waterman (1982), *In Search of Excellence*. Therefore, the dimensions of the concept will be identified, then its advantages are presented before highlighting the main criticisms in the literature review.

The F-Form” firm: definition

The first use of the term "Liberation Management" appears in Peters (1992), where this type of structure is described as an adhocracy, the firm being divided into individual micro-firms connected in a network and made up of multidisciplinary, autonomous and responsible

persons. But it is the book by Carney and Getz (2009) and the article by Getz (2009) that really put forward this notion. The media, especially in France and Germany, and the report "happiness at work" by Meissonnier (broadcasted in 2015 on the Arte TV chain) both contributed to the buzz of this concept. This interest is then perceived as a proof that the F-form company would meet a real societal need (Verrier and Bourgeois, 2016).
The definition of the F-form firm, as proposed by Getz (2009, p.34) is relatively vague because this type of organization is defined by "what it is not", i.e. by a counter model with the so-called traditional Taylorism approach: (2009, p.34): "*we decided to look for the answer to this non-adoption question by narrowing down the initiative-freeing form to its radical variant, which we call F-form: an organizational form in which employees have complete freedom and responsibility to take actions that they, not their bosses, decide are best* ". The F-form firm is then not defined by its characteristics but by its "functions: "*Just are architects define human-built structures by their functions rather than by a set of structural features"* (Getz, 2009, p.35).
Through the analysis of case studies of international leading companies in their field (such as Harley Davidson and Gore), with an approach described as narrative by the authors, and in line with Maslow (1943) and McGregor (1960), Carney and Getz (2009) report that an F-form firm finds some common characteristics, such as the fact that most firms have no organizational charts, no assigned office (everyone, including the CEO just selects an open desk), many allowing employees to pick up their leaders and choose their job descriptions, and in essence invent their own jobs. Other elements, which might seem more anecdotal, are mentioned as the replacement of ceilings by stairs to increase mobility and communication between employees or the fact that there are no time clocks.

The "how" firm and the liberating process
The F-form firm can therefore be compared to the "why" company in opposition to the "how" one, also referred as the hierarchical, bureaucratic company where the "command and control" model is very present (Carney and Getz, 2009). The "why" firm is a company that relies on "*the knowledge and abilities of all employees by promoting initiative and creativity and by facilitating proactive behaviours*" (Verrier and Bourgeois, 2016, p.8).
In order to adopt this type of organization, some conditions appear fundamental. The first one is the leadership style, which is named "liberating" one Carney and Getz (2009). The second one is linked to the work conditions, namely the introduction of self-motivation (Gagné and Deci, 2005; Carney and Getz, 2009): the need for "relatedness" (need for to be treated in an intrinsically equal manner), the need for competence (need to master competencies and to increase one's skills for example), and the need for autonomy (need to be self-managed and self-directed). Leadership is therefore diffuse. The third condition is the need for the company to have a world-class vision, and the fourth one is that the company has values similar to freedom values in its history and identity (Carney and Getz, 2009).
Finally, for liberating a firm, four steps seem to emerge:
(1) The dismantling of symbols and practices that prevented employees from feeling equal (Getz, 2012) in parallel with a reduction or even elimination of common management practices (Getz, 2009).
(2) The elimination of these practices must be replaced by the vision of the leader, that he/she must share, and the implementation of shared rules of behaviour.
(3) The setting up of an environment favouring self-motivation, strongly supported by the liberating leaders.
(4) The preservation of this new culture. Two risks are raised by Carney and Getz (2009): the tendency of employees to return to a "how" firm with a "command-and-control" perspective, and the trend to think about short-term issues instead of projecting into an ambitious vision in

long term. Leaders must therefore ensure that the vision remains shared and at the heart of practices.

The criticisms of the F-form model

Several criticisms emerge. The most common one is related to the "buzz effect" of the model which would be temporary, during its implementation, like other approaches (Geuze, 2015). As Aguilar notes (2016, p.18), "critics ask "but what does the company need to free itself from?". The choice of terms may indeed raise questions. If we refer to the title of the original edition of the book published in the United States, "Free Your Employees and Let Them Lead Your Business to Higher Productivity, Profits and Growth" (Carney and Getz, 2009), we understand that it is the "liberation" of the employees that is put into question and not the firm's. Nevertheless the question remains. Would there be imprisoned employees?" Getz (2009) also mentions the need to liberate leaders. But who are these leaders and what do they need to be released from?

More generally, research on new organizational forms such as autonomous teams or management by objectives also indicates that this type of organization presents risks and potential negative consequences for employees (Ajzen, 1991). Although they focus on empowering and the autonomy of employees, they do not increase sufficiently self-autonomy but rather increase control and pressure on employees (Geary and Dobbins, 2001). In the specific case of F-form organizations, some exclusions can sometimes be observed in the liberating process (Picard, 2015, quoted by Aguilar, 2016); this phenomenon is also underlined by Aguilar (2016, p.52) in the case of Decathlon company: "*Although the F-form company says that it contributes to the well-being of employees, the discourse of the actors of the field indicates that this well-being does not concern all employees and that the approach is more suitable for certain people than for others*". Finally, there is no single path: the company that initiates a liberating process starts from its own history, from its own organization. This process, as said earlier, is largely influenced by the leader.

Research on the implementation of this approach, with an intra-organisational vision, seems to have emerged in recent years. However, to our knowledge, no research has been done on an inter-organisational approach, to identify and understand, for example, what could be the consequences of this important change, especially in a customer-supplier relationship. Yet, the implementation of Supply Chain Management (SCM) is defined by Mentzer et al. (2001, p.18) as "*the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within a supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole*". The SCM approach aims to increase value creation for end customers and significantly improve the economic performance for stakeholders, although the performance measurement issue remains unanswered (Gunasekaran et al., 2004). This collective aptitude is based on efficient management of inter-organizational interfaces. Ballou et al. (2000) support this view and postulate three dimensions of SCM, namely: (1) intra-functional coordination, (2) coordination of inter-functional activities, and (3) coordination of inter-organizational supply chain activities. The impact of a "liberating" process in a firm will conduct to changes of intra-functional coordination and inter-functional coordination inside the firm which decides to introduce this process. The impact on inter-organizational supply chain activities could be questioned in the lean vision of SCM. In this working paper and using an exploratory approach, we question the potential impacts for the customer of the company that is released. A qualitative methodology is used.

Research methods, results and managerial implications

Data collection and analysis

The first step in a research methodology is to define the unit of analysis. In this research, it is a supplier-customer relationship in the specific context when a supplier decides to modify its intra-organizational management by liberating its organization. A semi-structured interview guide has been developed prior to data collection, as suggested by Yin (2009). Three semi-structured interviews were conducted with the purchasing firm, mainly with the relationship manager, between November 2016 and January 2017. Documents related to the supplier (including media communications) as well as documents on the buyer-supplier relationship before and during the liberating process were also collected. Those documents are complementary sources of information to better understand the context of the relationship and the interfaces between the two involved companies.

As suggested by Strauss and Corbin (1990), data coding was carried out based on the literature review and the interview guide derived from it. Two researchers coded, in parallel, the full transcripts of the interviews. The coding data were compared and discussed in order to analyse the results.

Stakeholders and context of the relationship

The supplier company, which we will call F, is a provincial company. Founded in the aftermath of the Second World War, it is the subsidiary of a group specialising in services. In 2016, it achieved a turnover of more than 100 million euros. Its field of intervention is broad since it meets the needs of its clients by implementing specific solutions, in technical terms, or in terms of the expertise of the employees that it makes available to client companies. The company is particularly active in the broad distribution, construction and ready-mix concrete sectors. With a national scope, it now covers the French territory through various subsidiaries. Company F has embarked on a process of "transformation of the company" following a succession of major difficulties (human and economic) encountered in 2011, according to the director's remarks. At that time, in the spirit of management, two important elements were needed: (1) to review the organization (qualified as too hierarchical, too centralised) in order to give more power to the operational teams by freeing up initiatives, granting them the right to make mistakes; (2) to take care of employees by moving from a traditional management based on obedience and fear to a dynamic based on trust and freedom. Since 2016, as an illustration, the members of the Executive Committee have set their own annual remuneration.

Subsidiary of an international group, the client company, which has been present in France since the beginning of the 1990s, which we will call C, is specialized in the distribution of food products to the points of sale of a network present in France. To ensure its activity, C relies on distribution platforms covering France entirely. This distributor operates with its own resources (warehouse and physical distribution activities) and subcontracts part of its activity. It is in this context that F is required to provide a service on behalf of C from four of the client's platforms.

Results: study of the client-supplier relationship and its evolutions

The client-supplier relationship

The relationship between the two companies, which has also existed since the early 1990s, is a classic supplier-customer relationship. A set of specifications formalizes the expected service, which is part of the field of physical distribution. The annual business flow between these two companies is in excess of several million. Like it does for its other service providers, C evaluates F annually. The persistence of the referencing of F in time allows us to deduce that the service provided by F to C is good and economically acceptable.

The relationship has been managed by C's operations manager since 2010, who has also defined the strategy for sub-contracting and distribution of the entire company on the territory

and is therefore in a key position to maintain regular contact with transport service providers, including F, at the highest level of their organisation. The subjects raised are, classically, subjects specific to the delivery process (service quality, economic follow-up, vehicle technology, etc.), and also subjects relating to the strategic evolutions of C's business and its potential impact on the supplier's activity. From an organisational point of view, the relationship between these two companies is also made up of meetings between F's subsidiaries and the platforms on which it provides services. These meetings, which are more operational, are intended to ensure the right service level expected and deal with possible site-specific difficulties.
It was in the context of meetings between senior management teams that F mentioned, in 2012, the first initiatives linked to the transformation process towards a liberalization of the company. The Chairman himself conducted a tour of France of the various subsidiaries to meet, through meetings held outside working hours, with all his employees to explain the process. The historical nature of the relationship between C and F seems important since it reflects the maturity of the relationship and the level of trust shared between the two companies. This allows the supplier to exchange with his customer in transparency on this organizational challenge (assuming that each company has its own strategy) and for the customer to follow, with “curiosity”, the modifications made by his subcontractor. In a way that might seem paradoxical, no change is noted in the relationship between 2011 and today, despite the major transformation experienced by the subcontractor. None of the actors at C (nor the person in charge of the relationship, nor the teams present on the platforms) report any situations related to this process that could raise questions about the quality or sustainability of the relationship. The relationship seems to continue under the same conditions and in the same way as before. Finally, if the subject was not raised regularly during discussions between senior management teams, this transformation process initiated by F would seem "transparent" to C. This observation raises questions about the perceived benefits and risks.

Perceived benefits and risks
From the customer's point of view, even if this transformation may seem at this stage to have no visible impact, nevertheless consider it interesting to question on the perceived benefits and risks, when one of its suppliers engages in a process of profound transformation of its internal organization.
Perceived benefits
As mentioned above, F’s desire to migrate towards a F-form of company dates back to 2011, the first initiatives leading to collectively building (with the involvement of all employees) the new company vision in 2012. The transformation process takes time and more than five years later, the company still continues its change. The decision of such an approach must therefore be widely considered before initiating changes, since it is a long-term questioning of the traditional model. From the point of view of actors in C, the following elements can be credited as advantages:
- Transfer to a liberated form of intra-organizational enterprise
This liberating process should have the advantage of reinforcing the motivation and involvement of the employees involved in this process without excluding the probability, particularly in the upper layers of the organisation, that the model will lead to some employees questioning their future role or even incite them to leave the organisation. As stated in the literature review, a priori, such a process of organizational change strengthens employee empowerment and eliminates managerial strata. In addition, this approach involves a profound transformation of the methods and tools used in the organization. It is also and above all the opportunity for an in-depth internal questioning of the traditional organizational

model that leads to changes. The advantages perceived in the relationship by the customer are to be confronted with a subcontractor who questions itself, which in the end confers a dynamic position expected to be positive in the context of the relationship. This could potentially be opposed to other subcontractors whose traditional organization could be considered as wait-and-see to their customers.

- *Quality of service and relationship*

Service quality and the quality of the service provided on behalf of the customer must not be affected by the intra-organizational form adopted by the supplier. Indeed, whether the organisational model of the company is "liberated" or more "classical", the demand for the expected service quality level is the same. The orientation taken by the organisation of the released company should also maintain or even strengthen service quality, since this type of approach, by its very nature, favours concepts such as work-life quality, employee well-being and any other approach that tends to give a "positive" view of the working environment. The sensitivity of the organisation involved in a release process does not affect its clients here (the approach seems to be sufficiently "controlled" and progressive enough not to disturb the existing relationship). Indeed, beyond traditional operational considerations, since F has been engaged in this transformation process, at no time has it come to question this approach in the context of its activity. Subcontractor F delivers an operational service in accordance with its client's requirements.

- *Potential customer benefits generated by this transformation process*

This orientation does not seem to have an impact on "traditional" criteria for evaluating the service provided (service quality, compliance with deadlines, etc.) but could correspond more closely to issues such as work-life quality, the OHSAS 18001 standard (the certification demonstrates a commitment to occupational health and safety and a clear and proactive consideration for employees) and could be beneficial to the client on more global elements:

- *Strengthen the professionalism of supplier teams*

By a better recognition of employees within their organisation, by a stronger corporate culture that employees have appropriated, it can be considered that the organization is more sensitive in seeking customer satisfaction.

- *Offer creativity and opportunities for new services/products initiated by the supplier's team.*

The innovation approach is at the heart of this approach, by liberating the organization and giving employees the opportunity for greater accountability, the consequence is to "unbridle" the communication of ideas and facilitate their implementation. In the case of client C, the precedence of the relationship, the perfect knowledge of the processes, in a context of liberalization of the organization at F, could lead F's employees to make proposals for improvement in the specific area of service that is carried out for this client.

- *Emphasize the stability of the company's teams engaged in a transformation process.*

In the context of road freight transport, and particularly in view of the current economic situation with regard to the labour shortage affecting this sector of activity, the Fédération Nationale du Transport Routier (FNTR)[1], announces 22,363 jobs in 1,666 freight transport companies to be filled in France at the end of November 2017. However, turnover in company F is almost non-existent, and the greater involvement/ association with the company's decisions seems to have an impact on employee loyalty and therefore on the quality of the relationship for company C.

Perceived risks

[1] FNTR website : http://www.fntr.fr/lactualite/actualites/emploi-transport-routier-de-marchandises-plus-de-22-000-postes-pourvoir-en-france?field_domaine_tid=All&field_expertise_tid=All consulted on the 01/07/2018.

There are two types of perceived risks. On the one hand, there is a potential risk in the very context of the relationship. Indeed, a process of this kind leads to organizational changes that can affect individual behaviour. The customer's historical contact person can change, or even this layer of contact person can be reconsidered. Under F, the position of Director of Human Resources has been abolished, resulting in the creation of an Innovation Director. In this relationship, the director of the company has remained the privileged interlocutor of the relationship, but other interlocutors have seen their positions evolve, with responsibility becoming shared in the company: collaborative recruitment practices; and taking on tasks by some teams of decentralized employees on the client's premises that, in a traditional vision of the manager's prerogative.

On the other hand, risks can also be commercial in the medium to long term:

- A client company with a traditional organisational model and which has some difficulties understanding a supplier who would be engaged in a liberalization process: in the medium term, this can even lead to a change in the way to do business because the client company will seek a supplier with a more standard organizational model and, therefore, more compatible with this traditional vision.
- Conversely, employees representing the released company, and the strategy of the released company itself, could seek work with client and supplier companies with similar values or even similar organizational choices and thus favour the relationship with this type of company rather than with more traditional companies. At the extreme, a client company that does not meet the standards of the new form of their company could lead to a questioning of the relationship.

Conclusion: discussion and research perspectives

While the liberated business model seems to bring major intra-organizational changes for the liberating business, the case analysed here suggests a strong stability in the client-supplier relationship. It would therefore appear that the impact of this type of change in the transformation process does not shake up previously established relationships. In particular, the results indicate that even if the client company can be made aware of the changes initiated in the supplier's organization over the last few years, the relationships have not been modified. One explanation would be given by the importance of the charismatic leader, which is not considered here in a vision sometimes evoked in the model's critics as a guru or a tribunal, but rather as a real leader, recognized by his employees and customers, whose values are in adequacy with the F-form of organization he/she wishes to implement, and who remains the privileged interface for the buyer. The maintenance of traditional management tools and a classic view of the customer-supplier inter-organizational relationship, combined with a stable service level, also explains the absence of turbulence in the relationship between the company involved in this approach and its customer.

The benefits perceived by the client company are numerous and are aimed above all at a medium-term horizon. Indeed, in a sector where the labour market is under stress (difficulty in recruiting and retaining staff), companies engaged in these initiatives could attract more interest. The employees involved who, in an ambassador's logic, convey a positive image of their firm, and firms that put forward specificities different from the traditional organizational model, can make this model more attractive on the labour market due to the originality of the approach and perhaps also the notoriety induced by this approach, for example in media.

Moreover, it is essential to bear in mind that these transformation processes of the company cannot be carried out in a proselytizing way: this type of approach, especially if the company engaged in a transformation process is a supplier, must not negatively impact relations with other organizations, especially with a customer. While it is important that the steps taken

within the organization are shared, it is even more vital that the resulting organizational changes do not modify the inter-organisational framework that binds the company to its customers/suppliers, and therefore do not disrupt relations. In general, if we look at the C - F dyad, we observe that this transformation process is really only known to a small part of the employees of the client company, and objectively, with a few exceptions, the interlocutors do not seem to express a specific view about this process. It could be considered that the employees of the client company are in their position: to expect a service from a supplier, if the latter is satisfied with it, considering that the "ethical" nature of this transformation process is de facto validated by the organization since this supplier is always evaluated.

In addition, limits can be identified. The first is like Agathocle de Syracuse who, in the 4th Century BC, decided to attack Carthage in North Africa. After disembarking his troops, he burned his ships to ensure that there would be no return. The comparison may seem excessive, but such an approach, which revises the traditional organizational model of the company, will hardly suffer from a backtracking: after having liberalised (and all that this entails in terms of changes in the company's habits), is it bearable for employees to see their organization become “traditional” again?

From the customer's point of view, the dissemination of responsibilities within the organization must be sufficiently controlled so that the supplier can only speak with one voice to his customer (even if this voice is shared in the company). Indeed, the questioning of the interlocutor in the company can be a factor of destabilization, since the new organizational model can lead to a dispersion of the background and specific practices of the customer.

By questioning C on the limits that it would set for F with respect to this type of approach and more generally in relation to a subcontractor, these would most likely be oriented towards the service level and cost of service expected as well as a notion of "everyone at home". On the one hand, as long as the performance of the supplier engaged in a transformation process complies with the specifications and is economically coherent, and on the other hand, as long as the organizational changes of its subcontractor do not disturb C's intra-organizational relations, there is no reason to consider questioning the relationship between these two undertakings.

Generally speaking, this type of organizational process requires a profound challenge to the traditional model of the organization and its acceptance. It seems to us that from the point of view of the client company, as long as this process does not interfere with its own organization, it remains passive and does not seem to show any interest in the "ongoing manoeuvres" at F. More marginally, some C employees, informed of this transformation process, look with curiosity and open-mindedness at the developments that result. It seems to us, however, that this positive viewpoint cannot call into question the role of the employee of the client company: to ensure that the subcontractor delivers the service at the qualitative level and within the economic framework defined by the specifications, which limits to a pragmatic framework the relations between these two companies and any type of initiatives that could be undertaken by the subcontractor. It could be interesting for C to take ownership of these changes undertaken by its subcontractor in order to seek to maximize the positive impacts that this could have in the context of the service rendered to it. These impacts could focus on aspects of innovation (R&D), customer service, and employee initiatives on behalf of C. The criteria stemming from this transformation process, which could affect other relationships, most probably concern the subjects around empowerment, employee autonomy and their ability to take on the tasks entrusted to them more easily. Unlike a company with a traditional organization, this ability to invest, and perhaps more clearly position the notion of customer service, could lead to a form of "positive discrimination" when selecting a supplier.

This case study has the advantage of questioning the potential impacts on an inter-organizational relationship of a major intra-organizational change. The inherent limitation of

the single case study choice is that the results are necessarily circumstantial and therefore not generalizable. It would be interesting to consider other case studies, via other dyads or the study of the relations established by company F with other of its customers. It would also be interesting to continue observing the evolution of the relationship over time to see if the process initiated by F is a contributor to innovations for C. Finally, it would also be interesting to question employees interfacing in the operational relationship, within the two structures, to understand their perceptions of these changes.

Industry 4.0 and how purchasing can progress and benefit from the fourth industrial revolution

Robbert-Jan Torn[1], Niels Pulles[2] and Holger Schiele[1]

1 University of Twente, The Netherlands

2 University of Groningen, The Netherlands

Abstract
Since its' announcement in 2011, the number of scientific publications on Industry 4.0 is growing exponentially. Significant investments by industrial firms, at present and planned for the coming years, indicate the expectations by the industry in terms of increased productivity because of the fourth industrial revolution. However, the link between purchasing and Industry 4.0 is largely lacking in scientific literature, despite the high financial impact of procurement for organizations. The fourth industrial revolution – cyber-physical systems with autonomous machine-to-machine communication – could enable several possibilities for purchasing. On the one hand support systems for purchasers are conceived, such as contract analysis software. On the other hand, the scenario of digital negotiations emerges, which could revitalize e-marketplaces. Operative processes can act autonomously, with automated demand identification in cyber-physical systems. In order to support the development of I4.0 strategies in purchasing, this paper further contributes by presenting the result of a project on developing a specific purchasing I4.0 maturity model.

Keywords: Purchasing; Supply Management; Industry 4.0; Smart Industry; Maturity profile; e-procurement; e-markets.

Introduction: Purchasing's central role in digital supply chains contrasting with a lack of specific research on I4.0's implications for purchasing

Not long after its introduction, the steam engine became the symbol for the transition from manual to mechanical labor and thereby the key technology of the first industrial revolution. Since then, two industrial revolutions followed: mass production enabled by electric power and the industrial advancements enabled by information technology. Now, a fourth industrial revolution (Industry 4.0 or I4.0) is envisioned: the merging the physical and the digital world by means of cyber-physical systems and machine-to-machine communication.

The expectations of I4.0 are high, but purchasing's contribution to its realization remains unclear. For instance, recent studies of PricewaterhouseCoopers among German industrial firms show that in the next five years, companies will invest 3.3 percent of their annual turnover in Industry 4.0 applications (Koch, Kuge, Geissbauer, & Schrauf, 2014). In addition, the Boston Consulting Group, estimated an increase in productivity of five to eight percent by adopting I4.0 (Rüßmann et al., 2015) and the Fraunhofer society expects a cumulative added value potential of 23 percent between 2013 and 2025 (Bauer, Schlund, Marrenbach, & Ganschar, 2014).

Similarly to the industry, academia regards I4.0 as a key research topic. Since 2012, the number of publications on I4.0 has rapidly increased for each consecutive year. This quick rise appears to be partly attributable to the German Government, which adopted the name for their high-tech strategy 2020 for future projects (Lasi, Fettke, Kemper, Feld, & Hoffmann, 2014). A similar trend is observed for terms related to I4.0 (Smart Industry, Smart Manufacturing, Industrial Internet, Cyber-Physical Systems). The general question is, how firms can profit from

I4.0? And how are supply chains changing in general and how could purchasing in practice contribute to seizing the chances the fourth industrial revolution if offering?

Surprisingly, while Industry 4.0 is flourishing in many streams of literature, research publications discussing I4.0's implications for purchasing seem to be largely absent from literature, as our extensive literature analysis has shown. This is a substantial gap in literature, since it is more than unlikely that the fourth industrial revolutions has no influence on purchasing theory and practice. Hence, firms, researchers and educators benefit from discussing possible scenarios of I4.0 in purchasing.

The intention of this research is to provide insight in the fourth industrial revolution and the distinction towards the third industrial revolution, followed by exploration of the relevance of purchasing with I4.0 for academics as well as practical relevance for purchasing managers. This paper aims to contribute to current literature by means of a literature review, presentation of results from more than 15 recent workshops on I4.0 in purchasing, and a design project, which summarizes findings in form of an actionable purchasing I4.0 maturity model.

First, after briefly characterizing current I4.0 research, the three preceding industrial revolution are described, whereby the technical and organizational aspects are deliberated upon. Then, the distinctive characteristics of the fourth industrial revolution as compared to the third industrial revolution (digitalization) are explained. Next, the paper focuses specifically on purchasing with I4.0 and supporting applications. Thereafter, maturity models in general, ones tailored to I4.0 and our own proposed maturity model are outlined. Closing, an agenda for future research in purchasing and a conclusion are presented to summarize the findings of this study.

Literature on Industry 4.0: absence of purchasing

Since 2015 publications on industry 4.0 and related topics have exponentially grown. To get a better understanding of the research fields that publish on the topic I4.0, we categorized publications on subject area. Table 1 makes a comparison between the subject areas of the documents found on Scopus for the four related topics. How publications are subdivided into subject areas indicates the relative importance of the subject areas for the respective topics. For clarity, the table is limited to only the top ten mentioned subject areas for I4.0. Thus, following the results in the table, publications from a business or management perspective typically connect to the term industry 4.0, compared to publications on Cyber-Physical Systems (CPS), which primarily refer to computer science.

Current frequently cited work in the field of Industry 4.0 is conducted by Kagermann et al (2013), Lee et al (2015), Lee et al. (2014), Monostori (2014), and Lasi (2014). In addition, Liao et al (2017) contributed the first published literature review on I4.0. Although the proportion of business literature on I4.0 is small, narrowed down to purchasing and I4.0, scientific literature is virtually inexistent. The query "purchasing" AND "industry 4.0" does currently not lead to any relevant results from academic search engines, and the query "purchasing 4.0" only mentions an exploratory case study classified as a master's thesis.

Table 1. Publications on Industry 4.0 and related topics in the last ten years by subject area (Reference date: January 30th, 2018; (percentages do not sum up to 100% due to overlap between subject areas)

Subject Area	Industry 4.0	Smart Industry	Smart Manufacturing	Industrial Internet	Cyber-Physical Systems
No. of publications	1958	69	480	596	7432
Engineering	65%	57%	59%	45%	74%
Computer Science	44%	56%	58%	75%	59%

Business, Management, and Accounting	16%	15%	8%	2%	8%
Decision Sciences	14%	8%	6%	4%	10%
Materials Science	12%	3%	5%	2%	8%
Mathematics	11%	8%	11%	19%	10%
Social Sciences	5%	8%	4%	4%	2%
Physics and Astronomy	5%	7%	7%	3%	3%
Chemistry	4%	-	3%	1%	2%
Energy	3%	3%	5%	3%	3%

According to the first literature review on I4.0 conducted by Liao et al. (2017) the enabling features of Industry 4.0 are the terms that most commonly appear in articles, e.g. Cyber-Physical Systems, Smart Factories, Industrial Revolutions, Internet of Things, Production Systems, Manufacturing Systems, Smart Manufacturing, Production Processes, and Cyber Physical Production Systems. In identifying the main research directions, the most-cited source at the time of writing (Kagermann et al., 2013) was referred to, which lists eight priority areas for actions. Before discussing the priority areas for action for purchasers, though, it is worth to clearly define I4.0 and distinguish the fourth from the preceding third industrial revolution.

Four industrial revolutions: Technological drivers turned into revolution by organisational changes

The industrial revolutions, so far, have been characterized a) by being ignited by new pacemaker technology, b) at first did only show slow productivity gains, which c) emerged only after reorganizing business. In the first revolution, the steam engine meant that one central power source became the center of one work environment – the first real factories emerging. The second industrial revolution is typically considered to have started in the 1860s with the advent of electricity and electrical motors. Having many decentralized power sources available, organizing production not following power transmission rules, but following a sequential logic of assembling a product became possible. The third industrial revolution, then, relied again on a new pacemaker technology, microprocessor enabled information technology, sometimes differentiated into computers and robots and called the “digital revolution” (Schuh, Potente, Varandani, Hausberg, & Fränken, 2014). Its start is typically terminated around the end of the 1960ies or the first oil price shock in 1974, which was a turning point in many aspects, for instance marking a shift in the spread of income (Greenwood, 1999; Jensen, 1993). An organizational consequence of digitalization was the reduction of variable costs. A globally accessible computer program virtually does not cost any cent more, if one or one hundred persons use it. As a consequence of reduced variable costs, a winner-takes-all economy emerged (Brynjolfsson & McAfee, 2014).

Finding new organizational forms made possible by new pacemaker technologies is exactly the challenge firms face now, at the beginning of the fourth industrial revolution.

Table 2 Industrial revolutions and key technologies.

Revolution	Pacemaker technology	Organizational transformation
First	Steam power	From decentralized manufacturing to a centralized factory
Second	Electric power (engine)	From power transmission to assembly line production
Third	Microprocessor enabled digitalization (computer, robots)	From distributed production to winner-takes-all platform monopolies
Fourth	Sensor enabled cyber-physical systems and autonomous m2m communication	?

Anatomy of the fourth industrial revolution: connecting the physical world with cyberspace

The question now is to identify the pacemaker technologies of I4.0, define industry 4.0 and, importantly, distinguish the fourth from the third revolution. A clear agreement on which would be the most important of these technologies lacks, though the literature analysis has shown that cyber-physical systems clearly get the most attention in publications. Also a widely accepted definition of I4.0 is still lacking in academia (Brettel, Friederichsen, Keller, & Rosenberg, 2014).

Several definitions for I4.0 have been proposed. Thoben et al. (2017, p. 5), for instance, define: "Industry 4.0 comprises a paradigm shift from automated manufacturing toward an intelligent manufacturing concept." It remains unclear, though, what "intelligent" may comprise. Kiel et al. (2017, p. 673) define I4.0 as " a novel manufacturing paradigm ensuring flexibility and adaptability of production systems and value chains in order to maintain the future global competitiveness of manufacturing enterprises". Here, a narrowing focus on manufacturing is given and also no clear distinction is made on what actually is ensuring flexibility; something, which has long been looked for. (Stork, 2015, p. 21) provides a detail in his attempt to define, I4.0, which in the context of purchasing studies is importance, by including the supply chain and suppliers: "The term Industry 4.0 […] refers to the "fourth industrial revolution," or the introduction of Internet technology in the manufacturing industry […] and integrate customers more closely into the product definition stage as well as business partners into the value and logistic chains." A problem with this definition, however, is the assumption of internet technology to be used, rather than other, more proprietary connectivity technologies. For data security reasons there are some serious doubts whether the relatively open internet would be the most feasible technological solution.

All in all, these definitions remain unclear in two aspects, namely in describing the constitutional elements of the fourth industrial revolution and in particular in clarifying how it differs from the previous, third industrial revolution of digitalization and automation. If the distinction between third and fourth revolution is not made clear, however, the danger remains that I3.0 applications are simply relabeled and no progress is made whatsoever. To differentiate between the industrial revolutions, we define I4.0 in the following way:

"Industry 4.0 is characterized by cyber-physical systems with autonomous machine-to-machine communication."

This definition on the one hand is not narrowing down applications by pre-defining technologies (such as claiming that the internet would be the connecting technology or that it would only refer to manufacturing) and at the same time allows to very clearly distil the novel aspects of the development inducing the next industrial revolution. There are three key concepts, which can be applied as a check-list, assessing the completeness of a vision or of a

solution provided, in terms of clarifying its progress from I3.0. In this way it becomes possible to accelerate technological progress:

(1.) Cyber-physical systems, explained as "transformative technologies for managing interconnected systems between its physical assets and computational capabilities" (J. Lee, B. Bagheri, & H. A. Kao, 2015, p. 21) stand at the core of I4.0. The particularly new feature is the connection between the physical and the digital world. The third industrial revolution introduced digital systems, which, however, did not by themselves connect to the physical world. In purchasing, the example at hand would be an electronic catalogue, which is a digital device requiring a human purchaser to enter his demand. In a cyber-physical system, on the other hand, the demand is detected by sensors, which observe that a material is running short.
(2.) Autonomy is the second of the constituting elements of I4.0 (Hwang, 2016), meaning that the system can "decide" for itself. Whether this decision is based on an pre-defined algorithms, expert systems or is based on artificial intelligence, it does not require further human intervention to function. An example would be smart machines, which can decide upon their own maintenance (Xu, 2017). In the third industrial revolution automated systems were installed. The difference to autonomous systems is that an automated system cannot react to novel situations, whereas an autonomous system reacts without external help. In purchasing, a simple application would be that a material decides on the moment of its replenishment. In an automated system (I3.O) the replenishment would work following a pre-defined plan, e.g. every first day of the month, whereas the autonomous system decides based on information it gets from the outside world when to replenish.
(3.) Machine-to-machine communication, finally, is another constitutional element, though a critical one as it requires safe communication to function (Sung, 2017). Instead of focusing on the human-machine interface, as in I3.0, now the novelty is that interconnected machines communicate with each other without requiring a human mediation. The classical case at hand are self-organized production environments, in which the machines communicate with each other and decide upon production, instead of leaving this activity to a central system. In purchasing, machine-to-machine communication would mean, for instance, that the computer of the buying firm orders material without an order from a human procurement agent.

One thing is worth to remark: While the origins of I4.0 lie in manufacturing, there is no reason as to why these principles should not apply to the entire supply chain (Tjahjono, Esplugues, Ares, & Pelaez, 2017). Therefore, it is worth (or even imperative) to explore in detail the potential implications of I4.0 also for the purchasing field.

The fourth industrial revolution in purchasing

To systematically start a discussion on I4.0's impact on purchasing, it is helpful to first briefly summarize purchasing activities and then, in a second step, based on this sequence of activities, verify the impact of industry 4.0. Regular purchasing activities can be depicted in the "purchasing year cycle". It can serve as basis for systematically assessing the I4.0 technologies' impact on purchasing.

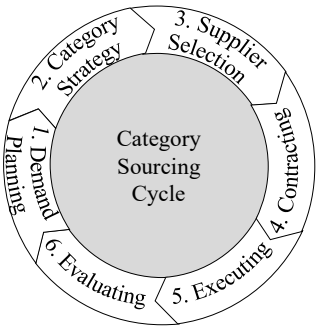

Figure 1: Purchasing year cycle (Hesping & Schiele, 2015).

Based on corporate planning that reflects the firm strategy, purchasing plans the supply for materials and services and selects and contracts suppliers (strategic sourcing; steps 1-4 in the category sourcing cycle depicted in Figure 1; Hesping & Schiele, 2015). Subsequently, these plans are executed (operative procurement step 5), and their performance is evaluated (step 6).

I4.0 applications supporting the purchasing year cycle

Implementations of I4.0 must satisfy three practical characteristics (Kagermann et al., 2013). First, horizontal integration, that is, the aggregation of distinct supportive IT systems through value networks, for instance the inclusion of suppliers of raw material or manufacturers. Second, vertical integration, meaning the integration of support IT systems used at different hierarchical levels (e.g. the sharing of data and acting upon this information during the successive stages of the manufacturing process). Third, End-to-End digital integration, the overarching aim of both horizontal and vertical integration. This refers to the integration of all functions across the entire value chain, from product design and development to production and services. End-to-end digital integration is regarded as the most difficult aspect to achieve, since it encompasses collaboration by mutually sharing digital information within and outside the firm (Kagermann et al., 2013). Concerning I4.0 implementations in purchasing and reflecting the above distinction of purchasing activities, the following paths can be suggested:

(1.) *Demand identification and planning*: Here, I4.0 technologies are not expected to show a big impact on the medium term, because the demand planning is mainly a company internal affair requiring data access on past demands, which is technically possible already by now. Next, it requires accurate sales planning, for which no I4.0 technologies have been presented, yet. One possibility, though, could rely in the use of big data analysis and artificial intelligence to improve or complement sales prognoses or to anticipate operative planning decisions (Dutta & Bose, 2015; Hofmann, Neukart, & Bäck, 2017).

(2.) *Category strategy*: Defining a category strategy follows the typical strategic management approach, requiring an internal and an external analysis. The external analysis in the case of a purchasing strategy refers to the supply market. Here, expectations are that artificial intelligence agents might be able to support supply market analysis. A data engine would collect information, while the AI would filter out those which are relevant and present them to the purchaser. The challenge lies in the learning process. How to define relevant news? And then, how to create sufficient cases so that the AI can be instructed to develop its capabilities of distinction?

(3.) *Supplier identification and selection*: In this process step, substantial achievements could be expected, exploring the ability for sophisticated text mining or artificial intelligence for analyzing the data available on suppliers (Hofmann et al., 2017). In the preparation of an RfQ it would be helpful to know all parameters of past offers, which may contain similar

parts like required. Currently such systems fail because of challenges in data classification. If this can be automatized through text mining. This could bring a break through. Based on a better knowledge on past projects, the purchaser could create a superior RfQ. Typically, then, suppliers may need some clarifications on how to respond. Here, the hope is that interactive bots could manage to answer many questions. Once the requirements are clarified, then, a big challenge for the purchaser arises: to analyze the offers submitted. Considering that offers for industrial components can easily exceed 100 pages, it becomes clear that currently a pre-selection has to take place and only a selected small number of offers can thoroughly be analyzed. The more a text mining system and in a next step an artificial intelligence can help to analyze offers and pre-select them, the more offers can be collected and seriously be considered, creating competition.

(4.) *Negotiation and contracting*: Cyber-negotiations would be a logical next step. In that case, the parties would instruct their negotiation-avatars, which would then – in thousands of iteration steps – realize the actual negotiation. At first, this process resembles an automated negotiation, as the electronic agents follow the pre-defined instructions (Cao, Luo, Luo, & Dai, 2015; Idrus, Mahmoud, Ahmad, Yahya, & Husen, 2017).There are two steps with this: at first instance, the involved parties could instruct their negotiation-avatars by establishing rules and giving clear instructions. In principle, then, pre-defined algorithms would optimize themselves. The advantage is at least fourfold: a) both, selling and buying firms have to very clearly define their expectations in order to fill in the instructions for the avatar. b) not only price becomes negotiable, but finally other criteria, which have traditionally been disregarded due to complexity, can be negotiated as well. Even fraud detection could be improved (Zhang & Liu, 2016). Different negotiation arenas can be optimized, e.g. price, diverse quality and delivery criteria, terms and conditions, liabilities etc., c) an optimum can be found, instead of just satisficing, d) there is much less danger to damage the relationship as consequence of the hard negotiations. A special challenge to be overcome here is of legal nature. For instance, who should own the data generated?

(5.) *Executing*: Cyber-physical systems could play a pivotal role in the execution phase, automatizing the demand generation in e-procurement systems, which are widely spread (Zunk, Marchner, Uitz, Lerch, & Schiele, 2014). Here, the connection between the physical world and the digital world needs to be added, for instance through devices like smart bins or sensor driven shelfs, which recognize the depletion of a store of physical objects.
In the execution phase, though of completely different nature, risk management support by artificial intelligence-driven systems. Similar to the expectation towards market analysis, a risk management system would identify and assess supply chain risks, relying on accessible data, for instance from internet resources. Another form of risk reduction could result from blockchain technology, which could find beneficial application in operative supply chains because of the creation of transparency (Tapscott & Tapscott, 2017). In case every legitimized member of a chain can access the chain data, potential delays or quality failures can already be detected early on and corrective action can be taken.

(6.) *Supplier evaluation*: Finally, in supplier evaluation an old dream of automated data analysis for evaluation could come closer. On the other hand, a more limited change impact could be expected, because such systems do not rely only on data extracted from the ERP system, but require subjective evaluations from the interface partners (in industrial applications typically next to purchasing itself, quality, logistics and engineering). These, by their nature, cannot be taken over by digital systems.

Some of the above elements could be combined, such as automatic demand generation through cyber-physical systems and cyber-negotiations. This combination could revitalize the idea of electronic market places, which failed during the “dot.com-hype” in the early 2000s,

presumably because as long as there is a human-machine interface in the moment of entering the demand into the system, an electronic market place could not offer very much more than a more comfortable paper catalogue. If demand is generated automatically and a cyper-negotiation takes place – every pencil could be negotiated, if it is electronically – emarkets could gain a new role.

Taking the perspective of a firm, the question arises how to systematically assess its potential for profiting from industry 4.0. To make a proposal for this, it could be helpful to have a maturity model, which allows to define a target to achieve and develop a step-wise roadmap to reach that goal. In order to develop this, we started a research journey.

Operationalization: A maturity model for purchasing

Method: Design case, workshops and an extensive literature review

The study originated from an aspiration to discover how purchasing can progress and benefit from the fourth industrial revolution. Several procedures were followed to ensure an academically sound prediction for the future of purchasing with I4.0. In the aim for both academic, and practical relevance, this research draws on four constructive elements: an extensive literature review; future directions for purchasing; 16 workshops on industry 4.0 application to purchasing; and a design case that integrated the preceding elements in form of a maturity model.

Starting, an exploratory approach was applied to familiarize with the topic I4.0. A systematic literature review was conducted, starting with terms including industry 4.0, smart industry, cyber-physical systems, and machine-to-machine communication. Hereby, results from Scopus were analyzed in depth to gain understanding of subject areas, geographical dispersion, frequently cited articles and authors, and the development of the number of annual results. This approach contributed to a fundament on which the design project built and contributed to the first attempt to sketch potential I4.0 applications in purchasing. The information required for this part was acquired from both academic literature as well as operational experience from the industry. Arising from the incentive to explore the future of purchasing, a total of 16 workshops on I4.0 targeted at purchasing managers were organized in Switzerland, Austria, France, Germany and Finland. Altogether more than 250 purchasers and purchasing managers attended these “fit for industry 4.0 in purchasing” workshops. Before the maturity model was constructed, alternative existing maturity models on I4.0 were analyzed and compared to identify their focus areas. The instrument was then evaluated by purchasing managers during the last two workshops. The feedback of the purchasing managers let us reconsider how advanced the first two stages of the maturity model should be.

Eight layers of industry 4.0: strategy, process, physical, p2p, kpi, sourcing, suppliers and human readiness

In developing a maturity model, a fundamental question refers to the question along which categories the maturity can be described. One approach could have been to pick the previously described purchasing year cycle and develop a scheme for each step. However, the problem with this is that often one implementation of an I4.0 tool would refer to several steps. Instead, it proved to be more operational to update a model originally conceived by Hazelaar (2016) who developed an I4.0 roadmap in indirect materials at a leading Dutch technology company.

In the context of the development, Industry 4.0 relates to implementations of machines that make decisions autonomously, facilitated by data-driven machine-to-machine communication and cyber-physical systems that convert the analyzed and communicated information to action. Nowadays, digitization takes place in business processes throughout the entire value chain instead of the role of back-office support that information technology once had (El Sawy, Malhotra, Park, & Pavlou, 2010). Despite its increased role of importance however, knowledge

regarding their level of digitization is lacking within firms (Leyh et al., 2016). As stated earlier, maturity models are helpful tools for organizations to assess their current level of development, of in this case digitization. Moreover, a practice-oriented definition of I4.0 is desired to propel further digitization in alignment with the long-term vision and strategy of organizations (Lichtblau et al., 2015).

The result of the preliminary research is the design a maturity model of eight layers: (1) strategy, (2) process, (3) physical level, (4) purchase-to-pay, (5) purchasing controlling structures, (6) sourcing, (7) supplier involvement and (8) human readiness. Within the eight layers, each item for assessment is described for four maturity levels where level one describes a pre-mature stage of I4.0, by which a lack of adoption of I4.0 concepts is meant. Level four represents world-class performance, a profound adoption of I4.0 concepts fulfilling all three constitutional criteria defined above (cyber-physical, autonomous systems and machine-to-machine communication) and alignment of concepts on a strategic level of the organization. For a more detailed overview of the maturity model see the Appendix.

1. *Strategy*: Before firms can start adapting the fourth industrial revolution, a strategy is required to prioritize the focus areas of the organization before moving towards the future desired state (Geissbauer et al., 2016). For this reason, strategy is the first layer of our maturity model. A distinction is made between an I4.0 strategy, determining requirements and priorities for the entire firm, and ultimately an I4.0 strategy tailored to purchasing. The latter is an important refinement, because strategic purchasing positively effects the financial performance of the firm (Carr & Pearson, 2002). Firms, in first instance, have to ask, if they do have an I4.0 strategy in purchasing?
2. *Process and systems*: A model that describes how to overcome the challenges of I4.0 and how to reach organizational targets is incomplete without processes that arise from the adapted strategy. At the beginning of the previous decade, the expected potential of e-procurement systems rose due to technological progression and an increased role of importance for procurement (Presutti Jr, 2003). In line with the role of procurement shifting from reducing cost to creating value, modern e-procurement systems facilitate many operational tasks, among which reducing transaction costs and increasing contract compliance, thereby saving time for purchasing personnel to concentrate on strategic, value-creating tasks (Aberdeen Group, 2005). Industry 4.0 offers improved capabilities for gathering and sharing information in real-time, and thus new opportunities for further improvement of purchasing processes. I3.0 e-procurement processes, often catalogue based, are the basis for further development into I4.0 processes, by enhancing the machine-to-machine communication and changing the interfaces to cyber-physical systems. Hence, the fundamental question for firms is to ask if they have fully implemented I3.0 (software) systems and have extended them into the physical world and autonomous connectivity? A combination of process improvement and software implementation is discussed. The two things should not be separated into two different layers in order to offer the chance and better comply to the requirement discussed above, that a technological update should lead to an organizational change, in order to generate a productivity enhancing revolution. Else, the danger arises of running again into a technology adoption paradox like in the beginning of the 1990ies (Brynjolfsson, 1993a).
3. *Physical level*: While Cyber-Physical Systems are inseparable from the fourth industrial revolution (Kagermann et al., 2013), existing maturity models only briefly mention CPS or omit the physical aspect entirely. Regarding I4.0 as a digitization solely thriving on IT-systems, Cloud, or Big Data would not do the fourth industrial revolution justice. Hence, the maturity model presented here includes a physical level. It is expected that a fusion of real and virtual systems is likely better suited to operational purchasing, for instance through self-filling systems equipped with Machine-to-Machine

communication functionality to order goods without human intervention (Fukui, 2016). In the third layer, hence, the main question firms may want to ask themselves is, where a connection to the physical world makes sense and how it is implemented? Please note that here a wide arrange of possibilities exist, starting with simple replenishment of small items in office and production, but also extending to such things as autonomous maintenance tasks.

4. *Purchase-to-pay*: Preventing or reducing, purchasing outside available contracts or 'maverick buying', is often mentioned as incentive for adopting e-procurement systems by firms (Angeles & Nath, 2007; De Boer, Harink, & Heijboer, 2002). The increased analytic and communicational capabilities associated with I4.0, such as Big Data analysis, are expected to progress contract compliance and increase automation of the payment process. The guiding question here is, in how far the P2P process of a firm is fully automatized and able to autonomously solve problems?
5. *Purchasing controlling structures*: Taking the right decisions is critical to stay in business in fast moving industries. With I4.0, end-to-end transparency of Key Performance Indicators in real-time becomes possible (Kagermann et al., 2013), which allows purchasing managers to intervene directly when needed. Hence due to its large impact on decisions, data should be carefully collected, stored, analyzed, shared and archived, and essentially treated as an asset by organizations (Wee, Kelly, Cattel, & Breunig, 2015). Nonetheless, the extended possibilities of retrieving and analyzing data also entail risks related to cyber security, for instance prevention of unauthorized access or modification of data. The question here is if the firm uses the I4.0 possibilities to collect and analyze purchasing data?
6. *Sourcing*: Data analysis based on data traffic from web shops is commonly used by companies to predict demand. For strategic purchasing, firms are expected to benefit more from data analyses when the results are shared within the organization via connected systems, this transition will require significant effort though (Geissbauer et al., 2016). Despite the expected increasing role of importance for data analytics, firms should aim for distilling useful information out of data to generate insights instead of generating as much data as possible (Lee, Lapira, Bagheri, & Kao, 2013). To provide guidance in beneficially using data for strategic purchasing, our model assesses sourcing by addressing predictive demand, market analysis, specification, and contracting including cyber-negotiations. Firms may want to assess and plan the applications of I4.0 technologies, mainly in data analysis, to support strategic sourcing?
7. *Supplier involvement*: To achieve horizontal integrated supply chains collaboration with suppliers is needed, so the willingness of suppliers to adopt I4.0 practices should be assessed in an early stage (Kagermann et al., 2013). A noticeable difference between the literature and experiences in practice is the desired level of supplier involvement. During discussions at several of our I4.0 workshop, purchasing managers indicated to be cautious about sharing data with supply chain partners. Conversely, literature deems collaborative networks essential to achieve I4.0 (Brettel et al., 2014; Geisberger & Broy, 2012). The fundamental question in this layer is if the suppliers of a firm – and in case: which – are ready to collaborate with the focal firm, as some I4.0 installations may incur substantial costs and increase competition?
8. *Human readiness*: The final layer of the model measures whether employees are ready for adopting I4.0. Other models support the importance of training personnel to achieve the necessary skill set (Geissbauer et al., 2016; Jodlbauer & Schagerl, 2016; Lichtblau et al., 2015; Schumacher et al., 2016). In our model a distinction is made between the expected required capabilities for employees and the degree of involvement of

employees during the change process. Here, the question is how have the employees in purchasing been prepared and trained to use the new technologies?

Based on these eight layers a systematic managerial and academic discussion can be started.

Conclusion: Contributions and a research agenda for purchasing to coin the ongoing industrial revolution

In this paper, we have analyzed the potential impact of the fourth industrial revolution on purchasing and developed a maturity profile which can serve for firms to develop an I4.0 strategy. By doing so, this paper contributes at least fivefold:

(1) The Literature, so far, has largely ignored purchasing as an object or subject of the fourth industrial revolution. This paper contributes with a first attempt to systematically analyze potential chances and challenges and integrate purchasing and supply management into the discourse on I4.0.

(2) In terms of managerial contribution, here, an actionable tool is proposed, the maturity model. In this way, practitioners – but also academics – can structure their approach to seizing and understanding the I4.0 implications for purchasing.

(3) Exceeding the purchasing domain, this paper contributes by providing a systematic and actionable definition of industry 4.0, whose three constitutional elements – cyber-physical, autonomous and machine-to-machine communication – can be used to check if a potential application is really an I4.0 application and likewise can serve as guideline to develop such applications.

(4) An obstacle to the progress of I4.0 can be seen in the lack of a clear differentiation towards digitalization, the third industrial revolution. Often, "old wine is served in new bottles". This paper contributes with a clear differentiation between I3.0 and I4.0, which clarifies definitions and thus enables research progress.

(5) Finally, providing a solid embedding in the history of the industrial revolutions, this paper contributes by pointing to the need to not only implement new technologies in existing processes, but to change these processes in order to achieve productivity increase. With this reminder, we hope to be able to contribute to shorten the unproductive investment paradox phase which was typical for the beginning of each industrial revolution.

If the decision to term the recent development as "industry 4.0" and hence embed it into the tradition of industrial revolutions had not effectively already happened, this paper would have made another point to the use of this term, as the historical review makes the concept much richer than competing terms, which are much more difficult to define and to turn actionable.

However, this study has also shown that research on I4.0 in general and I4.0 in purchasing in particular is still at its infancy. Before the fourth industrial revolution really reaches its productive phase, many pieces of research remain to be done, in particular (1.) concerning the operationalization of the eight layers developed for the maturity model, (2.) the stepwise analysis of the I4.0 technologies and their applicability for purchasing, (3.) the impact I4.0 has on the skills needed for the purchaser of the future and finally, (4.) strategic implications and possible business model changes induced.

(1) Concerning the need of research on the eight layers, in terms of purchase-to-pay process the operationalization and assessment of automated demand generation through cyber-physical systems strikes out. In combination with cyber-negotiations this feature could lead to a re-vitalization of the idea of electronic market places, which would be a fruitful path for future research. What also becomes clear in the context of autonomous

negotiations, is that we need much a better understanding on negotiation theory and empirics, which has been neglected in the past.

(2) Looking at the pacemaker technologies of I4.0 and their impact on supply management, the blockchain technology would need to be better understood, as it has the potential to create the transparency in the supply chain purchasers have been dreaming of since long. Transaction costs would decrease, trade without trust could become possible and hence a profound transformation of purchasing could take place. Likewise, the application of artificial intelligence, for instance as a source providing purchasers with a series of supporting tools, like in supply risk analysis or market analysis would be an important field in need for more research. Finally, the emerging digital twin technology could have as a consequence that a product is not sold once and then disappears from sight of the producer, but could stay connected through its entire life-cycle. In that case, new contracts would have to be made, for instance covering the liability issues resulting from a life-long perspective. Purchasing needs to adopt to this novel sourcing situations, for which further research could be very fruitful. Green procurement and creedal to creedal concepts can get re-vitalized.

(3) All of this is unlikely to leave the role model and hence the skills requirements of purchasers untouched. Here, a strong need for further research emerges: which are the competences needed and how to manage the change process towards a new role? If digital and autonomous negotiations establish, the task of purchasers would move out of a direct face-to-face negotiation focus, to more a thorough and cross-functional preparation of tenders and negotiation focus. Competition would increase, then calling for a better understanding of buyer-supplier relations in order to take suppliers with.

(4) All of these changes may have strategic implications. Fruitful research with a purchasing core would have to analyze I4.0's implication for supply chain configuration and business models. Are traditionally closed supply chains disintegrating and electronic market places with constantly changing partners taking over or would, instead, even closer supply chains develop with costly software integration?

Finally, some limitations of this study and its conclusions have to be acknowledged. The novel nature of I4.0 makes it almost endemically vulnerable towards errors in judgement. For instance, the assumptions underlying the maturity model will have to be checked empirically in the time to come. The same refers to the question which technologies will actually prevail and coin the fourth industrial revolution. It could also be that our study has a bias, as most of the attendants to the many I4.0 workshops we conducted came exactly for being unsecure about the future. Maybe the more knowledgeable purchasers and their insights have thus escaped to our attention. Probably, still quite some case studies of I4.0 in purchasing have to be added, but eventually a quantification of findings needs to take place.

Change toward Public-Private-Partnership in Strategic Public Procurement: Case study in a French State-Owned Enterprise

Pierre Minh-Hoang TRAN
CentraleSupélec

Abstract
Public procurement represents, on average in the OECD, 12% of GDP and 29% of total government expenditure (OECD, 2017). It can play a significant role on promoting innovation and sustainable development, subject to the condition to establish successful public-private partnerships (Essig and Batran, 2005). The move from an administrative, dominator/dominated relationship to a fair and goal-shared partnership is specific to each organization. Nevertheless, it requires a dedicated change management to redesign organizational procedures and ways of working. The purpose of this paper is to share a partnership-oriented procurement experience in a State-owned enterprise in France with a Kotter's (1995) approach. Its drivers, change levers and also resistances to change are addressed. The findings affirm decisive role of top management's involvement and importance of communication and training programs.
Keywords: change management; public private partnership; public procurement.

Strategic Role of Public Procurement

Public procurement (PP) is the process by which governments and other bodies under public administration (including State-Owned-Enterprises or SOEs) purchase products, services and public works. The purpose of such purchases varies from purely replenishing office supplies or refurbishing office buildings to matching national policy objectives like stimulating economic activity, protecting domestic industries or alleviating regional disparities. With government purchasers accounting for over 20% of the gross domestic product (GDP) in the US (Carter & Grimm, 2001) and 14% of GDP in the European Union (European Commission, 2016), these figures illustrate the large significance of public procurement for the economy and also indicate how the public sector can support policy objectives through public procurement.

In this perspective, public procurement is increasingly recognised as a strategic instrument and a policy lever for achieving government policy goals, such as innovation, the development of small and medium-sized enterprises (SMEs), sustainable development and social objectives like public health and greater inclusiveness (OECD, 2017). In the economy, public procurement plays an important role in promoting competitive markets (Cadwell et al., 2005).

Effectively, the importance and potential impact of the profession is obvious. Public procurement functions are indeed shifting from tactics to strategy. Duties like purchase order issuance and order tracking are being replaced by activities such as global sourcing and spend analysis (Matthews, 2005).

Public-Private Partnership (PPP)

The term Public-Private Partnership (PPP) refers to a long-term, contractually regulated cooperation between the public and private sector for the efficient fulfilment of public tasks in combining the necessary resources (e.g. knowhow, operational funds, capital, personnel) of the partners and distributing existing project risks appropriately according to the risk management competence of the project partners (Savas, 2000). PPP is mainly used to build infrastructure projects. PPP refers also to a partnership procedure where the contracting authority shall

cooperate with a company – selected in a regular competitive tender procedure – to develop a product, work or service (European Commission, 2015).

According to the Public Choice theory on contemporary macroeconomic and microeconomic external reforms, the public sector needs to reinforce more competition and their related microeconomic control mechanisms instead of bureaucratic control (Essig & Batran, 2005). Public procurement therefore attempts to adopt management methods from the private sector in order to enhance the performance of the public sector, such as outsourcing, supply chain management and closer relationships between supplier and buyer (OECD, 2017).

In fact, many of the goods and services, previously provided by public authorities are also well suited to being provided by private partners (Savas, 2000). Cooperation in PPP offers a closer relationship between markets and traditional hierarchical governance and economic advantage through the reduction of transaction costs (Parker & Hartley, 2003).

Change Management

The implementation of public-private partnership in bureaucrat institutions lead to organizational changes which are defined as premeditated, agent-facilitated interventions intended to modify organizational functioning towards a more favourable outcome (Lippit et al., 1958) and that are often conceptualized as processes.

Change process

According to Lewin (1947), planned change proceeds through three phases: unfreezing, movement, and refreezing. Based on Lewin's framework, Kotter (1995) suggested a change management model with eight steps to transforming organization in order to identify and implement the right actions during each stage and avoid common pitfalls: (1) Establishing a sense of urgency, (2) Forming a powerful guiding coalition, (3) Creating a vision, (4) Communicating the vision, (5) Empowering others to act on the vision, (6) Planning for and creating short-term wins, (7) Consolidating improvements and producing still more change, and (8) Institutionalizing new approaches.

Levers of change management

In addition to process approach, it is important also to consider the change management at the operational level in order to know whether the change is really made (Tran et al., 2012). In this perspective, Paton et al. (2008) proposed that employees' commitment, involvement and a shared perception are success guarantors for an organizational change. In order to achieve employees' understanding and adhesion, three most important levers identified are leadership (Eisenbach et al., 1999; Kotter, 1995), communication (Frahm and Brown, 2007; Klein, 1996) and training (Reed and Vakola, 2006). Sarker and Lee (2003) identify three key social enablers to implement organizational change: strong and committed leadership, open and honest communication, and a balanced and empowered implementation team.

The importance of leadership to the change management process is underscored by the fact that change, by definition, requires creating a new system and then institutionalizing the new approaches (Kotter, 1995). Brown and Eisenhardt (1997) identified three key characteristics of successful managers in continuously changing organizations. Successful managers provided clear responsibility and priorities with extensive communication and freedom to improvise.

According to Frahm and Brown (2007), organizational change communication is a crucial element in employees' receptivity to change. They suggest managers need to align employees' expectations of the change communication with understanding of the change goal. Communications are important as changes are planned and carried forth. Organizational changes often founder because not enough strategic thought is given to communicating the rationale, the progress and the impact of the change (Klein, 1996).

While the Center for Advanced Purchasing Studies has identified education as a critical area for world-class purchasers (Guinipero, 1998), Reed and Vakola (2006) suggest that training also plays an important role in organizational change. They argue that the development and piloting of the training requirements analysis process needed to be approached as a change management process. Linking the training requirements analysis process with existing organizational processes was a key factor in the success of the process and created a strategic dimension which influences levels of readiness in the organization.

Case Description

As the objective of this paper is to provide an exploratory study on the change toward PPP in a public entity, the case method is suitable. It is a structural change within a French state-owned enterprise specialized in energy production and distribution, named here ENPRODI, where the author has an opportunity to observe and analyse this organizational change so far inaccessible to scientific investigation.

In spite of its enterprise status, ENPRODI manages its strategic purchasing projects (€400,000 and beyond) in compliance with European Union's Public Procurement Directive N° 2014/25 (European Commission, 2015). Its procurement turnover is about €10 billion.

In order to foster ENPRODI performance and enhance innovation, its CPO initiated "Partnership for Productivity" program in the 2000s. This program aims to encourage innovative initiatives from SMEs suppliers throughout contractual term. Any new idea will be assessed and viable projects with high potential lead to planned cooperative actions from both parties, buyer and supplier, in order to achieve technical and financial improvements.

"Partnership for Productivity" is a PPP because leaving private suppliers to design and manage project, including the input mix. It includes also risk allocation, greater transparency.

Many changes are realized to implement this program:

Before	After
Inflexible specifications	Specifications open to optimization
Contractual clauses frozen during term	Amendments possible in case of innovative proposition approved
Contract management limited to purchase order issuance and order tracking	Contract life punctuated by meetings to discuss on innovation

Key Issues

Change process

(1) Establishing a sense of urgency: At "Partnership for Productivity" kick-off meeting, the CPO underlines the importance of developing a robust SMEs ecosystem in France, in particular in energy sector. ENPRODI signed its engagement into the Charter of Inter-Enterprise Relationship in 2010, the Charter of Innovative SMEs in 2012 and the Association of SMEs Pact in 2010.

Furthermore, public budget for utilities is downsizing. Public procurement receives from government the familiar call to "do more with less". It is urgent to make savings through technical and contractual innovations.

(2) Forming a powerful guiding coalition: A Steering Committee was created with CPO, CFO, and COO's representatives as members to communicate and promote this program at every organizational level (middle management, operational professionals).

(3) Creating a vision: It is a picture of the future. ENPRODI wants "Partnership for Productivity" program to become its pillar in terms of supply chain management and innovation

management. The program will facilitate suppliers' innovation and transform it into advantages for ENPRODI.

(4) Communicating the vision: "Partnership for Productivity" program was communicated widely to every ENPRODI's supplier at top management level. Workshops were organized, in both internal and external scopes, to understand program's objectives and mechanism. Suppliers and internal professionals are accompanied by devoted referents people.
An internal quarterly newsletter on "Partnership for Productivity" program is edited to address different topics and present success stories from divisions.

(5) Empowering others to act on the vision: In each procurement team, a senior buyer is named to be focal point for "Partnership for Productivity" program. She/he consolidates program's progress for reporting at his/her team level. She/he may give a helpful hand to colleagues to integrate program into their own procurement projects. In addition, team leader is also at everyone's disposal for any discussion and assessment of an innovative idea, from supplier or internal operational source.

Furthermore, training is a very powerful tool to implement program. Better a buyer is trained and informed, better she/he gets involved. ENPRODI's Academy of Procurement creates and offers a training session on "Partnership for Productivity" to every employee interested or involved in program. It is also an effective feedback channel to collect employees' opinion on this program throughout their experience sharing.

(6) Planning for and creating short-term wins: Every year, an Annual Meeting on "Productivity partnership" is organized and sponsored by the CPO to celebrated program's milestones and award significant successful achievements. Teams get acknowledged and motived to pursuit changes.

(7) Consolidating improvements and producing still more change: Success stories declared each year are collected, presented in program's newsletter then archived in a database available in internal network. Best practices are sectioned to integrate into program's guidebook which is reviewed once after Annual Meeting.

(8) Institutionalizing new approaches: Steering Committee organizes Senior Management Workshops to shape contractual framework and organization. New clauses on "Partnership for Productivity" are integrated in standard contract. Functional department in charge of "Partnership for Productivity" is well established in ENPRODI Procurement Direction's organigram. And "Partnership for Productivity" is now part of buyer's daily work.

Conclusion

The exploratory nature of this paper reflects a brief but rare narrative study on change management in PPP implementation. This paper seeks to highlight key role that may be played by top management in every step of change process, especially in large organization with complex contractual framework. It has aimed also to underline the importance of communication and training in change management.

I acknowledge the limitations of this study. It is a working paper summarising key issues from this case rather than attempting to validate those themes. More analyses are needed to reveal other insights.

Abstract

The environmental problem and the rising environmental consciousness of consumers generated the need for green supply chain management. Through the use of information and communication technologies and the development of collaborative practices companies attempt to reduce their environmental impact. As the adoption of environmental practices is increasingly more important for the sustainable development of organizations, this paper aims to study and analyze recent research developments in the field. It also aims to examine the role of new technologies in the development of green supply chains.

Keywords: Sustainable SCM, environmental practices, ICT

Introduction

Companies operating in a global competitive environment need to improve operations not only internally, but also at the level of their supply chain. Therefore, the operations optimization has moved from a specific organization to the entire supply chain (Linton *et al*., 2007). A supply chain contains various participants, such as raw material suppliers, manufacturers, final products suppliers, distributors and retailers. Supply chain management is the management of the activities taking place throughout the supply chain, starting from the purchasing of raw materials to the distribution of final products to the consumer (Sehgal, 2009; Heizer et al., 2014). The main purpose of supply chain management is to integrate all parts of the supply chain, in order to gain competitive advantage and keep the operation of the company profitable (Sehgal, 2009; Heizer et al., 2014). Therefore, contemporary supply chains need to reduce their costs, enhance their efficiency, develop collaborative practices and eventually satisfy the final consumer.

Furthermore, the environmental problem and the rising environmental consciousness of consumers generated the need for sustainable supply chain management. Sustainable supply chain management integrates the environmental, societal and economic elementsinto supply chain management from the design of the product to the reverse flow of the product after its usage (Lakshmi and Visalakshmi, 2012). In order to carry out their green vision companies should consider the environmental impact of a product from all phases of its life cycle with the objective of increasing the environmental sustainability of the whole supply chain and not only a part of it (Lakshmi and Visalakshmi, 2012; Heizer et al., 2014; McKinnon et al., 2015).

The efficiency and optimization of supply chain operations as well as the implementation of environmental practices can be supported by Information and Communication Technologies (ICT). The use of new technologies, especially of Internet-based technologies, may facilitate the exchange of real-time information between companies as well as promote sustainable development and efficient operations of organizations (Fuchs and Otto, 2015).

To address these issues, this paper examines recent research conducted in the field of ICT and green supply chain management. It focuses on the results of various European research projects and aims to examine their impact on the development of environmentally sustainable

supply chain management. It also aims to identify the main environmental practices followed by companies, as well as to examine the role of information systems and technologies at their implementation.

Therefore, the objective of this research is twofold. First, it examines recent research trends and practices related to the development of sustainable supply chain management, putting emphasis on green/environmental issues. Second, it discusses the role of technology and information systems in the development and support of these practices. The limited number of detailed studies demonstrating the role and support of information systems and technologies on sustainable supply chain management is the main reason for conducting this research.

Literature Review

The protection of the environment is an important issue concerning not only the society, but also the organizations. According to Walker et al (2008) there is an extended focus on the obligations of organisations towards the society and the environment. This has led to the adoption of the term 'sustainable development'. The World Commission Report (Brundtland, 1987) defines sustainable development as "the development that meets the needs of the present without compromising the ability of future generations to meet their own needs".

Sustainable development includes environmental, economic and social changes such as technological advancement, investments and institutional change that should be harmonized to support and promote present as well as future human needs. (Brundtland, 1987; Large and Thomsen, 2011). Green supply chain management integrates the element of the environmental protection in the management of the materials, products and information throughout a supply chain. The main stages of green supply chain management include (i) green product design, (ii) green procurement and inbound logistics, (iii) green manufacturing, (iv) green transportation and distribution, and (v) reverse logistics.

Environmental management practices and organization performance have been investigated and discussed by various researchers (Klassen and McLaughlin, 1996; Christmann, 2000; Lucas and Noordewier, 2016; Melnyk *et al.*, 2003; Montabon *et al*., 2007). The main issue that organizations face is how to manage the viability of the organization today without endangering the environment in the future (Wu & Pagell, 2011).

Different information systems and technologies can support the exchange of information between companies as well as promote the sustainable and efficient operations of organizations (Fuchs and Otto, 2015). There are various information systems and technologies that companies can use, such as Enterprise Resource Planning (ERP), Warehouse Management Systems (WMS) and Radio Frequency Identification (RFID) (Twist, 2004; Angeles, 2005). The use of information systems and technologies can enhance the operational performance of organisations as well as support their environmental efforts.

The technological development and the expansion of the use of the Internet in business operations have led to an increased use of software solutions and technologies in supply chain management (Helo and Szekely, 2005). According to Chou et al. (2004) the Internet facilitates business collaboration, offering low-cost, easy and real-time communication and connectivity between organisations. Web-based collaboration platforms include a set of services and functions that can be accessed through the web, assisting the collection, handling and sharing of information between the participants of the platform (Lai et al., 2012). The synchronisation and sharing of real-time information between organisations promote the operation of the supply chain as a single company, which can benefit all participants (Ross, 2003) and support their green practices (Gardas and Narkhede, 2013).

Research Approach

As mentioned before, in order to examine recent research developments in the field of green supply chain management, we examined the results of European Research Projects conducted under the FP7 and Horizon 2020 programs.

The chosen EU projects combine two important elements that have not been investigated in-depth in the past, information systems and technologies and their impact on environmental sustainability. The projects were chosen according to their degree of relevance to the fundamental objective of the research. All chosen projects develop and implement environmental practices with support by information systems and technologies in order to enhance environmental sustainability in specific supply chain stages or whole supply chains.

The research method suitable for our empirical data was interpretive case study. A case study is a practical research method that examines a subject in reality. In our research we follow a multiple case design, where the different case studies are the projects analysed.

The output of the different projects, selected for our research, is in the form of various documents, which include texts that describe the different components of the projects. The development of innovative technologies, information systems or environmental practices are described in different deliverables related to the various parts/stages of the projects. These deliverables are further categorized, based on their content, into ontologies, general aims, technical specifications, architecture and impacts of the project.

To analyse our data in-depth, we conducted an interpretive research. The theoretical foundation of interpretive research is phenomenology and hermeneutics. Hermeneutics is defined as the “theory or philosophy of the interpretation of meaning” (Bleicher, 1980). Hermeneutics is responsible for the procedure of analysing the collected data and concluding with an interpretive understanding (Butler, 1998). The perspective and understanding of the researcher is changing every time he/she reads an additional document. The researcher is reading a text repeatedly and understands more and more the meaning of the text.

A concept of hermeneutics that supports the understanding and interpretation of texts is the hermeneutic circle (Boell and Cecez-Kecmanovic, 2010). This concept involves the movement from the whole to the parts and back to the whole. This circular process is repeated until the researcher understands the texts and interprets what he reads. According to Gadamer et al. (2004) the iterations of reading the text conclude to a proper understanding and interpretation of a subject. The iterations are called interactions between the researcher and the text. The integration of the parts with the whole is essential for the appropriate interpretation of the subject.

The deliverables mentioned above constitute the parts while the projects comprise the whole. While reading the different deliverables our understanding for each project is deeper. There is a key connection between the deliverables and the projects. We read the text of a deliverable and understand better the subject (whole project), and then read the text of another deliverable and go back to the project as a whole.

Research Description and Preliminary Findings

The Framework Programmes for Research and Technological Development, also called Framework Programmes, abbreviated as FP1 to FP7, with FP8 renamed to Horizon 2020, are programmes funded by the European Union (EU), supporting the European Research Area (ERA). Horizon 2020, the biggest EU Research and Innovation programme, is the successor of FP7 with funding of around 80 billion euro for the period 2014 to 2020.

We examined completed projects from the FP7 program and projects that are still under development from the Horizon 2020 program. All the examined projects aimed at promoting the adoption of green practices of companies through the utilisation of information systems, as well as the development of innovative technologies. There were various projects for different parts of the supply chain, such as the production, but our focus was mainly on the projects referring to the logistics operations. We chose this sector for two reasons: firstly, logistics processes are an important cause of environmental pollution, and secondly, the logistics sector offers various opportunities for reducing the negative environmental impact of organisations. Therefore, from the various projects examined, we decided to use and analyse seven projects from the 7th Framework programme and six from the Horizon 2020.

The different projects analysed have various environmental objectives. Tables 1 and 2 depict the connection between the projects and the green practices that companies adopt, to support the reduction of their total environmental impact.

CIVITAS ECCENTRIC	✓	✓	✓	

Table 2: Connection between the Horizon 2020 Projects and their Green Practices

As demonstrated above, all FP7 and Horizon 2020 projects, except PLANTCockpit, attempt to reduce carbon dioxide emissions throughout their operation with the use of information systems and technologies. Some projects focus on the reduction of congestion, in order to reduce environmental impact, while other attempt to minimise operational waste. It should be

additionally noted that FP7 projects emphasise more on energy efficiency than Horizon 2020 projects.

The main focus of both FP7 and Horizon 2020 projects is the development of web-based communication platforms that enhance collaboration between supply chain partners. General projects' results demonstrate that the integration of different information systems and technologies, through web-based collaboration platforms, is imperative for the development of efficient of logistics operations and the exchange of information among supply chain participants. The cooperation between organisations as well as the interconnection of different information systems of organisations can lead to cost reduction, greater consumer satisfaction and reduction of the negative environmental impact of organisations.

More specifically, FP7 projects mainly focused on the development and utilization of various software solutions for the integration of individual organizations' systems such as ERP and WMS with a central platform, as well as with partners' systems. Some projects, also incorporated intelligent technologies in their technological solutions, e.g. intelligent cargo that can be identified and tracked throughout its transportation.

As Horizon 2020 is a more recent funding scheme, its projects incorporate research on more advanced technologies such as cloud-based solutions, mobile technologies, service-oriented architectures and intelligent technologies that were not widely available in the previous scheme (FP7). The solutions offered by Horizon 2020 consist of cutting-edge technologies deriving from and supporting the objectives of the individual projects. Horizon 2020 projects focus on the development of new innovative technologies, not only to reduce the negative environmental impact of companies, but also to improve the living conditions of the society as a whole, as well as enhancing the economic growth rate of European countries.

Conclusions

This paper examines current research trends on sustainable supply chain management. It identifies contemporary environmental practices and examines the role of information systems and technologies in their implementation.Our research results show that environmental sustainability in supply chains may be supported, not only by the promotion of environmental practices, but also by the development of collaborative practices and the integration of information systems and technologies.

To examine these issues we analysed the results of recent research projects conducted under the FP7 and Horizon 2020 programs. Although the objectives of the two funding schemes are similar, the implementation of Horizon 2020 projects is based on more advanced technologies, such as integrated systems, mobile applications and cloud-based solutions. Furthermore, while the FP7 puts emphasis on the use of information and communication technologies within the logistics sector, Horizon 2020 focuses on the combination of innovative technologies with the environmentally friendly aspect of the organisations' operations. Through research and innovation, and by focusing on scientific excellence, industrial leadership and societal challenges, Horizon 2020 promotes sustainable, smart and inclusive growth.

However, it should be noted that the projects conducted under the Horizon 2020 program are not completed yet. As a consequence, a more detailed analysis of the various technologies and collaboration platforms developed, as well as of the sustainable development practices suggested is still not feasible.

Nevertheless, our preliminary research results identify fundamental environmental practices and demonstrate the importance of collaborative practices and integrated technological solutions to their implementation. They can be used by practitioners as an initial guide for the

application of unified green practices solutions, supported by innovative technologies. Furthermore, they can provide a base for future research in the associated field of technological development and environmental sustainability.

Low-tech or high-tech? Relative learning benefits of serious games for construction supply chain management

Marc van den Berg, Alexandr Vasenev, Hans Voordijk and Arjen Adriaanse

Department of Construction Management and Engineering, University of Twente. P.O. Box 217, 7500 AE Enschede, The Netherlands. Emails: m.c.vandenberg@utwente.nl, j.t.voordijk@utwente.nl, a.m.adriaanse@utwente.nl

Abstract

Serious games can enhance supply chain education regardless of their delivery format being either a low-tech (analogue) or high-tech (digital) game. There is nevertheless a lack of serious games for construction supply chain management and the relative learning benefits of both types of games remain poorly understood. As studying, deploying and developing such games also demand specific resources and efforts, researchers, educators and game designers need to weigh their preferences for either a low-tech or high-tech serious game. To provide input for such decisions, this paper first develops a high-tech game for construction supply chain management based on an existing low-tech version. Through reflecting on the use of both of these variants in an exploratory experiment with 43 PhD candidates, it is concluded that learning benefits of low-tech and high-tech serious games for construction supply chain management are comparable. These insights can help researchers, educators and game designers in selecting the most appropriate type of serious game to enhance (construction-related) supply chain education.

Keywords: *construction supply chains; education; serious games*

Introduction

Coordinating activities regardless of functional or corporate boundaries is one of the key subjects in supply chain education. This subject is particularly challenging for the construction domain due to the convergent, fragmented and instable nature of its supply chains (Vrijhoef & Koskela, 2000). Compared to other industries, the construction industry is still lagging behind in terms of supply chain practices and efficiency. The typical large quantities of waste are mostly caused by poor communication, adversarial contractual relationships, a lack of customer-supplier focus, price-based selection and ineffective use of technology (Love, Irani, & Edwards, 2004). Construction professionals urgently need practically applicable knowledge about how to improve the performance of the supply chains. That is nevertheless complex and challenging, requiring a rare combination of deep, functional expertise and broad, holistic thinking (Fawcett & McCarter, 2008).

Serious games can be useful tools in teaching such aspects of (construction) supply chain management. Traditional lecture-based teaching methods assume that students passively receive information from a lecturer and internalize it through some form of memorization (Michel, Cater, & Varela, 2009), which is insufficient to convey the complexities and multiple intertwined factors found in practice. Serious games provide an "ideal alternative method of testing … concepts in an environment that resembles realistic work situations" (Al-Jibouri & Mawdesley, 2001). They are frequently defined as "(digital) games that contribute to the achievement of a defined purpose other than mere entertainment" (Susi, Johannesson, & Backlund, 2007). Serious games offer their users an experience that is planned to be meaningful – yet have rarely been used for construction-related supply chain education.

Depending on the technology used to design such an experience, two (main) types of serious games can be distinguished: low-tech and high-tech games. We use the term *low-tech* to refer to a subset of games in which the simulated environment is represented using analogue methods (e.g. board games), whereas we use the term *high-tech* to refer to games that use digital methods (e.g. video games). Both low-tech and high-tech serious games can represent the same environment. In order to select one of these two types, researchers, educators and game designers need to understand what the relative learning benefits of one type of game over the other are. This research seeks to answer that question for the context of construction supply chain management by systematically comparing the reflections of players of both low-tech and high-tech serious games for that domain.

Theoretical framework

Universities serve a critical role in disseminating (construction) supply chain management knowledge through teaching and scholarship. Delivering supply chain education poses extraordinary challenges, but has also "exceptional potential to educate, provoke and inspire students" (Brandon-Jones, Piercy, & Slack, 2012). Over the past few decades, there has been a significant growth in universities focusing on purchasing and supply management courses. With a survey into the dominant teaching approaches, Birou, Lutz, and Zsidisin (2016) revealed that undergraduate courses in this domain tend to focus on techniques and skills, while graduate courses highlight strategy to a higher degree. Supply management educational programs thereby need to respond to changes in the business environment driven by globalization, outsourcing and e-business (Ellram & Easton, 1999; Zheng, Knight, Harland, Humby, & James, 2007). Providing important and relevant supply chain management education is thus a major challenge (Bak & Boulocher-Passet, 2013), especially for hugely fragmented industries such as construction (Bankvall, Bygballe, Dubois, & Jahre, 2010).

The traditional model of lecturing and passive learning has been dominating these educational programs. The lecture-based format, complemented with basic problem-solving assignments, seems to be a convenient and expeditious way for delivering information to large groups of students, but its efficacy is increasingly questioned (Brandon-Jones et al., 2012). This model cannot cope with the many intertwined factors found in practice (Peterson, Hartmann, Fruchter, & Fischer, 2011), is limited in illustrating complex engineering topics (Deshpande & Huang, 2009; Rojas & Mukherjee, 2005), and does not actively engage students (Michel et al., 2009). This is particularly problematic for an applied field as (construction) supply chain management, where the focus moves beyond introducing basic topics towards the application of an established body of knowledge in real-life situations. As a response, leading educational scientists such as Kolb (1984) have suggested to move towards more applied, student-centered teaching methods that actively involve learners through experiential exercises.

A serious game is such an experiential exercise. Serious games are primarily intended to enhance learning of the players through providing a realistic environment in which they can deal with situations that are impossible or impractical in the real world for time, cost or safety reasons (Hussein, 2015; Mawdesley, Long, Al-jibouri, & Scott, 2011). The theoretical basis for serious games can be found in the experiential learning theory, which sees learning as a process whereby knowledge is created through the transformation of experience (Kolb, 1984; Kolb, Boyatzis, & Mainemelis, 2001). This learning-by-doing occurs when a learner is offered a meaningful experience with appropriate feedback in a continuous process of goal-directed action. Reported benefits of serious games include positive effects on knowledge acquisition, motivation and engagement (Bellotti, Kapralos, Lee, Moreno-Ger, & Berta, 2013) and an increase in the verisimilitude of the teaching material (Al-Jibouri & Mawdesley, 2001).

Serious games have a long-standing history in both supply chain management and construction project management education. Sterman (1989) developed the MIT Beer Game, which demonstrates the bullwhip effect and became an inspiration source for many other supply chain games for the manufacturing industries. Examples of such serious games include the Lean Leap Logistics Game (Holweg & Bicheno, 2002), the Supply Chain Puzzle Game (Fawcett & McCarter, 2008) and the Distributor Game (Corsi et al., 2006). Serious games for the construction industry have covered topics such as project planning and control (Al-Jibouri & Mawdesley, 2001), competitive bidding (Nassar, 2003) and boundary crossing in design projects (Van Amstel, Zerjav, Hartmann, Dewulf, & Van der Voort, 2016). Until recently, supply chain management concepts had nevertheless not been incorporated in serious games for the construction industry.

A first attempt to develop and test a serious game specifically for construction supply chain management was described by some of the authors of this paper (Van den Berg, Voordijk, Adriaanse, & Hartmann, 2017). Their one-player game, called Tower of Infinity, offers to act as a main contractor responsible for designing and constructing a high-rise building. The game unfolds in a number of simulated weeks in which a player needs to assign her/his available crews to Modeling, Ordering, and Assembling tasks to satisfy client requirements and make a profit. Since the game uses Lego bricks as primary game materials, we categorize it as a low-tech variant. With the intention to make supply chain management knowledge experientially available to the player, the authors concluded that players can learn about eight different strategies to achieve supply chain optimizations – grouped into: (1) coordinating design and construction tasks in a coherent manner; (2) taking constructability aspects into account when designing; and (3) continuously balancing scope, time, and cost throughout a project.

The authors acknowledged that the *relative* learning benefits of serious games like this one have nevertheless remained unclear. The *low-tech* serious game Tower of Infinity had been played and tested by 64 construction management students in the context of a master's level course, but it is unclear how their prior construction education influenced their learning perceptions. It is also unclear whether the reported learning objectives would also be achieved with a *high-tech* variant of the game. Consequentially, little is known about how players reflect on usages of either a low-tech or high-tech serious games that cover construction-related supply chain concepts.

Research methodology

The goal of this research is to compare learning benefits of a low-tech and a high-tech serious game for construction supply chain management. For the context of this study, the aforementioned low-tech serious game Tower of Infinity (Van den Berg et al., 2017) was first systematically and step-by-step digitized into a high-tech prototype. This resulted in two variants of the same game: a low-tech and a high-tech type (Figure 1). Background information about these games is presented in the next section.

We conducted an exploratory experiment with both low- and high-tech games to study differences in players' perceptions. The experiment took place during a serious gaming workshop, which was a part of an Operations Research summer school for PhD candidates. The first two authors of the paper led the workshop attended by 43 participants from around the globe. After a brief introduction to serious games in general, the participants were randomly split into two groups. Group 1 included 21 persons who individually played the low-tech variant of the serious game. Group 2, consisting of 22 persons, played the high-tech variant. The two (parallel) sessions lasted one hour each. These sessions started with a 15 minute game

explanation and ended with filling out questionnaires. Later, a plenary session followed in which the authors facilitated a structured group discussion about the two types of games.

During this serious gaming workshop, we collected data on learning benefits with a post-assessment survey – the most common assessment method (Bellotti et al., 2013). We assumed equivalence through randomization of the participants rather than pre-testing. This has the advantage of avoiding the threat to validity referred to as testing, since post-assessment results may be influenced by exposure to the same questions in a pre-assessment. Besides background information, the survey questions tried to assess learning benefits through a combination of recognized assessment methods: (i) game scores (a measure to evaluate whether the player was successful in the game), (ii) supply chain optimization strategies deployed (a measure based on earlier operationalizations of the learning objectives (Van den Berg et al., 2017)) and (iii) personal views (a measure focused on the game's perceived effectiveness). Most questions could be rated on a 5-point Likert scale (e.g. 'I recognize theoretical supply chain management concepts in the game' could be rated on a scale ranging from 'strongly disagree' to 'strongly agree').

Data analysis consisted of systematically comparing the data collected from both low-tech and high-tech groups. We entered all survey data into a database (Excel sheet). For each relevant question, we thereby excluded any missing responses from the two samples (which resulted in different degrees of freedom df per question). Assuming that the data are approximately normally distributed and have equal variances, we evaluated the learning differences between low-tech and high-tech participants with a two-tailed t-test ($\alpha = 0.05$). Based on these evaluations, we drew conclusions on the learning benefits that one type of game has over the other.

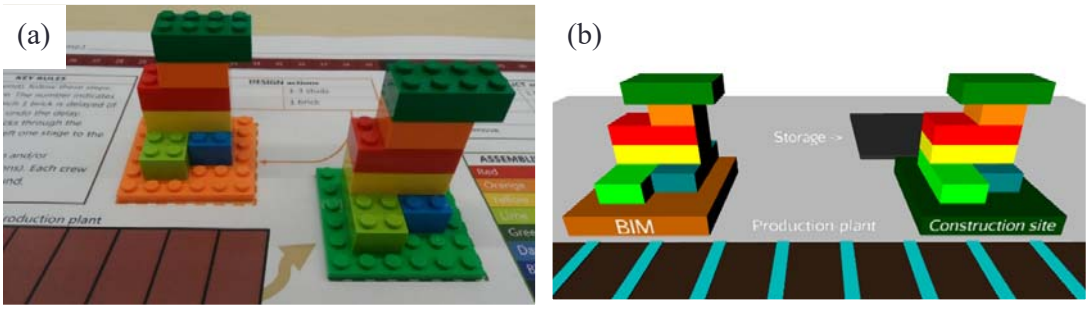

Figure 1 Prototypes of the serious game Tower of Infinity for construction-related supply chain education: (a) low-tech and (b) high-tech variants

Tower of Infinity: two variants of a construction supply chain management serious game

The serious games behind our experiment are low-tech and high-tech versions of a serious game called Tower of Infinity. Van den Berg et al. (2017) earlier developed a *low-tech* version of this game that uses Lego bricks as the main materials. This game was developed in line with the Triadic Game Design approach, which suggests that effective serious games need to balance a game concept (play), a value proposal (meaning) and a model of the real world (reality) (Harteveld, 2011). A *high-tech* variant was developed for the context of the present study by digitizing the low-tech version. This game is based on jMonkeyEngine 3.1, an open source Java-based game engine that comes with an integrated software development kit (Kusterer,

2013). The high-tech variant can be launched from a browser[1] (web start) or as a desktop executable. Players interact with the game using mouse and keyboard.

Both low-tech and high-tech Tower of Infinity variants are one-player games that put the player in the role of a main contractor responsible for designing and constructing a high-rise building. The serious games challenge players to make profits by delivering a tower according to a set of pre-defined client requirements. The two variants are intended to be played in a workshop setting, where a facilitator (acting as a client) reveals the requirements and players (each acting as a main contractor) then separately work on the project. Requirements relate to the desired number and size of the (Lego/digital) bricks and other project constraints: e.g. 'Minimally 8 RED studs', 'Finish the project within 23 weeks' and 'Build as high as possible' (hence the name of the game). The player can assign project tasks to the four multi-skilled crews assigned to the fictitious project. The three main – and subsequent – tasks include:

- Modeling: *place a 'Design' type of brick on a plane representing a virtual representation of the building (BIM);*
- Ordering: *purchase a 'Construct' type of brick by selecting one of the suppliers' offers;*
- Assembling: *place the (manufactured) 'Construct' type of brick on a plane that represents the construction site (at the same position as the corresponding design brick).*

In the high-tech version, the in-game actions (task executions) are automatically visualized in real-time at specified locations (Figure 2), while in low-tech version relevant calculations and updates are performed by players. Such, in the high-tech version, the first letter of the action is displayed in the project schedule in the color of the relevant brick. For example, when a player purchases (Orders) a red 4x2 sized brick with a lead-time of 5 weeks, a red 'O' appears in the schedule and the brick shows up at stage 5 of the conveyor belt (indicating 5 weeks to finish). When a week passes, the brick automatically moves to the next stage: in this example to stage 4 (indicating 4 weeks to finish). Delays may nevertheless randomly occur and affect the manufacturing times (yet can also be made undone at a certain cost). Productivity rates differ per type of action and per color brick. Bricks that are completely manufactured can be stored on site, yet need to be stored elsewhere (at a certain cost) with a lack of space. Ultimately, the game ends when the building matches completely with its design – at which point the player receives a notification of the profit/loss achieved.

[1] A prototypical playable version is available online at: mcvandenberg.com/game

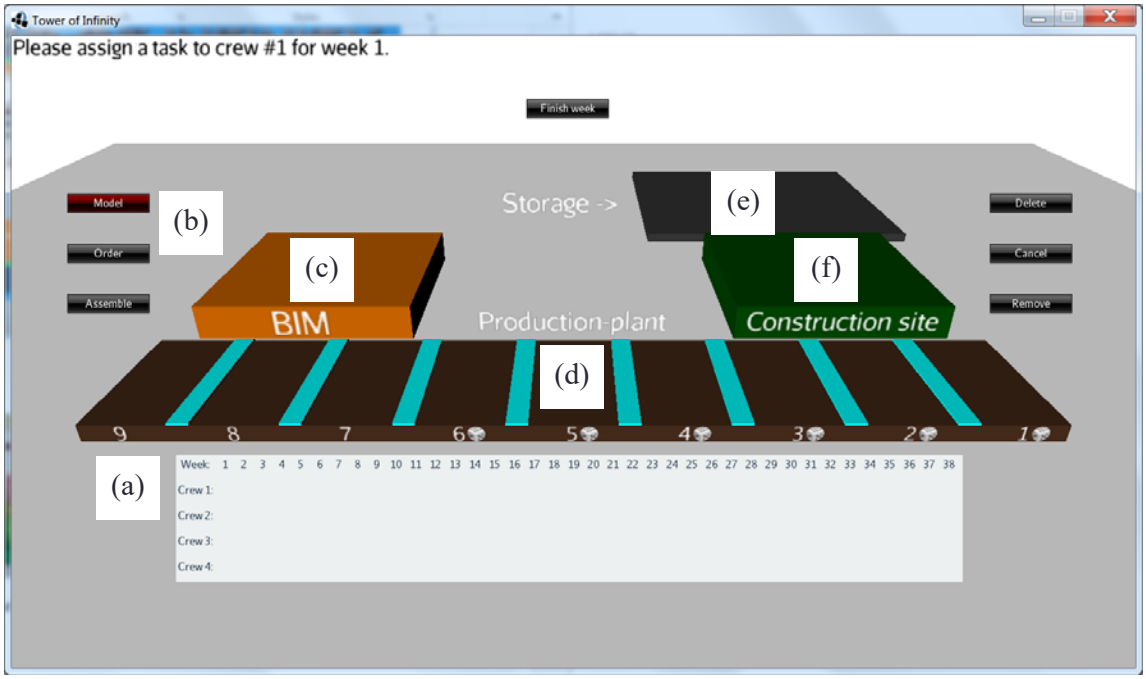

Figure 2 Overview of the high-tech version of the serious game Tower of Infinity, with: (a) a schedule with four crews available each week, (b) tasks these crews can be assigned to, (c) a Building Information Model (BIM) on which a design is created through Modeling, (d) a conveyor belt used by suppliers for manufacturing any Ordered bricks, (e) an optional external storage facility and (f) a construction site on which completed bricks are Assembled into a building

Results of an exploratory experiment

The results of the exploratory – low-tech versus high-tech – experiment are grouped into findings about game scores, supply chain optimizations and personal views. Background information of the 43 participants and their prior game experiences and (construction) supply chain management knowledge is first presented in Table 1. All participants were PhD candidates attending an Operations Research summer school and, as such, had similar educational levels and ages. There is no evidence that the two groups were different in terms of their preferences for playing board or video games, their knowledge about construction processes, supply chain management or construction-related supply chain management ($|t| \leq t_{\alpha/2}$).

Table 1 – Findings: background information rated on a 5-point Likert scale (1=strongly disagree to 5=strongly agree), with average ages of 27.5 (low-tech) and 26.5 years (high-tech)

	low-tech			*high-tech*			
	mean	*variance*	*n*	*mean*	*variance*	*n*	*t*
I like playing low-tech (board) games	4.00	0.90	21	3.83	0.50	18	0.61
I like playing high-tech (digital) games	3.60	1.20	20	3.23	1.23	22	1.09
I have good knowledge about construction processes	2.14	0.73	21	1.82	0.73	22	1.25
I have good knowledge about supply chain management	3.52	1.06	21	3.27	1.06	22	0.80
I have good knowledge about construction supply chain management	2.33	0.73	21	2.27	0.87	22	0.22

Game scores

The results of the two sessions in terms of the participants' game scores are shown in Table 2. Game scores refer to classical project management aspects: scope, time and budget. First, we found that 12 players (out of 21) finished the low-tech game and 7 (out of 22) the high-tech version. Their scores consequently represent either the 'final' game status (for those who completed it) or the 'intermediate' score (for those who did not complete it yet). The scope is operationalized as the height of the constructed tower (measured as the number of layers of bricks). Time is operationalized as the number of weeks the project was ongoing (so far). The total budget (expenses) is split in labor costs, material costs, storage rent and fees to solve delivery delays. Since the income of players was fixed at L$ 135, only projects with less than that amount of total expenses would make a profit. For all the variables identified, a two-tailed t-test was conducted. There were no significant differences found between the low-tech and high-tech groups ($|t| \leq t_{\alpha/2}$).

Table 2 – Findings: game scores, with the number of players that completely 'finished' the game being 12 (low-tech) and 7 (high-tech)

	low-tech			*high-tech*			
	mean	*variance*	*n*	*mean*	*variance*	*n*	*t*
Scope: height (including ground floor)	3.75	1.00	16	3,10	1.25	20	1,81
Time: number of weeks	22.23	14.73	13	20,42	66.37	19	0,74
Budget: total (L$)	140.14	474.44	14	156,33	2562.81	15	-1.10
- labor costs (L$)	70.59	679.26	17	92,20	492.20	5	-1,68
- material costs (L$)	38.47	47.14	17	43,25	72.25	4	-1,20
- renting temporary storage (L$)	13.57	570.88	14	6,25	156.25	4	0,58
- solving delays in deliveries (L$)	2.25	18.20	12	4,50	51.00	4	-0,78

Supply chain optimizations

The results of the strategies to achieve supply chain optimizations are shown in Table 3. Eight strategies (or learning goals) to reduce waste and/or improve efficiency had been identified in an earlier study by Van den Berg et al. (2017). Using a 5-point Likert scale, players of the low-tech and high-tech serious games answered whether they had applied these strategies. Affirmative answers (with higher ratings) thereby suggest that players were aware of the in-game learning goal. We found, among others, that the strategy 'recognizing construction sequences' scored rather high for both the low-tech ($M = 3.89; SD = 0.99$) and high-tech group ($M = 3.57; SD = 0.99$), suggesting that players adapted their designs to an efficient assembly sequence. For the optimization strategy 'making trade-offs in response to manufacturing delays', our two-tailed t-test revealed a significant difference between the low-tech group ($M = 2.72;\ SD = 1.39$) and the high-tech group ($M = 3.59; SD = 1.21$); $t = -2.41; p = 0.021$. No significant differences were found for the other optimization strategies ($|t| \leq t_{\alpha/2}$).

Table 3 – Findings: supply chain optimizations rated on a 5-point Likert scale (1=strongly disagree to 5=strongly agree)

	low-tech			*high-tech*			
	mean	*variance*	*n*	*mean*	*variance*	*n*	*t*
I used a systems perspective to focus on the entire supply chain	3.80	0.91	20	3.19	0.96	21	2.02
I tried to achieve a lean process and/or Just-In-Time deliveries	3.60	1.09	20	3.09	1.23	22	1.53
I recognized construction sequences	3.89	0.99	19	3.57	1.26	21	0.96
I adapted my strategy based on product lead-times and assembling rates	3.90	0.52	20	3.52	1.06	21	1.35
I based my design on the availability of materials and construction site characteristics	3.75	0.83	20	3.36	1.29	22	1.21
I made systematic trade-offs to fulfill client requirements	3.45	0.68	20	3.36	0.81	22	0.32
I balanced time and cost when ordering construction materials	3.25	1.46	20	3.55	1.02	22	-0.86
I made trade-offs in response to manufacturing delays	2.72	1.39	18	3.59	1.21	22	**-2.41**

Personal views

The results of participants' personal views about their (low-tech and high-tech) game experience is shown in Table 4 and Table 5. These views were linked to the three themes that are critically important in any serious game: play, meaning and reality (Harteveld, 2011). The respondents' agreements with statements related to these themes was measured with a 5-point Likert scale. Our two-tailed t-test did not reveal any significant differences between the two groups ($|t| < t_{\alpha/2}$). Three other questions invited the respondents to speculate whether they thought the version of the game that they did not play would be less (lower ratings) or more (higher ratings) fun, educative or realistic. Again, we conducted two-tailed t-tests for these variables. For the educative (meaning) theme, we found no significant differences between the two groups ($|t| \leq t_{\alpha/2}$). For the fun (play) theme, a significant difference was nevertheless found between the low-tech ($M = 3.15; SD = 0.56$) and high-tech players ($M = 3.67; SD = 0.43$); $t = -2.36; p = 0.023$. A significant difference was also observed for the realistic (reality) theme between the low-tech ($M = 3.55; SD = 0.47$) and high-tech group ($M = 2.81; SD = 0.76$); $t = 3.01; p = 0.005$.

Table 4 – Findings: personal views rated on a 5-point Likert scale (1=strongly disagree to 5=strongly agree)

	low-tech			*high-tech*			
	mean	*variance*	*n*	*mean*	*variance*	*n*	*t*
I had fun playing the game	3.48	0.96	21	3.45	1.59	22	0.06
I found the game educative with respect to construction supply chain management	3.85	0.66	20	3.95	0.90	22	-0.38
I recognize theoretical supply chain management concepts in the game	4.10	0.52	20	3.95	0.90	22	0.56
I think the game represents construction supply chain management issues realistically	3.85	0.45	20	3.86	0.50	22	-0.06

Table 5 – Findings: personal views rated on a 5-point Likert scale (1=much less to 5=much more)

I expect that the other version of this game (i.e. low-tech or high-tech) is … fun	3.15	0.56	20	3.67	0.43	21	**-2.36**
I expect that the other version of this game (i.e. low-tech or high-tech) is … educative	3.10	0.41	20	3.05	0.65	21	0.23
I expect that the other version of this game (i.e. low-tech or high-tech) is … realistic	3.55	0.47	20	2.81	0.76	21	**3.01**

Discussion

This paper compared the relative learning benefits of serious games for construction supply chain management. Based on an (existing) low-tech serious game called Tower of Infinity, a (new) high-tech prototype was developed within the context of this study. Both types of (one-player) games aim to make construction supply chain management knowledge experientially available to their players. They do that by challenging players to maximize profit in a project that concerns the design and construction of a high-rise building. As such, these games are one of the first to incorporate supply chain management knowledge specifically for the construction industry. Documented evidence of how these types of games can enhance education had still been limited to several game workshops with a low-tech variant. This paper took a next step with comparing the learning benefits of low-tech and high-tech serious games relative to each other.

First, this paper contributes with the development of a high-tech serious game for construction supply chain management. The original, low-tech, serious game Tower of Infinity was systematically developed through analyzing three Triadic Game Design themes (Harteveld, 2011). These were also considered throughout the process of digitizing that game. As an example, play-tests with fellow researchers suggested that the initial poor usability (play) could be improved by adding a tutorial to the game. The resulting game design is a digitized variant of the Lego-based game. We have here presented an overview of this serious game and its game mechanics. The novel game provides new opportunities to acquire construction-related supply chain management knowledge.

Second, this paper contributes with insights regarding the relative benefits of low-tech and high-tech serious games for construction-related supply chain education. We conducted two-tailed t-tests for the surveyed variables to compare the learning benefits of one type of game over the other. For most of the variables, no evidence was found of differences in learning benefits. This may be explained by the fact the high-tech game is a 'direct digitization' of the low-tech variant, without many differences in appearance elements, complexity of interactions, special effects, etc. For a few variables, statistically significant differences were found. More high-tech than low-tech game players agreed that they made ‘trade-offs in response to manufacturing delays’. Such delays occur randomly and force the player to choose between ‘waiting longer’ (accepting the delay) or ‘solving the issue’ (cancelling the delay at a cost). The differences between the two groups may be explained due to the fact that low-tech game players sometimes forgot that they could cancel a delay (as was also evidenced from additional comments on the survey forms), while the high-tech game prompts that option with a kind of pop-up screen. Other differences relate to personal views. More high-tech than low-tech game players expect that the alternative version of the game would be more fun than the version they played. On the other hand, we found that more low-tech than high-tech players expect the other version of the serious game to be more realistic than their version. While the latter finding is consistent with the

common perception that ‘high-tech’ means ‘more realistic’ (Meijer, 2015), we can only speculate about the other difference.

Third, the paper contributes with a better understanding on how both low-tech and high-tech serious games may enhance (construction) supply chain education. Our analysis of post-assessment questionnaires revealed, among others, that players (from both groups) found the games ‘fun’ and that they recognized theoretical supply management lessons. The game scores revealed, however, that less players in the high-tech game group finished their game. Only few could (therefore) break down the amount of fictitious in-game money they spent into subcategories, since the prototypical game only displays that after completion. Education can also be enriched with enabling participants to actually try and experiment with strategies to optimize the performance of (construction) supply chains. For example, we found evidence for ‘recognizing construction sequences’ and ‘considering lead-times and assembly rates’. These findings further support and strengthen the conclusions of the earlier low-tech game study (Van den Berg et al., 2017).

Conclusion

Based on the results presented in this study, we conclude that the learning benefits of low-tech and high-tech serious games for construction supply chain management are comparable. Within the context of this study, a high-tech variant of the low-tech serious game Tower of Infinity was developed. Both variants were then played by two groups of (in total) 43 PhD candidates in an experimental setting. We used a post-assessment survey to capture game scores, supply chain optimization strategies and personal views. Variables within these categories were then systematically analyzed using two-tailed t-tests. From this, we conclude that learning benefits (only) differ for people playing such a low-tech or high-tech game in ‘making trade-offs in response to manufacturing delays’ (favoring the high-tech game players). We also conclude that high-tech game players expect low-tech games to be more ‘fun’ and that low-tech game players expect high-tech games to be more ‘realistic’. No other differences were found between low-tech and high-tech serious game usages, from which we suggest that the game mechanics led to similar responses rather than the game technologies deployed. More experimental research with people from different backgrounds can further strengthen these conclusions. We hope that our insights on the relative learning benefits of low-tech and high-tech serious games for construction supply chain management help other researchers, educators and game designers in selecting the most appropriate serious game technologies for their needs.

Abstract

This study addresses perceptual distance between principal and agent in projects and how the principal attempts to prevent or mitigate this perceptual distance by means of control. Specifically, we investigate two controlling mechanisms: power-based control (i.e. *mediated power*) and contract-based control (*contractual specificity*) and we study how these two mechanisms influence the perceptual distance that is observed on several key relationship issues through their effect on social identification and information asymmetry. We investigate these phenomena in four rail-infrastructure projects. Based upon a cross-case comparison we can conclude that both control measures do not decrease perceptual distance; on the contrary, mediated power rather increases perceptual distance. Other findings are that *acknowledgement of power* that is held at both sides and *contractual quality* are features of the projects in which less perceptual distance is found.

Introduction

A well-known Indian allegory, poeticized by John Godfrey Saxe (1868), describes how six blind men intend to discover what an elephant is. The six men approach the elephant, but due to the size of the elephant each of these men experiences a specific part of the elephant. When all return with different observations and conclusions a heated discussion begins according to Saxe (1868, pp. 260–261)[1]. The men are ignorant of each other's arguments and are convinced of being right even though they have not seen the elephant.

---

[1] "*And so these men of Indostan*
Disputed loud and long,
Each in his own opinion
Exceeding stiff and strong,
Though each was partly in the right,
And all were in the wrong!
MORAL.
So, oft in theologic wars
The disputants, I ween,
Rail on in utter ignorance
Of what each other mean,
And prate about an Elephant
Not one of them has seen!"

This Indian allegory bears remarkable resemblance to project management. Namely, the elephant in this allegory is a complex project. Projects are characterized by many particularities. Therefore, these projects ask for a tailored, one-shot approach (Fulford & Standing, 2014; Segerstedt & Olofsson, 2010; Vaaland & Håkansson, 2003; Vrijhoef & De Ridder, 2005). This involves the expertise of many different organizations, contractors and subcontractors, which operate in a complex network with critical interdependencies (Bankvall, Bygballe, Dubois, & Jahre, 2010; Eriksson, 2015; Segerstedt & Olofsson, 2010; Vaaland & Håkansson, 2003). These organizations, represented by expert employees, are the Indian men in the parable. The actors all have a specific background and expertise that is of great value to the project, but also limits their perception and rationality regarding a new project. Furthermore, all actors work on a specific part at a certain hierarchical level of the entire project and, therefore, have different information and a different level of detail (Eriksson, 2015; Fulford & Standing, 2014). Hence, actors have bounded knowledge: they typically attend to only part of the project and are blind to other areas. As a result, the experts of different organizations have different perceptions which are all only a part of the truth. If not managed carefully, these different perceptions result in disputes and conflicts (Lambert, Emmelhainz, & Gardner, 1999; Rosenberg & Stern, 1971; Vaaland & Håkansson, 2003) when the actors are ignorant of the perceptions of others while each of them claims to 'know the whole truth'.

Hence, as in the allegory, conflicts between collaborating companies are not uncommon within the project and construction industry. Worse still, an increase in jurisdiction as a 'solution' to conflicts can be observed and eventually this jurisdiction can even escalate to court (Vaaland & Håkansson, 2003). This is (partially) the result of the previously mentioned one-shot approach, which results in short-term opportunistic relationships (Tazelaar & Snijders, 2010) in which collaborating companies focus on their own goals while investing limited time and resources in the joint project (Vaaland & Håkansson, 2003).

However, these days companies have to manage a broad supplier base and depend upon relationships with their strategic suppliers to realize good performance and to have competitive advantage (Kraljic, 1983; Lambert et al., 1999; Maloni & Benton, 2000; Oliver, 1990). Particularly in the project industry, where organizations need to find many partners with specific expertise in order to develop a project. Moreover, these projects nowadays regularly include design and engineering elements which increases the complexity (Vrijhoef & De Ridder, 2005). The network of supply chain relationships that has to be managed confronts buyers with considerable challenges. Specifically, the collaboration between representatives of different companies appears to be highly challenging, as they have different characteristics and cultures (Nyaga, Lynch, Marshall, & Ambrose, 2013). The cause of this challenge is that the 'merging' organizations do not recognize and accept their partners' perspectives on the collaborative project (Cartwright & Cooper, 1993). Differences in perceptions of collaborating partners is studied by Van der Krift, Van Weele and Gevers (2018) and has been referred to as perceptual distance, which they define as "*the difference between collaborating partners' perceptions of key issues in their relationship*".

In order to align perceptions buyer's representatives apply two means, namely power-based control and contract-based control. In power-based control, project managers apply mediated power in order to influence and control the dependent supplier. Mediated power is defined by Maloni and Benton (2000, pp. 54–55) as "*influence efforts that are deliberately engaged (or threatened) by the power source to guide target response*" and is seen as the negative manifestation of power (Benton & Maloni, 2005). Contract-based control refers to the practice in which project managers increase the level of contract specificity to formalize their project goals and expectations and obligations of both organizations. Through specification a mismatch

of perceptions can be prevented (Carey, Lawson, & Krause, 2011; Vaaland & Håkansson, 2003).

Despite their popularity, there is little empirical ground for the assumption that mediated power and contractual specificity can decrease perceptual distance. Therefore, in this study we aim to investigate their effectiveness in preventing or reducing perceptual distance in construction projects. This paper builds on an analysis and comparison of four rail infrastructure projects in the Netherlands. In the following, we firstly discuss the existence of perceptual distance and how mediated power and contractual specificity might influence perceptual distance in the theoretical section. Then, the methodology that is applied in this study is explicated, after which we present the results. Lastly, we discuss the results, its implications and we conclude the study in the final section.

Theoretical background

In this section, we firstly introduce the topic of perceptual distance and how this phenomenon has been explained in prior studies. Thereafter, we use the theories that are used in these studies, i.e. agency theory and social identity theory, to discuss how mediated power and contractual specificity are applied in buyer-supplier relationships to control perceptual distance. Moreover, we discuss potential effects of this mediated power and contractual specificity on perceptual distance.

Perceptual distance

Scholars have identified many relationship issues on which perceptions of collaborating partners differ. These include project objectives (Van der Krift et al., 2018), competences at either side (Homburg & Jensen, 2007; Van der Krift et al., 2018), nature or importance of regulations, trustworthiness (Andersen, Christensen, & Damgaard, 2009; Van der Krift et al., 2018), organizational responsiveness, internal task routines, and management style (Lavie, Haunschild, & Khanna, 2012; Van der Krift et al., 2018). Also other issues are proposed to be liable to perceptual distance, but research has not yet succeeded in finding perceptual distance on these issues, such as decision-making autonomy, flexibility and information exchange (Van der Krift et al., 2018).

Perceptual distance is explained by two mechanisms, namely information asymmetry and social identification (Oosterhuis, Molleman, & van der Vaart, 2013; Van der Krift et al., 2018). These two mechanisms are derived from agency theory (Eisenhardt, 1989) and social identity theory (Ashforth & Mael, 1989). Representatives of organizations are shown to have different perceptions of key relationship issues, firstly, when they do not possess the same information with regard to the project and partner involved, and secondly, when they identify themselves strongly with the interest, values and processes at their own organization. As a result of information asymmetry and social identification, collaborating partners will hold a different perspective towards the collaborative project, will interpret the behavior shown at the other organization differently, have a positive bias towards their own behavior and will more strongly identify with their own perspective (objective) and values. Altogether, these effects will cause that partners have different perceptions of key relationship issues in their collaborative project (Van der Krift et al., 2018). Because perceptual distance can have a negative effect on relational governance and project outcomes, it is important to understand what measures can prevent or reduce the emergence of perceptual distance. The aim in this study is to examine two of these measures that are applied by organizations, namely mediated power and contractual specificity.

Mediated power

Following Maloni and Benton (2000, pp. 54–55), mediated power is the attempt of the power holder (i.c. principal) to govern the behavior of the target (i.c. agent) through three types of power, namely coercive power (i.e. "*source holds ability to mediate punishment to target*"), legal power (i.e. "*source retains judiciary right to influence target*") and reward power (i.e. "*source retains ability to mediate rewards to target*"). In daily practice, this may imply that members of the powerholding company try to use this power to pursue their company's goals and interests.

When mediated power is applied by the principal in the relationship, a dependent agent likely complies with their requests (Benton & Maloni, 2005; Maloni & Benton, 2000; Nyaga et al., 2013). As a result, the behavior of the agent is aligned with the desires of the principal and perceptions are therefore well-aligned in the view of the powerholder. Overall, the agent follows the principal, in accordance with the information that is provided, wherever dictated.

However, the use of mediated power by the powerholding company might simultaneously increase issues of social identification. From a social identity theory point of view, power forms a part of the identity of the in-group and enlarges the group identification as the employees from the powerholding company can use their power to pursue their own company interests and goals (Cook, 1977; Cox, 2001). As a result, the separation of the roles of principal and agent is emphasized by the power wielded. Similarly, the employees of the other company might assume and identify with a victimized role due to being subjected to this mediated power. Consequently, the identification with the in-group increases due to the increased salience (i.e. explicit presence) of the out-group as manifested in the exercise of mediated power (Ashforth & Mael, 1989). Moreover, from the perspective of agency theory, information provides control (Eisenhardt, 1989) which is closely related to power (Cook, 1977; Maloni & Benton, 2000). The powerholder may be inclined to maliciously maintain the asymmetry of information as withholding information may provide a privileged, controlling position in the relationship. As prior studies have shown, information asymmetry is one of the mechanisms that explain the existence of perceptual distance (Oosterhuis et al., 2013; Van der Krift et al., 2018).

Hence, in the longer term the use of mediated power is believed to negatively influence the relationships because it might lead to perceptual distance (Nyaga et al., 2013), dissension (Benton & Maloni, 2005; Maloni & Benton, 2000), conflict (Benton & Maloni, 2005; Nyaga et al., 2013; Oliver, 1990) and decreased relational governance (Benton & Maloni, 2005; Nyaga et al., 2013; Terpend & Ashenbaum, 2012) and overall performance (Benton & Maloni, 2005; Maloni & Benton, 2000; Terpend & Ashenbaum, 2012). The rationale for this is that the use of mediated power indicates a focus on short-term objectives that are of interest to the power holder (Benton & Maloni, 2005; Cook, 1977; Nyaga et al., 2013). As noted earlier, particularly in projects the prevalence of short-term (usually financial) objectives is observed rather than a focus on issues that are important for maintaining a long-term relationship. This is explained by the discontinuous, one-shot approach that is found in project management (Eriksson, 2015; Fulford & Standing, 2014; Tazelaar & Snijders, 2010).

Concluding, while mediated power seems to align the behavior of the agent with the desires of the principal it may simultaneously reinforce social identification and information asymmetry in the relationship. Consequently, mediated power might influence the perceptual distance between partners in a collaborative project. The research question that we aim to answer in this paper is:

> *What effect can be expected from mediated power on the perceptual distance between buyer's and supplier's representatives in collaborative projects?*

Contractual specificity

The second means that is studied is contractual specificity, i.e. "*the extent to which contractual clauses related to obligations and behaviors are specified in detail*" (Sumo, Van der Valk, Van Weele, & Bode, 2016, p. 1483). From the perspective of agency theory, specification can be seen as a mechanism to share information and thus decrease information asymmetry between collaborating partners. By specification, the principal aims to align the expectations of principal and agent on the goals, the means and processes to obtain these goals, norms and many other contractual clauses(Carey et al., 2011). When everything is specified, both parties have the same information, and the potential of conflict will be limited between both partners (Vaaland & Håkansson, 2003).

However, contract specifications are always incomplete and subject to interpretation (Liu, Luo, & Liu, 2009) and parties may falsely believe that interpretations are aligned by having them formally stated in a contract. Thus, when detailed specifications are only limitedly discussed, it might eventually result in larger differences in opinions compared to less specific contracts where more is left for discussion and to the expertise of both partners. Moreover, leaving details unspecified may signal trust to the partner which gives the responsibility to not take advantage , whereas overly specified contracts may signal distrust (Huang, Cheng, & Tseng, 2014; Jap & Ganesan, 2000; Weber & Mayer, 2011) and might well lead parties to look for caveats in the contract and take advantage of ill-defined specifications at the expense of the other party without moral (relationship-oriented) concerns. Furthermore, from the perspective of social identity theory, the contract is an instrument that emphasizes the distinction between the role of principal and agent. Hence, the contract can stimulate the identification at both sides with their specific role. Thus, a highly specified contract makes more explicit that the collaboration is between two separate parties that both have their own interest, making them less cooperation- and trust-focused (Huang et al., 2014; Jap & Ganesan, 2000; Poppo & Zhou, 2014). Hence, by increasing the specification level both parties will more strongly identify with their own company.

Concluding, two conflicting arguments on the effects of contractual specificity seem to be provided by agency theory and social identity theory. On the one hand, contractual specificity might decrease information asymmetry between collaborating partners while on the other hand, it may increase the social identification in both groups. Hence, contractual specificity is likely to affect the level of perceptual distance, but the direction remains unclear. The research question that we aim to answer in this paper is:

> *What effect can be expected from contractual specificity on the perceptual distance between buyer's and supplier's representatives in collaborative projects?*

Methodology

Research design

To answer these research questions, the case study is a suitable method. Cases were purposefully selected based upon the variables of interest (Onwuegbuzie & Collins, 2007) which are contractual specificity and mediated power. Within these cases we gathered both quantitative data and qualitative data. The quantitative data provides us with an objective frame to compare the cases based upon the dependent variables, i.e. *perceptual distance*. The qualitative data provides us with insight in the relationship between the two means of control and perceptual distance. Furthermore, we gathered dyadic data as this study deals with perceptions of both principal and agent in collaborations. Moreover, according to Maloni and Benton (2000) dyadic data is preferred when dealing with the phenomenon of power.

Research context

Data was collected from four projects that are outsourced from a large semi-public organization in the rail-infrastructure industry in the Netherlands to one of the larger contractors in the Netherlands. The semi-public organization, which has the role of principal in these four projects, has large power because it is a significant player in the market with a market share of above 80 percent. Whereas on the supply side, there are quite some organizations competing in this industry. Hence, we can speak of a near monopsony. Furthermore, the principal uses past performance as a criterion in its tenders. This past performance is based upon evaluations on previous projects that are done by project managers at the principal's side. Although it does not necessarily imply the presence of mediated power, the use of past performance in tenders does provide the principal with a power base that approximates coercive power (i.e. bad performance in the current project will reduce the chance on getting future projects) and reward power (i.e. good performance in the current project will increase the chance of getting future projects). Therefore, it is a suitable, exemplary context to study mediated power (Onwuegbuzie & Collins, 2007). Moreover, the four projects vary in terms of size, duration and contract type for the purpose of generalizability (see Table 1). From here on, we refer to these projects as project alpha, project Bèta, project gamma and project delta respectively.

Table 1. Descriptives of the four projects that have been studied

Project	**Alpha**	**Bèta**	**Gamma**	**Delta**
Scope	Renewal and adaptation of a service center with many stakeholders	Connection of two trajectories with different voltage levels including design	The renewal of the superstructure at several locations in an important trajectory	The broadening and adaptation of a trajectory around and including a station
Selection method	Price	Best Value	Price, past performance, sustainability and safety performance	Price, past performance, sustainability and safety performance
Contract type	Specifications	Design & Construct	Design & Construct	Design & Construct
Duration	6-12 months	2-3 year	1-2 year	2-3 year
Size	€ 4 million	€ 32 million	€ 6 million	€ 28 million
Survey data sources	Principal 4, agent 5	Principal 4, agent 3	Principal 4, agent 4	Principal 3, agent 3

Data gathering

The questionnaire (see Appendix A) is based upon prior research by Van der Krift et al. (2018) but was adapted to enhance the reliability and validity of the scales. The questionnaires were gathered online. The applicant (the project manager on principal or agent side) was requested to answer five general questions with regard to the project (e.g. size, duration, type of project) and to specify the team members at both sides that were involved in the collaboration. After these questions were answered, his or her colleagues and also team members from the other organization received an invitation to fill out the questionnaire. This questionnaire consists of 103 questions regarding the relationship issues mentioned in the theoretical section of this paper and regarding mediated power. After all responses were gathered, participants received a report of the perceptions of both parties on these issues in their collaborative project. As is listed in Table 1, in total 30 responses were obtained from the four projects.

Based upon the questionnaires, individual interviews were held with the project managers on both sides separately. Hence, in total eight interviews were held. In the interviews, the relationship issues that were inquired in the questionnaire, as well as mediated power and contractual specificity were further discussed with the respondents. In Appendix A the definitions of these variables are provided. During the interviews, notes were made and proposed to the interviewee who was given the opportunity to comment on the wording. These notes have been used for the analysis section in this paper. Furthermore, the interviews were recorded to enable further analysis when needed.

Measures

The scales and definitions were mainly adopted from the paper of Van der Krift et al. (2018). However, adaptations were made to improve the validity and reliability of the scales. The scales for competences (on either side), decision-making autonomy, flexibility, and information exchange have been changed. The resulting scales are listed in Appendix A. All of the scales proved to be reliable by means of SPSS. Acceptable Cronbach's alpha values were obtained for the scales *nature of regulations*, *flexibility*, *information exchange*, and *management style* after removal of a single item.

Calculation of perceptual distance

Perceptual distance was calculated for each of the relationship issues by means of a standardized mean difference test, namely Hedges' g (Hedges, 1981; Van der Krift et al., 2018). For this calculation data was used from the responses to the questionnaire that were obtained. The visualization of perceptual distance for each of the four cases is depicted in Figure 1. From the figure we can conclude that perceptual distance is clearly found in both case Alpha and Bèta. In case Alpha large values for perceptual distance are found on many relationship issues, while in project Bèta perceptual distance is only found on a limited number of relationship issues. In cases Gamma and Delta smaller values of perceptual distance are found on several issues, but overall perceptions between collaborating partners seem to be well aligned. Consequently, we are able to compare the cases on the level of perceptual distance that is present between the collaborating partners.

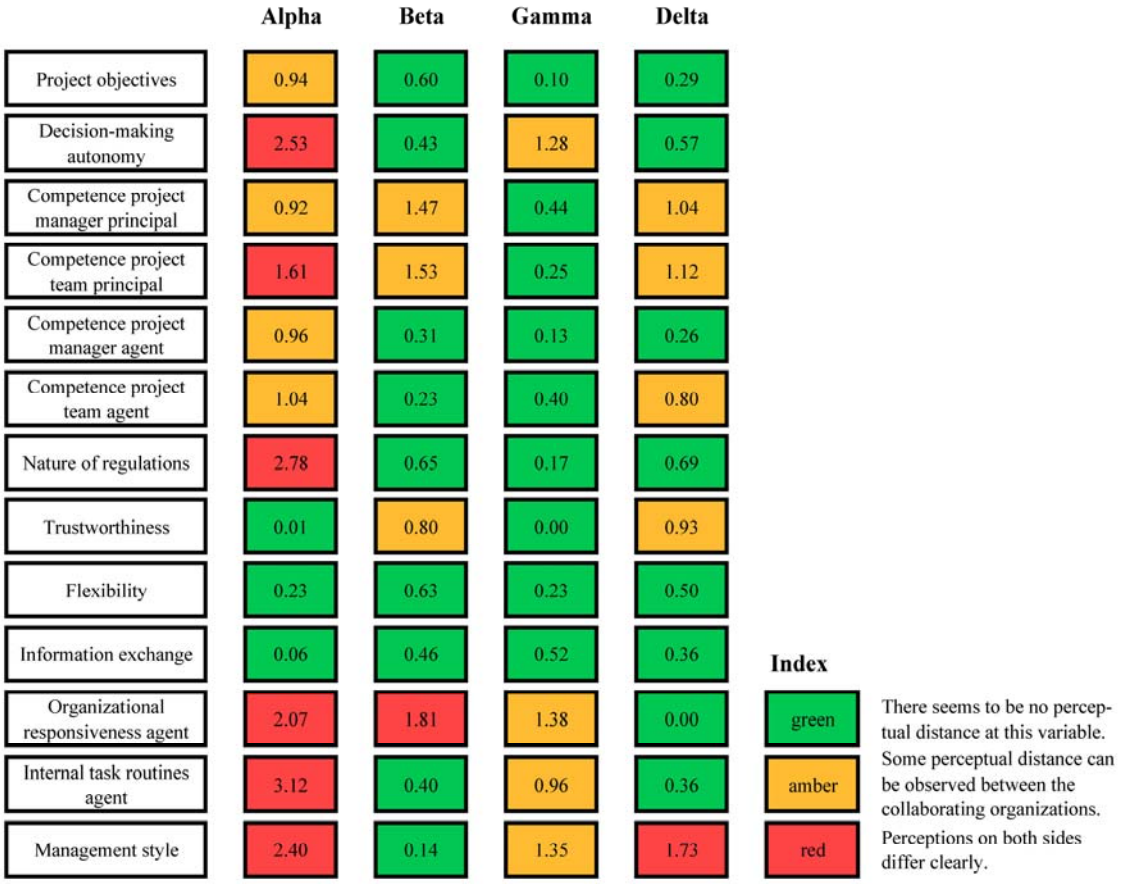

Figure 1. Perceptual distance levels on several relationship issues in the four projects; within the boxes the value for perceptual distance is found based upon Hedges' g.

Case findings

In the following section each of the four cases is analyzed. Each of the cases is shortly introduced before the application of both mediated power and contractual specificity is examined.

Project Alpha

The first project, project Alpha, concerns the renewal, adaptation and expansion of a service center. An increase of the capacity of the service center was needed as well as adaptation of the service center due to changes required for the working conditions of the service employees. These changes were required in a certain time period which has put a time pressure on the execution of the project. The overall project was not very complex in terms of technology, but involved many important stakeholders. The project had a difficult preparation process in which the first attempt to start the project had not succeeded. For the tender, specifications were developed by an external engineering office. After the bids were received, the supplier selection was fully based on price.

Mediated power

Within this project, both principal and agent indicate that the principal holds the power. The principal is decisive and determines what should be done in the project. However, while the principal says that they "*decide on the boundaries within which the agent has to do its work*" the agent makes use of a common saying which is usually linked with a traditional working

style in the construction industry, namely: "*Principal has much power. He who pays the piper calls the tune.*" In essence, the agent indicates that the principal decides on (almost) everything in this project. The project manager does so by making very explicit the distinct roles of principal and agent, and links the expected behavior to these roles. Hence, social identification is clearly present within project Alpha. While the contract type, i.e. detailed specifications, provides the principal with more power, the agent believes it has to follow the principal in its requests. From Figure 1 we can derive that principal and agent have a large perceptual distance on the decision-making autonomy of the agent. The principal perceived the agent to have much more autonomy (value of 4.95 on Likert scale) than the agent representatives perceived themselves (value of 2.68 on Likert scale). This indicates that the agent experiences the principal to have much power, manifested in the will to decide on many issues in the project. On the other hand, the principal perceives itself to make less use of its power but instead to provide autonomy to the agent. Overall, we can conclude that perceptual distance is indeed increased as a result of mediated power, through its influence on social identification.

Contractual specificity

Within project Alpha, a detailed, specified contract was expected by both parties. However, the level of detail was inconsistent over the different clauses in the contract as is indicated by representatives of the principal as well as the agent. The agent said that "*for some disciplines the contract was well-specified, but for some others it was incompletely specified.*" Hence, due to the incompleteness of the contract, information was asymmetrical between both parties. Furthermore, this incomplete specification had a major effect on the outcomes of the project according to the agent's project manager who eventually even had a loss in the project while "*there should not be any losses with this specified type of contract, because you know what has to be made* [and] *if somethings needs to be done differently, it will be settled.*" Generally, contractual specification is not believed to reduce or increase perceptual distance according to the project manager at principal, who said that "*with any type of contract, either traditional* [often described as 'technical specification' i.e. 'describing the technical properties and characteristics of what will be delivered, as well as the activities to be performed by the supplier' (Van Weele, 2014)] *or more functional* [i.e. 'describing the functionality which has to be offered to the customer' as opposed to technical specification (Van Weele, 2014)]*, there is a game between principal and agent with regard to the precise interpretation of elements from the contract.*" Hence, the interviews indicate that it is rather about *contractual quality* than about contractual specificity.

Project Bèta

Project Bèta is the largest project among the four that we have studied. The project concerns the connection of two important trajectories with different voltage levels. This connection asks for specialized engineering. Hence, it is a very complex work with regard to technology, innovation and time schedule. Because of the complexity and size of the project, the supplier was selected using the Best Value Procurement methodology (Van de Rijt & Santema, 2013). Hence, the principal did a request for proposal using a ceiling price. However, the agent was the only contractor that could deliver under this project sum defined, leaving no option to the principal other than to work with this supplier. The tender and selection method were relatively new to both sides and as a result the project managers were rather inexperienced with regard to the procedures and conditions in a project based upon this tender and selection method.

Mediated power

Project Bèta is characterized by a low use of mediated power by the principal. The project manager at the principal states that they "*must exactly not assert our authority here*" referring

to the fact that the agent has much say given the functional specifications that are provided by the principal. The tender procedure, based upon Best Value Procurement, is based upon the supposition that the agent is the expert, and, as such the agent is better in deciding what needs to be done for the best project result. As such, the agent's responsibility is to make and deliver a design to the principal. These designs and solutions did not have to be formally approved by the principal, only deviations from regulations were discussed with the principal according to the interviewees. However, while little attention was paid to the power that the principal holds the roles, responsibilities and expectations of both organizations were rather unclear. Within project Bèta, the principal requested several changes after the tender and contracting phase and during project execution. Due to the lack of attention that was paid to the power and roles of both parties, the agent followed the principal in its requests. As a result, there have been almost 300 changes in the project with, major negative consequences for project cost and schedule. Furthermore, due to the role ambiguity, at the agent they believed that information was not to be shared as they had to solve issues themselves. Logically, the large number of changes and the ambiguity in roles results in different perceptions of how the agent deals with changes. Hence, significant perceptual distance is observed on one specific variable, namely *organizational responsiveness agent*.

In project Bèta, we observe that a lower use of power has resulted in greater role ambiguity and information asymmetry, but it seems also to have led to low social identification with the own organization. As a result, some perceptual distance was found in this project Bèta.

Contractual specificity

In project Bèta specifications appeared to be rather inconsistent, notwithstanding the tender method (i.e. Best Value) and contract type (i.e. Design & Construct) that were used. According to principal's project manager "*not everything was yet straightened with this contract… Of some issues the protocols were not yet specified.*" The agent observed the same problem as was seen in project Alpha, namely that "*one section* [in the contract] *is very much specified in detail, another* [section] *is very abstract.*" According to the principal this caused quite some problems in contractual discussions. Both principal and agent agree on the fact that differences in interpretations and perceptions are not necessarily prevented by specifications in the contract. On the contrary, the agent mentioned that "*on the most specifically described section we needed most to engage in dialogue.*" Moreover, the principal states that generally "*the more functional you specify, the less chance there is of differences in interpretations because you hand more over to the agent.*" Again, we see that in this project it is more the lack of contractual quality than a lack (or abundance) of contractual specificity that will lead to different perceptions, due to the resulting asymmetry of information and ambiguity with regard to roles and expectations. Additionally, this case provides evidence that specifying contracts does not reduce the need for dialogue about the interpretation of the formal statements.

Project Gamma

Project Gamma concerns the renewal of the superstructure at several locations on a railroad trajectory. It is a smaller and not specifically complex project. Nevertheless, part of this trajectory is a crucial route to a big hub in the Netherlands. Mistakes and malfunctioning would cause much trouble for both principal and agent. The supplier was selected based upon Most Economically Advantageous Tender with criteria on price, past performance, safety and sustainability and the contract was based upon functional specifications.

Mediated power

Within this project, the agent's project manager said that performance reviews that are done by the principal are "*considered in the acquisition* [i.e. as a criterion in the tender] *of new projects.*

So they [i.e. principal] *could take advantage of this but that does not happen here* [i.e. in this project]." So the power that is held by the principal within the project is clearly recognized by the agent. The recognition of this power, and the awareness of its presence also enables the project manager to perceive that this power has not been abused by the principal. As a result, we can see that both parties identify with the end goal, that the collaboration is good and a separation of the roles of principal and agent is hardly present, as is indicated by the project manager of the principal who said that "*We feel and bear the responsibility for the project together. As such, the hierarchical line between principal and agent dissolves.*" Hence, social identification with their own organization becomes less strong due to a responsible handling of power that is hold by the principal. As a result, little perceptual distance is observed in project Gamma.

Contractual specificity

In project Gamma, the agent has to provide plans and descriptions of the processes to the principal. Subsequently, the principal has to accept these documents. The principal's project manager said that "*These plans provide us with trust that* [the project] *takes place safely and within time.*" This is done with the underlying thought that the more is described by the principal "*the more deviations will be found in these descriptions. We specify what we want and in this project we do need to deviate from the normal requirements sometimes.*" From this statement we can conclude that more details in a contract will not lead to a perfect contract but rather to the contrary, which has to do with the uniqueness of every project (Liu et al., 2009). This demands from collaborating partners and their representatives a flexible attitude (Weber & Mayer, 2011). Indeed in project Gamma, a flexible attitude was found at both sides, according to the project manager at the agent: "*We can also make suggestions that deviate from the requirements. Principal is receptive to anything but it needs to be discussed in advance.*"

Furthermore, the project manager at the agent stated that "*the quality of the contract determines how a project goes*" instead of the specificity of a contract. This is confirmed by the project manager at the principal who informed us that, contrary to most projects, in this project after the contracting few changes were requested by the principal, resulting in little effect on project planning and costs. Because the contract was of a higher quality in this project less information asymmetry was found between collaborating partners. As a result, little perceptual distance is observed within project Gamma.

Project Delta

Project Delta concerns the broadening of a station and the trajectory around that station. This includes the sub- and superstructure and overhead wire. This project had a difficult start. It was a large project which meant it was an important project to acquire for many contractors. As such, all contractors submitted bids on the project. Due to some lack of clarity and mistakes in the tender procedure, the supplier selection had to be settled in court. Eventually, the agent was selected and the project could start three months later than initially planned. This resulted in a change order request (COR) as investment was needed to still be able to meet the planning in the original plan. This was a difficult process which affected the relationship between principal and agent. Therefore, at both sides the project managers were changed after the COR was approved. As a result the new managers did not have a bad start in the project, but were able to start off a good collaboration.

Mediated power

Both principal and agent show to have a clear image of the power that is held at either side. The principal states that "*principal owns the money and has the performance review as means of power that can be used, but that should not be abused. At the agent's side it is time pressure,*

but also that has not been abused here." Hence, the principal is not the only power holder in the project and the collaborating partners are dependent upon the behavior of the other party. The agent confirms this statement mentioning that the power that is held by the performance reviews (see also Research context, in Methodology) for instance could be used as a coercive measure by the principal but that has not been done in this project. Furthermore, this project manager adds that "*Project managers at principal are dealing differently with power. In this projects it has not been abused, but that is not the same in every project.*" This indicates that among the different projects that are studied there probably are different ways in which is dealt with the power that is held. Here, the abuse of power is absent, which has resulted in little perceptual distance between the collaborating partners.

Contractual specificity

The project manager in project Delta indicates that it is the agent himself who develops the plans for the project. These plan only have to be approved by the principal. Although the contract had some grey areas according to the project manager at the agent, overall "*the contract was clear and well interpretable and that has affected the results.*" The project manager also spoke in general terms about contracts within the type of projects that are executed for his organization and said that "*A bad contract is a combat contract and that results in worse performance. The biggest risk is that a requirement can be interpreted in multiple ways.*" Still, there were many changes in the project, but these were mostly deemed legitimate and were thus considered to be beyond the original specification that was given by the principal. This means that the agent is compensated for the additional work that needs to be done. This is crucial for contractors as "*margins are small in this industry, and as such the discussions are often with regard to money.*" Overall, the contract was of good quality and therefore well interpretable according to the agent. As a result, less information asymmetry was found in project Delta, leading to similar interpretations of principal and agent. Overall, the interviewees clearly focused on contractual quality instead of contractual specificity as a mitigating factor for perceptual distance in their collaborative project.

Discussion

Overall, from the analysis of the four cases we can derive several insights. First of all, the use of mediated power results in a larger separation and distinction in the roles of principal and agent and thus increases social identification. However, also the acknowledgement of the power bases held at both sides is determining for the level of perceptual distance. Project Bèta showed that where principal and agent are less aware of the power base that both companies have, roles and expectations of both organizations remain ambiguous. In contrast, in project Delta collaborating partners know how the other is capable to assert influence but also what influence they have. As a result, the abuse of power is minimal or absent because the collaborating parties are dependent upon each other, hence their power (Cook, 1977; Cox, 2001), and do not benefit from games of power. Overall, the use of mediated power and a lack of the acknowledgement of power increase social identification and information asymmetry respectively, and thus instigate the determining factors for increased perceptual distance.

The second conclusion based upon the four cases is that contractual specificity in itself is not a denominator of successful projects. Contractual *quality* seems to be what determines whether collaborating partners have similar interpretations of the project. Subsequently, perceptions of how the project goes and how both organizations perform in the project will also be similar (Van der Krift et al., 2018). Concluding, collaborating partners should spend considerable attention to the development of the contract. In this development process, it might be advantageous to have both principal and agent evaluate the quality of the contract as their

perceptions of contractual quality might differ as well. Moreover, both parties eventually determine what needs to be done and how that needs to be done based upon the contract.

This study has several limitations as well. The first and most important limitation is the limited set of cases that were studied. Moreover, the cases have been selected from a single industry, and from two companies within that industry. However, we have been able to distance from company-specific characteristics that affect the dependent variable in these projects by studying different projects within a single collaboration between two organizations. The outcome in this study, perceptual distance, varies over the different projects while the context is largely similar. Hence, we can conclude that project- and collaboration-specific characteristics have influenced perceptual distance and that, as a result, this effect is likely to be found in other collaborations in this industry as well.

In future research, the presumed influence of contractual quality should be further studied. The cases indicated that the quality of the contract has considerable influence on the perceptual distance that is eventually found in a project. Therefore, both practitioners and academics would benefit from further research on this topic, such as a study on how high contract quality can be achieved. Another direction for future research is other bases of power that could have their influence on perceptual distance in projects. In this study we have specifically focused on the mediated power that is applied by the principal. However, the other bases could have influence as well. For example, the perceived level of expert power at either side may very well indicate which of the two parties has most say with regard to what needs to be done. Furthermore, it also indicates how likely the organizations will collaborate in their vision for the project (Maloni & Benton, 2000). Hence, expert power might have a decreasing effect on perceptual distance in projects.

Conclusion

In this study we have investigated the ability of a company to control the alignment of perceptions of principal and agent in complex projects. Two means of control have specifically been studied in four cases in the project industry. These two means are contract-based and power-based control. We have investigated the effects of these means of control on social identification and information asymmetry based upon a cross-case comparison. From these cases we can conclude that mediated power enlarges the distinction between the roles of principal and agent and thus increases social identification. Furthermore, the knowledge and acknowledgement of the power that is held at either side seems to create a situation in which both parties refrain from abuse of this power. Hence, a lack of acknowledgement of power bases increases social identification and information asymmetry in the project as it provides the condition for the abuse of mediated power. As a result perceptual distance between collaborating partners increases. The second means of control, contractual specificity, does not decrease the perceptual distance in the project. Rather, the cases show that it is contractual quality that plays a major role in aligning perceptions of collaborating partners. Therefore, organizations should investigate and acknowledge the power balance in their relationship and should assess the contractual quality from the very beginning of the project in order to align perceptions in their collaborative projects.

Appendix A. Variables, definition, operational definition and scale items

All items in this questionnaire are answered on a Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree). Words that are marked with a $ were adjusted to the individual to whom the questionnaire was sent to with regard to his/her company, project, and the principal/agent.

Reference definition or description	Pragmatic, operational description	Scale items (translated from Dutch), reliability and factor loading (in parentheses)	Source
Project objectives		**Project objectives (formative)**	*Van der Krift, Van Weele, & Gevers, 2018*
Satisfaction with the objectives that have to be achieved within the project by the agent and with the financial compensation that is provided for achieving these objectives.	*Goals, objective, aim, expectations, agreements with regard to (a) budget, (b) planning, (c) quality, (d) sustainability, and (e) innovation.*	*We were satisfied with the agreements that we have made with $partner regarding the budget.* *We were satisfied with the agreements that we have made with $partner regarding the planning.* *We were satisfied with the agreements that we have made with $partner regarding the quality standards.* *We were satisfied with the agreements that we have made with $partner regarding sustainability in the project.* *We were satisfied with the agreements that we have made with $partner regarding the innovativity (use of innovative techniques, processes and products) in the project.* *We were satisfied with the agreements that we have made with $partner regarding safety in the project.*	
Decision-making autonomy		**Decision making autonomy (Cronbach's α = 0.811)**	*Aiken & Hage, 1968*
The locus of expertise, responsibility, accountability and authority between principal and agent (Gibson et al, 2009).	*Decision making, autonomy of the agent, freedom of agent in making decisions, authority of the principal.*	*There can be little action taken by $agent until $principal approves a decision.** *If employees at $agent make their own decisions that would be quickly discouraged by $principal.** *Even small matters have to be referred to $principal for a final answer.** *$agent hardly ever has to ask $principal for permission for anything.* *Any decision made by $agent has to have $principal's approval.**	
Competence project manager principal		**Competence project manager principal (Cronbach's α = 0.829)**	*Self-developed for this research in consultation with representative*
The hard skills, i.e. "the depth of knowledge required to cope with a complex task*" and soft*	*Presence of competences in terms of knowledge, expertise, experience,*	*The project manager at $principal…* *has the (technological) expertise that is needed for the project* *manages the project well*	

skills, i.e. ability "to sustain conflicts, to communicate, and to convince*" of the project manager at the principal (Homburg & Jensen, 2007, p. 126).*	*communication, understanding, negotiation, and empathy.*	*makes proper assessments and decisions (for instance at interfaces of disciplines)* *reports and communicates clearly about performance on the project level* *formulates questions/problems clearly* *gets all project members involved*	*of head quarter management of participating company*
Competence project team principal		**Competence project team principal (Cronbach's α = 0.860)**	*Self-developed for this research in consultation with representative of head quarter management of participating company*
*The hard skills, i.e. "*the depth of knowledge required to cope with a complex task*" and soft skills, i.e. ability* "to sustain conflicts, to communicate, and to convince*" of the project team at the principal (Homburg & Jensen, 2007, p. 126).*	*Presence of competences in terms of knowledge, expertise, experience, communication, understanding, negotiation, and empathy.*	*The team members at $principal…* *have the technological expertise that is needed for the project* *work well together in a (multidisciplinary) team* *communicate clearly* *are convincing and assertive* *show great empathic ability* *are good at handling complexity*	
Competence project manager agent		**Competence project manager agent (Cronbach's α = 0.874)**	*Self-developed for this research in consultation with representative of head quarter management of participating company*
*The hard skills, i.e. "*the depth of knowledge required to cope with a complex task*" and soft skills, i.e. ability* "to sustain conflicts, to communicate, and to convince*" of the project manager at the agent (Homburg & Jensen, 2007, p. 126).*	*Presence of competences in terms of knowledge, expertise, experience, communication, understanding, negotiation, and empathy.*	*The project manager at $agent…* *has the (technological) expertise that is needed for the project* *manages the project well* *makes proper assessments and decisions (for instance at interfaces of disciplines)* *reports and communicates clearly about performance on the project level* *understands and complies with the principal's requests* *gets all project members involved*	
Competence project team agent		**Competence project team agent (Cronbach's α = 0.891)**	*Self-developed for this research in consultation with representative of head quarter management of participating company*
*The hard skills, i.e. "*the depth of knowledge required to cope with a complex task*" and soft skills, i.e. ability* "to sustain conflicts, to communicate, and to convince*" of the project team at the agent*	*Presence of competences in terms of knowledge, expertise, experience, communication, understanding, negotiation, and empathy.*	*The team members at $agent…* *have the technological expertise that is needed for the project* *work well together in a (multidisciplinary) team* *communicate clearly* *are convincing and assertive* *make a good translation from the principal's requests to technological solutions*	

(Homburg & Jensen, 2007, p. 126).		*are good at handling complexity*	
Nature of regulations		**Nature of regulations (Cronbach's α = 0.704)**	*Van der Krift et al., 2018*
"The nature of rules that shape economic activity *[…]* how a number of aspects in the buyer-supplier practice are influences by the rule and implementation of legislative institutions *[…]* the stipulation and enforcement of contracts as an important trait of market organization in business-to-business settings*." (Andersen et al., 2009, p. 815).*	*Importance and type of the contract and formal agreements. Use of contract and clauses during project execution.*	*The contractual agreements are important to $self.* *Within $self we attach little value to the contract as a tool within the collaboration.** *The contract is essential to the collaboration to maintain sufficient control over the execution (omitted).* *Within $self people point out to others anything in the project that does not pass off in accordance with the contract.* *It is important within $self to regularly bring out the contract in order to check all project matters.*	
Trustworthiness		**Trustworthiness (Cronbach's α = 0.769)**	*Van der Krift et al., 2018*
"The degree to which there is a correspondence between the stated rules and their implementation." *(Andersen et al., 2009, p. 815).* "The degree to which partners expect to be able to rely on each others' words and promises as a sufficient guarantee for establishing agreements on which they can plan future events." *(Andersen et al., 2009, p. 817).*	*Extent to which parties stand by agreements and stick to their promises, consistency in actions, and trustworthiness.*	*They ($partner) always stick to the agreements that we have made on paper.* *$partner properly establishes oral agreements regarding changes in the contract.* *Regularly, $partner tries to circumvent contractual agreements.*.* *The execution corresponds to what has been contractually agreed upon.* *We are satisfied with the type of contract that has been concluded.*	
Flexibility		**Flexibility (Cronbach's α = 0.852)**	*Stephen & Coote, 2007*
"Flexibility defines a bilateral expectation of willingness to make adaptations as circumstances change." *(Heide & John, 1992, p. 35).*	*Flexibility, open dealing with (requests to) changes.*	*In this collaboration, we are able to make adjustments in our relationship without significant disputes, conflicts, or uncooperative behaviors.* *When unexpected situations arose, we preferred to work out a new arrangement rather than holding each other to the original arrangement (omitted).*	

		When unexpected events occurred, both parties were open to modifying previous agreements. *$partner and $self are flexible in response to requests made by each other throughout the course of the project.*	
Information exchange		**Information exchange (Cronbach's α = 0.841)**	*Stephen & Coote, 2007*
"Information exchange is the expectation that the parties will freely and actively provide useful information to each other." (Heide & John, 1992, p. 35).	*Information exchange, communication, openness, sharing or withholding of knowledge.*	*Both parties are willing to provide proprietary information if it helps each other.* *Both parties keep each other informed about any events or changes that may affected either party.* *Information that was relevant to the project was exchanged willingly.* *Each party provided proprietary information that was helpful to the other (omitted).*	
Organizational responsiveness agent		**Organizational responsiveness agent (Cronbach's α = 0.806)**	*Lavie et al., 2012; Van der Krift et al., 2018*
"A firm's reactive to external entities and events occurring in its environment […] willingness to be open-minded […] responses to emerging industry opportunities." (Lavie et al., 2012, p. 1457).	*Level of creativity and open problem solving in and adaptability of the agent's organization.*	*$agent has an open attitude towards $principal in case of problem solving.* *At $agent they are open minded and creative in their approach to problem solving.* *$agent responds quickly to emerging situations, changes, and chances.*	
Internal task routines agent		**Internal task routines agent (Cronbach's α = 0.831)**	*Lavie et al., 2012; Pothukuchi et al., 2002; Van der Krift et al., 2018*
"[How] employees perform ordinary tasks *[manifested in]* the discretion that employees apply *[…]* the effort they exert when developing, attaining and master organizational skills*" (Lavie et al., 2012, p. 1458).*	*Efficiency of routines and process-based working. Speed and initiative in working ethics.*	*$agent has goal focused and achievement oriented employees.* *$agent has employees with a strong work ethic (defy the 9-to-5 attitude, willing to do whatever it takes to get the job done).* *Within $agent employees are encouraged to make decisions themselves.* *Within $agent teamwork and cooperation (e.g., collaboration among individuals from different business units) is emphasized.* *Employees of $agent are fast at work.* *Employees of $agent take initiative.*	
Management style		**Management style (Cronbach's α = 0.713)**	*Lavie et al., 2012; Van der Krift et al., 2018*
"A firm's management style is defined by its unique managerial approach, control systems, decision-making	*Level of bureaucracy and hierarchy, process of decision-making, and authority that project*	*$self is an informal organization (has few managerial layers, loose control and monitoring; few bureaucratic procedures and contracts).* *Decision making within $self is based upon consensus (of many people) rather than upon authoritarian decision making (by a senior person) (omitted).*	

style, and communication modes *[…]* reliance on hierarchy, formal rule systems and strict controls.*" (Lavie et al., 2012, p.1456).*	*members have in respective organizations (their back-office).*	*Within $self informal communication is preferred over formal communication (short presentations and no lengthy written reports).* *Within $self decisions are guided by concrete considerations and planned processes rather than by hidden agendas.*

* *Items marked with an asterisk are reversed in the scale*

Sustainable public procurement: legitimacy and legality versus appropriateness and efficiency

Abstract

Many public organizations, including municipalities, feel the need to proceed with the development of sustainable public procurement. Municipalities have shown a general tendency to buy in a sustainable manner, with mixed results in speed and real adoption of sustainable public procurement. Many studies have focused on internal drivers and barriers within public agencies, while less attention has been given to the impact of external actors and factors. Based on 34 interviews, we investigate ten different procurement projects in three mid-sized Dutch municipalities. As expected, the national government tries to force local governments to include sustainability criteria in public tenders. Although legal enforcement is generally believed to have a significant impact we observed a lack of legal pressure to enforce sustainable buying. Real pressure appears to stem from lobbying by sector organizations, individual companies, and citizens. Concerned citizens are frequently consulted in city planning and increasingly participate in reaching local goals, such as "a climate neutral city". Remarkably, the hybrid structure of the procurement function is an unexpected barrier: the central procurement function adds sustainability only to large public tenders. For the remaining two-thirds of public spend, only limited tendering procedures are used by decentralized procurement professionals, lacking time and knowledge to structurally include sustainability criteria. With some exceptions, we conclude that legitimacy and legality still prevail over appropriateness and efficiency in achieving sustainability by public procurement.

Keywords: public procurement, sustainability, external pressures, stakeholder theory, case study

Category: competitive paper (IPSERA 2018)

1 Introduction

Governments are putting pressure on business to make a shift to a more sustainable strategy. The national government is both forcing ('MJA agreements') and supporting ('Green Deals', 'PIANOo guidelines') a sustainable business strategy. The supply chain, with the procurement functionality as a significant part, can actively support and reinforce sustainability (e.g. Carter & Rogers, 2008; Wolf, 2014). Public procurement can make an effective contribution to the targets of the Paris agreement and consequently change supply chains (Bratt et al., 2013; Grandia et al., 2015).

In spite of reinforcement and support from Government and procurement institutions, several studies indicate differences in speed of the roadmap towards a more sustainable attitude and compliant actions within governmental bodies, i.e. municipalities (Ecorys, 213; Zoeteman et al., 2016). Various studies distinguish drivers and barriers that have impact on the level of sustainability in procurement (e.g. Ageron et al., 2011; Bos-Brouwers et al., 2010; Brammer & Walker, 2009, 2011; Carter & Rogers, 2008; Günther & Scheibe, 2006; Michelsen & De Boer, 2009; Preuss, 2009).

With respect to drivers and barriers on sustainable procurement in the public sector, results point at the omission of targets within the organization, lack of procurement professionalism and up-to-date knowledge, primarily internal factors (e.g. Brammer & Walker, 2011; Gelderman et al., 2015; Günther et al., 2013). Only a few of these drivers and barriers relate to external actors and factors that influence sustainable public procurement. There are signs that clear legislation is missing (Giunipero et al., 2012; Igarashi et al., 2015) as well as action-oriented attention from national and local politicians. Thai (2001) presents a roughly defined public procurement model with four external pressures: legal, political, market and social-economic. Up to now however, there has not been a more comprehensive investigation into the influence from external actors and factors on the development of sustainable public procurement. This study has a clear focus on collecting the external actors and factors with respect to (sustainable) public procurement and their influence on its development.

We executed a multiple case study among three mid-sized municipalities in the Netherlands in order to investigate external actors and factors, and their impact on sustainable public procurement. Through 34 in-depth interviews and document analysis we classified these actors and factors in five categories: legal, political, market and social/economic pressure (cf. Thai, 2001) and we added a fifth category, i.e. societal pressure.

2 Literature review

2.1 Public procurement

Procurement in general has made great progress in the last twenty years from a static, isolated and cost-oriented role into a dynamic and strategic function within the supply chain (Meehan & Bryde, 2011; Thai, 2001). A sustainable approach of markets results into a sustainable supply chain (Krause et al, 2009), in which the public procurement function (Thai, 2001) aims for sustainability through the Triple Bottom Line approach, the balance between economical, ecological and social aspects when purchasing goods and services.

Public procurement, however, has specific additional requirements (Telgen et al., 2012; Thai, 2001) as a result of a variety of stakeholders and their sometimes conflicting and opposing interests (e.g. McCue et al., 2015; Uyarra & Flanagan, 2010). Requirements include important aspects as accountability, responsiveness and transparency which refer to integrity and exemplary behaviour. These additional requirements influence internal procedures and processes, i.e. EU legislation, and national governmental procurement laws and governmental guidelines for sustainable procurement.

2.2 Sustainable public procurement

In sustainable public procurement, the Triple Bottom Line approach (Brammer & Walker, 2011; Elkington, 1997; Meehan & Bryde, 2011) is used to realize a balance in goal setting between economical, ecological en social aspects of the goods and services purchased. This starting point of sustainability adds to the widespread definition of the WECD (1987): ”utilizing resources to meet the needs of the present without compromising the ability of future generations to meet their own needs”. The public sector acknowledges its crucial role in making a high amount of supply chains more sustainable, by increased pressure from their significant purchasing spend, approximately 16% of the total purchasing spend of any EU country. As a result, the public sector is able to realize public oriented objectives such as social equity, economical development and ecological advantages (Nijaki & Worrel, 2012).

Public agencies should contribute to a sustainable society (Preuss, 2009; Testa et al., 2012). In daily practice, achieving these more strategic goals is difficult (Gelderman et al., 2015; Meehan & Bryde, 2011). One aspect is the limited knowledge and available data of the real footprint of products and services that goes beyond its ecological footprint (Tate et al., 2012). The size of an organization also matters: the bigger the organization, the more power on implementing sustainable pubic procurement in practice (Michelsen & De Boer, 2009). Also of great importance is the internal discussion between purchaser, deputy manager and city council on the cost allocation of a more sustainable procurement policy, which also refer to the need for efficient spend of tax payer’s money (Gelderman et al., 2015; Telgen et al., 2012).

One way to put force on sustainable supply chains is by adopting more sustainable selection criteria in EU tenders (Testa et al., 2012; Testa et al., 2016). Support comes from the EU Buying Green Handbook 2016, the 2012 Procurement Law in the Netherlands (effected in 2016) and sustainable guidelines from the government (PIAONOo) for many product categories (www.pianoo.nl). However, these criteria lack a legal status and as a result remain non-committal. Nevertheless, more and more municipalities use a strategic approach to make their procurement activities more sustainable (Bratt et al., 2013), by preferably buying local and as sustainable as possible, despite all difficulties in legislation, government criteria and a complex stakeholder management (Thomson & Jackson, 2007). Walker & Brammer (2009) conclude that successful sustainable procurement should keep four factors in mind, i.e. ‘good knowledge of legislation’, ‘perceived inefficiency and legal costs’, ‘cooperation with suppliers’ and ‘internal incentives and pressure’.

2.3 Actors and factors

Despite all available tools and good initiatives, there is no consistent positive view on the results of sustainable public procurement (e.g. De Boer, 2013; Zoeteman et al., 2016).

Reasons could be the missing ambition (Crespin-Mazet et al., 2012), the limitation to minimum green requirements in tenders (Melissen & Reinders, 2012), the lack of maturity in strategy and execution (Grandia & Meehan, 2017) and/or the perceived additional costs of sustainability (Bratt et al., 2013).

a. Relation stakeholder theory and sustainable procurement

The public sector in general and public procurement in particular have to deal with a variety of objectives, requirements and stakeholders. Stakeholder approach largely received attention after Freemans (1984) published the book "Strategic Management, a stakeholder approach" Mitchell et al. (1997) define three aspects that qualify the required attention (called 'salience') for any stakeholder: 'power', 'legitimacy' and 'urgency'. Identifying and classifying stakeholders in any of these aspects result in a typology of stakeholders prioritizing the attention to be given to a specific stakeholder ('salience').

Neville et al. (2011) point at the 'continuum of these aspects', not by being present or absent or excluding each other but in relation and interaction of the aspects. In contrast to salience from the typology only, managers should pay attention to all stakeholders, regardless of the typology and this also refers to the moral aspect of stakeholders' claims (Neville et al., 2011). In particular, public agencies, as external oriented organizations, have to deal with these moral aspects in relation to the interests of the variety of stakeholders. Stakeholders can be classified by 'extent of interest' and 'extent of power'(e.g. Johnson et al., 2005; Williams & Lewis, 2008).

Increasingly, the private sector experiences pressure from stakeholders (customers, suppliers, interest groups, NGOs and public authorities). Public agencies are faced with the risks of reputation (Carter & Jennings, 2004). Various studies conclude that stakeholders can be characterized as driver as well as barrier for an organization's sustainability (e.g. Bos-Brouwers et al., 2010; Giunipero et al., 2012; Walker et al., 2008). A multiple stakeholder approach influences the reputation of private and public organizations (Williams & Lewis, 2008) and contributes to a modern government (Foo et al., 2011). Government must balance between different interests which affects its policies, its sustainable objectives and, as a consequence, the public procurement strategy. Stakeholders with different views influence defining and adjusting sustainable procurement strategies and require salience (Mitchell, 1997; Williams & Lewis, 2008). Stakeholder management is a must for public institutions.

b. Internal actors and factors

The extent to which public procurement is moving towards a sustainable direction depends on several actors and factors. Drivers and barriers for sustainable public procurement can be found in several research papers (e.g. Amann et al., 2014; Bos-Brouwers et al., 2010; Brammer & Walker, 2011; Gelderman et al., 2017; Meehan & Bryde, 2011; Giunipero et al., 2012; Walker et al., 2008). Important internal factors include institutional tardiness, aiming for stability, resistance to change and desired predictability. For the implementation of new (sustainable) procurement practices, interaction between administration (e.g. city council) and purchasing department is needed. Sustainable procurement procedures require adaptation by purchasing employees and executive managers, but must also be supported by the (elected) board of the public institutions such as the parliament and the local councils. Public employees are asked to adapt new procedures and to change behaviour in personal commitment (Grandia, 2016; Thomson & Jackson, 2007; Walker et al., 2008) and incorporating sustainable criteria in public tenders (Testa et al., 2012).

Several publications emphasize the importance of knowledge and skills for effective implementation of sustainable public procurement (Brammer & Walker, 2010; Meehan & Bryde, 2011; Testa et al., 2012; Walker & Brammer, 2009). The overall conclusion is that best results stem from personal commitment and willingness to change, complemented by tools for evaluation and market research (Gunther & Scheibe, 2006; Walker & Brammer, 2008). However, a major barrier remains the perceived additional costs of sustainable procurement (Bratt et al., 2013) as well as lack of time (Bos-Brouwers et al., 2010). Balancing possible conflicting goals not only affect social, economic and ecological aspects but are also of great concern to the administrative top management such as city councils and government officials (Gelderman et al., 2015; Meehan & Bryde, 2011). Government (top) management and officials play a crucial role in achieving the best results in sustainable procurement.

c. External actors and factors

Several publications state that external actors and factors may be of more influence on the extent of sustainable public procurement (Crespin-Mazet et al, 2012; Walker et al., 2008) than internal forces. These publicatioins stress the importance of cooperation within the supply chain and with non-business actors (NGOs, labelling organizations). There is continuous interaction between external and internal actors and factors with impact on the process of implementing sustainable public procurement (Gelderman et al., 2017).

The public sector itself influences and is influenced by the external environment, which put pressure on policies. This external environment may have conflicting goals (Nijaki & Worrel, 2012, Uyarra & Flanagan, 2010) and is part of the Public Procurement System (Thai, 2001). This system includes legal forces, political forces, market forces and social, economic and other forces. We have added a fifth component ‘societal forces’ that include actions from citizens, both individually and as a group.

- Legal forces

As a result of the civil servant’s nature to comply to rules and regulations (Grandia et al., 2015), legislation is a very important external factor. Apart from international procurement standards (GPA) and EU procurement legislation, the Netherlands introduced a revised national procurement law (Aanbestedingswet 2012, AW2012). To support public institutions in buying green, the government issued sustainable guidelines (PIANOo) individual product categories in order to positively influence sustainable buying behaviour. Familiarity with legislation and supporting tools will encourage purchasers to comply to sustainable standards. The AW2012 supports buying on other aspects than lowest price (EMVI doctrine on selecting the best economic offer), but is not compulsory in the procurement process, which makes it non-binding/non-committal to the purchasing professionals.

Actors/factors in this study: RVO (PIANOo organization and guidelines), AW2012, best practices, (inter)national pressure, ambition

- Political forces

Political pressure has both internal and external aspects and has a relation with the principal-agent theory (Gelderman et al., 2015): political parties (‘principal’, external actor) are represented in administrations by e.g. majors and city councils (‘agent’, internal actor). The installation of city coucils is every four years after election. called ’the election cycle’ (Walker & Brammer, 2010). As actors, the city council (politician, external) and the civil servant (purchaser, internal) may have conflicting interests (Gelderman et al., 2015).

Actors/factors in this study: political parties, city councils, administration structure and agreements, ambition, governmental bodies.

- Market forces

In the supply chain, organizations are confronted ‘upstream’ with stakeholders such as the general public and customers. On the other side, purchasers have to deal with pressure from ‘downstream’ in the trade-off between sustainability and costs during the process of selecting suppliers, which aspects may be adversely (Reuter et al., 2012). From this perspective, the private sector takes more of a leading role in sustainable management than the public sector (De Boer, 2013) and sustainability is regarded as an important factor in new business models. From this point of view, public authorities support private sector sustainable ambitions by introducing so called ‘Green Deals’, to overcome legal and financial barriers.

Actors/factors in this study: companies, sector organizations, unions, Green Deals, disputes.

- Social and economic forces

The public sector feels pressure from actors of social and economic origin, who try to influence public procurement from their specific interests. Regularly, commercial interests may be the driving force, such as labelling organizations. These bodies introduce specific standards, start advising on these standards, and are controlling the market. If incorporated in tenders, labels and standards are of specific importance to realize sustainable procurement; they come third after aspects price and quality (Igarashi et al., 2015).

Crespin-Mazet et al. (2012) named these organizations ‘non-business actors’, stakeholders not related to the business. NGOs are developing themselves into the direction of cooperation instead of steering conflicts in order to realize their goals. Several studies point at the positive effects of non-business actors on achieving sustainability (e.g. Crespin-Mazet et al., 2012; Günther & Scheibe, 2006; Melissen & Reinders, 2012; Preuss, 2009; Thomson & Jackson, 2007; Walker & Brammer, 2009). Bügl et al. (2011) emphasize the possibility of conflicting interests between non-business actors and the challenges of the public sector authorities in managing these issues. Within the public sector agencies do cooperate, but may also have conflicting interests (Hoejmose & Adrien-Kirby, 2012).

Actors/factors in this study: NGOs (Greenpeace, Nature & Environment), research institutes (NEVI, SKAO, NEN), best practices, rankings of public organizations.

- Societal forces

We added a fifth element to the Public Procurement System (Thai, 2001, p. 33) by introducing ‘societal forces’. In the last decade markets and governments were forced into increased transparency. Due to technological developments, e.g. big data, internet, all organizations are influenced by the forced transparency coming from these developments (Telgen et al., 2012). Also within external forces (such as from citizens) there are modern options to stay in touch (email, WhatsApp, Facebook) and to cooperate in grass root initiatives. Results from recent research indicate that EU citizens expect their public authorities to evaluate other aspects besides the cost (quality, sustainability) in public procurement (Keulemans & Van der Walle, 2017).

The impact of societal forces has not been investigated extensively. Obviously, municipalities have an external orientation on citizens and local society. We investigated if the society develops a force towards their public authorities, comparable with societal force towards

sustainable procurement in the private sector (Foo et al., 2011; Wolf, 2014). Specifically, we looked at communities, local media and media attention, public participation, civil protests and disputes

We explored the external forces from five angles and their impact on the extent of sustainable public procurement. We include interactions between as well as within the external actors and factors and the consequences of that interaction on the development of sustainable public procurement.

2.4 Theoretical background

The problem statement of this study focuses on investigating the impact of external actors and external factors on the development of sustainable public procurement. From a theoretical point of view, our problem statement is related to several theories. The stakeholder theory (Freeman, 19084; Mitchell et al., 1997; Neville et al., 2011) describes the attention given to and the acknowledgement of a stakeholder ('salience'). Besides, the principal-agent theory has impact on the development of sustainable public procurement by pointing out the possible different opinions and strategies of the alderman (agent) and the principal (city council members from a political party). Finally, several publications point out that the public sector should contribute to a sustainable society (Preuss, 2009; Testa et al., 2012) and, in doing so, must take into account additional purchasing requirements (Telgen et al., 2012; Thai, 2001).

3 Research method

The design of our qualitative, exploratory study is aimed at investigating "a contemporary phenomenon in depth and within its real life context" (cf. Yin, 2014, p. 4). Three mid-sized municipalities in the Netherlands were included in our multiple case study. The selection of municipalities was based on location (spread among the country) and size (between 150,000 to 200,000 citizens). We have selected mid-sized municipalities because of their interesting position between the small municipality with little attention for sustainable procurement and the large municipalities with compliancy to sustainable objectives (Zoeteman et al., 2016). Data collection was focused on the inventory of external actors and factors in accordance with the four categories of Thai (2001).

We investigated the external forces and examined their impact on the development of sustainable public procurement by document analysis and interviews. We executed a document analysis from three different angles. First, we examined the procurement strategies of the cases organizations and investigated sustainable aspects. Second, we analyzed 10 procurement projects from all three case organizations, in which external force was perceived by the respondents as they have mentioned in the interviews (see Table 1). Finally, we looked into the various correspondence regarding sustainable elements in procurement perspective within the case organizations.

The in-depth semi- structured interviews were held with respondents inside and outside the municipalities, adding up to a total number of 34 interviews. The key players within the case organization were all functionally involved in procurement processes. Respondents held the following job titles: CEO, CFO, procurement manager, procurement advisor, facility manager, purchaser and sustainability officer. We also interviewed the aldermen of the three

municipalities as well as various members of their city council. From these interviews, we took notice of all external actors to which respondents refer to and held our interviews with those external actors as well. Key respondents from outside the municipalities were employed by or associated with the Ministry of Economic Affairs, Ngo's, political parties, entrepreneur and trade associations, branch organizations, knowledge institutes, and citizen pressure groups. All interviews were guided by an interview protocol which was based on the results of the literature review. The use of semi-structured interviews gave us the necessary flexibility and allowed us to zoom in on external actors and factors that potentially impacted the development of sustainable development of procurement. This approach also provided the possibility to identify other factors that were not found in literature, which is in line with the descriptive and explorative nature of our study.

Table 1 Investigated procurement projects

Municipality 1	Municipality 2	Municipality 3
Fleet of vehicles (2015)	Fleet of vehicles (2015)	Machines for hot beverages (2014)
Machines for hot beverages (2015)	Energy (2016)	Catering (2014)
Food/non-food (2014)	Digitization construction archives (2016)	Transport in the context of the Social Support Act (2016)
	Cleaning (2017)	

In addition to the interviews within the case organizations we investigated the five external forces with an impact on the development of sustainable public procurement. Moreover, we deepened our knowledge of interactions *between* external actors and factors but also *within* external actors and factors. The leading question is: if interaction takes place, in what way and in what direction does cooperation exists between parties with the aim to influence sustainable aspects of public procurement?

4 Results

4.1 Organization and development of sustainable procurement

The three case organizations are mid-sized and have a comparable organizational structure. Due to the economic recession between 2008 and 2014, municipalities suffered from cost savings and budget cuts. As a result, the number of sustainability functions (officials) was minimized or completely liquidated. This had a huge impact on focus on the subject and, as a result, the development of sustainable procurement within the public sector. In all three case organizations the need for a sustainable municipality is translated into the ambition of becoming climate neutral in the future. The speed to achieve a climate neutral municipality varies from years 2025 to 2050. Everyone expects the procurement function to contribute to this climate neutral objective. Although sustainable procurement is incorporated in purchasing policy, the level of sustainable procurement still lags behind. We found that accountants check for legitimacy of the process, and that the finance department monitors spending, while the effectiveness of sustainable procurement seems neglected. Apparently, with some

exceptions, legitimacy and legality still prevail over appropriateness and efficiency in achieving sustainability in municipalities.

The cause of this deficiency stems from the hybrid structure of the procurement function and its impact on the development of sustainable procurement. Each case organization strictly monitors of European tenders (1/3 of spend) and these tenders are subject to sustainability requirements. However, the remaining 2/3 of spend comes from purchasing projects within decentralized expert groups, and therefore stay 'under the radar' with a lack of monitoring of sustainable requirements. Our research shows that, in general, the large tenders (1/3 of the spend) are controlled by the staff function and, as a result, are more committed to sustainable procurement. Apparently, municipalities achieve less sustainability results by limited tendering for their smaller purchases (see Table 2).

The organizational position of the procurement function has a significant impact on the sustainable development of municipalities. Procurement as a function in mid-sized municipalities operates at two levels. The purchasing function is spread over expert groups for specific and specialized product categories and, at the same time, as a staff function with internal consultants for the procurement strategy and advisory on large purchasing projects (European tenders). As a staff member stated: "We only consider the larger tender projects. There is no time for the smaller ones." This lack of attention also refers to the accountants' control on purchasing projects: "We only assess on financial issues in individual purchasing projects."

As a result of the hybrid organizational structure, external pressure on public procurement may enter at two functional levels within the organization: the purchaser in a decentralized expert group and/or the procurement consultant in the central staff. The political function within the municipalities also operates at two levels: the alderman is part of the local government (internal actor) but at the same time is attached to his or her political party (external actor), who supervises the local government by the elected city councils.

Another factor of influence proved to be the targeting of operational goals and activities of municipalities. Mayor and aldermen hold the governance functions and agree on ambitions and policies in a so called 'governance agreement' for a four years period. From these ambitions and policies, administrative top management defines the distracted goals into the operational functional areas. Clearly, there are tensions between party-political aldermen, procurement professionals and department managers.

Table 2 Sustainable procurement in the investigated municipalities

Issue	*Municipality 1*	*Municipality 2*	*Municipality 3*
Structure of the procurement function	Hybrid: process control and advice are centralized; operational procurement is decentralized.	Hybrid: process control and advice are centralized; operational procurement is decentralized.	Hybrid: process control and advice are centralized; operational procurement is decentralized.
Development of sustainable procurement	Procurement strategy contributes to a climate neutral city.	Sustainable procurement plays an exemplary role. Goal is the optimum in	Sustainability is key. Goals of a climate neutral city is

		the triple bottom line.	translated into sustainable chain oriented purchasing.
Tendering procedures	Sustainability criteria for large public tenders (1/3 of total spend); less sustainability and limited tendering for smaller purchases (remaining 2/3).	Limited tendering is used for a large part of the total spend. Inclusion of sustainability criteria depends on decentralized operational procurement.	Sustainability criteria for large public tenders (1/3 of total spend); less sustainability and limited tendering for smaller purchases (remaining 2/3).
Monitoring and control	The accountants check for legitimacy, the finance department monitors spending.	A feeling of non-commitment stems from the lack of control by the legislature.	Internal accountants monitor the legitimacy of procurement projects.

4.2 External pressures on sustainable procurement

In all three case organizations, interviews with key players and document analysis have resulted in a cross case analysis with insights into the influence of the five external factors on the development of sustainable procurement, see Table 3.

- Legal forces

Legislation and the PIANOo guidelines are at the base of (sustainable) procurement in all of the three municipalities. However, these guidelines and principles are considered non-binding due to a lack of penalties in case of non-compliance and an internal focus on legitimacy and financial aspects. According to an alderman: "The lack of monitoring and control is a barrier for the development of sustainable procurement." Apparently, legitimacy and legality prevail over appropriateness and efficiency in achieving sustainable procurement.

- Political forces

The generic sustainability policy is developed by the municipal council of (party-political) aldermen who have signed a management agreement for a period of four years. The members of the city council are not involved in defining the sustainable procurement strategy nor in the execution and implementation in separate procurement initiatives and projects, such as tenders . Members of the city council merely perform controlling tasks, feeling that they "assume that the four years management agreement is executed in a proper way".

Table 3 External forces on sustainable procurement

Issue	*Municipality 1*	*Municipality 2*	*Municipality 3*
Legal forces	Use of sustainability guidelines (PIANOo). However, no legal enforcement due to a lack of penalties.	Compliance with laws and regulations, adaptation legal sustainable requirements in entire organization	Handling legislation and PIANOo guidelines; EMVI and convenants are non-binding and may restrict the desired extra steps
Political forces	Aldermen define the reach of city's ambition in the governance agreement; city council takes action if there	City council trust aldermen to execute procurement policies according to the governance agreement and	The political orientation of the alderman and the city council strongly impact sustainability goals.

	are (negative) external signals.	reacts to external signals.	Development and execution of policies are strictly separated.
Market forces	Branch organizations and companies monitor tenders and sometimes request other specifications. No pressure is felt if the legal obligations are met.	A local business collective runs a 'soft lobby' which results in more attention for the local economy.	Branch organization's lobbies have influence; market consulting enhances influence but reduces the pressure on sustainability.
Social and economic forces	The rankings published by NGOs raise issues in local media and meetings of the city council.	NGO reports raise questions that are discussed in meetings of the city council. However, policies are not adjusted as long as legal obligations are met.	Subject oriented NGOs are very active, they are invited for consultation by the local government. Most commonly consensus is achieved.
Societal forces	Citizens are being consulted on sustainability issues. Local initiatives are welcomed.	Local interest groups exert pressure on sustainability. There is pressure on sustainability in general, not on sustainable procurement in particular.	Neighborhood councils are actively involved in sustainable initiatives. There is pressure on sustainability in general, not on sustainable procurement in particular.
Most powerful external force	Most pressure from legislation and PIANOo guidelines, as well as the political orientation of the aldermen and city council.	Most pressure from legislation and PIANOo guidelines. Focus on local economy. Influence from local interest groups.	Most pressure from legislation and PIANOo guidelines, as well as the political orientation of the aldermen and city council.

- Market forces

Municipalities only meet with market pressure if tenders are not executed according to legislation and accepted guidelines. Whenever called for, the legal affairs department will be involved in particular cases. Branch organizations, for instance for building construction and waterworks, monitor public tenders and incidentally request other specifications (municipality 1 and 3). In municipality 2, a local business collective runs a rather soft but successful lobby for contracting local suppliers and stimulating the local economy. Actually, companies "have no means of pressure if municipalities can prove that they executed the purchasing process according to the Procurement Law 2012". This law does not enforce sustainable procurement; moreover, the PIANOo guidelines are non-committal.

- Social and economic forces

In all of the three municipalities, NGO reports that include the ranking of municipalities on sustainability, raise questions and issues that are discussed in meetings with aldermen and the city council: "a bad position in rankings always lead to critical remarks and questions from city council members". One of the interviewed alderman also pointed at the lack of pressure because: "Various researchers have different opinions on sustainable subjects". Such an observation offers a way out in delicate discussions. Again, no pressure is felt, if the legal obligations of the tender are met. The importance of certificates, hallmarks and quality labels are recognized. Corresponding requirements are most commonly included in the list of requirements (municipality 1 and 2). Despite of pressure from labor unions and local media, purchasing policies are never adjusted (municipality 2). Remarkably, trade unions only incidentally raise questions on the social part of the Triple bottom Line approach and are,

according to a city council member “completely lacking in discussions on sustainable procurement”.

- Societal forces
Generally, municipalities value open communication with their citizens. Local initiatives are welcomed and citizens are consulted about (local) sustainability issues (municipality 1 and 2). However, there is societal pressure on sustainability in general, but not on sustainable procurement in particular: “the procurement projects of the municipality as such is not a very sexy subject and does not interfere in any way with the regular interests from citizens”. On the other hand, the theme of sustainability is important for citizens, although sustainable procurement lies outside the area of interest of citizens.

The most powerful external force in stimulating sustainable procurement within the three case organizations appears to be the Central Government with its ‘Procurement Law’ and PIANOo guidelines. In fact, both national and local politics have the power to effectively realize a sustainable procurement strategy and implementation.

5 Discussion

Measuring the development of sustainable public procurement is not easy and therefore multiple studies report positive trends towards sustainable procurement but with different outcomes (De Boer, 2013; Zoeteman et al., 2016). The results of this study reveal that the cause of these differences may be due to the lack of monitoring the smaller, non-European tenders, which amount up to 2/3 of the total purchase spend. The new MVI covenant from the national Government for sustainable procurement will stimulate data collection and analysis, but is adopted by merely 80 (out of 388) municipalities.

There are internal and external influences on sustainable procurement. Internally, success of sustainable procurement depends on the tension between decision makers: alderman, purchaser and budget owner. The latter proves to be of crucial importance (Gelderman et al., 2015). It is obvious that public organizations acknowledge their responsibilities and agree various sustainable policies, among them the procurement function with the incorporation of sustainable criteria (Testa et al., 2012). The Triple Bottom Line approach (Brammer & Walker, 2011; Elkington, 1997; Meehan & Bryde, 2011) is well accepted as a starting point for sustainable procurement by the public sector, but the sector is also in need of up-to-date rules and regulations by the government. In short: ‘sustainability is here to stay’ and top priority for cities, citizens and companies.

The assumption that municipalities have adopted sustainability in their procurement policies and ensure this on strategic level is correct. However, there should be more focus on implementation of this strategy at a decentralized level. Moreover, monitoring of results is essential for a contribution to the objective of a ‘climate neutral city’. Citizens expect their local government to adopt green purchasing (Keulemans & Van der Walle, 2017). Nevertheless, there is unanimous commitment to sustainable procurement but still a way to go to change ‘default behaviour’.

The reviewing of external actors on the level of sustainable procurement suggests that the widely perceived societal pressure on private companies (cf. Wolf, 2014) is non-existing in the public sector, due to a lack of interest for local administration and procurement. However, citizens do acknowledge the importance of sustainable procurement (Keulemans & Van der

Walle, 2017). Authorities have tried to overcome this problem by involving local communities in the local decisions to be made and, to create legitimacy for the priorities within the municipality.

Within the five investigated external forces, most pressure comes from legal and political pressure. This observation refers more to the legality of the procurement process rather than the functionality of goods and services to be purchased. The national government sets standards (AW2012, Dutch Procurement Law) offers guidelines and suggests a more sustainable way of purchasing. Despite of good intentions, these initiatives are non-binding and as the CEO of one case organization states: "our city reports sustainability results on a very regular base to central government, but we are never getting any feedback". Politicians (aldermen, city council members, national political parties) can effectively stimulate and force new legislation and can make up-to-date sustainable guidelines applicable and binding. This will significantly support the internal administrative organization in sustainable objectives and puts pressure on changing default behavior within the internal organization (Grandia et al., 2015; Grandia, 2016; Thomson & Jackson, 2007; Walker et al., 2008).

The private sector seems ready for this new approach and takes steps to develop opportunities in sustainable products and services that may result in a competitive advantage over competition. Sustainable criteria in public tenders do not experience resistance from market parties, who in fact point out that public organizations do not fully benefit from all new (sustainable) technologies. Innovation and co-creation may, however, be difficult from a legal point of view, but definitely supports sustainable public procurement (Crespin-Mazet et al, 2012; Walker et al., 2008).

Reports from NGOs put pressure on the private sector and force markets and supply chains to reconsider their (production) strategies. In public organizations, those reports have a delayed effect: a poor ranking for the municipality means attention from local politicians as well as rethinking selection criteria for future tenders.

6 Conclusions and recommendations

Most studies on the development of sustainable public procurement have focused on internal drivers and barriers. This multiple case study has examined the influence of five external forces, i.e. 'legal forces', 'political forces', market forces', 'social and economic forces' and 'societal forces'. Based on 34 interviews, we have investigated ten sustainable procurement projects in three Dutch municipalities.

In general, there has been a positive development of sustainable procurement within municipalities, in policy and strategy as well as in implementation. However, the hybrid structure of the procurement function may be a barrier: procurement advisors on central level are watching over legality of the purchasing process and are adding sustainable aspects in the large public tenders (1/3 of the procurement spend). The remaining 2/3 procurement spend receive less attention from the central advisory department and, as a result, purchasers are independent in making their own decisions on purchasing issues. Sustainability receives attention but the real effects are not easy to monitor. Decentralized purchasers lack time and money to fully focus on sustainable procurement criteria. A sound and reliable conclusion on the level of sustainable procurement within municipalities can therefore not be drawn. Moreover, managing the sustainable execution of purchased services by selected companies is

not happening either due to lack of time and money. In procurement projects there seems to be a tendency towards more functionality (alignment of purchasing with the city's ambition), next to legality.

Although there are (social demographic) similarities between the three case organizations, there are differences in the speed of their roadmap towards the climate neutral city. In general, municipal procurement policies are compliant with legal requirements as demanded by AW2012 with the add-on of the PIANOo sustainability guidelines, per product category. The incorporation of sustainability is not significantly supported by law because all mentioned sustainable requirements are without any obligation. As stated before, intentions are present, but there is no move forward from legitimacy and legality to appropriateness and efficiency.

In this study, legal forces show similarities with political forces. Together they put pressure on sustainable procurement. Political pressure within and from the Administrative Board (mayor, aldermen) eventually lead to adjustments in national law. From that point, local purchasing officials commit themselves to new rules and regulations. Pressure on top management in the central organization is evident, but real pressure from the market is felt within decentralized purchasing departments. Sector organizations lobby on political level and individual companies exert pressure on requirements and criteria in the smaller purchasing projects. Incidentally, this pressure leads to adjustments in individual projects.

NGOs and labelling institutions are monitoring public procurement in order to reach their own objectives. They succeed in obtaining attention from city council members and have their viewpoints and hallmarks taken seriously. Most positively, they inspire instead of forcing new policies. Nowadays, city administrations acknowledge the role of citizens in developing a local strategy together. More and more, citizens are consulted for city planning programs. Besides, citizens are stimulated to participate in the pursuit of local goals such as the climate neutral city. In spite of initially expected interaction between actors (stakeholders), they respect and sometimes consult each other but never in a structural way.

Legislation should support the step from legality to functionality by taking an effort to make overall procurement legislation more 'agile', by bearing best practices in mind and adding these into a more dynamic legislation. As a result, purchasing officers will adapt functional criteria with more ease and confidence. From this perspective, legislation will become 'evidence based'. Currently, public agencies have a delayed response to societal and political discussions and the, permanently applied, PIANOo guidelines are regarded as 'old fashioned'. The needs of purchasing professionals with sustainable procurement objectives often exceed these outdated rules and regulations.

Next to these encouragements, the sector organization (VNG) must modernize its standard 'procurement strategy format' to the new legislation (AW2012) with its options for sustainable procurement, innovation and collaboration/co-creation.

Municipalities can benefit from the lessons learned within the three case organizations and could anticipate on the impact from the external forces on the procurement function. This study shows that local stakeholders are not interested in and not involved in the procurement achievements by local authorities. Not even local politicians are interested in purchasing policies and strategies and regard these as internal administration affairs and implementation of the local governance agreement.

This study is based on data from three midsized municipalities in the Netherlands which makes the sample too small to turn specific observations into general conclusions. Still, it is to be expected that research within comparable sized municipalities give similar results.

The paper has addressed an important topic with a novel angle, namely focusing on the external actors and factors influencing the adoption of sustainability related criteria in public procurement. We reported an apparent limited effectiveness of laws, guidelines and regulations on the adoption of sustainable public procurement. Future studies could address issues related to the effectiveness of legal pressure, for instance by investigating the gap between perceptions of legal pressure and the lack of enforcement.

This study provides a clear indication of the importance of the smaller purchasing projects on the development and the overall success of sustainable procurement. Future research may focus on the drivers and barriers for sustainability within the decentralized functional departments and the external actors and factors that could transform behavior on a structural base.

Major changes in sustainable public procurement take place within member states of the European Union. It is recommended to execute a ‘pan-European study’ into the external actors and factors and their impact on the development of sustainable procurement within Europe. Such research will make it possible to monitor the developments on a broader scale and will further add to the “EU Buying Green Handbook”.

Abstract

Large companies have embraced the idea of open innovation. They realize that in order to speed up development and reduce risk, they need to collaborate with supply and knowledge partners. However, mobilizing partner specialist knowledge seems problematic. Academic research demonstrates contrasting results. In some cases, supplier collaboration in new product development i.e. early supplier involvement may create large benefits. In other cases, it may lead to detrimental and even devastating results. This paper discusses why these contrasting results are found. It draws on over 30 years of academic research that has been conducted and/or supervised by the author. We conclude that, as the drivers and enablers of early supplier involvement today are clear, fostering effective human interaction aimed at sensitive knowledge and information exchange on behalf of organizations with conflicting interests is crucial in early supplier involvement. As the human factor in technology driven organizations is often undervalued, more research is needed to understand how to mobilize interorganizational knowledge sharing in such exchanges.

Keywords: innovation, early supplier involvement, knowledge management, supplier collaboration

Submission category: supply chain innovation

Introduction

In order to survive in today's rapidly changing global economies, companies need to innovate. Products, processes and business models need to be adapted continuously to meet the ever-changing business requirements and consumer needs. As most products and services today have a large supplier content, companies need to rely on knowledge and expertise of their supply partners. Mobilizing their supply partners to share and integrate their knowledge and expertise allows global manufacturers to speed up new product development (NPD) time and reduce risk. However, early supplier involvement is not a guarantee for NPD success. Hartley (1997) reported in her research that was conducted among 79 companies in the electromechanical industry that engaging suppliers early in NPD did not result in lower product cost, better products or reduce cycle times. On the contrary. Her findings were identical to those of Birou (1994), who reported even higher product and development cost as a result of early supplier involvement, combined with a lower product quality and longer time-to-market. Eisenhardt

[1] The author wants to express his gratitude to dr Jeroen Schepers, dr Jelle de Vries, prof dr Finn Wynstra, Christian van der Krift, MSc, and the reviewers of the WION seminar (2018) for their valuable comments on earlier versions of this article.

[2] This paper elaborates on an earlier version that was submitted as a chapter for publication in Moreira, A. and Ferreiro, L. (eds), 'Innovation and Supply Chain Management', Springer Verlag (forthcoming)

(1995) completed this picture with similar results, contrasting earlier research that presented successful cases on early supplier involvement.

Clark (1989) reported in his study on Japanese car manufacturers, who were able to reduce engineering hours significantly as a result of earlier and extensive supplier involvement. A finding that was equal to the landmark study on the American and Japanese car industry by Womack et al. (1990). Also, Ragatz et al. (1997) reported positive effects of engaging suppliers early in new product development. These studies reported on significant improvements in terms of product quality and cycle time. These results were substantiated later by Primo and Amundson (2002), who found positive effects when studying 38 projects in the electronics industry.

Engaging suppliers early in new product development seems not without trouble and may easily lead to disputes and even court cases. A recent example is Apple which ran into problems in its relationship with Qualcomm[3], that sued Apple because of infringements of intellectual property (on Force Touch and energy management). Moreover, being aware of Apple´s impressive profit margins, Qualcomm wanted to change its revenue model from a fixed price per chip to a percentage of Apple´s XPhone sales price, as a compensation for its development work. This request was unacceptable to Apple. As this dispute could not be settled in close harmony, Qualcomm sued Apple in China to stop the sales of its new XPhone immediately.

This example shows problems that may occur when working with suppliers in new product development: conflict of interest, knowledge misappropriation, a fair return on development cost, and a fair sharing of new product development outcomes. However, many other problems may impede successful collaboration in new product development.

Based on these observations during the mid-nineties, the questions emerged: ´Why are results and outcomes of early supplier involvement so controversial? What explains the different outcomes of these studies? What truths and threats are lying behind this often advocated practice of early supplier involvement? How to optimize supplier engagement in new product development or is this a mission impossible?´ These questions have been leading many research projects that we conducted and supervised over the past decades. As it will become clear, there was not a single study that was able to cover all of these questions. On the contrary: previous studies were necessary to create a fair understanding of early supplier involvement as a phenomenon. Research findings were fed into new research designs, leading to additional insight.

In the remainder of this chapter we will discuss the outcomes of the main (PhD)-research projects which we initiated and supervised during the past decades. First, we draw on previous work conducted by Wynstra (1998), who revealed the main areas and processes underlying early supplier involvement. His work predominantly covered how to manage Early Supplier Involvement (ESI) at the *inter-organizational level*. Next, we discuss research that was conducted on assessing effects of supplier involvement in new product development. Here, we will base our discussion on work conducted by Van Echtelt (2004). This work covered how to manage ESI at the *project level*. And finally, we will discuss the effects of both contractual and relational governance on innovation outcomes. In doing so, we will draw upon recent studies conducted by De Vries et al. (2017). These studies show that early supplier involvement is about creating both careful contractual and relational governance aimed at fostering inter-organizational, human interaction to foster knowledge sharing behavior among technology experts. This research discusses ESI at the *relational and individual level.* After our discussion of these studies, we will put these into perspective, and discuss several managerial implications.

Obstacles preventing early supplier involvement in new product development.

Many obstacles prevent effective early supplier involvement in new product development. These are partly due to limitations of the actual theories in use (Argyris (1990))[4] within companies. For another part these obstacles are present due to ill-defined processes on how to engage suppliers effectively. These obstacles may relate to the manufacturer organization, the supplier organization and to the manufacturer supplier relationship. We will discuss these topics shortly.

Supplier involvement is defined here as: "the contributions (capabilities, resources, information, knowledge and ideas) that suppliers provide, the tasks that they carry out and the responsibilities that they assume regarding the development of a part, process or service for the benefit of a current and/or future buyer´s product development projects" (Van Echtelt (2004), p.27).

When studying early supplier involvement in new product development, different theories can be used. A popular theory is transaction cost economics (see e.g. Williamson (1979)), which holds that buyers will predominantly seek for transactions resulting in lowest total transaction cost. Transaction cost include development and manufacturing costs, logistics and transportation costs, administrative cost etc. Companies that operate from a transaction cost perspective will predominantly consider cost and financial aspects as the prime consideration in supplier selection and decision-making. This usually results in a short-term orientation: investments made in suppliers should preferably generate a short-term return. This transaction cost orientation seems in conflict with new product development, as supplier investments will only materialize on a longer-term.

Another important theoretical perspective which we feel relevant here is the Principal-Agent theory (Eisenhardt (1989)). This theory assumes that, in commercial relationships, business partners will suffer from four basic problems. First, conflict of interest will arise as the buyer wants to spend as little as possible and the supplier intends to generate as much income from the relationship as possible. Secondly, the relationship may suffer from information asymmetry. Usually, the buyer is not aware of the problems that a supplier may incur in developing, testing and actually manufacturing and delivering a component. Whereas the supplier may not have a complete picture of the environment in which his component is embedded in the final product. The supplier may also not be informed about how the final product is being used by the buyer´s end-user. Thirdly, parties may suffer from risk. In commercial relationships, the buyer attempts to shift most of the risk to the supplier, whereas the supplier attempts to do the same in the relationship with the buyer. Usually this problem of risk allocation is solved by negotiating complex contracts, where duties, risks, liabilities, indemnities and guarantees are described in a high level of detail. It is assumed in such situations that all risks can be identified and arranged for beforehand. However, in practice risks may occur that were not foreseen. This is general practice in innovation and new product development projects, which by definition are surrounded by risks and uncertainty. Finally, agency theory holds that parties may suffer from moral hazard. This relates to a lack of trust and respect that the other party will have for the interests of the other party.

We conclude that holding a transaction cost theory perspective will lead to an overly short-term and financial orientation toward engaging suppliers in new product development projects. Whereas the agency perspective (the supplier needs to act in the interest of the buyer) may lead

[4] Theories in use: 'Those theories that are implicit in what we do as practitioners and managers. They govern actual behavior and tend to be tacit structures' (Argyris et al. (1974), p. 30. Argyris et al. argue that people have mental maps with regard to how to act in situations. This involves the way they plan, implement and review their actions. It is these maps that guide people's actions rather than the theories they explicitly espouse.

to a situation where a buyer will try to mitigate its risk and liabilities by shifting these to the supplier. We suggest that other perspectives than the transaction cost perspective and agency perspective may be used to guide buyer supplier collaboration in new product development.

The transaction cost and agency perspectives are reflected in a few main problems and challenges that have been reported in previous research to relate to early supplier involvement (Van Echtelt (2004), p.34-35):

- Loss of knowledge and skills: intensive collaboration with suppliers in product development poses potential risks for loss of proprietary knowledge and the loss of skills crucial for future product development.
- Supplier technology lock-in: in fast-changing high-tech environments, companies risk becoming locked into a supplier's technology (as is the case with Apple in its relationship with Qualcomm)
- High relationship costs: companies that involve a supplier earlier in the product development process or that collaborate in technology development need to spend more time and bring together different management styles and budgeting processes. This implies time and effort being spent on coordinating the work between the two collaborative parties.
- Reduced product development speed: involving suppliers can even slow down the overall development process, since several design iterations and technology alignments may be necessary before arriving at the final design and product.
- Diverging objectives, interests and levels of commitment: already at the beginning, parties may have different objectives and interests. This may be because of different views on how to recapture past investments among stakeholders. Moreover, expected results may change over time and unforeseen circumstances may arise which could give rise to relationship conflicts. Another challenge is related to the free rider problem: how to prevent that suppliers, that take part in a product development project, take it easy and wait for others to take the initiative?

Apart from these problems other problems are that both parties may be unwilling to take risks in establishing relationships, may have limited experience in new product development, may embark on a project without clear agreements, may have misunderstandings about how each organization functions and may have different cultures. Furthermore, disagreement may occur about sharing the pains and gains of the collaboration. Some problems may be related to the supplier organization, where the supplier conveys a need to capture and secure business on the short-term, be overly price sensitive and may work with incapable engineering staff and sub suppliers. Other problems may relate to the manufacturer's organization, where the different business functions (research and development, purchasing, production) are insufficiently aligned, where the culture is characterized by a not-invented-here syndrome, and supplier knowledge is seen as a threat to jobs in the research and development organization.

We conclude here, that effective early supplier involvement suffers from many challenges and problems that are not easy to overcome. These problems may be due to the manufacturer organization, the supplier organization and the relationship between parties involved. Next, these may originate due to an ineffective theory in use. We would argue here that theoretical perspectives, other than the Transaction Cost Theory and Agency Theory, such as the Resource Based View of the firm, Resource Dependence Theory (Brown and Eisenhardt, 1995) and Stewardship Theory (Davis et al., 1997) may be more useful lenses to study and understand complex interorganizational collaborations.

We start our journey to understand the intricacies of ESI with a discussion of Wynstra's work, which was aimed at understanding the key processes that need to be in place at the organizational level to benefit from ESI.

ESI from an organizational perspective: from early purchasing involvement to timely supplier involvement.

Wynstra (1998) observes that increasing specialization in European industry explained the manufacturers' decreasing share in the added-value of their own products (p. 1). Since part of the production activities, that were previously carried out by the manufacturer, were outsourced to suppliers, manufacturers became more dependent on the resources of their suppliers. As a result, the impact of the purchasing function of a company on its production value increased. This would lead to a different role of purchasing within those organizations. Following Axelsson et al. (1984), Wynstra distinguishes three different roles for purchasing, i.e. a rationalization role, a network or structure role and a development role. The first relates to purchasings' task to contribute to the firm's competitive strength by minimizing total cost of production, logistics, prices of inputs, etc. The second role relates to handling the firm's supplier network and managing the degree of dependency of the firm on specific suppliers. The third role concerns systematically matching the firm's technological development with the capabilities of suppliers and the supplier network. Based on this, Wynstra (1998, p. 65) defines purchasing involvement in product development as: "contributing knowledge, taking part in managerial processes and participating in decisions with regard to product development, from a perspective of purchasing, i.e. striving towards lowest possible total product cost, well-balanced dependencies on suppliers, and an optimal technological match with suppliers" .

As Wynstra intends to explore purchasing's contribution to new product development, he elaborates on this development role. In his view this role, essentially, consists of four key processes: prioritizing, mobilizing, coordinating and timing (p.67). *Prioritizing* concerns the choices manufacturers have to make on how and where to invest available resources. Following Håkansson (1989), *prioritizing* not only concerns the choice of actual collaboration partners, but also the choice for a specific form and intensity of supplier involvement. *Mobilizing* involves motivating suppliers to start working on a particular development. Whilst *coordinating* involves the adjustment and adaptation of development activities and resources between suppliers and manufacturer. Without coordination, joint development will result in poor integration of components, double work, incompatible technical solutions, etc. Of course, this need for coordination grows as a result of increasing specialization and fragmentation of development activities across different supply chain partners. Finally, *timing* requires the meticulous coordination and adaptation of development activities and resources across time. Without timing, product development will suffer from unexpected bottlenecks, unnecessary delays and missed deadlines. Having defined these four key processes, Wynstra argues that these are to be applied in *three areas i.e. suppliers, technologies and projects*. The challenge for companies is how to manage these processes across these three areas. The author concludes that therefore early purchasing involvement essentially is a cross-functional activity, which should not be exacerbated by functional boundaries within organizations. Following Dowlatshahi (see Figure 1), he argues that silo thinking in organizations, especially between purchasing, and research and development, is a major risk when collaborating with suppliers in new product development. The author then sets out to explore the mechanisms underlying these processes and areas in nine comprehensive, longitudinal case studies.

Figure 1. Purchasing and development orientations lead to contrasting interests (Dowlatshahi, 1992)

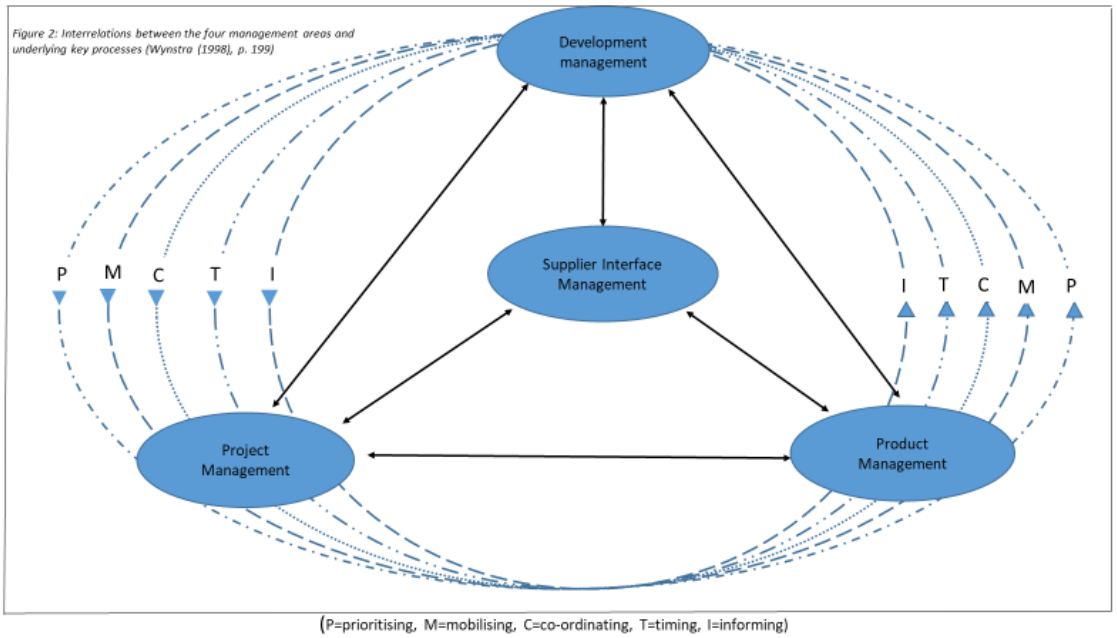
Purchasing orientation	Development orientation
• Minimum acceptable margins of quality, safety and performance • Use of adequate materials • Lowest ultimate cost • High regard for availability • Practical and economical contributors, specifications, features and tolerances • General view of product quality • Cost estimation of materials • Concern for just-in-time deliveries and supplier relationships	• Wider margins of quality, safety and performance • Use of ideal materials • Limited concern for cost • Limited regard for availability • Close or near perfect para meters, specifications, features and tolerances • Conceptual abstraction of product quality • Selection of materials • Concern for overall product design

Based upon these nine in-depth case studies, the author identifies five management areas that should be covered when engaging suppliers in new product development processes:

- Development management. Development management includes a clear strategy on what technologies to keep or develop in-house and which ones to outsource to suppliers. It also relates to policies that are in place on how to effectively engage suppliers in new product development in the relationship with internal business domains within the firm. Without development management, NPD projects will suffer from a lack of guidance and suffer from politics.
- Supplier interface management. This includes monitoring supplier markets for new technological developments that may be relevant for the company. It also includes pre-selecting suppliers per key technology area and exploiting their technical capabilities. Finally, it includes also the monitoring and evaluation of a supplier´s development capabilities and performance.
- Project management. This activity can be distinguished into two sub activities i.e. planning and execution. Project planning includes the actual decisions on a project level on what to develop inside or outside the company. In case of the former, the actual decision is made on what suppliers to engage in the project and when to do that. Project execution includes introducing and onboarding the supplier with the firm's business strategy, domains, projects and engineers. It also includes the actual orchestration of the activities of first tier suppliers in their relationship with second tier suppliers. Finally, it includes the ordering and approval of prototypes and managing technical changes and variations.
- Product management. This activity includes evaluating product designs in terms of part availability, manufacturability, lead-time, quality and cost and promoting standardization and simplification of designs and parts across products and suppliers.

To be able to engage suppliers in new product development effectively, each of these four activities need to be managed by the firm to some extent. Preferably through a concerted action by all internal stakeholders involved. Enabling factors that foster a successful execution of each of these four management areas are: the internal organization of the purchasing department just as the development team, the access to and availability of human resources information including quality performance. The last finding leads the author to conclude to a fifth key process: *informing*.

When summarizing, Wynstra argues that the involvement of purchasing in a product development project should aim to realize or contribute to five (instead of four) key processes: prioritizing, mobilizing, coordinating, timing and *informing*. These five key processes should focus on four management areas including new product development, supplier interface management, project management and product management. Valuable suggestions are: not to talk about early purchasing involvement but, rather, stress the role of suppliers in fostering and improving new product development success. Next, we recommend to talk about *timely* supplier involvement rather than *early* supplier involvement as it is important to engage suppliers, based upon their capabilities, at the right time and the right level of responsibility in a new product development process (see Box 1). The role of the human factor should not be underestimated.



Box 1 The supplier involvement portfolio (Wynstra et al. (2000))

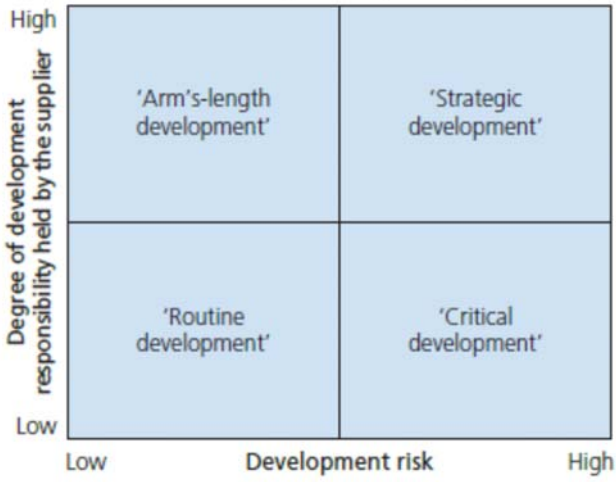
The objective of the supplier involvement portfolio is to provide guidance for setting priorities with regard to the involvement of suppliers in new product development. It will help companies to mobilize supplier expertise in the best possible way. As not all suppliers are equally important, only very few need to be engaged early. Other suppliers may be involved later, whereas most of the suppliers will be involved when the product design has been fully tested and is frozen. The portfolio
distinguishes four types of supplier involvement based upon two variables: (1) the degree of responsibility for product development that is contracted out to the supplier, and (2) the development risk involved (see Figure 3). Suppliers may assume responsibility for component design in four ways:

- Functional specifications. Based upon functional specifications for a component or module, the supplier is responsible for conceptual design, detailed design, prototype, testing and setting up its production and assembly process.
- **G**lobal design. Here, the buyer communicates a rough design to the supplier, who needs to work out a detailed design and submit this for approval to the buyer. When approved, the supplier is responsible for prototyping, testing and manufacturing.

- Detailed design. The supplier is responsible for submitting a prototype or sample to the buyer for approval, which is tested. Next, the supplier is responsible for setting up production and assembly.
- Standard design. Here the buyer decides to integrate a standard component in their product design. After the product design has been tested and is frozen, the supplier is requested to submit a price proposal and production planning.

Development risk is related to a number of factors. Examples are: the component is new to the buyer, the buyer is unfamiliar with the functionality of the component, criticality of the component for the buyer's product functioning, the component is on the critical path of planning and, the number of technologies represented in the supplier's component. Based upon these criteria, an assessment on part-level can be made per project to assess whether the buyer falls short in terms of knowledge and expertise. Those are the parts where specialized suppliers will be engaged early in the new product development project. Standard parts come with low risk in general and low technical complexity. Suppliers of standard parts therefore can be engaged late in the process. This is how the supplier development portfolio may guide buyer decision-making on ESI, which is better referred to as timely supplier involvement (see Figure 3).

Figure 3. The purchasing development portfolio (Wynstra et al. (2000))



The value of Wynstra´s work is that he provides a detailed insight into what it takes to engage suppliers within the product development processes of the firm, distinguishing the degree and timing of supplier involvement. A lot of processes need to be in place, in order to align the supplier contributions and match technology needs. Furthermore, enabling factors need to be organized in order to put these processes in place. As companies do probably not have all these processes in place equally, this may explain the different outcomes of early supplier involvement among companies and sectors.

Shifting suppliers into gear: effective supplier collaboration in NPD projects.

Building on Wynstra´s groundwork, Van Echtelt (2004) investigates the way in which inter-organizational collaboration, and specifically vertical collaboration between the manufacturer and its supplier, can strengthen a company's capability to develop new products. Again, the ´aim of this study was to identify what the critical processes are for managing the involvement of suppliers to lead to improved performance in product development´ (p.1). Van Echtelt observes that companies are being forced to develop and implement new strategies just as ways

to organize their product development function. In general, companies may pursue three different strategic and organizational responses: 1) outsourcing new product development, 2) concurrent development and cross functional collaboration, and 3) inter-organizational collaboration. The author observes that companies increasingly engage in collaborative arrangements with other companies in the area of technology and product development (p. 7). He further argues that this was in contrast to the more traditional arm's length supplier relationships in combination with a complete reliance on suppliers' development capabilities. Collaboration with other companies became a mechanism for tapping into external resources of knowledge to speed up development. Next, through supplier collaboration financial risks could be shared in developing new products. Supplier collaboration can however assume different, hybrid forms as well, such as mergers, acquisitions, joint ventures, strategic alliances, license agreements and collaborative arrangements with suppliers. With regard to the latter, Van Echtelt observes that there is a lack of sufficient empirical understanding of critical processes and conditions underlying effective supplier involvement that allow companies to attain short-term product development targets and long-term business goals. Next, he developed a framework that identifies the objectives, critical activities and conditions for effectively leveraging suppliers in product development. Again, this researcher builds his research on in-depth case studies, which are conducted at eight NPD projects at a global high-tech manufacturer. These case studies were followed by four additional case studies taken from NPD projects of companies in other business sectors.

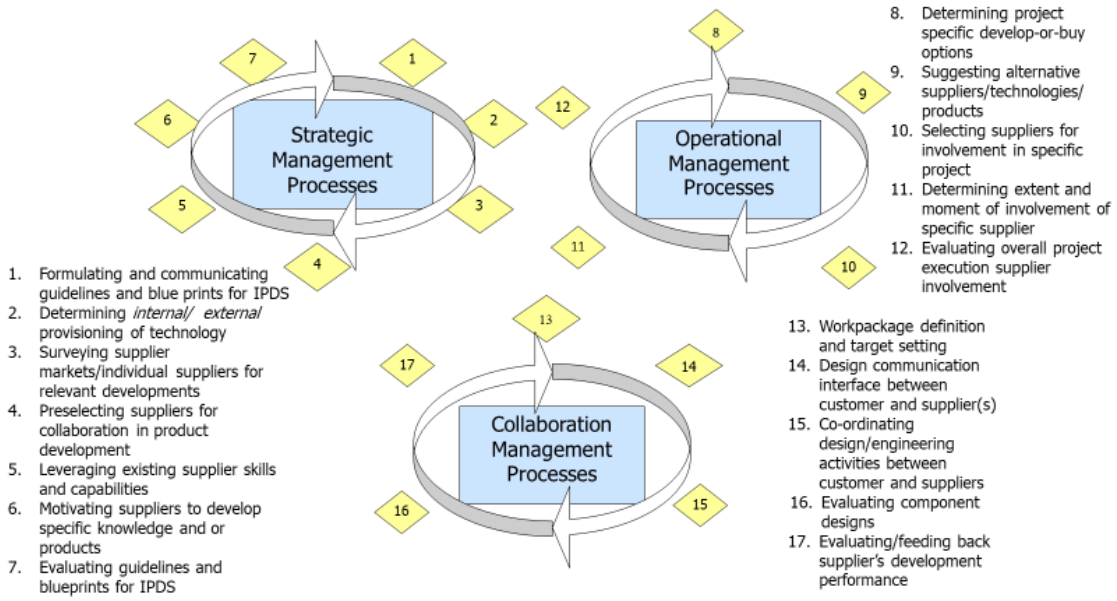
Based upon his extensive work, a number of adaptations to Wynstra's framework for analyzing management of supplier involvement are suggested. First, three instead of four relevant managerial arenas are suggested, i.e. the strategic management arena, the project management arena and the collaboration management arena (p. 264). A major reason for this is that companies may need to focus on managing individual collaborations with suppliers. As Van Echtelt (2004, p. 264) argues: "adopting a relationship view actually is like black boxing a phenomenon that itself is driven by events in different collaboration episodes that together drive an evolving relationship". As development projects aim at realizing both short-term and long-term objectives, the author maintains Wynstra´s original idea of the strategic management arena and project management arena. Here, only few ideas are added. However, the collaboration management arena includes activities aimed at designing the appropriate collaboration form, executing development activities in an individual collaboration and learning from each collaboration episode. For each of the three arenas, critical management processes are identified, which need to be managed collectively (see Figure 4). More specifically, the three management arenas seem to follow basic iterative cycles, rather than being sequential in nature. Based upon his extensive work, the author concludes that important enablers for making this integrated new product development framework work, are: collaboration between purchasing and research and development, human resource quality, recording and availability of information. Here, we conclude that most of the enabling factors that were identified by Wynstra, are confirmed.

The implications of this study are clear: if companies have made many efforts and have spent significant time in defining and describing critical management processes, these will not be successful if projects suffer from silo thinking, political plays between purchasing and research and development, lack of information support and management reporting, and lack of human resources.

The value of Van Echtelt´s work is that he translates his research results into a coherent and pragmatic audit tool, which can be used to assess the maturity of both the manufacturing and supplier organization for collaboration. The outcomes enable companies to either improve their processes and/or enablers for successful future collaborative innovations. In doing so they

might focus on putting things right first before embarking in joint collaboration in new product development.

Figure 4. Schematic overview of Van Echtelt´s Integrated Product Development and Sourcing framework (2004; adapted by the author)



Both Wynstra's (1998) and Van Echtelt´s (2004) research reveal the key areas and critical processes that need to be in place to allow for effective supplier collaboration in new product development projects. Both studies emphasize the importance of cross-functional teamwork among research & development engineers and purchasing professionals: an open atmosphere to exchange information between parties involved and the role of human resources. Enabling cross-functional collaboration, in essence, occurs at a person-to-person level, and thus may explain why supplier involvement is successful in certain cases and in other cases not. This insight was the reason to further deepen our initial research questions to include: what exactly motivates supplier specialists to contribute to the innovation goals and objectives of a manufacturer during collaborative innovations projects? Here, the inter-human dynamics within innovation teams needed to be more clearly understood such as the psychological factors and processes that affect inter-organizational and intra-organizational knowledge exchange. As a result, we became particularly interested in the social and human factors behind supplier involvement, which was the trigger to the next series of studies.

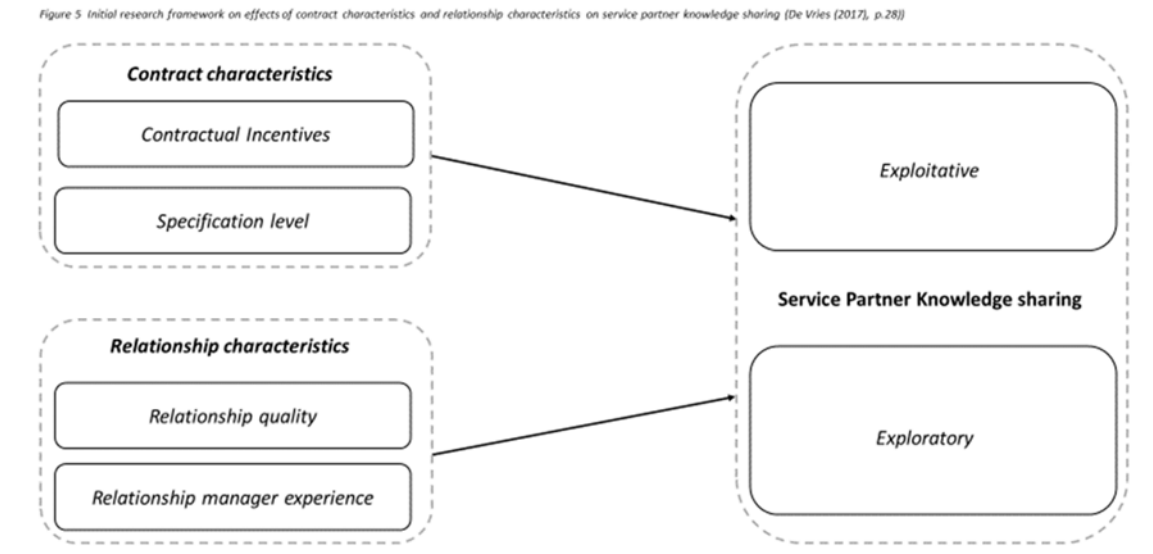
How to release external expertise: effects of relational and contractual governance

Following upon the previous research, De Vries (2017) conducted three studies aimed at understanding the psychological factors that influence actual knowledge sharing in interorganizational collaboration in new product innovation. His studies were different from the previous ones. Through Wynstra's and Van Echtelt's work, we intended to obtain in-depth insight in the mechanisms, processes and enablers underlying early supplier involvement. Hence, these studies were explorative, qualitative and case based. Through De Vries' research we intended to assess the effects of human interaction in conflicting interorganizational settings. More specifically, we were interested in discovering the actual drivers underlying effective

inter-human information and knowledge exchange, as information management and exchange emerged as a key enabler from the previous studies. Therefore, De Vries's research is of a different nature, i.e. quantitative and more specific in terms of independent and dependent variables. Here, we report on two of the three studies.

The first study, which was conducted among 70 experienced relationship managers at a large, global electronics manufacturer, was aimed at investigating how contractual and relationship characteristics enhance exploitative and exploratory knowledge sharing by service partners to whom manufacturers have outsourced customer facing services (De Vries (2017), p.18). As many manufacturing firms today outsource aftersales services to third-party service providers, these service providers have become crucial for the knowledge exchange about quality and usage behavior by end-users. Manufacturers can greatly benefit by integrating knowledge on post sales experiences by end-users into their new product designs. However, how could manufacturers capture such knowledge from these service providers? To address this question, the effects of both contractual governance and relational governance on knowledge sharing behavior were investigated. A distinction was made between exploitative knowledge sharing (aimed at obtaining knowledge to improve existing products and processes) and explorative knowledge sharing (aimed at obtaining knowledge to create entirely new products and processes). Effective knowledge sharing was, in line with organizational learning theory (Bell et al., 2002) deemed necessary for delivering successful innovation projects. Figure 5 provides a schematic overview of the research model. Contractual governance was explained by using two sets of variables: one was related to contractual incentives. The other set was related to contract specifications. It was hypothesized that both variables would positively affect service partner knowledge sharing behavior. With regard to relationship characteristics the differentiation was made between relationship quality and relationship manager experience. Relationship quality was measured by assessing the level of cooperation, responsiveness, empathy, assurance and trust among parties. Also, for these variables a positive effect on knowledge sharing behavior was assumed.

Figure 5. Initial research framework on effects of contract characteristics and relationship characteristics on service partner knowledge sharing (De Vries, 2017, p. 28).



Using multivariate analysis, the findings were the following. First, clearly defined contracts seem to be characterized by higher levels of knowledge sharing. Positive relationships were found between the level of contract specification and knowledge sharing. Which confirmed earlier research that unclear contract specifications hinder knowledge transfer. Unarticulated expectations leave service partners guessing for desired performance levels, resulting in disappointing service performance. We conclude that clear contractual specifications provide a frame of reference that makes a service partner share those insights that provide value to a manufacturer. Secondly, a strong negative relationship between contractual incentives and exploratory knowledge sharing was found. This negative relationship was not found in the relationship with exploitative knowledge sharing. As the study shows, contractual incentives focus suppliers on realizing short-term objectives and gains and reducing risks that could jeopardize the realization of agreed incentives. Contractual incentives avoid suppliers to think out-of-the-box. However, they may be useful when pursuing exploitative knowledge sharing aimed at continuous improvement or improving existing product and process designs. Thirdly, a positive relationship was found between relationship quality and both types of knowledge sharing. Relationship quality builds a long-term commitment among parties and as a result, both are willing to make idiosyncratic investments to the relationship. Experienced relationship managers may also trigger explorative knowledge sharing as they seem to better manage and guide the interactions with the service partner. This is important to note, as changing relationship managers too frequently and within a too short period of time, will be detrimental to exploratory knowledge exchange and, hence, collaborative innovation outcomes.

Concluding, the value of this research is that it shows that both contractual governance and relational governance seem to affect knowledge sharing between partners in collaborative innovation projects. Of course, with regard to contractual governance, this research only tested the effects of contract specification and contractual incentives. Clear contractual specifications are required to guide the development activities among innovation partners. Contractual incentives, in general, foster incremental innovation. However, they do not seem to foster radical innovation. On the contrary, relationship quality is positively related to knowledge sharing and therefore a key variable for driving collaborative innovation. Therefore, it does not come as a surprise that tenured relationship managers, who build on their past experiences, seem important in building trustful relationships.

Exploring the drivers of human interaction and knowledge sharing in NPD projects.

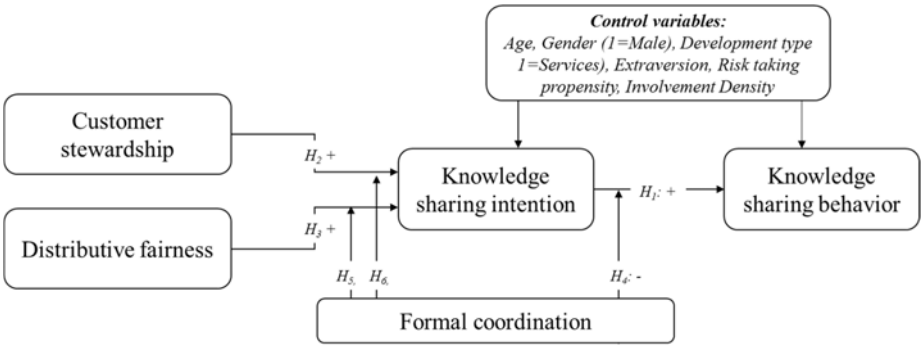
The previous study indicated that relational governance seems important in collaborative innovation projects. Especially cooperation, responsiveness, empathy and trust correlate positively with knowledge sharing. This all may be true, but what makes supplier engineers actually share their knowledge? This was the major research question underlying a second, quantitative follow-up study among 187 supplier technical engineers, who were engaged in collaborative innovation projects of seven global high-tech manufacturers (De Vries, 2017, p. 42). This research was deemed relevant since evidence from practice showed that engaging suppliers and integrating supplier knowledge into new product designs was not without problems. As an example may serve here: Goodyear, the global tire manufacturer. Its tire engineers imitated a technological innovation of the supplier, whose employees had been involved in an R&D project. Next, this supplier's technology was pushed out of the new product and the supplier did not get a fair yield on its contribution (De Vries 2017, p. 41). Similar experiences have been reported in the relationship between Compuware and IBM (Cowley & Larson, 2005) and Lexar Media versus Toshiba (Thomas, 2003). These cases suggest that suppliers do not always get a fair return for their development work in collaborative innovation projects. This makes technical engineers cautious, as they have to consider both the

responsibility to advance the manufacturer's business as well as obtaining a fair reward for the supplier´s development efforts.

Clearly, knowledge misappropriation and unfair distribution of rewards in collaborative innovation projects may lead to misalignment of interests, and hence may demotivate supplier engineers to share their knowledge with their clients. Therefore, this follow-up study aimed at investigating the importance of alignment of interests and economic rewards in collaborative innovation projects. Here, fairness theory (Fehr & Schmidt, 1999) was used to explain how individuals balance their invested efforts against expected outcomes. Fairness theory holds that when the balance is assessed as fair, self-regulation motivates individuals to contribute to collaborative innovation projects. Next, stewardship theory (Davis, Schoorman, & Donaldson, 1997) was used which defines stewardship as an individual's (here: supplier engineer) felt ownership and responsibility for the manufacturer's overall welfare. Based upon this, it was hypothesized that customer stewardship would positively influence knowledge sharing behavior, and, hence, affect collaborative innovation project outcomes positively. In line with Golden and Raghuram (2010), knowledge sharing behavior was defined as knowhow relayed to others on an impromptu basis, whereby individuals feel comfortable to spontaneously disclose personal experiences. This definition reflects that knowledge sharing is rather an interpersonal, spontaneous activity, than a planned or programmed activity. Knowledge sharing behavior was defined as the actual disclosure of information, whereas knowledge sharing intentions were defined as the willingness to engage in knowledge sharing behavior in the near future. Based upon these ideas, a preliminary research framework was built and tested (see figure 6).

The framework assumes that actual knowledge sharing behavior in conflicting, interorganizational settings is determined by knowledge sharing intention. Whereas knowledge sharing intention is affected by customer stewardship, and perceived distributive fairness. Through this framework we wanted to assess to what extent the care of a supplier expert's for the manufacturer's interest and his perception of a fair return of his development efforts would affect his willingness to share sensitive knowledge.

Figure 6. Research model for investigating effects of fairness and rewards on knowledge sharing behavior (De Vries, 2017, p. 45-46).



The hypothesized research model explained 33.5% of the variance in knowledge sharing behavior. The results indicate a positive effect between knowledge sharing intention and knowledge sharing behavior. Next, customer stewardship related positively to knowledge sharing intention. Furthermore, a positive interaction effect was found of formal coordination on the relationship between knowledge sharing intention and knowledge sharing behavior. An interesting finding was that a supplier engineers' risk-taking propensity and extraversion related

positively to knowledge sharing behavior and intention. These findings were in line with earlier works, which reported that risk averse individuals tend not to engage in risky behavior such as knowledge sharing. Surprisingly, no evidence was found for the effect of distributive fairness on knowledge sharing intention. However, the moderating effects of formal coordination on the relationship between fairness and intention did turn out to be significant. Therefore, it was investigated what levels of formal coordination (i.e. high, medium or low) could moderate the effect of distributive fairness on knowledge sharing behavior. It appeared that under conditions of low formal coordination, both the alignment of interests (stewardship) and alignment of rewards (fairness) drive knowledge sharing behavior through knowledge sharing intention. However, under circumstances of high formal coordination only alignment of rewards drives knowledge sharing behavior (De Vries 2017, p. 63).

Hence, the degree of formal coordination in collaborative R&D projects seems an important influencer of supplier engineers' motivations to share knowledge. Based upon this research, R&D managers need to make a conscious choice with regards to the level of formal coordination in collaborative R&D projects. They should instruct their employees either to heavily rely on informal coordination mechanisms such as trust and mutual understanding, or to provide strict guidance to supplier engineers by frequently referring to what has been agreed.

When formal coordination is high, managers are encouraged to emphasize the benefits for the supplier of being involved in this project. They should convince the supplier engineer that his/her knowledge contribution allows both parties to attain their business interests. Furthermore, they should secure that future revenues will be fairly distributed over the parties involved. When formal coordination in R&D projects is low, managers may have to do much more. In such a situation they have to make sure that supplier engineers experience a sense of stewardship for the manufacturers well-being. Supplier engineers should be allowed a fair degree of autonomy to work and share know-how in the R&D team. In order to realize this, the manufacturer should explicitly deploy onboarding practices to make the supplier engineers feel at home. Next, they should be appreciative of the unique competences that supplier engineers bring to the table.

Concluding, the value of this study is that it reveals the intricate and sensitive mechanisms underlying knowledge sharing behavior between individuals in collaborative innovation projects. It shows that, in essence, collaborative innovation is a process of human interaction. If this human interaction is not guided through both formal and informal mechanisms, knowledge exchange will suffer and, hence, will affect collaborative innovation project outcomes negatively.

Early supplier involvement: a mission impossible?

After many years of research, we finally have found the answer to the contrasting results of early supplier involvement. First, we have found that ESI operates at four different levels: the inter-organizational level, the project level, the relationship level and the individual level (see Figure 7). When doing so, different research methodologies (qualitative and quantitative) and different theoretical perspectives seem to be helpful. We conclude that, for understanding the effects of ESI, it is not sufficient to limit yourself to one methodology and/or theory only. The contrasting outcomes found in literature on the effects of ESI can be explained by differences among companies and their suppliers on practices and processes on each of the four levels.

Differences found in terms of early supplier involvement outcomes indeed can be explained by the fact that strategic management processes, operational management processes and collaboration management processes are not or not sufficiently in place. However, these differences may also be due to the manufacturer's inability to engage and mobilize supplier expertise effectively in the relationship with the manufacturer's engineers. It is the human

interface that seems to make most of the difference. The main reason for this is that in collaborative innovation, it is all about sensitive knowledge sharing and information exchange between engineers that usually need to operate in a setting with conflicting interests.

Dimension	Core issues	Methodology	Theoretical perspectives	Solutions
Organizational level	• How to create supplier alignment in collaborative NPD (intercompany level)?	• Qualitative, case studies	• Transaction Cost Economics (TCE) • Principal-Agent Theory	• Change from early to timely supplier involvement in NPD • Critical processes: prioritizing, mobilizing, coordinating, timing, informing
Project level	• How to create supplier alignment in collaborative NPD (project-level)?	• Qualitative, case studies	• Resource Based View of the Firm • Resource Dependency Theory	• Three arenas to manage: strategic management, project management, collaboration management • Critical processes: cross functional R&D, human resources quality, information management
Relationship level	• How do formal and informal governance affect buyer-supplier knowledge transfer?	• Quantitative, surveys	• Organizational Learning Theory • Social Exchange Theory	• Arrange for clear contracts: decide about level of formality • Arrange for mechanisms to recoup NPD investments • Arrange for incentives in case of exploitative knowledge transfer • Focus on relationship quality (ie trust, commitment, consistency) to foster knowledge exchange
Individual level	• How does human interaction affect formal and informal knowledge exchange?	• Quantitative, surveys	• Stewardship Theory • Fairness Theory	• Foster supplier stewardship through onboarding • Arrange for fair distribution of benefits and rewards • Arrange for right level of formal coordination • Allow for sufficient supplier autonomy

Figure 7. Early Supplier Involvement Framework: four levels of intervention

Knowledge and information exchange essentially occurs between people, is by definition person to person exchange. Making people share sensitive information both contractual and relational governance are important. Contractual governance is necessary in order to formally align business interests and expectations and to provide for rewards and incentives for the work that is to be delivered by suppliers. Relational governance relates to cooperation, responsiveness, communication, consistency, empathy and trust. It is needed to make supplier engineers feel respected and rewarded for their inputs. Depending on the type of innovation which the company wants to pursue (incremental versus radical innovation) the manufacturer should adapt its rewards and incentives in the relationship with suppliers. In both situations, careful selection of suppliers and their representatives, and deployment of effective onboarding practices are important. When working with suppliers in new product development projects, the manufacturer should secure a fair return on the supplier's inputs and efforts to generate sufficient stewardship and alignment from suppliers. As collaborative innovation projects are unique, so are the teams and the individuals that need to work on these. Different innovation projects represent different technical and commercial challenges that need to be overcome by different teams and people.

What can we learn from the previous studies? What should managers do to benefit from early supplier involvement in collaborative innovation projects? What should be avoided to prevent failure? The lessons are many, as are the challenges ahead. Based our research on collaborative innovation projects, and following our suggested four levels of abstraction (i.e. inter-organizational, project-, relational and individual level), we suggest the following:

- *Arenas and key processes*. Following Wynstra (1998) and Van Echtelt (2004), apart from contracts, formal governance mechanisms should be created around three important processes
    - Strategic management processes
    - Operational management processes
    - Collaboration management processes.

  Each of these processes is to be divided in several sub processes (17 in total) which need to guide internal and external stakeholders, who take part in the innovation project. Regular audits should secure that most of these processes are defined and followed in practice. In many product development projects, we have observed that most of these processes were not in place. In such cases collaborative development teams need to improvise i.e. need to make up their own decisions.
- *Cross-functional teamwork, information management and human resources* are important enablers to foster inter-organizational innovation projects. Cross-functional teamwork should be encouraged and should be in place to avoid suppliers to be confronted with political plays and differences of opinion among the manufacturer's representatives. Information management is necessary to create common IT-platforms for design,- planning-, and data sharing. It is of utmost importance that information systems among stakeholders are compatible and connected. Human resources seem to be a key asset in collaborative innovation projects. Not only in terms of the expertise that is required from both parties, which makes it mandatory that team members are highly qualified and experienced. However, also in terms of the ability to collaborate and operate in teams. This makes it necessary in any innovation project to invest sufficient time and money in project startup and onboarding, to allow team members to get acquainted with the project, what is expected from them, with their own roles and with their colleagues. Having witnessed many collaborative innovation projects, we observe that the necessary investments in these three important enablers are often insufficient.

- *Contractual and relational governance mechanisms.* Engaging suppliers early in new product development successfully requires a fair mix of both contractual and relational governance. It seems that innovative inter-organizational collaborations cannot do without formal contracts. As contracts guide and provide the context of the future collaboration. Development contracts, which stipulate how to deal with intellectual property and how investments will be recouped by both parties, are necessary to manage the expectations of the parties involved. Next, the manufacturer can opt to manage the project in a formal or informal way. The manufacturer should avoid an unclear mix of both, as this will be confusing to the supplier partner. Formal governance mechanisms are important; however, informal governance mechanisms may make the difference. As cooperation, responsiveness, empathy, assurance and trust seem to determine the motivation of supplier engineers to actually share knowledge and contribute to the manufacturer's new product development goals. Here, seniority of the manufacturer's relationship managers and their tenure is important. Contractual incentives may be used to stimulate supply partners to share their knowledge. Incentives are useful when pursuing incremental innovation. They should better not be used when pursuing radical innovation.
- *Contractual governance*. Our research shows that collaborative innovation cannot do without contractual guidance. Here, R&D managers should differentiate between low and high degrees of formality. High degree of formality would create clear guidance to all stakeholders. High degree of formality should be accompanied with a fair sharing of the pains and gains of the innovation project. When R&D managers opt for low formality in terms of contractual governance, they should do more. They should make sure that the supplier engineers feel at home, and feel respected as a valued member of the team. Investing in onboarding practices is inevitable. Being inconsistent i.e. changing between low and high formality in dealing with supplier engineers, will make them uncertain and uneasy and unwilling to share their knowledge and insight. Wrong contractual incentives may exacerbate the problem.
- *Relational governance*. As collaborative innovation seems to be predominantly a human interaction process, the value of investing in the relationship with suppliers can hardly be overstated. Suppliers should be considered by the manufacturer as is an important asset to the company. More particularly, manufacturers should aim for constantly improving the quality of the relationship with business-critical suppliers. Suppliers who have outstanding performance, should be rewarded with more business and deeper engagement in new product development projects. When they do, suppliers should have a fair return on their investments. In case of project failure, the consequences for all parties involved should be clear upfront and remedies in-line with contributions. Professional project management, risk management and relationship management would be necessary to create a climate in which a supplier can contribute.
- *Knowledge sharing and innovation*. As De Vries´s research (2017) shows, collaborative innovation, in essence, seems to be a human process i.e. a process of human interaction and socialization. The process of human exchange aims at knowledge sharing to foster product-, process- and business model innovation. There are many reasons why supplier engineers will not share their ideas freely in innovation projects. One is that they need to overcome conflict of interest, as they need to take care of their own company's interest as well the manufacturer's innovations interest. This conflict is not easily solved. Next, they need to be valued in their area of expertise as an engineer and as a human being. A hostile, ´not invented here´ culture, arrogance, or downright ignorance at the manufacturer, could jeopardize a supplier engineers´ motivation to contribute.

Heading for early supplier involvement: are you ready for it?

Based upon our previous discussion, it is now clear why extant research on the effects of early supplier involvement has produced such contrasting results. Given the many challenges that need to be overcome, early supplier involvement may easily result in disappointment. Joint collaborative new product innovation represents a trajectory which is full of problems, risks and disappointments. Is early supplier involvement a mission impossible or not? It is a mission impossible for those who think that early supplier involvement can be managed as a systematic structured process. But it is not for those who think that early supplier involvement primarily is all about fostering human interaction in conflicting business settings. However, then engaging supplier engineers in new product development is far from easy. When embarking on such a journey, we recommend manufacturers and supply partners to start with the end. Which is: to start with the human side of the enterprise. To establish a cross-functional, cross-organizational team of capable engineers and specialists that are well prepared and equipped for their tasks and which is supported by an adequate (though sparse) governance and project structure. Next, the team should be equipped with sufficient resources. This seems more valuable than to try to structure all 17 processes around the three areas as this will, apart from the huge effort, only provide for limited control and certainty. In reality, every collaborative innovation will develop differently than originally anticipated. The joint project team should be allowed, based upon the manufacturer's initial feasibility studies, to develop their own project mission, restate the project objectives and prepare a global project and work plan. These may serve as the input for an initial, flexible development contract, which stipulates how parties will deal with intellectual property and how investments made will be recovered, i.e. how financial losses will be spread. Rather than working sequentially, parties need to prepare for iterative loops which allows parties based on the progress made, to regularly review and mitigate incumbent project and work plans. Next, the quality of the relationship should be reviewed and discussed regularly to secure that everyone is still committed and contributes. Only then early supplier involvement may turn into a mission possible.

Abstract: This study analyzes whether customer perceptions towards sustainability are affected by a company's country of origin and sourcing strategies. Customer perceptions of company sustainability was found to have an impact on purchasing behavior. This study builds upon the literature about customer interest in sustainable products. It adds the country of origin to the link between customer and company, and analyzes if and how customer perceptions change when they are introduced to a sustainability scandal, hence analyzing possible 'association by guilt'. It compares their reactions to offshore scandals and to local scandals therefore taking spatial distance as an important variable into consideration. Findings show that perceptions are influenced by proximity. Furthermore, companies should take into account the risk of association by guilt when developing their global sourcing strategies.

Keywords: Supply Chain; Sustainability; Customer Perception; Sourcing

Introduction

In a world of scarce resources companies have come to realize that it is not simply a trend but a responsibility to act more sustainably (Prahalad & Hamel, 1994). Irresponsible, unethical or opportunistic behavior has become detrimental for a company´s reputation. At the same time, in order to stay competitive, companies are expanding their businesses globally and outsource non-core activities (Ortas, Moneva & Álvarez, 2014). They build supply chains that consist of a network connecting different partners, countries, and consumers. This growing complexity leads to considerable challenges for sustainable sourcing. One strategy to pursue sustainability is to re-shore (Ashby, 2016). Reshoring brings offshored business back home and may cater to sustainability goals. Growing news coverage of supply chain scandals leads to increasing customer interest in sustainability. These scandals mainly occur at the place of production, mostly developing countries, but cause public outcry in the developed world, where the majority of products is sold (Gualandris, Golini & Kalchschmidt, 2014). Often, the production process has been outsourced to factories belonging to the supplier. This vertical disintegration means that the focal company (FC), which sells the product under their brand name to

(Western) consumers, is legally not responsible for the conditions at the point of production. Nevertheless, scandals may automatically be associated with the FC. Molet et al. (2013) call this phenomenon 'association by guilt'; when two parties are linked to each other, the negative reputation of one can impair the reputation of the other.

This form of supply chain contagion might trigger customer awareness of sustainability and demand for more transparency. Supply Chain Transparency includes vertical as well as horizontal transparency so that all stakeholders and supply chain players have better access to corporate supply chain information (Bastian & Zentes, 2013). In order to create transparency, a firm needs to increase control over outsourced services. One approach is to establish a set of guidelines that suppliers need to follow, concerning child labor, safe work places or waste disposal. This approach is already adopted by multinational companies like IKEA and Danone (Johnsen, Howard & Miemczyk, 2014). Moreover, sharing positive information about sustainability measures is becoming a standard for being competitive (EY, 2014). Thus, rankings of the most sustainable companies have become a popular tool for benchmarking (e.g. DJSI, Global 100, Thomson Reuters ESG Index). Investments in sustainability could also be justified by customer demands for more sustainable behavior (Gualandris et al., 2014). It is however unclear whether they really care about sustainability along the entire supply chain or only at the point of sale when purchasing from the FC.

We take a closer look at customer perception of company sustainability and the link to supplier sustainability by taking into consideration the role of countries. Thus, we use existing literature about the company-customer link and add country influence to the model. The following research questions (RQ) are focused upon:

> RQ1: Do the countries of origin of both the Focal Company (FC) and supplier influence the customer purchasing behavior (CPu)?
>
> RQ2: Is customer perception of the FC sustainability linked to distance and perception of country sustainability?

Based on the literature regarding sustainable supply chain management, customer perceptions and country sustainability, nine hypotheses have been developed. Data have been gathered through four separate types of questionnaires. A total number of 129 valid responses were gathered. This paper is organized as follows: section 2 provides the literature review and hypotheses derived from the literature. Section 3 describes the methods, while section 4 presents the results, including reliability and validity issues. Section 5 discusses the results of this study in light of previous insights from the literature. Section 6 concludes this paper by providing managerial recommendations, as well as possible limitations of the study and potential pathways for further research.

Literature Review and Hypotheses

Sustainable Supply Chain Management

In the context of supply chain management (SCM), the business case to integrate sustainability and foster sustainable supply chains has been developed, since sustainability becomes a growing demand within global business settings (Quarshie, Salmi, & Leuschner, 2016). Different definitions and interpretations are available for Sustainable Supply Chain Management (SSCM), ranging from a narrow focus towards environmental issues (also referred to as Green Supply Chain Management, GSCM), to a holistic interpretation of economic, environmental, social and ethical aspects in the supply chain (Ahi & Searcy, 2013). One of the working definitions of SSCM, which is adopted in the context of this paper as

well, is: “The integration of sustainable development and supply chain management [in which] by merging these two concepts, environmental and social aspects along the supply chain have to be taken into account, thereby avoiding related problems, but also looking at more sustainable products and processes” (Seuring, 2008, 132). As a result of a systematic literature review, Seuring and Müller (2008) present a conceptual framework for SSCM, consisting of three elements: triggers for SSCM; supplier management for risks and performance; and SCM for sustainable products (Seuring & Müller, 2008). Another popular conceptualization of sustainability is the triple bottom line (Elkington, 1998), in which sustainability is about finding a balance between economic, environmental and social performance. A triple bottom line framework for SCM was provided by Carter and Rogers (2008), who state “we are not suggesting that organizations blithely undertake social and environmental goals relating to the supply chain”, thereby referring to the extra costs that these goals would bring to an organization (Carter & Rogers, 2008, 369).

Such interpretations, in which SSCM is reduced to the supremacy of financial and economic dimensions over environmental and social dimensions, is criticized by Pagell and Shevchenko (2014), who state that “the question of how to create truly sustainable supply chains remains unanswered” (Pagell & Shevchenko, 2014, 44). A ‘truly SSCM’ might then be defined as follows: “To be truly sustainable a supply chain would at worst do no net harm to natural or social systems while still producing a profit over an extended period of time; a truly sustainable supply chain could, customers willing, continue to do business forever” (Pagell & Wu, 2009, 38).

Traditionally, the economic dimension received more attention in business (e.g. Friedman, 1970), but as customers have emerged as a driving force, more attention should be paid to environmental and social issues. This approach is supported by Xie (2014) whose research only concentrates on these two areas, as well as Gualandris et al. (2014) who suggest that what really matters are a firm’s environmental and social performances. Both argue that customers are more interested in these two aspects and therefore, firms concentrating on them will see a positive impact on their overall sustainability performance.

Emotions may play a major role in sustainability scandals. The growing awareness of negative effects due to unsustainable behavior results in demand on firms to take responsibility. In the last few years many sustainability scandals linked to companies have been exposed. Well known cases include the Rana Plaza factory collapse which was linked to Primark (Butler, 2014), child labor at a factory for Nike products, as well as harmful ingredients in Mattel products (Gualandris et al., 2014). While in the past this was mainly communicated via TV and newspapers, today’s social networks and media spread information faster than ever and reach people all over the world (Khuntia, Sun, & Yim, 2016). This resulted in a demand for transparency along the entire supply chain, and increased attention towards the effects of individual processes on sustainability (McWilliams et al., 2016).

Shoring and sourcing strategies

The focus on sustainability shifts from the individual firm level to the entire supply chain. Different shoring and sourcing strategies have been developed throughout the years, each having a positive or negative effect on supply chain sustainability. One strategy is to wholly own the supply chain by the FC such that every link of the chain is located in spatial proximity to the other. When parts of the supply chain are moved to other countries but are still operated by the FC, this strategy is called offshoring (Bhalla, Sodhi, & Son, 2008). Whenever a service is purchased from a supply chain partner, it is no longer wholly owned by the FC and we talk about outsourcing (Ellram, Tate, & Billington, 2008). Outsourcing can

take place in the same country or may involve going abroad, which is then called offshore outsourcing. Reasons for offshoring are lower wages, extended working hours due to the presence in different time zones, or proximity to important resources (Bhalla et al., 2008). Offshore outsourcing causes negative environmental impacts, such as an increase in (global) carbon emissions (Gurtu et al., 2016), and agricultural land grab in impoverished regions (Oguamanam, 2015).

The increasing complexity of global networks and sourcing strategies are challenging companies to act sustainably. Production processes are often spread across continents and the supply chain partners are linked by the flow of information, material and capital (Seuring & Müller, 2008). Different factors influence the supply chain and leads to increased uncertainty, which needs to be understood and managed (Menhat et al., 2014), and global sourcing should be interpreted within the context of sustainability (Zeleny, 2007). Each process step has environmental and societal effects and often it is the FC which will be held responsible for these outcomes. This poses a challenge for the FC to manage the complete supply chain, including direct, second and third tier suppliers. Therefore, the company has to ensure that corporate sustainability is practiced internally and that these values are followed equally by their supply chain partners (Seuring & Müller, 2008).

Two more strategies gained popularity in recent years. Reshoring aims to bring the business back home, especially manufacturing. These initiatives are responses to the decreasing income gap between the West and its offshore locations and a growing supply chain complexity (Goodwill & Goodwill, 2012), as well as the result of economic crisis and customer demand for flexibility and improved cost performance (Tate, 2014). Similarly, nearshoring moves the business not fully home but closer to home, i.e. to a nearby country (Ashby, 2016). In order to ensure sustainability at the supplier, effective supplier management needs to be in place. Therefore, the reason to offshore in order to save costs has lost in importance while closer ties with the supplier, made possible by geographical proximity, have become a priority. However, the process of moving offices and people as well as creating new ties is costly. Different initiatives have been presented to encourage reshoring and local sourcing, such as a framework to 'right-shore' which considers the initial decision making process to offshore and then re-evaluates that decision (Joubioux and Vanpoucke, 2016), sustainability factors for reshoring (Ashby, 2016), and carbon footprint tax (Choi, 2013). Gualandris et al. (2014) compare firms with local businesses and firms with global businesses with regard to their sustainability strategies. They found that for local firms traditional supply management (SM) is a sufficient prerequisite for sustainable behavior. For global companies, in addition to SM, SSCM has to be introduced to show significant improvement in sustainability performance. They also claim that adopting global sourcing strategies does increase supply chain complexity but may at the same time push the company to introduce SM and SSCM more effectively and improve environmental and social performance.

Customer Demand and Perception

In the literature, different drivers to integrate sustainability are identified, such as compliance to laws and regulations. More and more however, customers demand sustainability and companies find ways to meet this demand, e.g. by analyzing and lowering product carbon footprints (Arıkan & Jammernegg, 2014). Attention towards sustainability can lead to an increase in sales and a growing customer base. This has resulted in companies reporting on their Corporate Social Responsibility (CSR) (Milne & Gray, 2013). Customers and clients are important drivers behind these reports (EY, 2014). Also, the attention to supply chain

scandals leads to increasing customer demand toward sustainability and transparency (Gualandris et al., 2014).

An important aspect of customer demand is the perception of the focal company and its supply chain. Irresponsible behavior of one SC partner can have a negative impact on the reputation of the remaining partners. Following Molet et al. (2013) an individual will be evaluated negatively when associated with someone else who has a bad reputation. This is called 'association by guilt' and can be compared to a supply chain contagion (Molet et al., 2013). Referring back to the differentiation between offshoring and outsourcing, this concept indicates that outsourcing a sustainably weak part does not necessarily increase the reputation of the FC's sustainability. It will still be associated with the FC's supply chain, and thus, whenever a problem is identified at a supplier, this can negatively impact the FC, too. The opposite, association by honor or the 'halo effect', is also possible. Products sold by companies that engage in social initiatives will automatically be perceived as more valuable or sustainable even though the product itself might have no link to any of the initiatives (Chernev & Blair, 2015). Often, this is the main reason for businesses to engage in CSR. Further, people tend to project their own traits onto others, which is called 'Spontaneous Trait Transference' (Molet et al., 2013). This could mean that consumers who act sustainably might expect firms to act the same.

For this study, it is important to consider whether the transference of traits differs with distance. According to Lii, Wu, & Ding (2013), the closer a customer is to a company, whether considering spatial or social distance, the stronger is the effect that CSP may have on customer perception. Xie (2014), on the other hand, suggests that consumers have adopted a globalized perception. CSR initiatives to them are global initiatives and therefore not necessarily linked to an individual country. In view of these opposing positions, spatial distance between a customer and a company will be studied in more detail in a separate section.

Homburg, Stierl, & Bornemann (2013) suggest that business oriented CSR increases trust in the company while philanthropic CSR supports the consumer's identification with the company. Accordingly, Xie (2014) explains that satisfaction, trust and identification are important values that contribute to strong customer support. If the relationship between company and customer scores low on these three values there is a greater chance of the customer boycotting the brand in case of a scandal (Sen & Bhattacharya, 2001) or switching to a different brand (Friedl & Wagner, 2012). Therefore, we propose that customers identify more easily with companies of low spatial distance and, thus, are more loyal to those than to foreign companies of high distance. Thus, it is very valuable for companies to know what is important to their customers and which initiatives can evoke the greatest emotions and identification with the cause. A report by Morgan Stanley (2015) has also taken a look at whether age or gender influence personal evaluation. It shows that Millennials, people born around 1980-1999, and especially female customers are interested in sustainability.

The strong focus on the link between customer and company has led to the question whether customers are purely interested in the point of sale, and thus, only the sustainability of the FC. This would indicate that consumers take a great interest in CSP of businesses with low spatial distance but are likely to ignore the rest of the supply chain. Further, consumers might show less interest in sustainability when there is high spatial distance or intuitively evaluate these companies as less sustainable. Therefore, the next section extends the discussion about customer-company by 'country' and suggests that customer perception of sustainability can be influenced on all three levels.

Country Sustainability

Country sustainability indices, like the one for companies, vary in size as well as in indicators. Some of them only measure the ecological footprint or, like the Human Development Index (Neumayer, 2001), mostly social and economic sustainability. One index measuring all three indicators of the TBL is the Sustainable Society Index (SSI). The SSI analyzes 151 countries and includes 21 indicators in three categories: economic wellbeing (5), human wellbeing (7) and environmental wellbeing (9) (SSF, 2015). Neumayer (2001) suggests there is no direct relationship between environmental and social factors. The Sustainable Society Foundation (SSF), however, has found at least some negative correlation in their SSI and therefore decided to publish separate rankings for each indicator instead of an overall sustainability index (SSF, 2015). For instance, while Mozambique as well as the Central African Republic score very low on human wellbeing, they can both be found in the top 10 of the environmental index.

The linkage between a country's national culture and corporate sustainability efforts has been analyzed by Vachon (2010), in which corporate sustainability is related to a nation's degree of individualism and uncertainty avoidance. Lopez and Balabanis (2015) have found support for their hypothesis that consumers' perception of a country's industry and corporate landscape impact their perception of that country's sustainability. Therefore, we take a closer look at a country's effects on consumer opinion about company sustainability. The question is, whether the sustainability of individual sourcing countries and the FC's country of origin influence the consumer's perception of the brand's sustainability.

Table 1. Hypotheses

Hypothesis	Derived from
*H*1: The customer's perception of a company's sustainability is expected to have a direct impact on the customer's willingness to continue buying from the focal company	(Sen & Bhattacharya, 2001; Friedl & Wagner, 2012)
*H*2: The customer's perception of a company's sustainability is expected to have a direct impact on the customer's willingness to pay a price premium for sustainable products from the focal company	(Lii et al., 2013; Xie, 2014)
*H*3: The customer's interest in sustainability has a moderating effect on the link between the customer's perception of a company's sustainability and the customer's willingness to continue buying from the focal company	(Molet et al., 2012; Chernev & Blair, 2015)
*H*4: The customer's interest in sustainability has a moderating effect on the link between the customer's perception of a company's sustainability and the customer's willingness to pay a price premium for sustainable products from the focal company	(Molet et al., 2012; Chernev & Blair, 2015)
*H*5: Females are more interested in sustainability than males	(Morgan Stanley, 2015)
*H*6: Spatial distance is expected to have a direct impact on a customer's perception of a company's sustainability	(Lii et al., 2013; Xie, 2014)
*H*7: Low spatial distance of the supplier's country of origin is expected to have a direct positive impact on a customer's perception of a company's sustainability	(Lii et al., 2013; Xie, 2014)
*H*8: Low spatial distance of the focal company's country of origin is expected to have a direct positive impact on a customer's perception of a company's sustainability	(Lii et al., 2013; Xie, 2014)

*H*9: The customer's perception of a country's sustainability is expected to have an impact on the customer's perception of the company's sustainability, when associated with that country	(Lopez & Balabanis, 2015)

Hypotheses

In line with the literature on SSCM, customer perception and country sustainability, nine hypotheses are formulated. Table 1 presents the hypotheses, as well as the main sources from which they are derived.

Methods

Research setting, data collection and survey instrument design

Four different types of questionnaires were created to test the hypotheses. The surveys contained an identical case and identical questions but the countries of origin of the companies differed across the survey types. The surveys were aimed at respondents from Western Europe to keep a similar spatial distance between the respondent and the FC and supplier countries mentioned in the case. The surveys were created and shared via the online platform 'Free Online Surveys', and shared via social media. Due to a snowball effect, this also yielded many responses from non-European countries. After deleting invalid replies, 129 responses remained, having received >30 replies for each of the four survey groups. Table 2 provides the demographics. It is notable that most respondents were female and between 20 and 40 years old.

The case introduced in the surveys focused on unsustainable poultry production, because it is a pressing issue locally (Germany), as well as abroad (Indonesia). This facilitated the decision to test the link between local/foreign countries. The case presents a negative situation caused by the supplier of the FC. It intends to find out whether this negative situation will be projected onto the FC by the respondents. As the company is fictitious and presented negatively, the answer is expected to be influenced through 'association by guilt' (Molet et al., 2012; Chernev & Blair, 2015). The FC in the survey cases is either Japanese or Spanish, while the supplier is located in Germany or Indonesia. Thus, it resulted in a total of four combinations (Table 4) ranging from very low distance (2) to very high distance (3).

Table 2. Descriptives

Category	**(1)**	**(2)**	**(3)**	**(4)**
#Respondents	34	32	31	32
Male	38.2%	40.6%	35.5%	50%
Female	61.8%	59.4%	64.5%	50%
Average Age	24	24	24	36
German	64.7%	78.1%	90.3%	84.4%
Dutch	23.5%	18.8%	3.2%	3.1%
French	2.9%	3.1%	3.2%	0%
British	5.9%	0%	3.2%	9.4%
Irish	2.9%	0%	0%	0%
Scottish	0%	0%	0%	3.1%

Measurements

Country attributes (CO) consists of spatial distance between respondent and country as well as respondent perception of country sustainability. Research suggests that people may show stronger support for local than foreign companies but this hypothesis is not supported (Xie, 2014). One reason could be that perception of CSR is not directly dependent on the country of origin. Rather, it might be influenced by the perceived honesty of intentions and the trust of customers in a company. Trust however may vary due to the countries in which CSR is implemented. One possible reason is that trait transference of good faith and trustworthiness might be harder to apply the more foreign and unknown a company or country is.

Table 3. Survey Constructs

Construct	Reference
Spatial Distance	Lii et al., 2013; Xie, 2014
CP	Molet et al., 2012; Chernev & Blair, 2015
CPu	Lii et al., 2013; Xie, 2014; Molet et al., 2012; Chernev & Blair, 2015
CI	Morgan Stanley, 2015
Case	Indonesia: Brienen et al., 2014 | Germany: Klawitter, 2011

Table 3 provides an overview of survey constructs. CPu refers to customer purchasing behavior as a (possible) reaction to the case. It is analyzed whether the perception of the company, which is hypothesized to be influenced by spatial distance and the personal assessment of country sustainability, has an impact on the customer's buying behavior (Molet et al., 2012; Chernev & Blair, 2015). It considers whether customers would simply continue to buy from this brand (CPu1) or would even pay a price premium (PP) if the brand would sell sustainable produce (CPu2) (Lii et al., 2013; Xie, 2014). In addition, a closer look is taken at the mediating role that Customer Interest in Sustainability (CI) might play. Here, three items refer to the case and three to general preferences towards local vs foreign products. Furthermore, gender related differences in answers to CI will be analyzed.

Analysis

The analysis of the hypotheses is done with IBM's SPSS software. Normality is assumed as each survey version received >30 responses. First, the model is tested for reliability by calculating each construct's Cronbach alpha (Pallant, 2013). In some cases inconsistency was found, therefore it was decided to reduce the number of items or split the construct. Next, a principal component analysis (PCA) has been performed to test construct validity (Pallant, 2013), results showed whether the combination of items is correct or whether additional factors can be identified. Overall, the results are satisfactory. For the hypothesis testing, items are first tested for correlation. This aims at testing possible relationship between the CPu items and whether the earlier decision to split and test them separately was correct. For $H1$ and $H2$ a regression tested whether CP is a predictor for CPu. A simple linear regression is used as there was only one predictor variable (CP) (Field, 2009). Next, a partial correlation test calculates the moderating effect of CI on the link between CP and CPu ($H3$; $H4$). For partial correlation variables need to be continuous, therefore, this study would violate this assumption. However, Bortz, Lienert and Boehnke (2008) suggest that satisfactory results can still be achieved. For $H5$ the difference between male and female responses to CI is compared. As there are only two groups, a t-test is chosen (Pallant, 2013). For $H6$-$H8$ four independent groups are compared, and a one-way between groups ANOVA helps to test for

significant differences. Finally, the impact of customer perception of country sustainability on his/her perception of the company's sustainability (*H*9) is tested with a linear regression. The following sections explain the procedure and the results in more detail.

Reliability and Validity

Every construct is tested for reliability by checking its Cronbach alpha, a valid alpha being ≥0.7. In some constructs this is not the case and, thus, the Inter-Item Correlation Matrix has to be checked for low correlation values. Items with values <0.3 are taken out of the group. Another way to detect an unfit item is to look at the 'Alpha if Item Deleted' table to see the impact of each item when removed from the scale. Table 4 shows the final Cronbach alphas for the 'Customer Interest in Sustainability' (CI) scale. The 'Customer Perception of Company Sustainability' (CP) scale was reduced to one item; "company XY is a sustainable company", and thus no reliability check is necessary. 'Customer Purchasing Behavior' (CPu) scores a Cronbach alpha <0.7 for every country combination and therefore, it is reduced and split into two items testing the effect of company perception on customer purchasing decisions separately (CPu1; CPu2). 'Customer Perception of Country Sustainability', part of CO, only achieves a Cronbach Alpha >0.7 in (1). It is decided to test the effect of FC country and supplier country one by one, thereby enabling a comparison between the two items.

A PCA is performed in order to test whether the current constructs show more underlying linear combinations than assumed. There are two conditions to see whether such factorial analysis is appropriate: the Kaiser-Meyer-Olkin value, which should exceed 0.6 (Kaiser, 1974), and the Bartlett's Test of Sphericity (Bartlett, 1954), which reports statistical significance. The CI scores significant results for every country combination and, therefore, is analyzed for factors. Except for combination (3), which shows two possible components, the scree test and parallel analysis result in only one component with a total initial Eigenvalue >1. This supports the strength of the scale and it is decided to keep one component for (3) too, to ensure comparability between the groups. Therefore, the grouping proves to be appropriate. On this basis, the next section describes the results of the hypothesis testing.

Table 4. CI Scale, Reliability Test

Country Combination	Cronbach Alpha
Japan_ Germany (1)	0.816
Spain_ Germany (2)	0.878
Japan_ Indonesia (3)	0.799
Spain_ Indonesia (4)	0.9

Results

The hypotheses are tested within groups. Only for the spatial distance item, a one-way ANOVA is performed in a master file containing all responses to test the variance between groups. First, correlation between the two items of the CPu scale is calculated again, to see whether the decision to test them separately is appropriate. No significant correlation is present. Thus, the decision is supported.

Next, a linear regression helps to test *H*1 and *H*2. *H*1 is supported for groups (1), (2) and (4). For group (3), the results only show marginal significance. The tests show no support for *H*2 throughout groups (1)-(3) but do show marginal significance for (4). Therefore, it can be concluded that the perception of a company's sustainability is a prerequisite to the decision on

whether to continue buying from that firm (CP-CPu1). However, there is no or very little evidence that it is a prerequisite to the decision to pay a price premium for sustainable products (CP-CPu2).

Table 5. ***significant at p<0.01; **significant at p<0.05; *significant at p<0.1

Group	CPu item	R	R2	B (Constant)	B (Independent Variable)
(1)Japan_Germany	CPu1	.347	.120	1.263	.370**
	CPu2	.065	.004	3.754	-.099
(2)Spain_Germany	CPu1	.792	.628	.684	.693***
	CPu2	.156	.024	3.649	-.158
(3)Japan_Indonesia	CPu1	.326	.106	1.250	.375*
	CPu2	.013	.000	3.553	.018
(4)Spain_Indonesia	CPu1	.606	.367	.630	.699***
	CPu2	.331	.110	4.417	-.454*

Partial correlation is used to explore the relationship between perceived company sustainability and CPu, while controlling for scores on the CI scale (*H*3-*H*4). There are weak, partial correlation coefficients for (1) and (3) and strong partial correlation coefficients for (2) and (4) controlling for CI on CPu1. For CPu2 only results for (4) are calculated as the other groups showed no link between CP and CPu2 in the first place. Here, the partial correlation coefficients are also weak. An inspection of the zero order correlation suggests that controlling for CI has very little effect on the strength of the relationship of CP-CPu. Thus, *H*3 and *H*4 do not find support. A t-test helped to examine whether there is a significant difference in CI depending on gender (*H*5). Only 21% of all items show a significant difference (<0.5): In (1), no significant results are found, while for (2) three items show significant values. For (3) and (4) each group shows a significant difference for one item. The majority shows no significant difference in responses and thus, *H*5 is not supported.

Table 6. ANOVA Results

‘Company X is a sustainable company’					
	Sum of Squares	**df**	**Mean Square**	**F**	**Sig.**
Between Groups	8,945	3	2,982	4,301	,006
Within Groups	86,652	125	,693		
Total	95,597	128			

For *H*6-*H*8, a one-way between-groups analysis of variance is conducted to see if the responses to ‘company XY is a sustainable company’ differ (Table 6). There is a significant difference at p < .01 between the four groups: F(3, 125) =4.3,p =.006. The result supports *H*6. The post-hoc test shows that the significant differences are between the groups Spain_Germany and Japan_Indonesia (.014), as well as Spain_Germany and Spain_ Indonesia (.011). Looking at the mean plots, it is interesting that (2) has the highest mean score (M: (2)=2.13; (1)=1.68; (3)=1.48; (4)=1.47), meaning that the group with the lowest spatial distance, for FC as well as supplier, receives on average better results for the perception of the company’s sustainability than combinations with higher distance, which supports *H*7 and *H*8. Additionally, the partial eta squared effect size is calculated to show how strongly the independent variable can explain the variance of the dependent variable. According to Cohen (1988) there is a small effect at .01, a medium effect at .06 and a large effect at .14. This analysis shows an effect of .0936 or 9%, resulting in a medium to large effect.

Finally, a linear regression helps to test *H*9. The country of the supplier and the FC are tested separately to detect possible differences. None of the *R*2 values explain more than 9% of the variance in the models. Looking at the output summary in Table 7, no significant results are found and, therefore, *H*9 cannot be supported.

Table 7. *significant at p<0.05

Group	Country of _	R	R2	B (Constant)	B (Independent Variable)
1	FC	.053	.003	1.587	.036
	Supplier	.189	.036	1.149	.146
2	FC	.3	.09	.903	.444
	Supplier	.199	.039	.913	.337
3	FC	.183	.034	1.016	.148
	Supplier	.132	.017	1.200	.133
4	FC	.186	.035	1.939	(-).186
	Supplier	.004	.000	1.462	.003

Discussion

This study puts forward nine hypotheses, out of which three can be supported. Two can only be supported for some groups and four do not show significant results (table 8). *H*1 examines a possible impact of the consumer's assessment of a company's sustainability on his/her willingness to continue buying from that firm. A significant impact is found for all groups except (3), which is the combination of highest distances for FC and supplier, Japan_Indonesia. Here, only marginal support can be found. *H*2 looks at a possible impact of the consumer's assessment of a company's sustainability on his/her willingness to pay a premium for sustainable products. Only (4), Spain_Indonesia, receives marginal support while the null hypothesis cannot be rejected for the other groups. These results support the theory that consumers show stronger loyalty for companies of lower distance. It might be due to a lack of trust for foreign businesses and products as well as the inability to identify with the issues (Homburg et al., 2013; Lii et al., 2013). However, one needs to differentiate between the two CPu items. On average, people are not willing to continue buying from the company but would consider paying a PP if the company started selling sustainable products. This shows there is a general interest in and activism for sustainability which is also supported by the motivation to share the information about unsustainable production with friends and family. The answers also support the hypothesis that customers are more tolerant towards local than foreign countries and companies. When asked whether they prefer local over foreign products, respondents agree on average. The same is true for trusting local products more than foreign ones and considering local products to be more sustainable.

Customers' interest in sustainability seems to have no moderating effect on the relationship between their company perception and the willingness to continue buying from that brand (*H*3). This seems to be contradictory to the results of Sen and Bhattacharya (2001) who claim that customer interest in a topic strengthens their support for a CSR initiative, thus showing an impact by CI. A closer look at the mean answers shows that respondents of group (3) were the most indifferent to CI items (ranging from 3.71-3.97). This seems to indicate that customers care less about countries of high spatial distance. However, responses to CI in groups (1), (2) and (4) do not vary greatly and, therefore, this interpretation should be tested again in a more detailed research about customer interest in sustainability.

To summarize the first four hypotheses, perceived company sustainability has a larger impact on the decision to continue buying products from that firm than on the willingness to pay a premium for more sustainable products from the same company. This can be due to the fact that people who rate company X as very (un-)sustainable probably will (not) continue buying from that firm. The lack of a significant proof if CP has an impact on PP is a result of the variance in responses. On the one hand, people that have rated the firm as unsustainable and are not willing to pay a PP might not want to support this company at all, while others might give it a chance and pay a PP given that the company starts offering sustainable products. On the other hand, customers giving responses that score higher on CP are probably satisfied with the current situation and would not see the necessity for more sustainability, thus, not willing to pay more. The inconsistency highlights once again that people have very different understandings of sustainability. However, respondents show on average the same interest in sustainability across all groups, therefore, CI does not seem to have an impact on CP–CPu. *H*5 aims at finding out whether gender might also influence CI and, therefore, the link between CP and CPu. The results cannot support this hypothesis. Looking at the answers it is also interesting that in eight cases (33.3%) female respondents show less interest than male respondents, contradicting the study by Morgan Stanley (2015). Therefore, gender can be excluded as a possible influence on CI in this study.

Table 8. Hypothesis Results

Hypothesis	(1)	(2)	(3)	(4)	Tested between groups
H1	Yes	Yes	Yes(marginal)	Yes	
H2	No	No	No	Yes(marginal)	
H3	No	No	No	No	
H4	No	No	No	No	
H5	No	No	No	No	
H6					Yes
H7					Yes
H8					Yes
H9	No	No	No	No	

Lastly, it is tested whether responses to CP significantly differ between the groups depending on the country combination to strengthen the suggested reasons for varying results in *H*1-*H*2. On the one hand, this is implicitly tested due to the four separate groups. On the other hand, respondents were directly asked to assess the countries according to their sustainability. The first part (*H*6-*H*8) receives significant results and, thus, it can be concluded that the countries of the FC and the supplier do influence the consumer perception of the FC on a subliminal level. Especially in the case of low distance to both parties (2), a significant positive impact can be noted. Again, this supports the assumption that consumers trust more or feel more loyal to the FC, the closer its supply chain is (Lii et al., 2013). However, this is not necessarily because consumers think that close countries are more sustainable than distant ones. *H*9 does not find support in this analysis.

Conclusion

Sustainability has been widely discussed in the literature. Consumers increasingly care about sustainability and demand more transparency about the way products have been sourced. This study aims at adding the impact of country sustainability to the common company/customer effect models. Results point out that it actually does matter to the customer where FC and

supplier are located. It highlights that in a supply chain contagion not only can the SC partners affect each other but also the countries of origin can transfer their characteristics on the firms.

Managerial implications can be made for the supply chain as well as the marketing side. When a supply chain scandal occurs, customers would not continue buying from the same company and would feel compelled to raise awareness. Furthermore, they trust and prefer local over foreign products, considering them to be more sustainable. In consideration of the recent debate about reshoring, these findings play an important role. Apart from the closing cost gap between Western and Eastern countries, an important incentive to re-locate is the growing demand for local products. This study suggests that being local and sustainable is closely connected in the consumers' perceptions and they are willing to acknowledge these efforts by paying a higher price. For marketing purposes, the interest in sustainability seems to be lowest when spatial distance is high, so it might be worthwhile to highlight local sustainability measures. Customers' decision to purchase products depends not only on the perceived sustainability but also on the associated countries in the supply chain. A full reshoring of the supply chain and end-to-end sustainability might not be necessary. It is important to keep the core business local to promote trust and identification. Sustainability measures may also have the greatest effect on customer support if they aim at local problems. However, as Lii et al.(2013) already warned, customers need to trust the firm and identify with the cause in order to support it, and to pay a premium. This also leads to specific recommendations for policy makers, as they should carefully identify policies to encourage re- or near-shoring, and support local competitiveness.

This study also has some limitations, leading to specific recommendations for further research. The sample size is one such limitation. Each group consisted of >30 participants but larger samples are more reliable. Further, the majority of respondents are Millennials. This is supported by Morgan Stanley (2015) as they claim that this age group has the greatest interest in sustainability. However, it can also be seen as a bias and, therefore, in the future a greater variety in the respondents' age should be considered. Another limitation is the case. While the pilot test, with and without case, did not show any significant differences between groups, the answers might differ depending on the content of the case. The topic of poultry production was chosen due to the presence in countries close to and distant from the respondents. As public commitment in these areas is quite new, this case might also have led to more emotional answers to the survey. Therefore, it would be interesting to compare reactions to different cases, including larger variety of products (e.g. Clothing: Osibanjo & Nnorom, 2007; Electronics: Freise & Seuring, 2015).

Companies need to reconsider their supplier ties and their sustainability measures to avoid suffering from association by guilt. The perceived sustainability of the country of origin of the FC and its suppliers seem to influence customers' perceptions of the FC itself. While customers tend to perceive countries of low spatial distance as more sustainable, they also expect them to act more sustainably, and show greater interest in local initiatives.

Abstract

Research on value-based approach in purchasing and supply management is scant thus pointing to need for more knowledge in this domain. This paper reports the findings of in-depth dyadic case study regarding the implementation of value-based approach between a manufacturer and their service supplier in outsourced service context. The findings highlight the various challenges that were experienced by the buyer and the service provider as the companies engaged in selling and purchasing engineering services as a value-added service package. The findings contribute to the evolving discussion on value-based approach in purchasing and supply management.

Keywords: Value-based purchasing, service purchasing, dyadic case study

Introduction

The role of purchasing and supply management has become increasingly strategic in improving cost effectiveness, value generation and ultimately, the competitive advantage of a company (Tchokogué, Nollet and Robineau, 2017). A key area where purchasing can contribute to improved performance outcomes and company value creation is service outsourcing (Ellram and Tate, 2015). However, recent research indicates that most of the purchasing decisions in this domain are driven by short-term price savings and cost reductions with less consideration for longer-term effectiveness, innovation or business improvements (Meehan, Menzies and Michaelides, 2017; Ellram, Tate and Billington, 2008). The concept of value-based purchasing refers to collaborative efforts between the buyer and the supplier whereby the intention is to align the supplier's resources, products and services so that they best meet the outcome-based goals of the buyer (Meehan et al., 2017). While previous research on value-based business strategies has almost exclusively focused on selling approaches i.e. the supplier perspective (e.g., Terho, Haas, Eggert and Ulaga, 2012; Keränen and Jalkala, 2014), research on value-based approaches in purchasing is scant and only emerging (Meehan et al., 2017; Pinnington,

Meehan and Scanlon, 2016). Furthermore, despite the notion that the implementation of value-based approach requires intense collaboration between the buyer and the supplier (Hallikas, Immonen, Pynnönen and Mikkonen, 2014) research in dyadic settings is virtually missing. In order to contribute to these observed knowledge gaps, our purpose is to explore the implementation of value-based approach in the context of purchasing professional services from a dyadic perspective. The research question reads: *What challenges relate to selling and purchasing engineering services as value-based service packages?* The findings contribute to the evolving discussion on adopting a value-based approach in purchasing and supply management (Tchokogué et al., 2017; Meehan et al., 2017).

Literature background

Traditionally, sourcing has been regarded as a tactical function, yet today it is acknowledged that purchasing is increasingly strategic that can contribute to overall company competitiveness in various ways (Tchokogué et al., 2017. Inherent to the tactical orientation, the emphasis in purchasing and supply management has traditionally been on cost reduction. Yet, it has been suggested that the mere cost focus is not adequate, but it should be complemented with initiatives that aim at company capability improvement through outsourcing non-core functions and activities (Gottfredsson, Puryear and Phillips, 2005). The importance of resources residing outside company boundaries has thus grown, and companies are increasingly faced with the task of managing their external resources, finding best potential partners, combining internal and external resources together, and utilizing external resources in effective ways (Tanskanen, Ahola, Aminoff, Bragge, Kaipia and Kauppi, 2017).

As the strategic opportunities related to purchasing and managing external resources are becoming increasingly acknowledged, there is a need for taking a more holistic view to purchasing and supply management and related opportunities. “Value-focused supply”, as conceptualized by Monzcka, Blascovich, Parker and Slaight (2011) goes beyond mere cost reduction and competitive bidding strategies by describing an approach that aims to secure current value as well as create new value for a company. Consequently, the approach acknowledges several strategies that the buying company can implement with suppliers in order to increase revenues and manage company tangibles and intangibles in efficient ways (ibid). Yet as noted by the authors, taking a value-focused perspective into purchasing and supply management requires considerable changes from the buying organization. These changes relate to introducing a new philosophy regarding supply, implementing new goals and metrics, taking new supply management approaches into use and establishing new organizational teams, both internal and external (Monzcka et al., 2011). Eltantawy and Giunipero (2014) also address the need for new mindset and philosophy in purchasing and supply management organizations and top management that would enable purchasing to be regarded as an increasingly strategic function that creates value through working with suppliers. According to the authors, the need for a new orientation is accentuated by the fact that the emphasis in many companies has shifted from the exchange of tangibles towards exchanging skills, processes and knowledge as suggested by proponents of the service-dominant logic (SDL) (see Lusch, 2011; Lusch, Vargo and O’brien (2007). The implication to purchasing or more extensively, to supply chain management is that instead of viewing the supplier as mere provider of outputs (as per the traditional goods-oriented logic), the supplier is seen as a provider of inputs or services, that the buyer then integrates with its own activities and processes (Lusch, 2011). The service dominant logic is closely associated with outcome-based supply chain strategies, performance-based logistics and contracts (Wittmann, Nowicki, Pohlen and Randall, 2014) as well as outcome-based contracting (Ng and Nudurupati, 2010).

Based on these views, it appears that adopting a value-based approach into purchasing is becoming increasingly relevant. The concept of value-based purchasing refers to collaborative efforts between the buyer and the supplier whereby the intention is to align the supplier's resources, products and services so that they best meet the outcome-based goals of the buyer (Meehan et al., 2017). Nevertheless, research on the adoption of the value-based approach in purchasing and supply management is scarce, and studies related to this topic are only beginning to emerge (Meehan, Menzies and Michaelides, 2017; Immonen, Hallikas and Pynnönen, 2016; Hallikas, Immonen, Pynnönen and Mikkonen, 2014). Adopting a value perspective to purchasing and supply management may also prove a challenging task in practise. In the domain of professional services for example, the study by Ellram, Tate and Billington, (2008) found that service outsourcing decisions are dominantly driven by short-term price savings, with only sparse consideration for potential quality and process improvements i.e. longer-term opportunities that exist outside the price savings - cost reduction realm. Indeed, compared with the conventional purchasing approaches that centre on price savings and / or cost reduction, the value-based approach requires taking a long-term perspective into the costs and benefits of the purchased product or service over its lifecycle (Meehan et al., 2017). Additionally, the buyer needs to think in broader terms with respect to the purchased services and products and focus on the outcome instead of the input (ibid.; Anderson and Wynstra, 2010). In a recent study, Hallikas et al., (2014) raise the issue of purchasing service bundles in comparison to separate services whereby the former means that the buyer has to justify higher prices with expected time and cost savings that take place in the future. This may prove difficult given that the cost reductions still form the main driver for purchasing professionals (Eltantawy, Giunipero and Fox, 2009).

Value-based selling approaches from the supplier or service provider perspective has received plenty of scholarly attention (see Terho, Haas, Eggert and Ulaga, 2012; Töytäri and Rajala, 2015). Here, the value-based approach can be related to solutions selling whereby solutions are regarded as integrated combinations of products/and or services, which are customized to the buyer's needs and aim to produce desired outcomes and help to solve the customer's problem (Miller, Hope, Eisenstat, Foote and Galbraith 2002; Stremersch, Wuyts and Frambach, 2001). From the solution provider i.e. supplier perspective, the key idea is to pinpoint and identify areas in the customer's i.e. buyer's processes where the solution offering can potentially create value, and where the supplier can help the customer to improve its performance on long-term (Keränen & Jalkala, 2014). Yet as noted by Töllner, Blut and Holzmüller (2011), most of this research has been conducted from the seller i.e. supplier perspective, leaving the buyer or customer side to lesser focus (the authors point Tuli, Kohli and Bharadwaj 2007 as an exception). This is surprising given that the success of the offered solution depends ultimately on the buyer (Töllner et al., 2011). In their review of solutions selling literature, Nordin and Kowalkowski (2010) observe that the driver for purchasing solutions is not always clear, as this can relate to both the need to "getting more benefits for the same money" or simply to total cost reduction. Given the relatively sparse attention to implementation of the value-based approach in purchasing and supply management literature and the emphasis on the supplier perspective in solution selling literature, it appears that enhanced knowledge is needed on the adoption of the value-based approach from both the buyer as well as from the supplier perspectives. This paper aims to contribute to this discussion by studying challenges that relate to selling and purchasing engineering services as value-based service packages.

Research design and method

As the study focuses on complex inter-organisational issues, qualitative and exploratory single case study research design was adopted (Yin, 2009) due to its strength in revealing insights into the individual and organizational activities, perceptions, and decisions. Theoretical and

purposeful sampling logic (Patton, 2015) was used to select the case companies comprising a manufacturing company and their key service provider of engineering services. The empirical context illustrates a case, where the buyer outsourced engineering design services to a service provider, who in turn introduced value-based elements into the relationship with the aim of becoming a value-oriented supply partner that increasingly provides solutions and service packages. The project thus provided a unique context for investigating the implementation of value-based approach on both sides of the dyad. The service provider is a multi-national company that provides industrial engineering services, yet recently the company introduced a new business strategy with emphasis on two issues in particular: gaining growth through their key customers, and selling service solutions. The buyer represents a company operating in processing industry that provides technology solutions as well as services to its customers. Together, the companies share a long-standing business relationship.

The empirical data comprises 15 semi-structured interviews of which seven were conducted with the buyer and eight with the supplier. The length of the interviews ranged from 60 to 120 minutes. Two researchers were involved in data collection that took place between April 2017 and February 2018. Interview data were supplemented with information from the company websites, commercial material, memos and observations from multiple meetings with the companies. By the time of writing this paper, 13 interviews were transcribed by using external transcription service. Data analysis followed open and thematic coding process to identify major factors that influenced individual and organization decisions and perceptions (Miles, Huberman and Saldaña, 2014). The analysis was conducted by using Atlas.TI qualitative data analysis software. Based on the initial categorization, more detailed excel-matrices with main categories, sub-categories and illustrative quotes were crafted.

Findings

Traditionally, the service provider has been providing CV's (pointing to curriculum vitae of individual persons), meaning that emphasis in sales has related to providing individual engineering resources to their customers. In general, this has had both negative as well as positive consequences. On the positive side, providing resources to key customer's projects allows the service provider to work very closely with the key customers and be an inherent part of their daily operations and the customer organization. However, on the negative side, providing resources somewhat limits the service provider's potential to offer and deliver larger entities, such as outsources projects, or full service solutions. Providing resources is based on hourly fee which are negotiated annually by the case companies. The service provider's resources are tied into the customer's projects for up to several months and are thus not available nor transferrable to other projects during this time. The new strategic focus of selling service solutions aims to reduce the emphasis on traditional "CV-exchange" and re-establish the service provider's role as a partner for value creation that manages and delivers outsourced projects on behalf of their customers. "*The business can't be only about selling hours, but we need to have certain areas which we want to develop and these we need to agree upon and decide on together with our customer" (VP, Service provider).*

In the investigated project, the service provider took an active role in promoting themselves as a provider of service packages i.e. provider of larger service entities instead of hours, or individual resources. In the investigated project, the buyer and the supplier agreed on the provision and delivery of a service package at a fixed fee. Compared with the conventional way of purchasing engineering services, which had been dominantly input-based i.e. the buyer purchased a certain amount of hours that were charged by hourly fee, purchasing a service package and agreeing on a fixed fee reimbursement indicates a step towards a value-based approach in the mutual exchange. With regard to the investigated project, the companies shared

understanding that key criteria with respect to the purchased service package comprised quality, in-time delivery and cost efficiency. In selling the service package however, the service provider offered the package at a considerably lower price compared to competitors. This was a deliberate strategy to get the business and to obtain a customer reference in order to establish themselves as a provider of larger service entities. The buyer acknowledged this, and since the buyer was under price-pressure from their end-customer, the offer was chosen.

In the following chapters, the findings concerning challenges related to selling and purchasing engineering services as value-based service packages are reported.

Improving customer cost-efficiency was emphasized strongly by the service provider and used as a key sales argument for the service package. The strategy for improving customer's cost efficiency through a more extensive service package was linked to the service provider's offices in China and the ability to divide work and engineering tasks internally between different locations. For the buyer, this showed as an opportunity to improve their cost efficiency and reduce design-related costs, which they considered as an important value element: "*It's not about the low cost but about the best cost through which value comes into picture. Here, it's is not only the cheapest price that is sought after, but thinking in terms of price and used hours"(Dpt manager, Buyer).* Benefits related to using resources in best-cost-country are in general acknowledged in the buyer organization: *"It is savings that we are after, and this is why I define at the beginning of the year, how large a share (or total engineering hours) should be done in a best-cost-country" (Dpt manager, Buyer).* These benefits are similarly seen in the service provider side, who has been developing work productivity through their Chinese resources. "*Through our best-cost-country operations we can bring (our customers) considerably better cost efficiency compared with performing the work only in Finland" (VP, Service provider).* Yet, the service provider acknowledged a need to truly show and prove the benefit to the customer: *"It is an issue of how many hours are used…that we are able to use less hours compared to what (the customer) thinks"(Dpt manager, Service provider. "We need to be able to show (the customer) how cost efficient we are."(VP, Service provider).*

The potential value through reduction in design costs appeared evident and lucrative for the buyer. Yet, using the supplier's best-cost-country resources for engineering services proved to be a somewhat controversial issue for the buyer. Using Chinese engineering resources was seen to create a risk that related to fears of losing intellectual property and receiving potentially poor quality services. Utilizing BCC was also influenced by an internal mind-set that fed reluctance to purchase engineering service from BCC as noted by Department Manager at the Buyer: "*People are reluctant to purchase (from China) because they fear poor quality or losing our IPRs" The biggest hurdle (to utilizing BCC resources) are in the people's heads. This is largely a mind-set issue, if and how widely we can give (people in BCC) access to our systems where they could search for certain information".* Thus, the buyer acknowledged that a substantial barrier to using Chinese engineering resources was due to internal "mental blocks" that prevented the buyer's personnel from seeing BCC as an equally sound option to the service provider's domestic resources. In addition, the buyer project members were accustomed to working with the supplier resources side-by-side, and breaking this habit was not straightforward. Challenges were also seen related to cultural differences, and the way how tasks were divided into very small entities in the Chinese engineering teams. The buyer felt that that this was not optimal considering the whole project.

In the investigated project, the companies agreed on a certain level of engineering workload that would be conducted by the service provider's BCC resources. Yet, an interesting observation here was the fact that the buyer did not have a clear purchasing strategy for engineering services. In general, the buyer was inclined to make purchasing decisions and

service provider selection on ad-hoc basis. To this regard, the buyer acknowledged that developing strategy for engineering services was highly in need: *"Asking for quotes for service packages is too ad-hoc at the moment, it should be more strategic. It is not clear who takes part, and who decides (on purchasing), we need to make these clearer (internally) (Director, Buyer).* The buyer realized that guidelines related to using BCC for engineering services were also missing. *"I think we need to define how we will purchase (engineering services) (and what share of this) is (conducted in) BCC. We don't have that kind of strategy.* (*Director, Buyer)* Additionally, the service provider recognized that the buyer's IPR strategy was not clear throughout the buyer organization.

Offering capable resources were underlined by the service provider as bringing value to the customer. The service provider ability to provide resources with right kind of capabilities for the specific knowledge domains was emphasized by the buyer, and the service provider paid close attention to fulfilling the buyer's needs in this respect. As the companies had been working together for years, the buyer had gathered in-depth knowledge on service provider personnel and individual skills and capabilities. Thus, the buyer was used to requiring a certain person from the service provider, whom the buyer knew that possessed a certain capability profile to execute a specific task. For the service provider, the idea in selling a service package however largely based on shifting emphasis from individual capabilities to capability on firm level with respect to delivering the agreed service package. *"From our perspective, it can get even too personified, whereby capabilities are related to a certain individual" (Dpt Mgr, Service provider).* With respect to the service package, the service provider was able to assume larger responsibility for resource planning and transferring resources between projects. Yet, as services were packaged to a larger entity, the buyer experienced that they lost visibility into the persons who were actually executing the tasks at hand.

Offering flexibility It was emphasized by the service provider that it was important that the customer could trust the service provider to be a flexible service provider. Perfoming as a flexible partner was seen to link with BCC resources: "*Flexibility comes from the fact that the customer has their own limited resources (for engineering) and considering that the needs differ, they need external service providers. We can provide these resources flexibly and bring cost efficiency by utilizing China"(VP, Service Provider).* Yet, the service provider experienced that being flexible was challenging due to changes at the end-customer: *"We need to be have the kind of collaboration whereby the customer trusts in us to be a global partner and flexible. But when timetables are delayed (at the end customer) this creates challenges (for us) (Director, Service provider).* Related to changes at end customer, the buyer similarly acknowledge that here, the service provider could have conducted more careful with resource planning "*The service provider could have been more understandable in a situation where the end customer was slow. I would have wished that the service provider would have been more careful with manning the tasks. Since when there are delays, the supplier will then tell us that we have idle resource standing here, they have nothing to do, and this will cause extra costs".* (*Engineering manager, Buyer).* Thus the buyer experienced that the service provider was not able to fully meet the expectations concerning flexibility in the investigated project.

Concentrating on core competencies constituted a key benefit that the service provider emphasized in the context of larger service packages. *"When we discuss value and benefits that we can bring to our customer, this is the corenerstone…the more (the customer) can shed their non-core (operations), the more they can reduce their fixed costs, because non-core can be done somewhere else"(VP, Service provider).* Yet, the data suggests that for the buyer, the issue of core-vs non-core and related outsourcing of engineering was not entirely straightforward. Some buyer informants saw risks relating to transfer of excessive knowledge and capabilities to the service provider that could potentially result in narrowing down the

buyer's own capability and knowledge base. To this end, the buyer was keen to preserve critical know-how within company own walls:*"We need to develop partnerships and BCC (share) in engineering. But this needs to be done with caution. So that we can keep our own technology knowledge in-house."(Director, Buyer).* At the same, the buyer wanted to ensure that their dependence on one supplier would not become too substantial. The service provider saw that by discussions with the buyer, they would be able to entice new ideas and thoughts around what could be potentially outsourced. Yet, the VP for engineering at the service provider did not relate outsourcing larger entities with a risk of losing proprietary knowledge in the same way as the buyer.

Introducing new ways of working between the companies related mostly to the habit whereby the supplier resources were situated in the buyer premises, working side-by-side with the buyer engineers during the projects. The continuous physical presence of service provider resources was regarded by the buyer as a comfortable and efficient way of working especially with regard to communicating. The buyer also appreciated the flexibility that this brought with respect to organizing tasks for idle supplier resources. The service provider acknowledged that the buyer appreciated this way of working, yet from their perspective, the set-up was also somewhat challenging. The service provider experienced that the buyer was tempted to think that only certain people at the service provider had the required capabilities. Delivering services in a larger package allowed the service provider to reduce their physical presence at the customer premises and conduct work from their own offices. The new way of working pushed the buyer personnel to renew their habits related to working with the supplier personnel. For the buyer, this was not an entirely positive change, as the buyer experienced this made communicating more difficult: *"Communication (with the service provider) could have been better. It is difficult to have two locations. It goes hand by hand in any case. (We use) e-mail and Skype but it is easier to sit together and explain things"* (*Chief Engineer, Buyer).* The buyer also felt that the new set-up where supplier resources were no longer physically present at the buyer premises increased the need for monitoring. The fact that service provider resources were no longer physically present in the buyer organization as previously also meant that the buyer was no longer able to use idle supplier resources for other internal engineering tasks.

Delivering a service package instead of individual engineering hours created the main difference in the project from the service provider perspective, and this was, according to their new sales strategy the way how they wanted to grow and the direction to where they wanted to develop their service offering in the future. Yet, delivering a service package meant that more emphasis needed to be paid to scoping the project and contracting than traditionally: "*As an appendix to the contract we crafted a table with two columns where it had been defined on detailed level what the buyer delivers to the service provider. And in the other column, what the service provider delivers to the buyer. This was a tool for our planning, and since we had a tight offer, and a tight contract, we also kept very closely to (what was defined) in the columns." (Chief Engineer, Service provider).* Yet, the buyer acknowledged that they would have needed to pay more attention to the contents of the contract and ensure that important terminology was understood in similar way on both sides of the dyad. The companies had agreed on principles related to charging additional work yet personnel in the project team on the buyer side were not informed about the principles. This accentuated the importance of communicating the agreed principles to people involved in the project**.**

Discussion

The findings highlight the various challenges that were experienced by the buyer and the service provider as the companies engaged in selling and purchasing engineering services as a value-added service package. The results suggest that improving customer cost-efficiency,

offering capable resources and flexibility, allowing the customer to concentrate on their core competencies and adopting new ways of working comprised ways of introducing value-adding elements to the relationship, which the service provider attempted to provide by delivering a service package instead of individual hours and resources. To this end, the study points to factors that appeared to hinder adoption of the value-based approach. The service package implied more utilization of the supplier's best-cost-country engineering resources in order to gain full benefit related to cost efficiency, yet this was met with resistance from some of the buyer personnel. The service package also implied less consideration for individual capabilities and skills of individual service provider persons, which had been the norm in the relationship up until the investigated project. So in this sense, the buyer felt that they lost visibility into who was actually conducting the tasks as well as the opportunity to use idle supplier resources for other tasks, which had been used to. The service provider saw one of benefits of a service package relating to the buyer's increased ability to concentrate on their core competencies. Yet, the data suggests that for the buyer, the issue of core-vs non-core and outsourcing of engineering was perhaps not as straightforward, and the buyer saw more potential risk in losing proprietary knowledge than the service provider. Finally, the service package implied that the supplier personnel was no longer working side-by-side with the buyer, yet the buyer's project team appeared to prefer the traditional way of working here the service provider's resources were physically present at the buyer's premises. In fact, working in separate locations was seen to cause difficulties in communicating with the supplier, and increased the need for monitoring that had not been needed previously. These findings contribute to advancing knowledge on implementation of value-based approach in service exchange with respect to factors that may slow down the adoption on both sides of the dyad (e.g. Meehan et al., 2017).

Abstract
The purpose of this study is to analyze the effect of the home country on reshoring processes. Using a sample of 529 cross-industry reshoring initiatives from five countries (i.e., US, Germany, UK, France, Italy), we find that these initiatives significantly differ in terms of industry, entry mode choice, firm size and motivations among the countries analyzed. This study contributes to both reshoring and international business literature by highlighting the influence that the home country platform exerts in manufacturing repatriations. The study provides also significant implications for policy makers at a time when several governments are considering the economic and employment potential of reshoring.

Keywords: Reshoring, Home country effect, Multinational corporations (MNCs)

Paper type: competitive paper

Introduction

For several decades, offshoring – namely, the (re)location of activities from one country to another (Doh et al., 2009) – has been regarded as one of the most important strategies by Multinational corporations (MNCs), particularly in developed nations (Albertoni et al., 2016; Contractor et al., 2010). Although it is still ongoing, a converse trend has occurred referred to as "reshoring", i.e., "a voluntary corporate strategy regarding the home-country's partial or total re-location of (in-sourced or out-sourced) production" (Fratocchi et al., 2014)[1]. The reshoring phenomenon has been labeled with several terms (e.g., "reshoring", "back-reshoring", "backshoring"). In this paper, we adopt the term "reshoring".

According to some scholars (i.e., Tate, 2014), reshoring has been largely driven by industrial polices aimed at "bringing jobs back home". US represents probably the most evident case:

[1] The definition adopted in this study highlights these elements: a) it is a voluntary decision that it is not determined by nationalization and expropriation by host country governments, hence it is part of the firm's strategy; b) it may involve some specific production activities or the entire production of a foreign plant; c) it may concern both out-sourced and in-sourced activities, irrespective of the ownership mode. For a semantic discussion on the term and its different disciplinary origins, see Fratocchi et al. (2014, 2015).

the Obama administration has established the Advanced Manufacturing National Program (AMPSC, 2012) and implemented actions to strengthen the manufacturing sector (The White House, 2014). Assuming that reshoring will contribute to additional 2.5 to 5 million jobs in the US by 2020 (Boston Consulting Group, 2013), the US administration has offered financial and fiscal support to reshoring companies. In UK, the government agency UK Trade & Investment has joined forces with the Manufacturing Advisory Service (MAS) to launch a project titled "Reshore UK", which aims to help companies to bring production back home (GOV.UK, 2014). In Germany, the government has launched the "Industry 4.0" program and has offered financial incentives in order to facilitate reshoring (Stentoft et al., 2016). These evidences alone could suggest that home country matters in reshoring processes. But what does "home" mean? By the term "home country" we mean – according to a specific stream of studies – the firm's headquarters country. It could be argued that the "home" concept loses meaning in a global economy where companies are ready to move their roots to countries other than the country where the company is founded to capture location advantages (e.g., tax benefits). Some authors speak about 'nationless' organizations (Ferner 1997; Ohmae 1990). However, empirical evidence suggests that the aforementioned situation is relatively rare. More than 90% of firms are headquartered in the countries where firms are founded and have original and core operations (Ghemawat, 2007). For most MNCs, the home country is regularly the headquarters country (Mcgahan and Victer, 2010). Empirical evidence also suggests that even the most global MNCs are still deeply rooted in their home country (Hu, 1992; Noorderhaven and Harzing 2003; Ruigrok and Van Tulder 1995).

Scholars in international management fields have shown that culture, resources, national policies, and institutions of both home and host countries (i.e., countries that host their operations) influence the internationalization path of companies (e.g., Cuervo-Cazurra and Genc, 2008; Elango and Pattnaik, 2007; Holburn and Zelner, 2010; Mcgahan and Victer, 2010). Nevertheless, these studies are mainly focused on outgoing internationalization, that is, on the foreign expansion of an enterprise.

Considering the literature specifically focused on reshoring, prior studies have put much emphasis on the motivations (e.g., Gray et al., 2017; Wiesmann et al., 2017) and the "geography" of the reshoring process (e.g., Bailey and De Propris, 2014; Kinkel, 2009; Tate et al., 2014; Uluskan et al., 2016). However, they offer mostly *descriptive* pictures.

To the best of our knowledge, no study has analyzed so far the relationship between home country and reshoring. This relationship has potentially significant implications for re-internationalization strategies of companies and industrial policies of governments. Thus, the research question that inspires this study is the following:

How does the home country affect MNCs' reshoring processes?

Using a sample of 529 manufacturing reshoring initiatives, this study investigates the home country effect on the reshoring processes by comparing initiatives of five countries (i.e., US, Germany, UK, France, Italy).

The remainder of this paper is structured as follows. We first present the literature background. We then describe the methodology (data collection, sample description, data analysis). The main results of the statistical analysis are illustrated and discussed. Finally, we highlight the contribution of the paper and its limitations.

Literature background

The study of how home country affects firm's internationalization has been a mainstream topic in international business for decades (see Cuervo-Cazurra, 2011; Ramamurti, 2012 for reviews). Although prior research mainly focuses on the offshoring activities rather than reshoring, it provides valuable insights into the concept of home country and it shed light on the way in which home country effect manifests (i.e., the main factors that influence MNCs'

internationalization). We therefore frame and summarize this debate in the section *home country effect*, highlighting both its theoretical roots and the main factors/effects.
Besides this literature of international business, another research stream exists rooted in operations management and specifically dedicated to reshoring. Although this literature does not contain any in-depth cross-country study that analytically investigates the link between country and reshoring, it offers some useful insights for our study. The section *reshoring country-specific studies* summarizes this second stream of research.

Home country effect
The literature on the home country effects on firm's internationalization processes mainly draws from three theoretical perspectives: institutional theory, cultural/cognitive perspective, and resource-based view (RBV). The influence of home institutions and culture on firms' operations abroad and on overall performance has in fact been a predominant issue for scholars (Hoskisson et al., 2000; Peng et al., 2008). We summarize these perspectives in Table 1, also highlighting the main country-specific factors related to them.
The ***institutional*** approach argues that firms' strategic decisions, behaviors and performances are all shaped by the institutional context (DiMaggio and Powell, 1983). Institutions typically refer to a wide range of structures and include a vast array of regulative, normative, and cultural/cognitive elements. The ***cultural*** approach emphasizes the influence of home-country cultural values and norms on the management decisions and practices of MNCs (Hofstede, 1980). According to this perspective, individuals' (e.g., managers, executives, employees) behaviors are affected by experiences, values, beliefs, and attitudes that are in turn significantly shaped by their home-country environment. The ***resource-based view (RBV)*** theory considers firm as a bundle of resources, ranging from human and financial assets to managerial and technological skills (Grant, 1991). Under this perspective, the home country can be seen as a significant basin of resources: natural resources, image/made-in effect, and technology. As the reader may note, there is some overlapping among these theories, e.g., cultural aspects are included also in the institutional theory.
Each theoretical perspective, and in particular the institutional, the cultural/cognitive theories and the RBV, therefore identifies a set of factors associated with different forms, paths, modalities and outcomes in the internationalization processes of companies. We can classify these factors into five main groups: geographical (e.g., physical environment), political (e.g., politic risk, corruption), socio-cultural (e.g., values, norms, believes), economical (e.g., market size, economic development), and technological factors (e.g., technology development).

Table 1. Theoretical frameworks explaining home country effect

Theory/Concepts	Key assumptions	Country-specific factors
Institutional theory	Organizations must conform to the rules and beliefs prevailing in the environment. Coercive, mimetic and normative pressures generate institutional isomorphism.	- National business system - Political risk - Government policies - Institutional actors (e.g., state council, bank, ministry of commerce) - Regulations
Cultural/Cognitive perspective	Culture affects individual perception and behaviour, as well as firm-level processes, such as management styles, decision making and conflict resolution.	- Norms - Believes - Values - Imprinting - Risk taking attitude
Resource-based view (RBV)	Firms are bundles of tangible and intangible resources/capabilities (assets, processes, knowledge, and capabilities). To	- Country image - Technological level - Natural resources

	provide sustainable competitive advantage, these resources/capabilities should be valuable, rare, imperfectly imitable, and non-substitutable.	

As far as ***geographical*** factors are concerned, the literature highlights how climate, morphology, position and natural resources of the home country influence the way in which companies build their competitive advantages in foreign markets and address the internationalization processes.

As far as ***socio-cultural*** factors are considered, a large body of literature confirmed that 'cultural distance' has impact on firms' entry mode choice and Foreign Direct Investments (FDI). In this regards, the cultural approach relies heavily on Hofstede's (1980) dimensions. For example, Rothaermel et al. (2006) find that high uncertainty avoidance in a target country lowers the probability of market entry by US internet firms. Barkema and Vermeulen (1997) find that higher differences in uncertainty avoidance between the home and the host country increase the likelihood of a wholly-owned subsidiary over shared equity.

With regard to ***political*** factors, institution theory predicts that the political environment affects firms' internationalization. Scholars have examined an array of factors such as government form, politick risk and corruption. For instance, Brouthers et al. (2008) take a macro look at the effect of corruption on different types of FDI. Feinberg and Gupta (2009) find evidence of the increase of within-firm sales as an operational strategy when a firm faces greater political uncertainty.

Considering ***economical*** factors, authors argued that internationalization processes are significantly affected by the industrial development of the home country as well as by the home market size (e.g., He, 2011). Similarly, the ***technological*** development of the home country has been argued to affect these processes.

The aforementioned home country factors have been argued to affect a wide set of decisions in the internationalization processes, including (1) whether a company internationalize or not (He and Cui, 2012; Yaprak et al., 2017); (2) where does the company internationalize (i.e., host country) (Child and Rodrigues, 2005; Khanna and Palepu, 2010); (3) how does the company internationalize (i.e., entry or governance mode) (Chen et al., 2016; Contractor et al., 2014).

In sum, theories/concepts and factors analyzed above show that home country matters in internationalization processes. However, all these studies and theories are focused on offshoring processes.

Reshoring country-specific studies

Research on reshoring has mainly focused on motivations. In existing literature, scholars have identified a vast array of reshoring motivations such as made-in effect, government incentives, labor costs' gap reduction, energy costs (see Fratocchi, 2014; Di Mauro et al., 2017; Stentoft et al., 2016 for reviews). Although previous studies have pointed out that changes in the characteristics of either the home or host country influence the reshoring decisions (e.g., Ellram et al., 2013), and scholars called for further research on the role of home country in reshoring phenomenon (Tate, 2014), no empirical study investigated the impact of the home country on reshoring initiatives. The only exception is represented by Baraldi et al. (2017) who analyze the impact of the home-country and the host-country networks on reshoring processes. However, the network represents just one specific factor related to the home country and the paper is based on a single case study method.

The comparison of the country-specific reshoring studies could provide us some preliminary insights on the impact of the home country in reshoring processes. We therefore summarize

these studies – which focus on Denmark, Germany, Italy, New Zealand, Spain, US, and UK– in Table 2, highlighting their main findings. The table shows that reshoring companies of different countries have different features in terms of industry, firm size, entry modes, and main reshoring motivations.

In sum, while there is a wide literature on the home country effect on internationalization processes, such effect has not been analyzed so far in the reshoring context.

Table 2. Country-specific studies

Country	Industry involved	Firm size	Entry modes	Main reshoring motivations	Authors
Denmark	/	/	/	Quality, Lead-times, Increased use of automation in Denmark , Recognition of having production close to the Danish R&D department	Arlbjørn and Mikkelsen (2014)

Methodology

Data

In order to analyze of the reshoring phenomenon, we used two databases: the "Uni-CLUB MoRe Back-reshoring" and the "European Monitor on Reshoring." The latter was funded by the European Union Agency Eurofound and is managed by a research team that includes the authors. Secondary data have been used both in international business and in operations management research (Roth et al., 2008; Yang et al., 2006).

Data were collected from 2011 to the end of 2016 through a keyword search in the major international and national business-related newspapers, reports, and magazines, as well as white papers published by relevant consulting firms and public institutions. The keyword search included terms such as: "Back-reshoring", "Backshoring" "Back-shoring", "Inshoring", "In-shoring", "Nearshoring", "Near-reshoring, "Onshoring", "on-shoring", "Production relocation", "Production repatriation", "Relocalisation", "Reshoring".

The unit of analysis was the individual reshoring decision[2]. For each individual case, information was collected on firm size, industry, headquarter location, reshoring motivations, duration of stay abroad, off- and re- shoring countries, entry modes (i.e., out-sourcing vs. in-sourcing), and years. Industries were classified into seven groups based on the Standard Industrial Classification (SIC) codes: clothing, electronics, mechanical, automotive, home appliance, furniture, food and other sectors. Regarding firm size, we classified companies into two categories (i.e., small and medium, and large) based on the number of employees and revenues, following a recommendation of the European Union Commission (2003/361/EC). The information on reshoring entry mode was classified into two groups: in-shoring vs. out-sourcing (see Pan and Tse, 2000). Finally, motivations were coded based on an extensive review of the reshoring literature (see Fratocchi et al., 2016).

Further methodological information concerning the database and the data collection is available on the observatory's website (https://reshoring.eurofound.europa.eu/) and in previous studies (e.g., Ancarani et al. 2015; Fratocchi et al., 2016).

Starting from the 747 reshoring cases recorded in the databases, 70 cases were removed due to missing or unreliable data. A further 148 cases were removed because the number of cases

[2] The single project (single reshoring decision) has been widely used as unit of analysis (UOA) in reshoring studies. MNCs do not necessarily reshore the whole of offshored activities or close a whole plant in host countries. In some instances, they just repatriate part of offshored activities. In addition, many MNCs offshored production activities in various host countries, and it is not always the case that MNCs reshore the entire production activities from all the host countries. Repatriating production activities from two different host countries by the same MNC is considered as two reshoring decisions. Thus, the single project (individual reshoring decision) is used as UOA in our study.

belonging to a specific country was lower than 20, the threshold we used for a minimal country-based characterization. Our final sample includes therefore 529 reshoring cases covering five countries (US, Italy, UK, Germany, and France).

Descriptive statistics of the sample

Table 3 provides the main descriptive data on industry, firm size, reshoring entry mode and motivations for the full sample (N=529) and the five national subsamples (US, Italy, UK, Germany, France).

The data shows that the home countries of reshoring initiatives are almost equally distributed between European Union (45%) and US (55%). If we consider the country (rather than the region), US is at the first position (290 cases) followed by Italy (92 cases), UK (60 cases), Germany (49 cases), and France (30 cases). Most of the cases in the full sample belong to four industries: clothing, electronic, mechanical, and automotive. Significant differences can however be observed among the analyzed countries considering the most frequent sectors: clothing for Italian companies, mechanical for German companies, "other" (mainly chemical products, toys, bio-medical, and sports equipment) for US and French companies. As far as firm size is considered, SMEs and large firms are almost equally distributed for the full sample (233 vs. 296, 44% vs. 56%). However, the share of large firms is significantly higher in the German subsample (89.8%). Regarding the entry mode choice, the data shows that in-sourcing has been adopted by most of reshoring case regardless of the home country. The share of German companies that adopted in-sourcing entry modes is however higher than the one of other companies (i.e., 98% vs. 79.2% on average), thus suggesting that the entry mode choice of reshoring companies may be affected by home country. With regards to the reshoring motivations, we present the most frequent motivations identified (8 out of 26): logistic costs, made-in effect, quality issues, labor costs' gap reduction, delay in delivery, total cost, customer proximity, and government incentives. Again, it is possible to notice some significant differences between countries, among which: (1) the "made in effect" seems to be very important for Italian companies; (2) the labor costs' gap reduction is not much relevant for Italy, Germany and France companies; (3) logistics costs are very important for US companies; and (4) government incentives are mentioned only by US, UK, and France companies.

Table 3. Sample characteristics (N=529)

	Home country												
	All (N=529)		**US (N=290)** (55.0%)		**Italy (N=92)** (17.3%)		**UK (N=60)** (11.3%)		**Germany (N=49)** (9.2%)		**France (N=38)** (7.1%)		**Chi square test[a]**

[(a)] Fisher's exact test (rather than Chi square) was performed for two variables (i.e., total cost and government incentive) as the data was non-normally distributed.

Data analysis

We performed two set of statistical analyses.

First, we compared the reshoring initiatives of the five countries in terms of industry, firm size, reshoring entry mode, and reshoring motivations and tested the significance of these overall differences through Chi square test or Fisher's exact test (when data were non-normally distributed).

Second, to shed light on the peculiarities of each country compared to the others, we performed five binary logistic regression models. Such models have estimated the probability that a reshoring case belong to a particular country rather than to the others based on the industry, the firm size, the reshoring entry modes, and the motivations. The dependent variable (i.e., the home country) was therefore a dummy variable equal to 1 if the case belongs to the considered country and to 0 if it belongs to the other countries. The independent variables were operationalized through dummy variables too: *clothing*, *electronic*, *mechanical*, and *automotive* for industry; *large firms* for firm size, *in-sourcing* for

reshoring entry mode; and *logistic costs, made-in effect, quality issues, labor costs' gap reduction, delay in delivery, total cost, customer proximity, and government incentives* for reshoring motivations. The final resulting logit equations are shown below:

$Y_i = \beta_1 X_{i1} + \beta_2 X_{i2} + \beta_3 X_{i3} + \beta_4 X_{i4} + \varepsilon_i$

(Y_i=home country$_i$, X_1=industry, X_2=firm size, X_3=reshoring entry mode, X_4=reshoring motivations)

Results

The results of the first set of analyses (i.e., Chi square / Fisher's exact tests) are reported in the last column of Table 3. They show that the reshoring initiatives of the five analyzed countries significantly differ in terms of industry, firm size, reshoring entry mode, and reshoring motivations.

To further shed light on the peculiarities of each country, we then performed a set of binary regressions reported in Table 4. The correlation matrix and the analysis of the Variance Inflation Factors (VIF) (all lower than 2) reveal that multi-collinearity was not an issue (Allison, 1977, 2012).

Our analyses show that the ***industry*** distributions of reshoring companies are different between countries, especially for Germany and Italy. While mechanical and automotive reshoring companies are more likely to be German (β=1.231, P<0.01; β=0.960, P<0.05, respectively); clothing and electronic ones are more likely to be Italian (β=1.497, P<0.01; β=0.953, P<0.05, respectively). Similarly, clothing reshoring companies are less likely to be American (β=-1.018, P<0.01), and mechanical reshoring companies are less likely to be French (β=-1.893, P<0.1). For UK companies, the industry variables are not statistically significant.

Considering ***firm size***, we found that large reshoring firms (β=2.131, P<0.01) exhibit a higher propensity to be German, by contrast, reshoring SMEs are more likely to be American or English (β=-.410, P<0.05; β=-622, P<0.1, respectively). For Italian and French companies, the variable firm size is not significant.

As far as reshoring ***entry mode*** is considered, we find that reshoring companies adopting an equity solution (i.e., in-sourcing) are more likely to be German (β=2.535, P<0.01), while reshoring companies adopting non-equity solutions (i.e., out-sourcing) are more likely to be American (β=-.502, P<0.1). The entry mode variable is not significant for the other countries.

Considering ***reshoring motivations***, US companies are motivated strongly by the government incentives (β=1.285, P<0.01), logistic costs (β=.696, P<0.05), labor costs' gap reduction (β=.628, P<0.05), made-in effect in home country (β=.466, P<0.1), and higher production quality in home country (β=.478, P<0.1). By contrast, Italian companies are motivated strongly by made-in effect (β=.807, P<0.01), while they are less likely to be motivated by delay in delivery (β=-2.895, P<0.01), labor costs gap reduction (β=-1.394, P<0.05) and higher production quality in home country (β=-.813, P<0.1). UK companies are motivated strongly by delivery reliability in home country (β=1.162, P<0.01), while they are less likely to be motivated by logistic costs (β=-1.542, P<0.01), made-in effect (β=-1.515, P<0.01), and higher production quality in home country (β=-.718, P<0.1). German companies are motivated by the higher production quality in home country (β=1.238, P<0.01), while they are less likely to be motivated by made in effect (β=-2.327, P<0.05) and total cost (β=1.177, P<0.1). Finally, French companies are less likely to be motivated by higher production quality in home country (β=-1.819, P<0.1) and made in effect (β=-1.819, P<0.1).

$^{*}p < 0.1$, $^{**}p < 0.05$, $^{***}p < 0.01$

Note: Government incentives variable was excluded from the Italy and Germany models since there were no cases pointing out this motivation. Customer proximity variable was also excluded from the Germany model for the same reason.

Discussion

Overall, our empirical results provide strong evidence that reshoring differs significantly in terms of industry, motivations, entry mode, and firm size between the countries analyzed. To the body of studies that reveal that the home country matters in firms' offshoring, this study shows that it also influences the reshoring process. In the following subsections we will discuss the results assuming a country-based perspective, i.e., trying to understand which factors distinguish reshoring in each country.

US

Compared to other countries, the distinctive characteristics of US reshoring processes concern the industry (clothing significant and negative), the firm size (significant and negative), the entry mode (outsourcing prevails), and some motivations (logistic costs, made-in effects, quality issues, labor costs' gap reduction, government incentives). As far as industry is concerned, the US textile and clothing sectors have reduced considerably in recent decades:

the share of these sectors on gross domestic product fell to 0.16% in 2015 from 0.57% in 1998 (Lu, 2017). Unlike other countries such as Italy, US textile and clothing has migrated massively abroad, this way weakening the domestic manufacturing base and making it less able to take productions back.
US reshoring is also characterized by the smaller size of the reshoring enterprises and a greater propensity to outsourcing. These figures may come as a surprise, since US is generally regarded as the country of the large global multinationals. One possible explanation is that in the US, more than in other countries, manufacturing activities are in the hands of small businesses, while large companies privilege other value chain activities. In other words, we can assume that large US manufacturing firms tend to maintain a "smiling curve" pattern in geographical value distribution (see Mudambi, 2008).
Instead, it is not a surprise to see that government incentives and labor and logistic cost motivations distinguish American companies from others. The US Government has provided substantial fiscal incentives and other support to reduce the manufacturing costs in order to attract investments. It is then possible that the renewed energy efficiency, thanks to shale gas, has allowed the reduction of some cost categories.
This finding is consistent with the study conducted by Tate et al. (2014), which show how cost is a significant driver of the reshoring decision. In addition, US companies increasingly realize that quality problems can be serious in some markets, even if they are considered to be a factor that is not fully quantifiable (Gray et al., 2017). Poor production quality in offshoring countries (e.g., China) is another important driver. In line with the national survey conducted by the Consumer Reports National Research Center, 78 percent of Americans would like to buy the product made in the USA rather than abroad (Consumer Report, 2013).

Italy
Italy is in second place after the United States by number of reshoring initiatives. Its reshoring processes are significantly characterized in terms of industry (clothing and electronic) and some motivations (made-in effect). These results should be understood in the light of Italy's manufacturing specialization, where textile/clothing industry and some electronics subsectors represent relevant part of the manufacturing system. In the last few years, these industries have undergone intense relocation processes that in many cases have betrayed the quality, delivery, and even costs expectations. Especially in fashion-sensitive markets, a remote production increases delivery and quality problems. In order to differentiate against the offer coming from low cost countries, many Italian companies have decided a market reposition in segments with higher added value, where the made-in effect is more important. The fashion market has been considerably reactive to first-class products entirely “Made in Italy”, a country that stands for an array of unique and irreplaceable qualities (Vladi, 2016) and that can give a specific value to the made-in factor. It is worth noting that both the clothing and the consumer electronics industries are characterized by dynamic demand patterns, short product life cycles, and high mix and volumes flexibility requirements. These aspects have reasonably favored the re-composition of a manufacturing base closer to the outlet European markets.

Germany
The distinctive characteristics of German reshoring processes concern the industry (mechanical and automotive), the firm size (large), the entry mode (insourcing prevails), and some motivations (quality issues, made-in effects and total cost are both significant and negative). The excellence of the mechanical and automotive industry, and more generally of German engineering, is known worldwide. This country has built a significant competitive advantage in these sectors based on world-class R&D infrastructures, highly skilled

workforce and integrated value chains. Germany continues to heavily invest in innovation and is now one of the pioneering countries in Industry 4.0 technologies. It is also characterized by the originality of industrial relations, where workers and trade union representatives have significant power, particularly in large-sized companies. There are examples of German firms where precisely a shareholder agreement between ownership and workers ("mitbestimmung") has allowed to save or even to increase jobs. The consultation between government, unions and the Federation of German Industries on industrial projects based on innovation and quality has led to significant wage growth in the last years.
Our data are consistent with this country profile. German companies, particularly large ones operating in the leading manufacturing sectors, are focusing on quality and pursuing reshoring paths based on internal governance. Insourcing (equity solutions) can in fact better protect jobs and justify intangible (workers educations) and tangible investments, particularly in high-tech and capital-intensive industries. This evidence is in line with earlier observations by Lewin and Couto (2007) and Hutzschenreuter et al. (2011).

UK
Reshoring in the UK is distinguished by the smaller size of the companies and the dominance of time motivation, while logistics costs and made-in effects are significant motivations but have negative coefficients. Therefore, UK reshoring processes appear to be less characterized than those of US, Germany and Italy. This figure may be the result of two opposing factors. On the one hand, several surveys highlight the need in many British manufacturing sectors to create shorter and more responsive supply chains and easier communication with customers (Moradlou et al., 2016). Actually, UK's manufacturing has undergone relevant changes over the past few decades, ceasing to focus on price and now concentrating on customization and service. On the other hand, UK is one of the western countries that saw a greater reduction in manufacturing, although it currently ranks at ninth position among the largest manufacturing nation. In addition, a large part of the manufacturing industry (such as the automotive) is controlled by foreign investors, who may therefore not consider UK as "home".
It should also be noted that the UK has probably been the most active European country in terms of reshoring policies, but this effort does not seem to be recognized by businesses (the "government incentives" factor is not significant). Finally, it is possible that in the future the depreciation of the pound after "Brexit" may encourage domestic sourcing and greater investment into the UK.

France
Reshoring in France appears significantly different in terms of industry (mechanical, significant but negative) and motivations (made-in effect, quality issue). It is worth to remember that this significance must be understood in comparative terms: it is less likely to find mechanical companies, made-in effect and quality-issues motivations among French reshoring firms compared to companies in other countries. According to the data of this study, France therefore appears to be the least characterized country, an aspect that we are unable to coherently interpret at this stage of the study.

Conclusions and limitations
This study contributes to the literature on home country effect in three significant ways. *First,* this research extends literature on home country effect to reshoring initiatives, demonstrating the home country has strong effects on reshoring practices. *Second,* by comparing the effect of home country on reshoring practices between five countries, we empirically contribute to a

deeper understanding of reshoring phenomena from knowing which factors affect the likelihood of undertaking reshoring strategy in each country. *Third*, this study develops a broadened interpretation of the home country effect by analyzing practices jointly.

This study also offers several implications for both mangers and policy-makers. For mangers, it helps them to make deliberate decisions by carefully evaluating the home country environments and the specialization of business. For policy-makers, it highlights the importance of being aware of the demand of the companies in different industry and making policies which could provide competitive advantages.

We acknowledge some limitations in this study. *First*, our study used secondary data, further research could build on our work and improve the reliability of the data by conducting a survey. *Second,* we did not include contingency factors in our model. To further advance the understanding of home country effect, future research could for instance explore the moderating role of the country from where the company move back production.

Why offshore manufacturing to high-cost countries?

- Evidence from Chinese firms

Abstract

Earlier research has studied offshore manufacturing from high-cost countries to low-cost countries, while recent years have seen the investigation of reshoring, i.e. the reversal of previous offshoring decisions from low-cost countries to high-cost countries. However, few studies have examined offshore manufacturing initialed by firms from low-cost countries to high-cost countries. In this paper, we fill in the gap by studying the motivational factors for Chinese firms to offshore manufacturing to high-cost countries, by analyzing secondary data extracted from newspapers and magazine sources. Additionally, we propose a theory-based classification framework for the analysis of offshore manufacturing from low-cost countries to high-cost countries.

Keywords: Offshore manufacturing, High-cost countries, China

Introduction

Since the emerging of the offshoring phenomenon decades ago, firms from high-cost countries (in this paper, we regard all developed countries as high-cost countries) have been motivated to offshore their manufacturing activities mainly to low-cost countries for sustained competitive advantage (Ferdows, 1997). This phenomenon of offshoring has received very much attention from not only the business world but also academia (cf. Fredriksson and Jonsson, 2009; Jia, Lamming, Sartor, Orzes, and Nassimbeni, 2014; Wang, Singh, Samson and Power. 2011). However, various costs have been drastically rising in some of the former low-cost countries (Kumar, 2009). At the same time, other factors such as trade policies (Ellram, Tate and Petersen, 2013) and government subsidies on repatriations (Livesey, 2012) also come into play. More and more firms from high-cost countries that once offshored their manufacturing to low-cost countries have started to gradually reshore manufacturing activities back to their home countries (Kinkel, 2014; Kinkel, 2012). In academia, this notion of reshoring by reversing earlier offshoring decisions from low-cost countries to high-cost countries also attracted a lot of interest, especially in recent years (cf. Förstl, Kirchoff and Bals, 2016; Zhai, Sun and Zhang, 2016; Gray, Esenduran, Rungtusanatham and Skowronski, 2017; Ketokivi, Turkulainen, Seppälä, Rouvinen and Ali-Yrkkö, 2017). Although numerous earlier studies have examined the motivations of firms from high-cost environments to offshore manufacturing to low-cost countries as well as the relocation of manufacturing from low-cost environments to high-cost countries, few studies have attempted to investigate the motivations of firms from low-cost environments to offshore manufacturing from their home countries to high-cost countries.

This paper aims to fill this gap by investigating the motivations for firms from low-cost environments to offshore manufacturing from their home countries to high-cost environments. Furthermore, it also attempts to understand the home- and host-country specificities of the manufacturing locations. There are two research questions for this study, first, *what are the motivational factors for firms from low-cost environments to offshore manufacturing to high-*

cost environments?, and secondly, *what are the home- and host-country specificities of the manufacturing locations?* By examining these two research questions through the theoretical lens of Dunning's "eclectic paradigm" (Dunning, 1980, 1988, 1998), a theory of international production by multinational enterprises (MNEs), this study contributes to the literature of manufacturing location decision and provides managerial implications for firms from low-cost countries on why they might need to relocate their manufacturing from their home countries to high-cost environments.

In the following sections of this article, a review of literature will be provided first. Then, the research methodology of this paper will be presented. Followed by the demonstration and analysis of data, the research questions of this study will be answered. In the end of this article, the theoretical contributions as well as managerial implications of this research will be discussed. This paper will conclude with the limitations of this research and suggestions for future research avenues.

Literature review

Three streams of literature will be reviewed for this study: 1) Offshoring and its motivations; 2) Reshoring and its motivations; and 3) Eclectic paradigm, which together will form the basis for understanding the motivations of offshore manufacturing for firms from low-cost countries to high-cost countries.

Motivational factors of manufacturing offshoring

Offshoring is defined as being located or operating outside a country's boundaries (Jahns et al., 2006). Since academia started to focus on the concept of offshoring in the early 2000s, a large number of empirical studies have investigated the motivational factors of companies for offshoring manufacturing. Notably, *Cost reasons, opening up new markets, access to foreign distribution channels, access to materials and goods, producing in the proximity of the customer, securing knowledge* as well as *following the investor* are among the most important factors of manufacturing offshoring identified in extant research. (cf. Dunning, 1980, 1988; Hollenstein, 2005; Kinkel, Lay and Maloca, 2007; Kinkel and Maloca, 2009; MacCarthy and Atthirawong, 2003).

Reshoring and its motivations

Reshoring is defined as the relocation of value creation tasks from offshore locations to geographically closer locations such as domestic or nearshore countries (Förstl et al, 2016). Since the notion of reshoring emerges as a hot top in recent years, many studies have examined the motivations of reshoring (cf. Ellram, 2013; Fratocchi, Di Mauro, Barbieri, Nassimbeni and Zanoni, 2014; Gray, Skowronski, Esenduran and Rungtusanatham, 2013). In a research on the motivations for reshoring manufacturing, Fratocchi, Ancarani, Barbieri, Di Mauro, Nassimbeni, Sartor, Vignoli and Zanoni (2016) identified 31 prominent motivations of reshoring by reviewing both scholarly and practitioner studies, which include: *labor costs' gap reduction*; *lack of skilled workers in the host country*; *logistics costs*; *supply chain coordination costs*; *made-in effect*; *energy costs*; *total cost of sourcing*; *exchange rate risk*; *freight costs* and *national subsides for relocation* among others.

Although as many as 31 motivations were identified from different sources in their study, Fratocchi *et al.* (2016) also pointed out that only fewer than three motivations were suggested in 15 of the 33 papers while 11 motivations were found in only one paper. Two motivations, namely *reduction of labor costs between host and home countries* and *poor quality of production abroad* were found to be the most frequently cited motivations of reshoring. Based

on the former studies of reshoring motivations, Fratocchi *et al*. (2016) moved on to examine secondary data extracted from newspapers and magazines and built a database of cross-country and cross-industry reshoring decisions/projects. This laid the foundation for a theory-based interpretative framework for motivations of manufacturing reshoring, which highlights four main typologies of reshoring motivations, namely *customer perceived value*, *cost efficiency*, *internal environment* and *external environment*.

Eclectic paradigm

Many theoretical perspectives including transaction cost economics (TCE) and resource-based view (RBV) have been adopted to explain firms' manufacturing location decisions (Ellram, Tate and Billington, 2008; Williamson, 2008; Canham and Hamilton, 2013). In addition, Dunning (1980; 1988; 1998) suggested three determining variables of foreign direct investment (FDI) by MNEs in his "eclectic paradigm": *ownership advantages*, *location advantages*, and *internalization advantages*. In spite of the original aim to help understand firms' international expansion, this theory has also been employed to explain manufacturing location decision, including offshoring and reshoring (Ellram et al., 2013). In this study, we select Dunning's eclectic paradigm, specifically the *location advantages*, as the theoretical lens to help us categorize and interpret motivational factors derived from our data. As our study focuses on manufacturing location decisions on country-level and we do not consider the make-or-buy aspect, eclectic paradigm's *location advantages* make a suitable tool for our analysis.

In 1998, Dunning modified his eclectic paradigm developed in the 1970s and 1980s, as "firm-specific assets have become mobile across natural boundaries" (Dunning, 1998, p.5). Four updated locational factors were proposed: 1) *Resource seeking*: availability of natural resources, infrastructure, and local partners. 2) *Market seeking*: access to domestic and regional markets, availability and price of skilled labor, availability of related firms (e.g., leading suppliers) and users in knowledge intensive sectors, and host government policies. 3) *Efficiency seeking*: production cost related factors, governments' removal of trade obstacles, and availability of specialized special clusters. 4) *Strategic asset seeking*: price and availability of knowledge-related and "synergistic" assets, and access to different cultures, institutions, systems and consumer demands and preferences.

To sum up, from the above literature, it can be noted that companies from high-cost countries have traditionally left their home countries to relocate manufacturing activities to low-cost host countries, due to cost reasons, opening up new markets and access to foreign distribution channels, materials and goods. Recently, companies from high-cost countries that once moved their manufacturing to low-cost countries are either returning to their home country or relocating to a location that is considered high-cost, due to factors such as customer perceived value, cost efficiency, internal environment and external environment. In this research, the research problem of motivations for firms from low-cost home countries to high-cost host countries are in essence relating to the concept of offshore manufacturing as well as the reshoring notion of moving production from low-cost countries to high-cost environments. After reviewing the motivations for offshoring manufacturing and reshoring, and by means of location advantages from eclectic paradigm, this research attempts to reveal the motivations for firms to offshore manufacturing from low-cost countries to high-cost countries.

Methodology

In this study, we built a data set involving cross-country and cross-industry cases using secondary data extracted from newspaper and magazine sources, a method adopted from Fratocchi *et al*. (2016), to understand Chinese firms' motivations and home- and host-country specificities to offshore manufacturing to high-cost environments.

Secondary data has been adopted in social science, business ethic research and international business research (Judd, Smith and Kidder, 1991; Cowton, 1998; Yang, Wang and Su, 2006), and has become an emerging trend in the operations management field as well (Roth, Schroeder, Huang and Kristal, 2008; Yeung, Lo, Humphreys and Wiengarten, 2016; Fratocchi et al., 2016). The use of secondary data on the one hand allows researchers to "verify and/or extend previous empirical research built on primary data" (Yeung et al., 2016, p.309), on the other hand, it also offers data sources when primary data is difficult to obtain (Cowton, 1998). In our case, the phenomenon of Chinese offshoring manufacturing to high-cost environment is unfolding and ongoing, thus public secondary data is not widely available. In addition, newspaper articles, as a type of secondary data, can provide timely and pertinent research source (Bain, 1994) to assist us capture the essence of these contemporary events in a longitudinal context.

We have created a data set on offshoring manufacturing from China to high-cost countries from 2001 to early 2017. Our data set includes an excel file of cases with company names, industries, host countries and regions, offshoring year, and article sources, another excel file of motivational factors of each case, and a list of searched keywords. Before the data collection, we carried out a pre-testing with twenty sources, to ensure the two researchers have an aligned inclusion and exclusion criteria for cases. Chinese firms' overseas production activities involving joint ventures with local firms, mergers and acquisitions of local firms, and natural resource exploitations were excluded. The agreed criteria was then applied to the entire sample.

We collected the data according to the following steps. First, we searched for newspaper articles adopting offshoring-relating keywords (such as moving production to, start production in, and establishing a factory in, etc.) together with names of developed economies based on UN's most recent country classification (see Table 1) in the CNKI (China National Knowledge Infrastructure) database. UN has categorized developed countries based on their geographic locations, and this categorization will be adopted in this study to analyze the location of the host-countries. CNKI is China's largest and most comprehensive academic online library, which covers more than 600 core full-text Chinese newspapers (CNKI, 2017). Both authors are native Chinese speakers and the working language of the team is English. We have discussed carefully and reached consensus on the translation of each keyword and motivational factor extracted. A keyword table in both Chinese and English language is created to ensure transparency and traceability. We then used internet search engines, namely Google and Baidu, to search for magazine articles as well as company announcements, with the above-mentioned keywords to further check that no relevant information concerning moving manufacturing from China to high-cost environments was missing. Similar to Fratocchi et al. (2016)'s approach, our unit of analysis was the single decision/project move manufacturing from China to high-cost environments. We accounted two cases if a company has moved production from China to two different high-cost host countries.

Table 1. Developed economies (UN Country classification, 2017)

EU Member countries		**Other Europe**	**North America**	**Developed Asia and Pacific**
EU-15	EU-13	Iceland	Canada	Australia
Austria	Bulgaria	Norway	United States	Japan
Belgium	Croatia	Switzerland		New Zealand

Finland	Czech Republic			
France	Estonia			
Germany	Hungary			
Greece	Latvia			
Ireland	Lithuania			

Italy	Malta			
Luxembourg	Poland			
Netherlands	Romania			
Portugal	Slovakia			
Spain	Slovenia			
Sweden				
United Kingdom				

For data analysis, we applied a content-analysis method inspired by Krippendorff (2004). The purpose was to identify the various motivational factors influencing firms' offshoring manufacturing decisions. Motivational factors were inferred from interviews with companies reported in the article, or from reporters' description of the case. As the process of extracting motivational factors from large text pieces and categorizing them is interpretive, to avoid misinterpretation, both researchers reviewed each case and categorized observed motivations independently. Then the results were cross-validated. In case of different results, both researchers reviewed the source article together, discussed carefully, and reached an agreed decision.

Results

The data set consists of 101 cases belonging to 86 unique companies, as 14 companies (over 16 percent of the total) implemented more than one offshore manufacturing operation (from two to four). In summary, a few industries stand out by a higher number of cases, such as clean energy, milk powder, automotive and household appliances. Our data show that the vast majority of the firms that have engaged in offshore manufacturing are private firms, and only a minority of firms are state-owned (20 out of 86). In addition, our data show that almost all of the firms that have offshored manufacturing to high-cost countries are large firms, only a small handful firms are SMEs (3 out of 86). Our data indicate that the most common motivational factors for Chinese firms to offshore manufacturing to high-cost countries are expanding to new market in/from host countries, avoiding trade barriers, availability of technology, skilled labor and raw materials in host countries, as well as the made-in effect. Other factors such as home country consumers' demand, proximity to clients in host countries and host country government incentives also prevail.

Publication year

Figure 1 presents the publication year of the data sources used in our research.

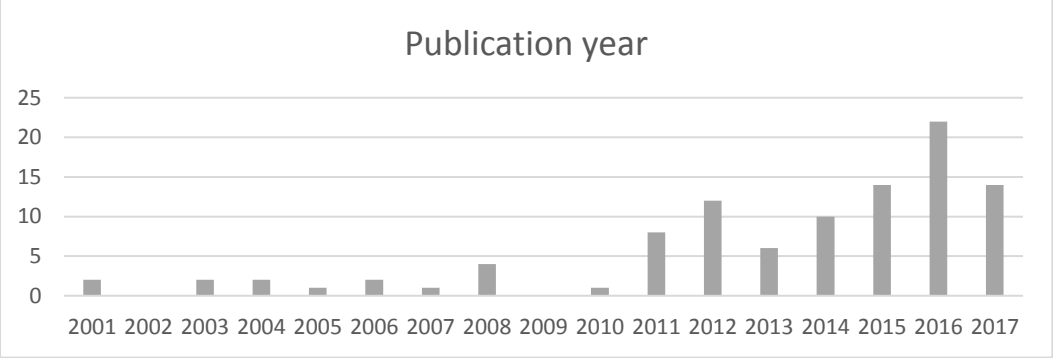

Figure 1. Publication year of the data sources

Our data was retrieved from newspapers and magazines published since 2001. From the figure, we can see a clear increasing trend of more Chinese firms that offshore manufacturing to high-cost countries from 2001 to 2017.

Host countries

Breakdown by host country locations (Figure 2) reveals that EU countries and North America are the two most significant areas represented in our sample (respectively around 46 percent and 43 percent). Other than EU and North America, Developed Asia and Pacific is also featured.

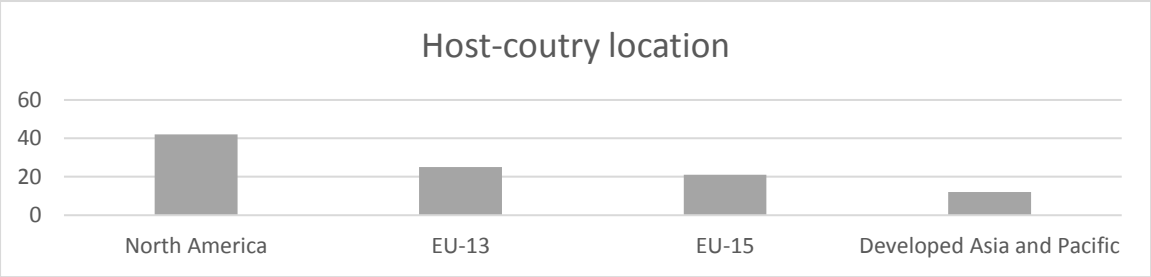

Figure 2. Host countries in which Chinese firms offshore their manufacturing

North America – Industries and motivational factors

Figure 3 presents the industries in which Chinese firms offshore their manufacturing in North America. Figure 4 shows the motivational factors for Chinese firms to offshore their manufacturing to North America.

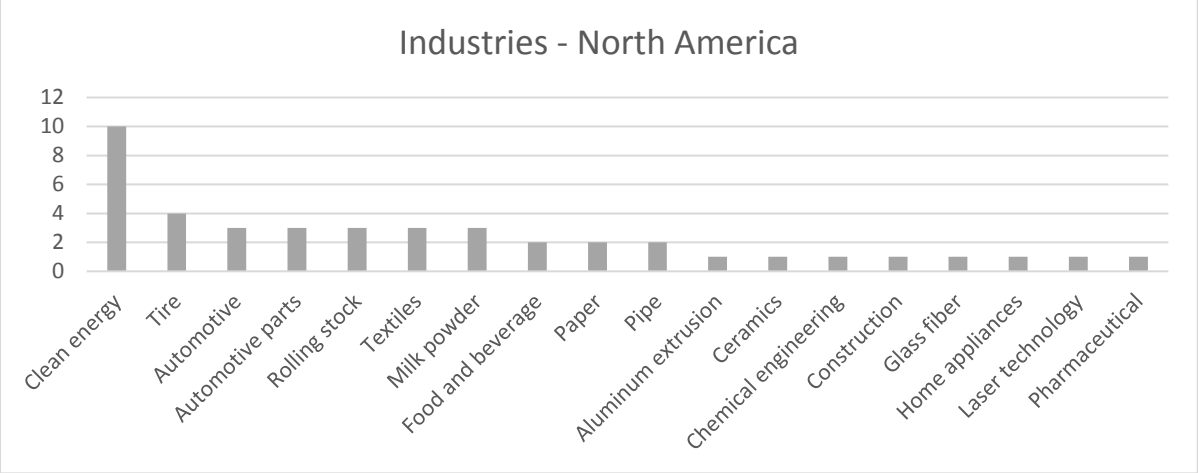

Figure 3. Chinese offshoring firms in North America by industry

The most significant industries in which Chinese firms offshore their manufacturing to North America are: *clean energy* (10), *tire* (4), *automotive* (3), *automotive parts* (3), *rolling stocks* (3), *textiles* (3), and *milk powder* (3).

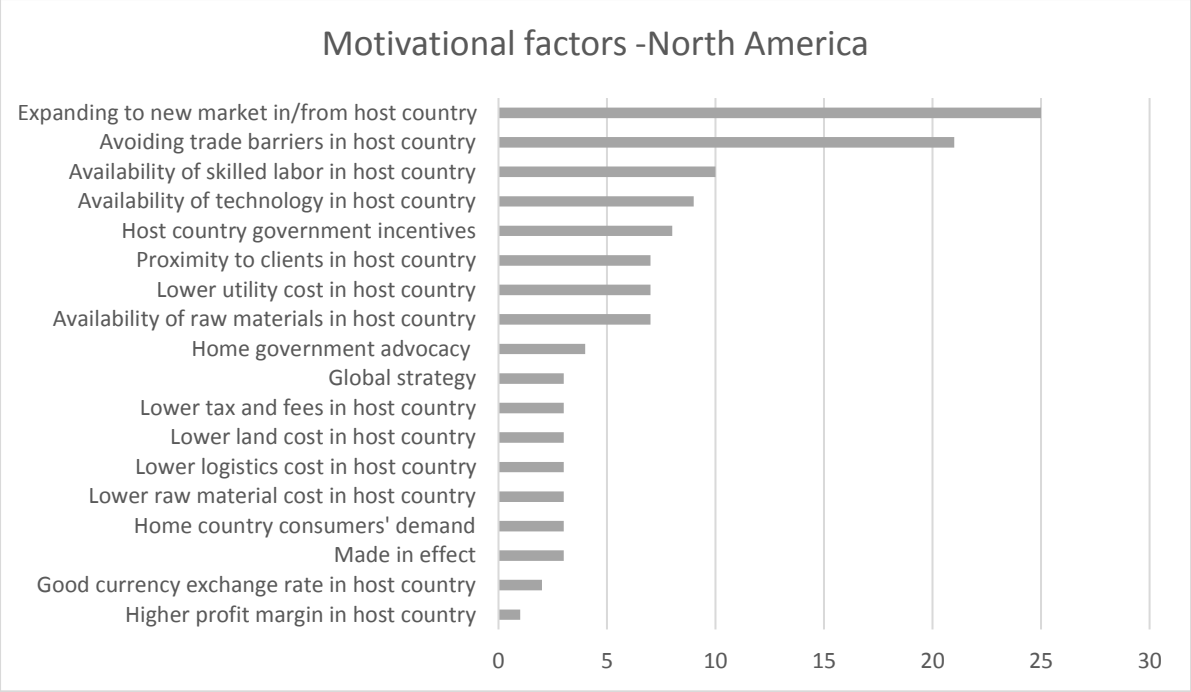

Figure 4. Motivational factors for Chinese firms to offshore manufacturing to North America

The most significant motivational factors for Chinese firms to offshore manufacturing to North America include: *expanding to new market in/from host country* (25), *avoiding trade barriers in host country* (21), *availability of skilled labor in host country* (9), *host country government incentives* (8), *availability of technology in host country* (8), *lower utility cost in host country* (7), and *proximity to clients in host country* (7).

EU-15 – Industries and motivational factors

Figure 5 presents the industries in which Chinese firms offshore their manufacturing to EU-15. Figure 6 shows the motivational factors for Chinese firms to offshore their manufacturing to EU-15.

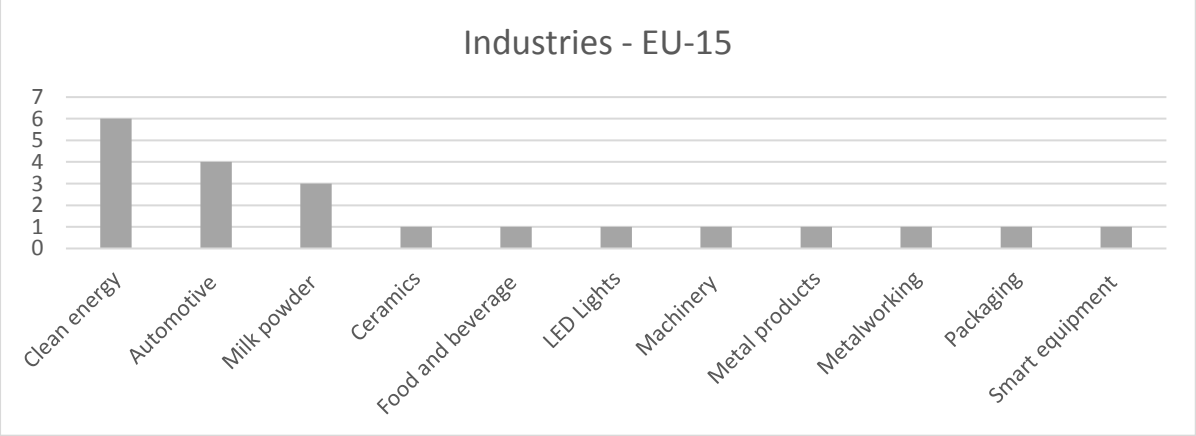

Figure 5. Chinese offshoring firms in EU-15 countries by industry

Within the EU-15 countries, the most important industries Chinese firms offshore manufacturing to include *clean energy* (6), *automotive* (4), and *milk powder* (3).

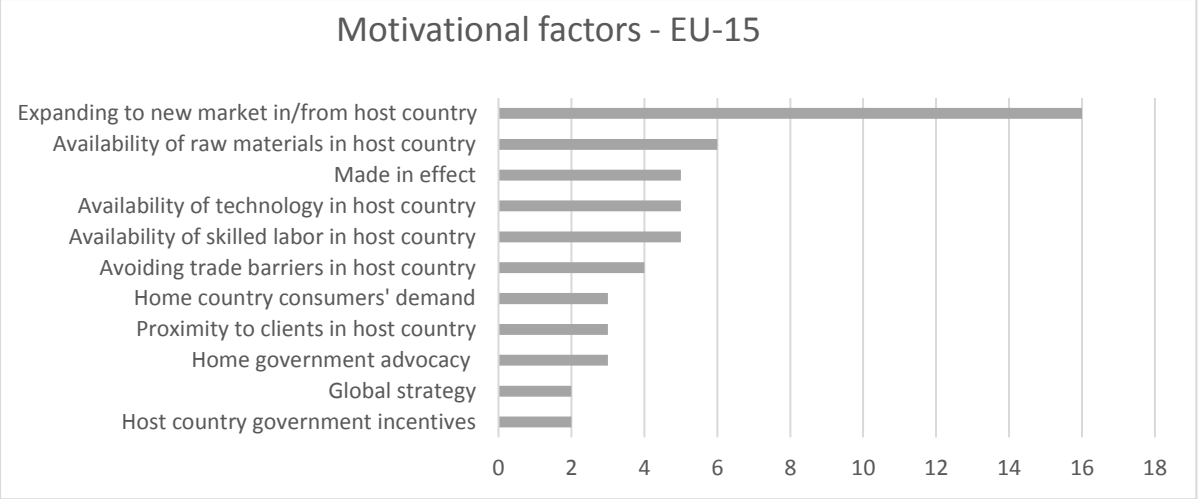

Figure 6. Motivational factors for Chinese firms to offshore manufacturing to EU-15

Motivational factors of *expanding to new market in/from host country* (16), *availability of raw materials in host country* (6), *availability of technology in host country* (5), *availability of skilled labor in host country* (5), and *made-in effect* (5) are the most occurring for EU-15 countries.

EU-13 – Industries and motivational factors

Figure 7 presents the industries in which Chinese firms offshore their manufacturing to EU-13. Figure 8 shows the motivational factors for Chinese firms to offshore their manufacturing to EU-13.

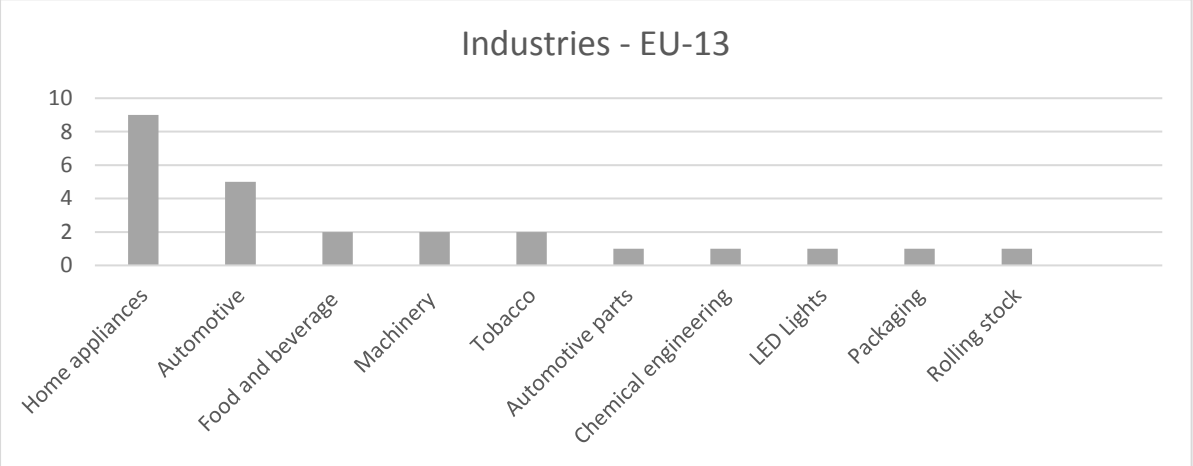

Figure 7. Chinese offshoring firms in EU-13 countries by industry

The industries of *home appliances* (9), *automotive* (5), *food and beverages* (2), *machinery* (2) *and tobacco* (2) are among the most popular for Chinese firms that offshore their manufacturing.

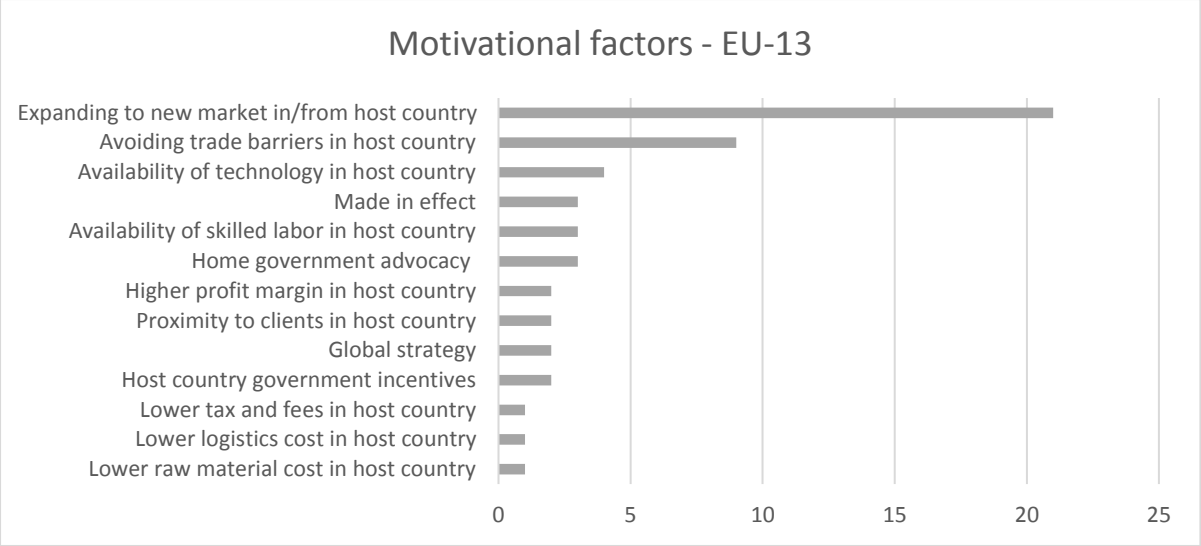

Figure 8. Motivational factors for Chinese firms to offshore manufacturing to EU-13

For the EU-13 countries, Chinese firms are motivated most by the following factors: *expanding to new market in/from host country* (21), *avoiding trade barriers in host country* (9) and *availability of technology in host country* (4).

Developed Asia and Pacific – Industries and motivational factors

Figure 9 presents the industries in which Chinese firms offshore their manufacturing in Developed Asia and Pacific. Figure 10 shows the motivational factors for Chinese firms to offshore their manufacturing to Developed Asia and Pacific.

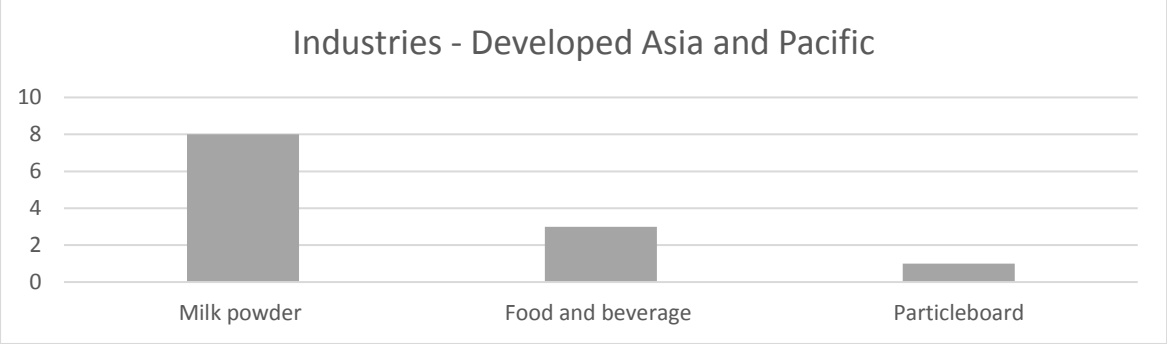

Figure 9. Chinese offshoring firms in Developed Asia and Pacific countries by industry

Chinese firms offshore their manufacturing to Developed Asia and Pacific countries are within the following three industries: *milk powder* (8), *food and beverage* (3), and *particleboard* (1).

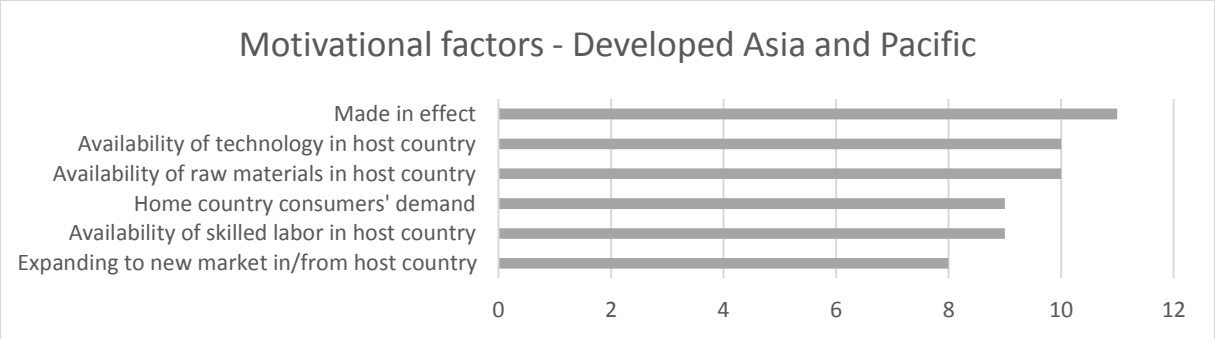

Figure 10. Motivational factors for Chinese firms to offshore manufacturing to Developed Asia and Pacific

Offshoring manufacturing to Developed Asia and Pacific countries by Chinese firms are motivated especially by the following factors: *made-in effect* (11), *availability of raw materials in host country* (10), and *availability of technology in host country* (10).

An interpretive classification framework for offshore manufacturing from low-cost countries to high-cost countries

An interpretive theory-based classification framework is depicted in Table 2. Since eclectic theory's location advantages mainly concern host country-specific advantages, we incorporate also home country aspect in our framework to better explain the motivational factors resulted from our study.

Table 2. An interpretive theory-based classification framework

Motivational factors	
Home country	• Home government advocacy (10) • Home country consumers' demand (14) • Lack of domestic need (2) • Appreciation of RMB (2)
Host country	Resource seeking advantage: • Availability of raw materials (22) Market seeking advantage: • Expand to new market (70) • Proximity to customers (12) Efficiency seeking advantage: • Host country government incentives (12) • Avoid trade barriers (34) • Lower utility cost (7) • Lower raw material cost (4) • Lower land cost (3) • Lower tax and fees (4) • Lower international transportation cost (4) • Higher profit margin (3) Strategic asset seeking advantage: • Availability of technology (27) • Availability of skilled labor (26) • Made-in effect (21)

Discussion

From the data and interpretive framework provided above, it is evident that the motivational factors for Chinese firms to offshore manufacturing to high-cost countries are dynamic, and those factors vary across different locations. Underpinned by the eclectic theory, we developed the interpretive theory-based classification framework above to categorize and interpret the motivational factors identified in our study. By comparing our study results to the eclectic theory, we identified characteristics and patterns of Chinese manufacturing offshoring decisions. This study contributes to manufacturing location decision, manufacturing offshoring, and reshoring literature by better understanding a novel and contemporary phenomenon—manufacturing offshoring from low-cost country to high-cost countries. Below, we will discuss in detail the implications of this study from both theoretical and practical perspectives.

Home-country specific motivational factors: home country advocacy and incentives

While Dunning's eclectic theory focuses on host country-specific advantages, our study results indicate the important role that home country, especially the government, plays in Chinese firms' manufacturing offshoring location decisions. Home country managers should follow closely the trend and changes of government policies.

Economic reform and government policies have historically had fundamental impact on Chinese state-owned enterprises (SOEs) (Girma, Gong and Görg, 2009). One unique feature of Chinese offshoring is the government's role in motivating firms to manufacture abroad, and the influence is especially evident with SOEs. Ten cases in our study, all from SOEs, indicate the importance of the "Belt and Road Initiative" (一带一路) and "Go Global" strategy (走出去) in facilitating their manufacturing location decisions. The Silk Road Economic Belt and the 21st-Century Maritime Silk Road, better known as the Belt and Road Initiative, was proposed in 2013 by Chinese central government, aiming at promoting economic prosperity and fostering cooperation among pan-Eurasian countries (Belt and Road Portal, 2017). Implemented in 2001, "Go Global" strategy acts as a proactive part of China's new opening-up strategy (The State Council of the People's Republic of China, 2017). Although government initiative is not a novel factor in manufacturing location studies, Mann (2012) for instance emphasizes governments' contribution to improve a country's competitiveness and attractiveness, government that encourages firms to engage in manufacturing activities beyond home country's border is rather new to manufacturing location literature. This can be partially seen from Chinese outward FDI, which showed an upward trend since China's opening-up reform in the 1980s, reaching the historical highest point at USD 183,100 million in 2016 (UNCTAD, 2017). The Chinese phenomenon echoes Dunning (1998)'s statement that "the renaissance of the market economy, and the consequential changes in the macroeconomic policies and macro-organizational (micro-management) strategies of many national governments" have had a profound effect on the geography of MNEs.

Host-country specific motivational factors: host country government incentives

On the other hand, our results (12 cases) suggest that host governments' incentives have also influenced Chinese firms' foreign investment decisions, which is similar as the reshoring motivation of national subsides for relocation (Tate, 2014). These incentives include tax reduction, subsidies, and supportive policies. From host governments' perspective, Chinese investments will create employment opportunities and assist local economic growth.

"This new factory brings opportunities…I expect that the business will do well, and bring more fortune and employment to Spain." (Spanish local official, Xinhua News, 2015)

Cost factors

Cost factors have been a main concern for both offshoring and reshoring decisions (Kinkel and Maloca, 2009; Tate, Ellram, Schoenherr and Petersen, 2014). In eclectic theory, cost-related factors represent the most significant influence on location decisions (Dunning, 1980). The overall logic is that companies from developed economies move production to developing countries where costs are lower, and manufacturing investments from developing countries go to other developing countries with even lower costs (Dunning, 1998). China, as a developing economy, has been traditionally perceived as destination of low-cost production (Fang, Gunterberg and Larsson, 2010). To our surprise, a great number of our cases suggest that manufacturing in particular developed countries such as the USA can actually help firms reduce costs. This perhaps echoes the findings of high total cost of sourcing and labor costs' gap reduction as motivations for reshoring (Power, 2011; Canham and Hamilton, 2013; Kinkel, 2014; Tate et al., 2014). These reduced costs for Chinese firms might come from raw material

cost, land cost, utility cost, tax and fees, and international transportation costs. Despite the relatively higher labor cost, Chinese firms are convinced that the accumulated cost savings from other categories would exceed the extra labor cost.

"The land is basically free, energy costs are much lower than in China, electricity price is half, and natural gas is one fifth that of China. In general, our profit in the US will be over 10% higher." (Automotive glass firm, 2016)

"Even though the labor cost is high in the US, just the raw material cotton alone, we can save RMB 7,5 hundred million (around USD one hundred million). Plus the electricity cost is less than half that of China." (Textile firm, 2013)

Expand/access to market and made-in effect

Similar as offshoring manufacturing from high-cost home countries to low-cost host countries, a major motivation for Chinese firms to offshore manufacturing to high-cost countries is expanding to new market (Dunning, 1991). However, a difference can be noted: some firms are offshoring manufacturing to a certain high-cost country not only to expand to this country, but also to other countries in the same region. For instance, many Chinese firms have offshored their manufacturing activities to relatively low-cost European countries, such as Poland (9 out of 46 EU cases) and Hungary (6 out of 46 EU cases), with the hope to gain access to the whole EU market.

"Although Bulgaria is one of the poorest countries in EU, its low-cost and geographic advantage could help Chinese firms go to European market, as it is a member of EU….We will sell in Bulgaria first, then expand to its neighboring countries such as Macedonia, and gradually to Germany." (Automotive firm, 2013).

Another relating motivation for firms from low-cost countries to offshore manufacturing to high-cost countries is because of the "made-in effect", which is similar to the motivation for some firms to reshore from low-cost countries to high-cost countries (e.g. Martínez-Mora and Merino, 2014). A noticeable example is in the Chinese milk powder industry: an estimated 300,000 babies in China got sick from contaminated domestic milk powder, and further kidney damage led to six fatalities (Jacobs, 2008). Not only did the incident damage the reputation of China's food exports, it also dealt a devastating blow to the booming Chinese dairy industry, resulting in a series of mergers and consolidations and making the 2008 incident one of the largest food safety scandals in PRC history (Huang, 2014). Chinese consumers have lost confidence in the Chinese domestic milk powder industry, and to offshore manufacturing from China to countries that consumers regard as "reliable milk producing countries", such as Australia and New Zealand (Luo, 2011), Chinese firms in the dairy industry could regain their consumers in their domestic market.

"Since 2008, Chinese consumers have lacked confidence in domestic milk powder brands, while at the same time; they blindly trust milk powder products from abroad." (Dairy firm A, 2017)

On the other hand, consumers from other countries might also prefer products manufactured in developed countries than made-in-china products, as made-in-china products are often perceived as having poor quality (The Economist, 2009). Due to this reason, some Chinese firms are offshoring manufacturing to high-cost countries to eliminate the "made-in-china" effect, so as to also attract consumers from other countries.

"With milk source and technology from New Zealand, not only can we expand our market in China, but also we can enter the international market, and lay a foundation for our strategy in Southeastern Asia and the Middle East." (Dairy firm B, 2016)

Avoiding trade barriers

Many developed countries have imposed anti-dumping and anti-subsidy duties on certain products imported from China (Brown, 2010), in order to avoid such trade barriers, Chinese firms in certain industries, such as solar photovoltaic, tires and home appliances, are motived to offshore their manufacturing activities to countries that are not affected by such duties.

"[To avoid trade barriers] our production capacity in China needs to be transferred somewhere else, so we started a factory in Chicago in 2010, and that is our solution to anti-dumping and anti-subsidy duties imposed by US." (Solar photovoltaic firm, 2014)

Availability of skilled labor, technology and raw material

Similar as offshoring manufacturing from high-cost countries to low-cost countries, availability of skilled labor, technology and raw materials (Dunning, 1991; Lewin, Massini and Peeters, 2009) is an important factor for Chinese firms to offshore manufacturing to high-cost countries.

"Not only is US one of the biggest producing and consuming countries for glass fiber, but also US is the biggest overseas market for us. At the same time, US has the highest industrialization level of glass fiber, the biggest market, and abundant talent pools. In addition, US also has abundant and excellent energy resources and mineral resources." (Glass fiber firm, 2016)

Other remark: failure and bankruptcy

Despite the many benefits that motivate Chinese firms to go abroad, risks coexist with opportunities. During the follow-up searches, we noticed that out of the 101 cases, five cases from four different firms ended up with bankruptcy. These unsuccessful cases include two clean energy firms that moved production to the USA and Italy, one canned food manufacturer in Czech Republic, and one automotive manufacturer in Bulgaria. Reasons for the bankruptcies are multi-faceted. Solar panel manufacturer firms declared bankruptcy partially due to the declining prices for solar products globally resulting from overcapacity and high tariff for components imported from China. The canned food manufacturer started production in Czech Republic because the brand was known among Eastern European consumers in the 1970s, but it could not challenge local competitors' market position when commercial products are much more available today. The automotive firm were not able to produce cars with quality that meets the EU standards, and the price was not competitive enough. In general, host government policies towards FDI in certain industries, lack of knowledge of host market, and insufficient quality are the major causes for the failure of Chinese manufacturing in high-cost countries. Managers should be aware of the potential risks and conduct comprehensive market analysis before engaging in offshoring activities.

Conclusion

In this research, we made an attempt to understand the motivations for firms from low-cost countries to offshore manufacturing to high-cost countries by analyzing 101 cases extracted from newspaper and magazine sources. Based on the data set, we built a classification framework derived from eclectic paradigm. This paper contributes to the literature streams of offshoring and manufacturing location decision, and it provides managerial implications for firms from low-cost countries on why they might need to offshore manufacturing to high-cost

countries. However, this research is not without limitations: first, we only studied Chinese firms' motivation to offshore manufacturing to high-cost countries, as our data did not include firms from other low-cost countries. Secondly, our data comes from newspaper and magazine sources, while media coverage might have a preference on certain types of firms, e.g. well-known large firms, and certain host countries, e.g. USA. Future studies investigating firms from low-cost countries' offshoring to high-cost countries could involve first-hand data from sources such as surveys and interviews, and examine why some of the firms' offshoring succeeded while some others failed. Additionally, future research could attempt to identify and analyze the different types and strategic roles of foreign factories (Ferdows, 1997) that Chinese firms have established in high-cost countries. Finally yet importantly, longitudinal studies following the trend and shift of the phenomenon could be helpful.

Summary

For purchasing managers it is difficult to assess the individual of purchasing professionals' contribution working in buying centers to the overall department's performance. As literature mainly focuses on purchasing department's performance this work-in-progress paper aims to present a basic research model focusing on the purchasing professional individual performance. The data to test the presented basic research model applying reliability as well as factor analysis stem from 82 responses obtained from an online survey sent personalized to purchasing professionals of firms in Austria. The results validate the proposed model and may help to support the purchasing department's management control system.

Keywords: Purchasing Professionals, Performance, Measurement

Submission Category: Working paper

Introduction

The high potential of the purchasing function to increase efficiency and effectiveness of firms and thus to pursue important business objectives and form sustainable buyer-supplier relationships is widely reported in literature (Cousins, 2002; Eßig et al. 2013). In practice, both the buyer-supplier relationship management as well as the purchasing success itself are determined by buying centers integrated in purchasing departments and thus by each individual purchasing professional. However, management control systems for purchasing departments and subsequently for purchasing professional individuals have been neglected both in theory and practice (Hofmann et al., 2012; Lardenoije et al. 2005). Therefore, this work-in-progress paper aims at the conceptualization and initial validation of a basic research model by answering the following guiding research question: *Which factors describe the individual performance of purchasing professionals?* To answer this question a short overview on the theoretical background as well as the relevant literature is provided in the next section. Based on this, seven factors which may facilitate the description of the purchasing professionals' individual performance are identified and put together in a basic research model incorporating four operational and three strategic factors. In a further step the research design including the measures applied for developing our key construct – the purchasing professionals' individual performance, the survey instrument and the sampling process – are presented. The results section states the findings obtained from the data analysis and, consequently, the test of the introduced basic research model. The concluding section outlines and discusses the findings, refers to limitations of this study and carves out directions for future research.

Theoretical Background

In practice purchasing performance is accepted as an important determinant of a firm's competitive advantage. Research has already shown that the efficiency and effectiveness of purchasing departments (Bals and Turkulainen, 2017) depend on the education, motivation, skills, experience of their purchasing professionals, the incentive systems in firms as well as the dynamics between members of buying centers (Nollet et al., 2017; Price and Harrison, 2009; Walker et al., 2012). The motivation of each individual purchaser helps organizations to survive and prosper (Frey and Jegen, 2001) and to develop in a sustainable way (Busse, 2016; Knight et al., 2017; Mogre et al., 2017; Patala et al., 2016; Rahman and Islam, 2017). In order to increase the individual's motivation it is necessary to build systems that enable purchasing managers to control the purchasing departments and the purchasing professionals' individual performance. However, there is lack of measurability of individuals purchasing success, which makes it difficult for purchasing managers to implement a performance-based system in purchasing departments (Jääskeläinen and Thitz, 2018; van Weele, 1984). According to Pagell et al. (1996), this is due to the difficult and manifold measurement models (Lima-Junior and Carpinetti, 2017) of the factors describing the performance of purchasing professionals. To solve this problem, specific factors (key performance indicators) that are both (i) easy to communicate to employees and (ii) measurable have to be (1) identified (Table 1) and (2) operationalized (Table 2). The basic research model displayed in Table 1 incorporates seven factors (divided into four operational and three strategic factors). These factors were derived from empirical research driven literature. Accordingly, Giunipero (1990) suggests measuring the effectiveness of the purchasing function on the basis of its ability to manage delivery, suppliers' quality as well as lead time and the ability to control the total acquisition cost. Chao et al. (1993) apply ten measures (quality, on-time delivery, commodity knowledge, accuracy, professionalism, negotiating ability, Purchase-Order cycle time, target cost, cultivate supplier, teaming). Shin et al. (2000) deploy five measures to model buyer performance (product performance, product features, product reliability, product conformance, product durability). Krause et al. (2001) use cost, quality and delivery measures to operationalize purchasing performance. Wen-li et al. (2003) propose supplier performance improvement and supplier's contribution to a buying firm's competitive advantage as two dimensions of purchasing performance of a buying firm. Terpend et al. (2011) regard purchasing performance as a composite of innovation performance, quality, cost, delivery, flexibility and purchasing efficiency. Caniato et al. (2012) use six categories (cost, time, quality, flexibility, innovation, sustainability) to measure purchasing performance. In this context, the findings of Hüttinger et al. (2012) make it reasonable to add the supplier satisfaction construct to the conceptualization of the purchasing professionals' individual performance measure. Foerstl et al. (2013) define the performance of the purchasing and supply management function in terms of price savings, total cost, quality, lead times and contribution to purchased items. Nair et al. (2015) present a five-part multi-perspective research model consisting of operational and strategic measures (cost, quality, delivery and flexibility, performance, innovation). Based on this and by adding strategic and operational management perspective (Gälweiler and Malik, 2005), Table 1 displays the final selection of factors (constructs) which should enable the description of the purchasing professionals' individual performance.

Table 1: Basic Research Model

		Factors (Constructs) Describing the Purchasing Professionals Performance
Purchasing Professionals Individuals Performance	Operational	Cost Optimization
		Quality Improvement
		Delivery System Support
		Process Flexibility
	Strategic	Innovation Orientation
		Supplier Satisfaction Contribution
		Purchasing and Supply Management (PSM) Integration

Research Design

Sampling

To test the basic research model describing the purchasing professionals' individual performance, data were collected from a large-scale on-line survey. For this purpose an online questionnaire was designed and sent out to purchasing professionals. For the online survey the sample frame was drawn of the "Federation of Materials Management, Purchasing and Logistics in Austria" (BMÖ) which represents a total population of about 1,600 purchasing professionals among all industries in Austria. Following the guidelines of Bethlehem (2010) and Sax et al. (2003), the final instrument was sent via e-mail to all of the approximately 1,600 purchasing professionals of the BMÖ member list. About 950 e-mail addresses were not valid which resulted in a reduction of the sample to 650 potential participants. The mailing package consisted of a cover letter and a link to the questionnaire in LimeSurvey. A first e-mail reminder addressed the 650 valid e-mail addresses of the BMÖ members after two weeks and a second reminder was sent after four weeks. Participating respondents were offered a summary report as an incentive. This resulted in a total of 82 responses, excluding returns, refusals and unusable responses. It represents a response rate of 12.62%. Only complete responses were included in the data analysis. The data collected was used to analyze the basic research model applying a confirmatory factor analysis as well as a reliability analysis. The profile of the sample is structured as follows: 81.71% of the study participants are male and 18.29% female. 67.07% are aged between 30 and 49. 57.32% of the responding persons have a third level education (PhD, MBA, bachelor degree, college education) while 86.59% have already continuous work experience of more than 5 years in the field of purchasing. 31.71% of the respondents are engaged in operational purchasing functions, 20.73% of the responding purchasers play a role as members of staff in strategic purchasing functions and 47.56 % of the respondents hold a management position (senior manager, purchasing manager, chief buyer, executive director, buying director). The purchasing volume participating purchasers are responsible for is averaging 50 Mio. EURO and can be broken down as follows: 9.76% investment goods, 9.76% services, 15.85% mass products, 26.82% serial products, 29.72% individual products (project purchasing) and 8.54% others. No significant differences could be found in the responses when controlling for gender, age, education, firm size, work experience or hierarchical levels in purchasing departments.

Instrument Development and Measures

The constructs as well as item measures for the purchasing professionals' individual performance were adopted from purchasing and operations management literature (Table 2) and built from existing scales and conceptual works (Table 2). Item scales were graded on a 7-

point Likert-scale (1= strongly agree, 7= strongly disagree). Preliminary to the online survey, a pre-test was developed and pilot-tested among four senior-level purchasing and three junior-level managers as well as four academics in the field of purchasing and supply management. Feedback was also obtained for other aspects such as completion time, instrument lengths and format. The received feedback was used to drop or add individual items and a final instrument was developed for large sample administration.

Table 2: Operationalization of the Factors (Constructs)

	Factors (Constructs)	Items	Referring to
Operational	**Cost Optimization**	Purchasing performance in reducing cost of inputs.	(Nair et al. 2015)
		Purchasing performance in reducing cost of purchasing activities.	
		Purchasing performance in exploiting the ability and willingness of the supplier to share data cost.	(Terpend et al. 2011)
	Quality Improvement	Purchasing performance in improving the quality of inputs.	(Nair et al. 2015)
		Purchasing performance in improving the quality of outgoing products.	
		Purchasing performance in increasing standardization of inputs.	
	Delivery System Support	Purchasing performance in reducing the procurement cycle time.	(Nair et al. 2015)
		Purchasing performance in improving the on-time deliveries.	
		Purchasing performance in increasing inventory turns.	
		Purchasing performance in increasing percentage of Just-In-Time suppliers.	
	Process Flexibility	Purchasing performance in responding quickly to design changes.	(Nair et al. 2015)
		Purchasing performance in responding quickly to requirements arising out of changes in production volumes or schedules.	
		Purchasing performance in responding quickly to the integration of new suppliers in the purchasing process.	* added by Authors
Strategic	**Innovation Orientation**	Purchasing performance in gaining access to new technologies.	(Nair et al. 2015)
		Purchasing performance in participating in product development project/efforts.	
		Purchasing performance in exploiting the ability of suppliers to design new products or make changes in existing items.	(Terpend et al. 2011)
	Supplier Satisfaction Contribution	Purchasing performance in technical excellence by involving suppliers early in the value creation process of the own company.	(Hüttinger et al. 2012)
		Purchasing performance in investing in supplier value and having long-term time horizons.	
		Purchasing performance in finding the adequate mode of interaction (communication).	
		Purchasing performance in operational excellence in forecasting and planning.	
	Purchasing and Supply Management (PSM) Integration	Purchasing performance in an active contribution of PSM to supply base knowledge and supplier innovations to optimize cost and customer value of new products.	(Foerstl et al. 2013)
		Purchasing performance by involving PSM in all important manufacturing value creation considerations such as “make vs buy”, lean operations and vertical integration.	
		Purchasing performance of PSM in an active exploitation of the supply base opportunities to provide access to new markets, new customers, and new products.	

Results

To validate the basic research model, confirmatory factor analysis (CFA) was used. As an initial step the Kaiser-Meyer-Olkin (KMO) Test was carried out to test how suited the collected survey data is for factor analysis. The KMO value of 0.802 indicates that the sampling is adequate. An exploratory factor analysis (EFA) preceded the CFA and showed an acceptable corrected inter-item correlation of > 0.4 (Bühl, 2016) for all 23 items displayed in Table 2. The results of the CFA show that all items load significantly ($p < 0.05$) on their hypothesized factors (constructs). The reliability of the latent variables was assessed by applying Cronbach's alpha and composite reliability values (Fornell and Larcker, 1981). The Cronbach's alpha values of the seven factors (constructs) suggest acceptable reliability for each of the scales. Table 3 presents the results obtained from the reliability analysis and the CFA. Discriminant validity was evidenced at acceptable levels by means of an examination using chi-square difference test (chi-square = 1234.992; df = 253). The item loadings as well as the overall model fit resulting from CFA provide strong evidence of convergent validity and unidimensionality (Bagozzi et al., 1991) for the 23 item measures underlying the seven factors (constructs) divided into four operational factors (Cost Optimization, Quality Improvement, Delivery System Support, Process Flexibility) and three strategic factors (Innovation Orientation, Supplier Satisfaction Contribution, PSM Integration). A potential source for bias of survey data lies in the subjective nature of the survey method. Miller et al. (1997) suggest overcoming this issue of subjective data by fulfilling two criteria: (i) Potential respondents are motivated to provide accurate data and (ii) questions within the survey instrument do not require recall data from distant past. In the recent survey and data collection both criteria were met by (i) ensuring the confidentiality of responses and providing a free-of-charge report or the core findings as an incentive for participation, (ii) focusing the questions solely on ongoing PSM processes in the focal firm the participant is employed at.

Table 3: Construct Measures, Validity and Reliability

	Factors (Constructs)	Items	Standardised item loading
Operational	**Cost Optimization** (Cronbach's α = 0.836)	Purchasing performance in reducing cost of inputs.	0.838*
		Purchasing performance in reducing cost of purchasing activities.	0.836*
		Purchasing performance in exploiting the ability and willingness of the supplier to share data cost.	0.700*
	Quality Improvement (Cronbach's α = 0.714)	Purchasing performance in improving the quality of inputs.	0.604*
		Purchasing performance in improving the quality of outgoing products.	0.764*
		Purchasing performance in increasing standardization of inputs.	0.774*
	Delivery System Support (Cronbach's α = 0.886)	Purchasing performance in reducing the procurement cycle time.	0.866*
		Purchasing performance in improving the on-time deliveries.	0.826*
		Purchasing performance in increasing inventory turns.	0.783*
		Purchasing performance in increasing percentage of Just-In-Time suppliers.	0.762*
	Process Flexibility (Cronbach's α = 0.872)	Purchasing performance in responding quickly to design changes.	0.836*
		Purchasing performance in responding quickly to requirements arising out of changes in production volumes or schedules.	0.813*
		Purchasing performance in responding quickly to the integration of new suppliers in the purchasing process.	0.739*

Strategic	**Innovation Orientation** (Cronbach's α = 0.903)	Purchasing performance in gaining access to new technologies.	0.856*
		Purchasing performance in participating in product development project/efforts.	0.915*
		Purchasing performance in exploiting the ability of suppliers to design new products or make changes in existing items.	0.824*
	Supplier Satisfaction Contribution (Cronbach's α = 0.806)	Purchasing performance in technical excellence by involving suppliers early in the value creation process of the own company.	0.613*
		Purchasing performance in investing in supplier value and having long-term time horizons.	0.786*
		Purchasing performance in finding the adequate mode of interaction (communication).	0.849*
		Purchasing performance in operational excellence in forecasting and planning.	0.642*
	Purchasing and Supply Management (PSM) Integration (Cronbach's α = 0.858)	Purchasing performance in an active contribution of PSM to supply base knowledge and supplier innovations to optimize cost and customer value of new products.	0.841*
		Purchasing performance by involving PSM in all important manufacturing value creation considerations such as "make vs buy", lean operations and vertical integration.	0.719*
		Purchasing performance of PSM in an active exploitation of the supply base opportunities to provide access to new markets, new customers, and new products.	0.816*

Conclusion

In practice, individual members of purchasing departments consider themselves to be an operational performance-boosting as well as a strategic value-adding player within a firm's purchasing function. The present work-in-progress paper addresses this practitioner's view by providing a literature-driven identification of factors describing the purchasing professional's individual performance. This allows for the consideration of either a purchasing professional's individual or a purchasing manager's perspective on purchasing performance. When monitoring the overall performance, actions, attitudes and competencies of purchasing professional individuals can be taken into account for management control systems of purchasing departments. Based on the results from analyzing the data for Austrian firms, a purchasing professional's individual performance measurement model should contain strategic and operational factors. The test of the basic research model contributes to the existing body of literature by validating that "Cost Optimization", "Quality Improvement", "Delivery System Support" and "Process Flexibility" as operational constructs and "Innovation Orientation", "Supplier Satisfaction Contribution" and "PSM Integration" as strategic constructs might be appropriate measures to operationalize, assess and control purchasing professional's individual performance. Thus, the contribution of this paper is two-fold: the results of the study (i) add knowledge to the existing literature on purchasing performance measurement of departments regarding the purchasing professional individuals' performance; (ii) help purchasing managers with the design of a management control system that is able to evaluate the contribution of purchasing professional individuals to the operational and strategic performance of the department.

A work-in-progress paper as this one in its current status has, of course, several limitations. Firstly, the presented literature overview is too narrow and needs to be extended. Secondly, the presented literature review methodology needs to be done and reported in greater detail. Thirdly, the reshaping of the data analysis might help to carve out the core idea of focusing on a personal level instead of an organizational firm level. Fourthly, only data from Austrian firms were used in the data analysis. Therefore, it is not given that these findings will hold true in other geographical contexts and in specific lines of business. Fifthly, our study has limitations associated with perceptual measures of performance. Finally, the basic research model was built on literature and studies that report a status-quo of the last years. By considering the high dynamics of the business environment in the model building process phenomena such as environmental performance, operational risk or the risk caused by the change of the work attitude of individuals of the generations Y and Z entering the job market, value might be added to this kind of research. Referring to further research projects this working paper including its limitations might serve as a collection of ideas for an updated and refocused in-depth study of the purchasing performance construct that would be vitally important for empirical research applying partial least squares (PLS) path modelling. Regardless of all the mentioned limitations the presented study is one that comprehensively considers strategic and operational dimensions of purchasing professional individuals' performance in a basic theoretical framework.
