across different industries (cp. e.g. Clarke and Gershenson, 2007, S. 70; Fandl, Held and Kersten, 2014; Giudice, La Rosa and Risitano, 2006; McDonough and Braungart, 2006, S. 39). It will be tested by looking at how strongly environmental aspects are considered and how much respective data for their measurement is provided to customers (Bras, 1997; Mackenzie, 1991; McDonough and Braungart, 2006).

To analyze the core hypotheses, several sub-hypotheses were formed (see Table 1). These hypotheses were reformulated as statements or questions and, after discussing them inside the research team, they were tested with a convenience sample of 10 casting experts from industry for content validity by evaluating whether the scale items adequately represented the construct domain (DeVellis, 2017). The experts reviewed the questions posed in the survey, evaluating concept and instruction clarity, ambiguity and readability. After modifications, the questions were finally included in the surveys.

H1. A deepened client collaboration is perceived beneficial for casting development		
Cost	H1a	Deepened collaboration has the potential to lower development costs
Development time	H1b	Deepened collaboration has the potential to lower development time
Knowledge transfer	H1c	Foundries have higher know-how concerning optimized casting development than their customers
H2. Early supplier integration/involvement of casting companies in product development is increasing		
Integration timing	H2a	Foundries are integrated increasingly in the idea/concept phase
	H2b	Foundries are integrated increasingly in the design phase
	H2c	Foundries are integrated increasingly in the test phase
Integration intensity	H2d	Foundries are more aware of the development processes of their customers
	H2e	Customers are more aware of the development processes of their foundry suppliers
	H2f	There are more regular mutual adjustment processes during product development
	H2g	More cross-company development teams were used during product development
H3. The role of environmental aspects in joint product development is increasing		
Consideration of aspects	H3a	Ecological aspects are increasingly considered during joint product development
	H3b	Foundries know more about ecological aspects during joint product development
	H3c	Customers expect more key performance indicators about ecological aspects during product development
Measurement and communication of environmental KPIs	H3d	Foundries provide more data about energy consumption of castings during joint product development
	H3e	Foundries provide more data about CO_2-emissions of castings during joint product development
	H3f	Foundries provide more data about water consumption of castings during joint product development

Table 1: List of hypotheses used as basis for the surveys

Trend study results – The development of ecological product development partnerships in the German foundry value chain

This part of the paper shows and discusses the results of the trend study survey. This is done by analyzing each sub-hypothesis and consolidating the results in order to test the main hypotheses.

Potentials of increased customer collaboration

The first hypothesis "H1 – A deepened client collaboration is perceived as beneficial for product development" is tested by analyzing its three sub-hypotheses: Regarding H1a and H1b, results show that a relative majority of respondents see a potential of 7-15% to improve development time and costs of new products through a deepened collaboration with their clients (see Figure 4). Even though the results for development time and costs follow the same pattern, a stronger potential for the reduction of development time can be observed – a 55% higher feedback on an improvement of 30% or more and a 47% lower feedback on an improvement of 1% or less. (Please note that the questions regarding hypotheses H1a and H1b were asked in the 2013 survey with a different scale, so no direct comparison can be provided here). Interestingly, respondents from "successful" companies (with an increase in market share) rated the development time and cost-saving potentials (significantly) higher than respondents from "unsuccessful" companies (with decreasing market shares). Conducting further bivariate ("rank correlation") analysis detected no differences between e.g. casting companies of different sizes or dissimilarities between casting houses with different customer industries.

H1a – "Deepened collaboration has the potential to lower development costs"
H1b – "Deepened collaboration has the potential to lower development time"

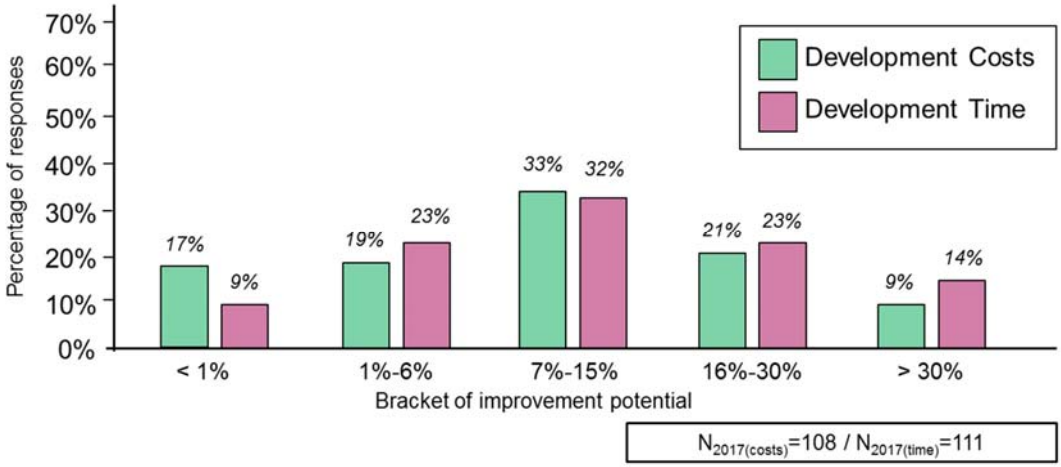

Figure 4: Potentials of increased customer collaboration (1/2) (Hypotheses H1a-b)

The respondents were also asked about their knowledge advantage compared to their clients in the area of product development (see Figure 5; cp. Hölttä, Eisto and Mahlamäki, 2009; Saarelainen et al., 2008). A similar percentage of respondents agreed to this statement in 2013 and 2017. Having superior know-how should enable improvement potentials that could not be realized by product development by customers alone (Brewer and Arnette, 2017; Fandl, Held and Kersten, 2014). This confirms potential advantages of deepened foundry integration in product development. Interestingly, this conclusion was also observed by another empirical study in 2013 in which more than 70% of machine tool manufacturers agreed to the statement that their foundry suppliers had predominant know-how in the development of casting products (Fandl, Held and Kersten, 2013; Held, 2015a).

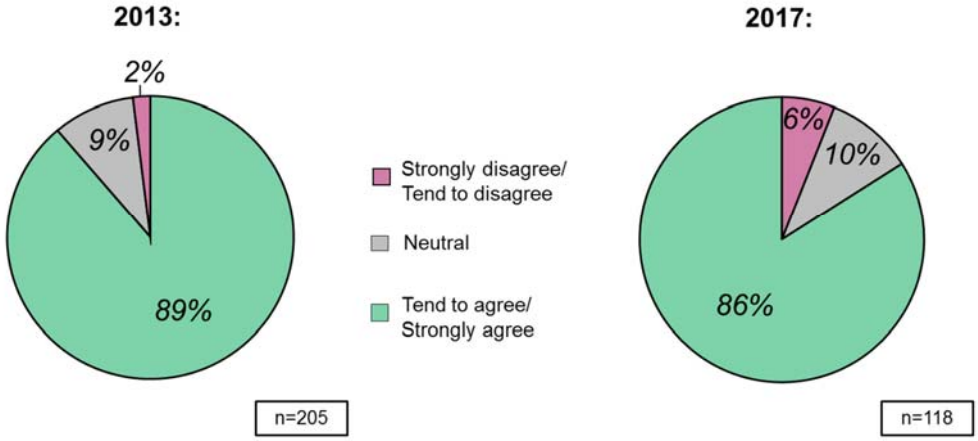

Figure 5: Potentials of increased customer collaboration (2/2) (Hypothesis H1c)

Based on the results in this section, it can be confirmed that the respondents deem a deepened client collaboration beneficial for a more successful product development as it will have positive impacts on development costs, development times as well as an increased synchronization of knowledge.

Having confirmed the hypothesis that "A deepened client collaboration is perceived beneficial for product development", the next two sections will look at how this translates into increased supplier integration (H2) and the increasing role of environmental aspects in joint product development processes (H3).

Trends in early supplier integration/involvement of casting companies in product development

Considering the previously discussed perceived benefits of deepened client collaboration, this section examines the potential trend of increased casting supplier integration over the last four years. The hypothesis "H2 – Early supplier integration in product development is increasing" will be analyzed based on a comparison of survey results from 2013 and 2017. The tests´ sub-hypotheses are grouped into integration timing and integration intensity as fundamental parameters for supplier integration (Handfield et al., 1999; Monczka et al., 2000; van Echtelt and Wynstra, 2001; Wagner, 2003; for the fuzzy front end cp. Schoenherr and Wagner, 2016).

Hence, the first important aspect of examining trends in early supplier integration and cross-company cooperation in product development projects is the integration timing. The surveys explore three main phases of the product development process – idea or concept, design and testing (Jayaram, 2008; Song and Di Benedetto, 2008; data about the production phase was also collected, but will not be presented here). The 2013 survey shows that about half of the participating foundries collaborated with "no or very few (<5%) customers" at an early development stage (during the idea or concept phase) (see Figure 6). Only about one-fifth of the foundries could already integrate more than 25% of their customers in this early phase when most degrees of freedom exist. Only minor or insignificant changes seem to have taken

place since the first survey (rejection of H2a; Chi-squared test with four degrees of freedom and p=0.05). During the design phase, even a (insignificant) slight decrease in the integration of castings suppliers in product development was detected (rejection of H2b). Concerning the integration of casting suppliers in the test phase, also no major or significant increase could be found in the survey data (rejection of H2c; Chi-squared test with four degrees of freedom and p=0.05). As a result, an increase in supplier integration regarding the timing of the different stages of the product development process cannot be confirmed for German foundry value chains. This result is further supported by a more differentiated subsample analysis of casting companies of different sizes and casting houses with different customer industries.

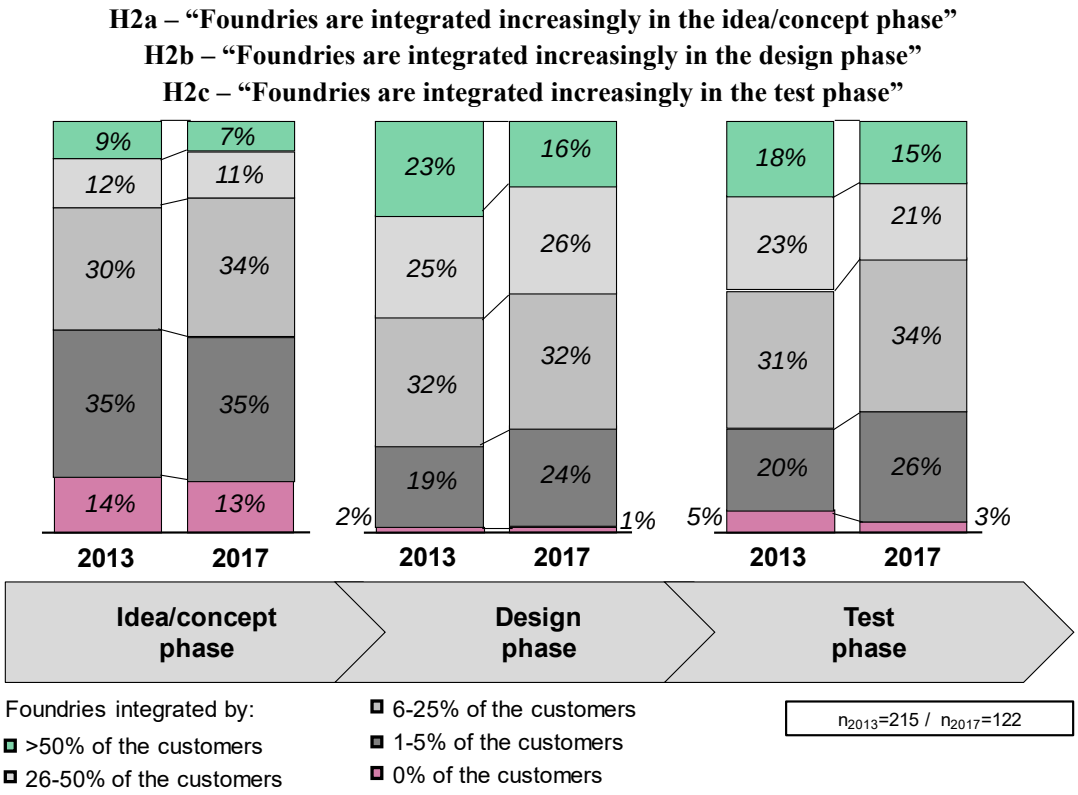

Figure 6: Trends in integration timing (Hypotheses H2a-c)

The second aspect of examining trends in early supplier integration and cross-company cooperation in product development projects is the integration intensity. This aspect is covered by four sub-hypotheses – two on mutual knowledge about product development processes between partners and two on coordination and cross-company team usage between suppliers and customers.

The results of the surveys concerning hypotheses H2d and H2e can be seen in Figure 7. No significant differences could be found concerning the knowledge of the casting suppliers about their customers' product development processes (rejection of H2d; Chi-squared test with four degrees of freedom and p=0.05). A slight improvement concerning the knowledge that customers have about the suppliers' product development processes was found. A share of responses has moved one bracket (1-5% to 6-25%). However, this shift did not disseminate through to the higher brackets of 26% and above (Chi-squared test acceptance of H2e with four degrees of freedom only at p=0.15).

H2d – "Foundries are more aware of the development processes of their customers"
H2e – "Customers are more aware of the development processes of their foundry suppliers"

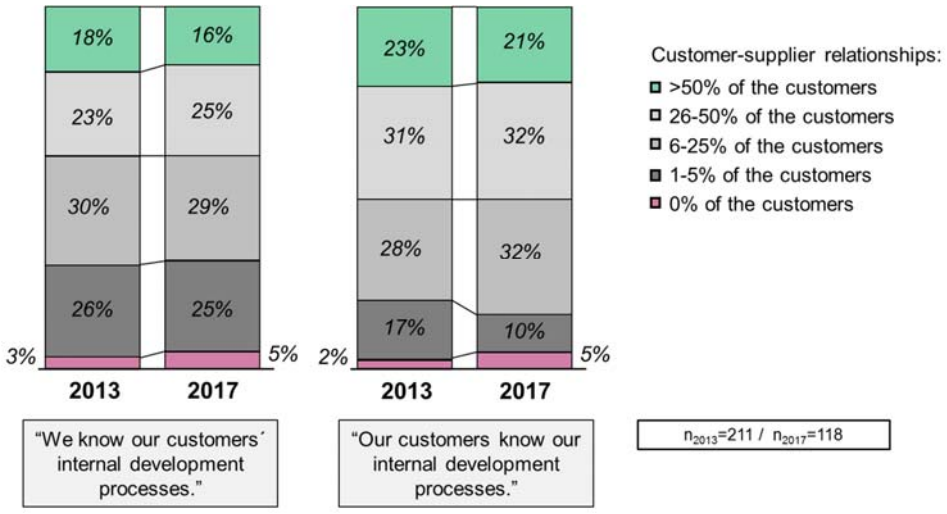

Figure 7: Integration intensity – knowledge about product development processes of partners (Hypotheses H2d-e)

Figure 8 shows the results with regards to the Hypotheses H2f and H2g. It could be found that mutual coordination activites during the product development process have sightly increased and now occur for a higher share of customers – 83% of respondents conduct mutual coordination activities with more than 5% of their customers compared to only 76% in 2013 (acceptance of H2e: Chi-squared test with four degrees of freedom and p=0.05). An even more specific coordination activity is the formation of cross-company teams for product development (Beckmann, Hoegl and Cordery, 2015; Potter and Lawson, 2013). The percentage of cross-company development teams used has increased slightly – only 34% of respondents are not using cross-company teams with any of their clients in 2017 compared to 39% in 2013. However, no significant overall increase of cross-company team usage was found (rejection of H2g; Chi-squared test with four degrees of freedom and p=0.05).

H2e – "There are more regular mutual adjustment processes during product development"
H2f – "More cross-company development teams were used during product development"

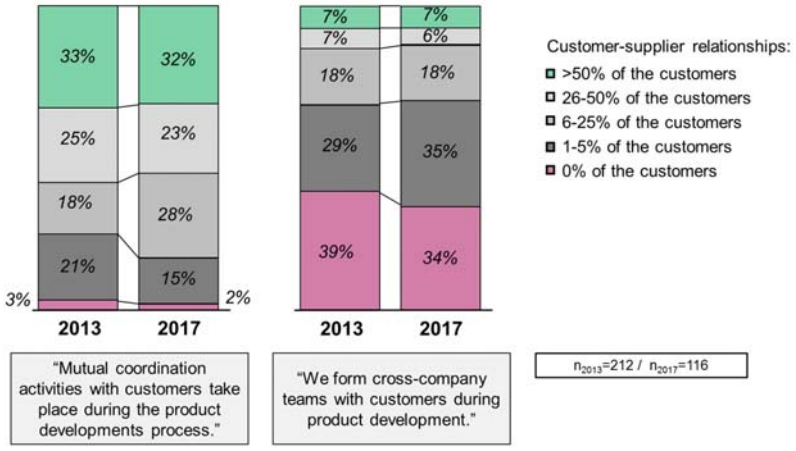

Figure 8: Integration intensity – Coordination and cross-company team usage (Hypotheses H2f-g)

Summing up, no substantial changes concerning timing or depth of supplier integration during product development in the German casting industry seem to have happened in the last four years. The arrangement of relationships and design partnerships appear rather unchanged.

Trends in environmental aspects in product development partnerships

Increased requirements to consider ecological aspects of casting products (should) play an important role in collaborative efforts of product development (Fandl 2017; Wagner and Enzler, 2006). The following section will therefore specifically investigate a potential increase in the importance of environmental aspects during joint product development efforts based on the 2013 and 2017 survey results (cp. Alting, Hausschild and Wenzel, 2007; Fritzgerald et al., 2007; Myer et al., 2007). The hypothesis "H3 – The role of environmental aspects in joint product development is increasing" will be tested based on its sub-hypotheses grouped into the generic consideration of environmental aspects and the specific measurement and sharing of environmental KPIs (Fandl, Held and Kersten, 2013; Held, 2015a; Walton, Handfield and Melnyk, 1998).

Regarding trends in the consideration of environmental aspects, the surveys explored three related aspects (Figure 9). There is a slight upward trend in the number of respondents who (partially) agreed that ecological aspects are considered during the development of casting products (up 19%). Surprisingly, the other end of the spectrum also sees an increase – 15% more respondents (partially) disagreed with the same statement. Thesis H3a is rejected (Chi-squared test with four degrees a freedom and p=0.05).

H3a – "Ecological aspects are increasingly considered during joint product development"
H3b – "Foundries know more about ecological aspects during joint product development"
H3c – "Customers expect more key performance indicators about ecological aspects during product development"

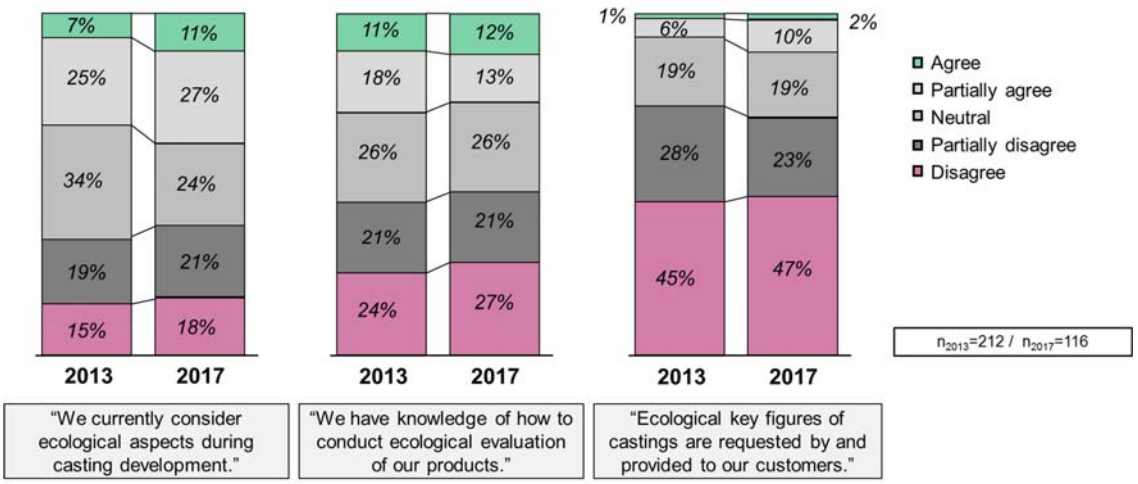

Figure 9: Consideration of environmental aspects in product development (Hypotheses H3a-c)

Consideration of ecological aspects is linked to the knowledge of how to evaluate ecological performance of one's products. Surprisingly, the survey results indicate that this knowledge seems to have decreased in the perception of the participants over the last four years – a 14% decrease in (partial) agreement and a 7% increase in (partial) disagreement. Hence, a (insignificantly) downward trend can be observed (rejection of H3b with Chi-squared test with four degrees a freedom and p=0.05). This observation is contrasted by an increased demand of ecological key figures by the customers – 71% higher (partial) agreement in 2017 compared to 2013 (from 7% to 12%). However, overall, only few customers seem to request ecological data from their casting suppliers during product development. Just 12% of the casting suppliers said they would have to provide ecological data in 2017 compared to 70% which did (partially) not provide such information (rejection of H3c; Chi-squared test with four degrees a freedom and p=0.05).

The second group of sub-hypotheses deals with trends in the measurement and communication of environmental KPIs between foundries and their customers. For this, the fundamental KPIs "Energy consumption", "CO_2-emissions", and "Water consumption" are highlighted here (see Figure 10). These KPIs are regarded to be of high importance in the casting industry and have been focused on for a long time (Lownie, 1978; Robison, 2011; Wagner and Enzler, 2006). Firstly, it is worth noting, that the overall communication of these KPIs to customers lies well below half of all respondents: most customers expect no statements or key performance indicators concerning environmental (energy, CO_2, water) aspects from their casting suppliers. In addition, the reported communication of CO_2-emissions has even decreased by 9% (rejection of H3e). However, communication of "Energy consumption" and "Water consumption" data has increased (by 15% and 46% respectively) (acceptance of H3f with Chi-squared test with one degree a freedom only at p=0.10; rejection of H3e with Chi-squared test with one degree a freedom and p=0.05). While only 32% of respondents from "unsuccessful" companies (with a decrease in market share) provided energy data to customers, more than 51% of the respondents from "successful" companies (with increasing market shares) did so.

H3d – "Foundries provide more data about energy consumption of castings during joint product development"

H3e – "Foundries provide more data about CO_2-emissions of castings during joint product development"

H3f – "Foundries provide more data about water consumption of castings during joint product development"

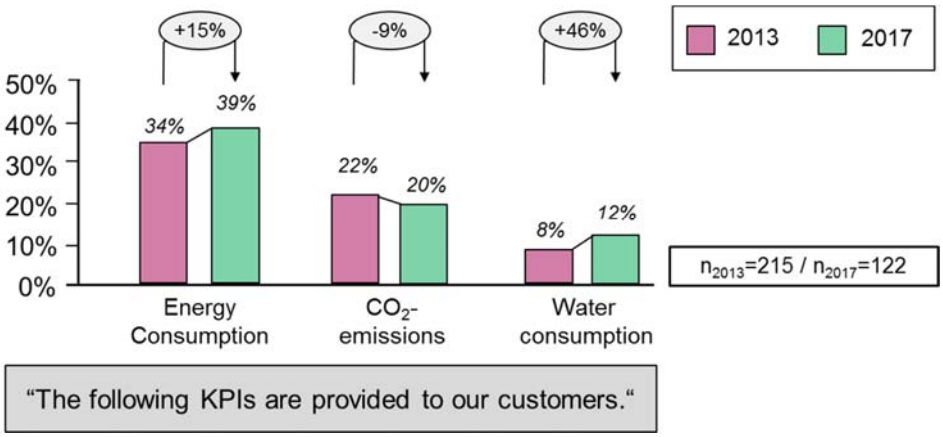

Figure 10: Measurement and communication of environmental KPIs (Hypotheses H3d-f)

In summary, it has to be deduced from the surveys that the importance of environmental aspects in joint product development activities has mixed results and has only marginally increased in the last four years.

Conclusion and outlook

Product development partnerships between foundries and their customers seem to take different shapes and depths in German foundry value chains. A promising starting point for optimization of product development constitutes intensive and early integration of customers and suppliers. According to the feedback from respondents, there are considerable improvement potentials, such as reduction of development times and development costs as well as improvement of production costs, casting functionalities and weight (the last three perspectives were also examined in this study, but not presented in this paper). More than three-quarters of respondents agreed with the statement that intensive integration of foundries during casting development could help realize optimization potentials. However, the hypothesis of a trend towards increasing integration of casting suppliers in product development activities could only be confirmed partially. The hypothesis of a trend towards more consideration of ecological aspects in joint new product development could also only be supported to some extent by the survey data analyzed. Figure 11 shows that the predicted increase in importance of environmental aspects did not realize as expected. Ecological aspects are considered by the majority of respondents with most consideration spent on energy consumption and CO_2-emissions; but the importance of joint product development is assessed lower than improvements in the production area[1] with one reason being that (still) only a limited percentage of customers ask for environmental KPIs.

[1] According to the results of the surveys, most methods for process improvement regarding ecological aspects are related to the *production* area and less to joint *development* activities. E.g. an evaluation of collected free texts identified the following areas with most foundry projects: introductions of energy management systems, heat recovery procedures and investment in more efficient furnaces and exhaust systems.

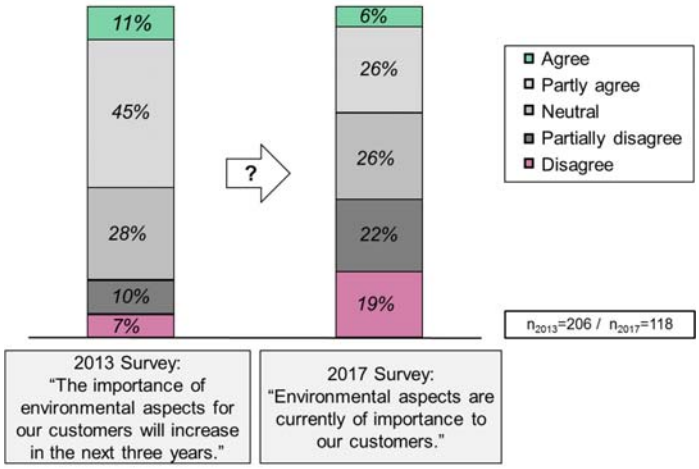

Figure 11: Importance of environmental aspects – prediction vs. actual progress

In summary, from this empirical survey it could be derived that the relationships between German casting suppliers and their customers have not undergone a radical change in the last four years: early supplier involvement has neither been altered significantly nor has the consideration of environmental aspects in joint product development increased considerably as a whole.

The outcomes of this research contribute to existing literature by investigating the impacts of early supplier integration in product development activities on sustainability. For this, the case of the German foundry industry was chosen. The high energy consumption of casting and Germany's position in the TOP 5 casting producing countries worldwide with very high productivity and quality levels make this an example of high relevance (American Foundry Society, 2018; FolkGroup, 2015). Compared to - for example - the electronics or the automotive industries, the foundry industry supplies products to a larger variety of industrial sectors, which further supports the selection of this industry as a case. In addition to that, Germany is known for its leading role in sustainable development, making insights into the perception of sustainability effects of supplier collaboration in product development projects a promising source of knowledge for research on this topic in other industries or countries (Buehler et al., 2011; OECD, 2018). Transfer potentials are considered to be highest to industries with similar values in the core parameters of the case such as size of energy footprint, importance of product development activities and complexity of supplier networks. The German automotive supplier industry, in which complementary studies regarding green supplier integrations have been conducted, seems like an obvious candidate (Caniels, Gehrsitz and Semeijn, 2013).

The results show that realizing the improvement potential through stronger supplier integration does not lead to significant initiatives trying to execute this. This is surprising, especially considering the big impact potentials due to the industry's high energy footprint. Future research could hence therefore look into:

a) What internal roadblocks hinder execution of supplier integration activities despite the knowledge of its potential, and

b) How might changes to regulatory frameworks and incentive systems help leverage these potentials?

Acknowledgements
We would like to thank all the industry experts who have been willing to participate in the surveys conducted. Special thanks to the Bundesministerium für Bildung und Forschung, the Bundesverband der Deutschen Gießerei-Industrie and the Verband Deutscher Maschinen- und Anlagenbau e.V. who all supported the surveys.

BUYERS BETTER BE SOCIAL

JOB-RELATED SOCIAL MEDIA USE AS ENABLER FOR CREATIVITY IN PROCUREMENT

Jonas Heller[1], Frank Rozemeijer[2] and Lieven Quintens[2]
1 The University of New South Wales, Australia
2 Maastricht University, The Netherlands

1. INTRODUCTION

In recent years, the continuous development of social technologies has changed the way how people connect and communicate, seek and share information and acquire new knowledge (Hanson, 2007). The use of social media platforms - such as social networking sites, blogs, wikis or other content-sharing websites - is growing at an increasing pace. Social media has revolutionized the lives of nearly every person on this planet, given that of the 3.7 billion people with access to the internet in 2017, more than 70% are active social media users (Statista, 2017). Compared to 2015, active social media use grew by 10% (Chaffey, 2016). From a marketing point of view, various scholars have researched how to use social media platforms to support (industrial) marketing and sales performance (Pratyush et al., 2015; Stephen and Galak, 2012; Woodcock et al., 2011). However, insights from the other side of the buyer-supplier dyad are much scarcer. Based on a large number of blogs that discuss the potential contribution of social media in procurement (Albert, 2010; Barnato, 2011; Busch, 2011; Evans, 2011; Handfield, 2011; Ranson, 2011), it is expected that the use of social media can also lead to improved connectivity among procurement professionals as well as positively affect their performance by allowing for more creativity in their daily tasks. Information, networks, and relationships are crucial for procurement professionals to solve everyday challenges (Dion et al., 1995; Kiratli et al., 2016; Rozemeijer et al., 2012; Smith, 1998). A combination of active and passive use of social media could enable these procurement professionals to efficiently network with their peers, internal stakeholders, business partners and potential suppliers and facilitate creative problem-solving.

However, although procurement professionals think that social media has the potential to support them in their daily job, many of them do not use it to its fullest potential (Rozemeijer et al. (2011). Knowledge on social media's impact on procurement professional's creativity or on how it alters their task routines at the job is limited (Tsay et al., 2012) and empirical research present today focuses on particular and small samples (Cao et al., 2012). Some research even suggests that social media is considered as a security trap for companies (Turban et al., 2011). Consequently, some company policies are blocking social media use in the workplace and tend to be reluctant to exploit the positive sides of it.

Social media enables receiving and spreading information across the globe between individual that have potentially never personally met, thus cues that people traditionally use to determine trustworthiness of information and whether to share information with someone else are somewhat obsolete in social media environments (Flanagin and Metzger, 2013). We have learned from previous research that social media self-efficacy, a concept based on Bandura's (1997) self-efficacy theory, is one of the primary drivers for private social media use and how information received or transferred via social media are evaluated or trusted (Hocevar et al., 2014). Yet, we know little about the role of social-media self-efficacy and collective-efficacy in procurement work environments.

As companies are driven by competitive pressures, sourcing strategists are trying to establish creative ways of securing supply value, reducing supply risk as well as lowering long-term

supply costs (Kiratli et al., 2016). The creativity of individual procurement professionals relies on the strength of their networks as well as on in-depth knowledge of their supply markets and supply chains to be able to creatively exploit opportunities (O'Toole and Donaldson, 2002; Wang and Archer, 2007). Barnato (2011) stated that "[…] procurement professionals should be proactive in their use of social media as it is an excellent source of free supply market intelligence and those who refuse to engage may be significantly disadvantaged in the long term". According to the IDC report of 2014, buyers highly value trust in their supply chains/networks and could increase trust with potential suppliers using social media. However, contrary to what we might expect, research on job-related use of social media by procurement professionals and the potential impact on their creative ability is mostly absent. Therefore, this study aims to empirically investigate the effect job-related social media use can have on the creativity of individual procurement professionals.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Job-related Social Media use

Several studies have investigated why and how much people use social media in a private context, including its effect on creativity and collaboration (Alahuhta et al., 2014; Dabbagh and Kitsantas, 2012; O'Keeffe and Clarke-Pearson, 2011; Peppler and Solomou, 2011). Job-related social media use, however, is barely researched. Recent literature takes two different perspectives and either focuses on the potential downsides such as individual psychological stressors, security lacks or distraction from work tasks (Appel et al., 2016; Fox and Moreland, 2015; Hildebrand et al., 2013), or highlights the positive aspects as network creation and increased motivation (Cao et al., 2012; Leftheriotis and Giannakos, 2014; Turban et al., 2011).

In line with Leftheriotis and Giannakos (2014) and Cao et al. (2012), it is crucial to distinguish between social media use for private purposes, such as maintaining a private network to stay connected with friends, family, and job-related use of social media. The latter describes the use of social media to execute a particular task or reach a certain goal related to the job responsibilities of an individual. Typical examples are marketers using social media to promote a product, business analysts looking for trends in certain industries by analysing blogs or social networking sites, or recruiters using public professional networks such as LinkedIn or Xing to screen potential job candidates (Nagendra, 2014; Steyn et al., 2010).

The job-related use of social media has been associated with a positive impact on performance of both individual workers and organizations (Leftheriotis and Giannakos, 2014). Charoensukmongkol (2014) found a positive relationship between co-worker support, job-demand, and social media use. These findings support a connection between the job-related use of social media and organizational performance (Tassabehji and Moorhouse, 2008). Interpersonal communication skills are crucial for procurement professionals and identified by several scholars as necessary part of their primary skillset (Carr and Smeltzer, 1997; Erridge and Greer, 2002; Walker et al., 2000). Next to the need to network to perform the job effectively, procurement professionals need to stay up-to-date on industry trends, understand changes in the supply market and learn more about the goods and services to procure (Giunipero and Pearcy, 2000). Using and interpreting this information to an advantage are additional skills which are indispensable for procurement professionals to perform well on an individual level (Luo et al., 2009; Tassabehji and Moorhouse, 2008).

The individual creative ability of each member of a procurement team is a significant element of the purchasing department's contribution to the corporate success (Feisel et al., 2011; Giunipero and Pearcy, 2000; Kiratli et al., 2016; Tassabehji and Moorhouse, 2008). Hence there is a growing interest to understand whether job-related social media use impacts individual creativity in the procurement environment. Creativity is generally defined as the development of new, original and, useful ideas that lead to an improvement or solution of a given situation

that are not just theoretical in nature but can be transformed into practical actions (Amabile et al., 1996). In a procurement context, the creative ability of the individual manager is therefore crucial when developing innovative ideas for sourcing and buyer-supplier relationship management. Challenged by small margins in procurement budgets and the movement away from simple cost-cutting strategies towards sustainable long-term buyers supplier relationships, procurement professionals are forced to network efficiently to maximize potential information exchange that fosters creative solutions (Kiratli et al., 2016).

Conceptually, job-related social media use can be divided in "active" and "passive" social media use, as there are significant differences between these types of social media use (Pagani et al., 2011). Active use of social media refers to producing, reproducing, or sharing social media content of any kind. Passive use of social media describes the consumption of content, hence reading or viewing content created or shared by others on social media platforms (e.g., Twitter, Facebook, LinkedIn, Xing). It is essential to make a distinction between these two concepts for two reasons. First, from an exploratory perspective, it is imperative to conceptually differentiate between these two constructs as antecedents and outcomes of job-related social media use are still unknown (Pagani et al., 2011). Second, from a managerial standpoint, active and passive use differ regarding the time employees spend using them. Also, differences in outcomes are expected. Active use of social media, for example, communicating with suppliers, peers or competitors, can, if not executed correctly, lead to adverse outcomes such as reduced supplier- as well as buyer-performance (Paulraj et al., 2008). Hence, companies and academics are interested in understanding what type of social media use benefits their procurement professionals (Leftheriotis and Giannakos, 2014).

Social media self-efficacy

The use of job-related social media platforms depends on the access to the Internet and web-enabled devices, individual skills, and personality. Previous research shows, that more outgoing persons are more likely to make use of social media (Amichai-Hamburger and Vinitzky, 2010; Correa et al., 2010). Also, the extent to which the skill set of an individual enables quick adoption and effective use of new technology seems to be an essential factor, as could be observed at previously introduced new technologies (Agarwal et al., 2000; Bandura, 1993). Research shows that the more computer self-efficacious individuals are, the more likely they are to use computers (Durndell and Haag, 2002). Self-efficacy is defined as the individual's belief in his/her ability to structure, organize and execute a certain task or activity (Bandura, 1982). In the context of social media, self-efficacy describes the individual's belief in his/her ability to participate both actively and passively on social media platforms. The theory of self-efficacy implies that the more often individuals are using social media platforms, the more self-efficacious they become and the higher their expectations of potential outcomes (Hocevar et al., 2014). Thus, the more often procurement professionals use social media, the higher the likelihood of future use (Bright et al., 2015; Eastin and LaRose, 2000). Recently, Hocevar et al. (2014) introduced the concept of social media self-efficacy and defined it as "[…] a person's beliefs about his or her capabilities to perform desired functions specifically in the social media environment." The study concluded that the higher the social media self-efficacy of an individual is, the more likely it is that this person trusts the information gathered on social media and uses this information to expand individual knowledge. Based on the findings of the previous studies, we hypothesize the following:

Hypothesis 1 a + b: Social media self-efficacy of procurement professionals has a positive and direct impact on their active (1a) and passive (1b) social media use.

Collective social media efficacy

Procurement strategies for today's organizations are seldom developed by only one person but more often by teams of (procurement) professionals who work closely together (Giunipero et

al., 2005). It is therefore essential to consider not only the individual's belief in its own abilities, but also the belief in the ability of direct colleagues in the procurement department. We endorse Bandura (1986), who highlights the independence of self-efficacy beliefs and outcomes expectancies in groups and apply Riggs et al. (1994) definition of collective efficacy to social media use in procurement organizations. According to Riggs et al. (1994), collective efficacy refers to an individual's assessment of their colleagues' collective ability to perform job-related behaviours. People's beliefs in the collective efficacy of their team's ability to perform or execute a certain task, such as using job-related social media, influence the individual's behaviour and group's performance (Gibson et al., 2000; Gully et al., 2002) and result in an individual change of behaviour. Hence, if a procurement professional beliefs that a team is performing well in utilizing social media for job-related tasks, the individual might engage more in social media use as well. We therefore hypothesize:

Hypothesis 2 a + b: Collective Social media efficacy of procurement professionals has a positive and direct impact on their active (2a) and passive (2b) job-related social media use.

Creativity

For procurement professionals, fostering creativity has become a necessity, instead of an option, for being able to successfully compete in today's turbulent market environments (Rozemeijer et al., 2012; Shalley and Gilson, 2004). Following Csikszentmihalyi (1996), we view creativity as a combined system of individuals, knowledge domains and experts, revealing that creativity is more than individual efforts but rather a result of social interaction processes. A more recent social identity perspective by Haslam et al. (2013) explains the importance of teams and their social relationships as antecedents for individual creativity. Social relationships are important for collecting innovative ideas from peers, as well as generating new ideas based on knowledge and information acquired from others. Network theory takes a similar perspective in suggesting that the position of a person within a network can give that person access to information that can be used for task-relevant knowledge development as well as fostering job-related creativity (Perry-Smith and Shalley, 2003; Shalley and Perry-Smith, 2008). Previous research has shown that creativity has a positive impact on job performance outcomes of both individual procurement professionals and sourcing teams, making it relevant to develop a deeper understanding of how creativity can be fostered in the procurement context (Hargadon and Bechky, 2006; Hargadon and Sutton, 1997; Zhou and Shalley, 2011). On the individual level, this implies that procurement professionals could benefit from using social media for job-related tasks to enhance their creativity.

Hypothesis 3 a + b: Active (3a) and passive (3b) Job-related social media use has a positive and direct impact on creativity

Connectivity

We introduce connectivity, defined as being closely connected with your internal colleagues and stakeholders, as a mediator between social media use and creativity in the procurement context. Rozemeijer et al. (2012) stated that procurement professionals "[…] spend a significant amount of their time developing their social networks (i.e., internal stakeholders, partners, and customers) and engaging with them to develop strategies that support the business strategy and in the end increase customer value" (p.67). According to Cao et al. (2012), using social media for job-related purposes has, among other motivations to use, the ability to increase connectivity by, for example, developing and maintaining professional networks, strengthening social ties with peers, collecting and analysing information and sharing knowledge and resources.

Besides the motivation to use social media, we know little about the impact of social media on the network ties within a team or department (Tsay et al., 2012), albeit some studies confirmed a positive relationship between the use of social media and productivity increases at the workplace in restricted, non-procurement related samples (Cao et al., 2012). Rozemeijer et al.

(2011) found that procurement professionals perceive social media as a tool to improve collaboration with stakeholders as well as suppliers, to increase purchasing performance as well as to improve the quality of sourcing decision-making. One reason is that increased connectivity between team members encourages trust and leads to a feeling of psychological well-being, which can lead to increases in creative work involvement (Kark and Carmeli, 2009; Ryan and Frederick, 1997). The first contact established with colleagues is usually done through the individual's engagement (Uzzi, 1996), and social media provides one way for procurement professionals to overcome relationship initiation barriers and connect with internal stakeholders as well as external peers (Ellison et al., 2007; Scharlott and Christ, 1995). Even though relationships are established via the social ties of individual professionals, they may, over time, be transformed into personal work relationships (Granovetter, 1985). Relationship development capability is seen as crucial for both managers and professionals (Leuthesser and Kohli, 1995; Smith, 1998) and the trend towards fewer, but more collaborative buyer-supplier relationships and more, tied relationships within a procurement team underlines the importance of relationship development capabilities. A positive effect on creativity might only take place, if social media is used for a certain purpose, namely to connect with peers to work on the higher goal of achieving creative solutions. It is assumed that the direct positive effect of job-related social media use on job-related creativity is only present if valuable connections are established, maintained and developed.

This study will test the mediation effect of connectivity among team members on the relationship between social media use and creativity.

Hypothesis 4 a + b: The relationship between active (a) and passive (b) job-related social media use and procurement job performance is mediated by individual connectivity

Combining our hypotheses results in in the following conceptual model that we try to validate in the coming section.

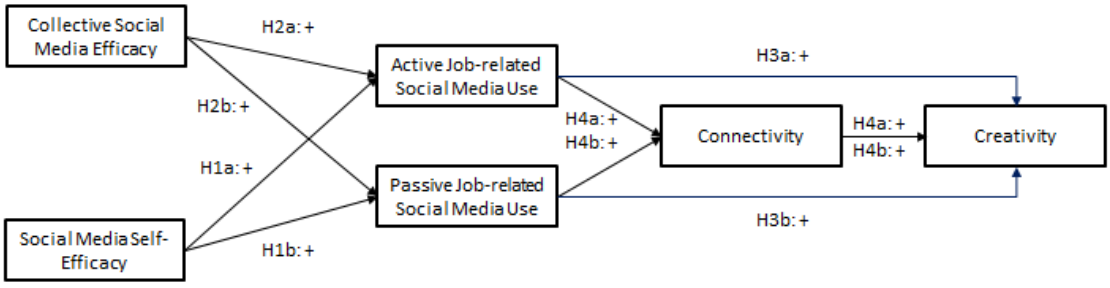

Figure 1: Conceptual Model

METHODOLOGY

Model validation

We interviewed several procurement professionals from different industries to validate the findings of our literature review and to sharpen our research hypotheses. The semi-structured interviews followed the guidelines regarding conducting and documenting research-interviews to ensure academic validity (Yin, 2013). All interviews lasted about one hour, were held on the phone and promised confidentiality to facilitate candid responses. The guide was divided into general questions about job-related social media use, questions on the connectivity among team members and creative processes or results that emerged from projects that were resolved creatively, as well as demographic differences that the procurement professionals observed concerning job-related social media use.

A purposeful sample was chosen, consisting out of five procurement professionals from different industries (i.e. Retail, Consultancy, Automotive), positions (i.e., Team lead, Consultant, Director) and ages (i.e., 25–55 years) to reflect the broad spectrum of procurement professionals. All interviewees pointed out there is a substantial difference between the types of use (either active or passive). Hence, we maintain to split the use of job-related social media use into *active* and *passive* use. For the antecedents influencing the use of social media (i.e., social media self-efficacy and collective social media efficacy) most the interviewees proposed a positive effect on both active and passive use of social media and to stay connected with peers. The insights from the interviews confirmed our conceptual model.

Sampling and data collection

The data collection for this study was executed utilizing a self-administered online questionnaire due to reasons such as cost-limitations, rapidity of responses and a respondents perseveration of anonymity (Manzo and Burke, 2012). The sample was restricted to procurement professionals (e.g., strategic buyer, CPO, commodity manager). Furthermore, only procurement professionals who could make use of social media at work (hence, social media use was not blocked by firewalls or strict company regulations) were selected for the survey to ensure that the self-reported effects were not imaginary. Hence, in accordance with the techniques proposed by Fricker (2008), two convenience sampling techniques were applied: (1) Harvested e-mail lists and (2) unrestricted, self-selected surveys.

The invitations to participate in the survey, including a direct link to the web survey, were distributed via emails in the authors' professional networks. In addition, the web survey link was shared on different social media channels. First, the link was shared multiple times (different weekdays and times during the days) via the social micro-blog Twitter. Second, the link was shared on the public professional networking sites LinkedIn and Xing via posts containing the link as well, as well as through posting the invitation to participate and the link in procurement related groups. Third, the link was shared on the public procurement specific social networking site Procurious (www.procurious.com) using status updates and discussion groups. Lastly, the link was incorporated in one edition of the Procurious[1] Newsletter, which is sent to all Procurious members who have been subscribed to the mailing list as well as shared among all NEVI[2] members in the Netherlands.

In total, 245 respondents started the survey. After assessing the first filter question (do you work in a procurement related position?), 26 respondents (10.61%) were excluded. Of the remaining 219, 26 respondents (11.87%) indicated that they were not allowed to use social media at work (second filter question). In the next step, a list-wise deletion of non-random, non-complete entries was conducted as well as an outlier removal process was examined. After deletion of all outliers and missing data, 149 valid responses were obtained, for which median replacement for responses with less than 5% missing data was used (Lowry and Gaskin, 2014). An effective response rate cannot be determined due to the different, non-traceable channels used to obtain respondents. Sample demographics show an even distribution of positions and tenures representable for each position present in the sample.

Sample-selection, non-response bias, and common method variance

[1] Procurious.com: An online business network for procurement and supply chain professionals
[2] NEVI: Nederlandse Vereniging voor Inkoopmanagement (Dutch Purchasing Management Association)

According to Manzo and Burke (2012), a survey need to be unrestricted, open to public and self-selected. The survey of this study was shared via multiple social media channels and private communication. To avoid a selection bias of respondents who are familiar with social media platforms, the last question of the survey asked respondents how they got access to the survey. The analysis of the responses to this question indicates that non-probability sampling is not an issue in this study, as many different channels to access the survey were used by respondents. Furthermore, to test for the existence of the non-response bias, this study followed the assumption of Fielding et al. (2008), stating that late respondents and non-respondents share similar attributes. Using demographics variables and at least one randomly selected indicator per construct, there were no significant differences found between the early and late respondents (at $p < .001$).

Due to scope restrictions of this study, information about the dependent and the independent variables was gathered from the same individuals. Hence common method variance could be present in this sample. Common method variance can inflate or deflate the observed relationships between constructs, therefore leading to Type I or Type II errors (Armstrong & Overton, 1977). Several steps were undertaken in the survey to avoid common method variance, namely assuring anonymity, careful wording of items and placing predictor and dependent criteria far away from each other in the questionnaire to avoid relationship-guessing by the respondent. In addition, Harman's single-factor test was conducted to prove the non-existence of common method variance (Podsakoff & Organ, 1986). A factor analysis in SPSS was performed using all constructs to test the un-rotated factor solution. The largest factor did account for 15.87% of the variance. Consequently, it was concluded that common method variance is not present in this study.

Measures

All constructs consist out of multi-item scales, which were previously proven to be highly reliable, based on their Cronbach alphas from preceding research (Podsakoff and Organ, 1986). Some of the scales were slightly adjusted and adapted towards the specific procurement context of this study. Unless stated differently, all variables were measured on a five-point Likert scale to ensure statistical validity (Santos, 1999).

Social media self-efficacy: Social media self-efficacy is a reflective construct of a participant's (1) perceived social media skill, (2) confidence in the ability to find information, (3) level of content production and (4) level of content consumption and measured with ten items in total. As the scale was not publicly available, Hocevar et al. (2014) provided us the scale on our request. The scale was slightly adapted to fit in our research context. Social media skill (1) and confidence in ability to find information (2) were measured using a five-point Likert scale ranging from (1) "much worse" to (5) "much better" including items as *"On a scale of 1 to 5 (1 = much worse, 5 = much better), rate your ability to find what you are looking for on the social media, compared to other Internet users"*. Social media content production (3) and consumption (4) included four items each, measured on a five-point Likert scale ranging from (1) "never" to (5) "very often".

Collective social media efficacy: We utilized the collective efficacy beliefs scale by Riggs et al. (1994) and adapted the scale towards the belief in social media efficacy of a department. Three items were measured on a five-point scale containing items such as *"This department is poor compared to other departments doing similar work"* which was rephrased to *"Compared to other departments, the department I work in is only poorly using social media for work-related purposes"*.

Use of job-related social media: This study is eager to differentiate between the active (creating and sharing content) and passive (consuming content) use of social media. Hence, by expanding the active job-related use of social media scale and altering the passive scale, the scale was

adapted based on the results of Pagani et al. (2011). The active use of social media at work construct contained four items. For example, *"I often spend time in creating social media content related to procurement"* or *"I frequently talk to other people from my industry or professional community via social media"*. The passive use of social media at work was similarly established with four items, asking the respondent questions like *"I often use social media to obtain work-related information and knowledge"* or *"I often spend time browsing social network content related to my work created by others"*.

Connectivity: The connectivity scale was borrowed from Kark and Carmeli (2009) to measure how well an employee is connected to his procurement department. A four-item five-point Likert scale as in the original study was adapted to fit the content of this study.

Creativity: Following Dobni (2008), we used the innovation scale as a proxy for creativity of procurement professionals. The items consist of questions such as *"I consider myself to be a creative/innovative person"* and *"I feel that I am good at generating novel ideas"*. In total, seven items were administered on a five-point Likert scale ranging from (1) completely disagree to (5) completely agree.

ANALYSIS AND DISCUSSION

Variance-based structural equation modeling was used (Partial Least Squares; PLS-SEM) to maximize the total explained variance of the dependent variables, caused by the independent variables (Haenlein and Kaplan, 2004). The PLS-SEM analysis was conducted in SmartPLS (version 3.2.3), using a path weighting scheme with 500 iterations and a stop criterion of 10^{-7} and a bootstrapping procedure with 5,000 subsamples, individual sign changes and a two-tailed significance level of $p < .05$ (equivalent to $t > 1.965$; Hair et al., 2011).

Outer Model – Results

This study employs an iterative process to remove insignificant indicators and indicators with low loadings while monitoring the effects on Cronbach's alpha, Composite Reliability and the Average Variance Extracted (AVE). All latent variables scored higher than .70 for Composite Reliability and all but one Cronbach's alphas pass the threshold of .70. For the Collective Social Media Efficacy construct, the Cronbach Alpha value is 0.621 which is acceptable given that the rho_A (1.263) and composite reliability (0.704) values are above the thresholds (Dijkstra and Henseler, 2015).

Following popular literature, the AVE is used to assess convergent validity of reflective constructs, which should surpass the threshold of .50 (Fornell and Larcker, 1981). All AVE values exceeded the value of .50, which implies validity at construct level, as the indicators explain more than half of the variance in the respective constructs (Peng and Lai, 2012). To address the discriminant validity, this study uses three approaches, namely the Fornell-Larcker criterion, the examination of cross-loadings and the heterotrait–monotrait ratio (HTMT). Discriminant validity has been established for all latent variables in this study when assessing the Fornell-Larcker criterion, the cross-loadings approach or the HTMT ratio.

Inner Model – Results

The R^2-value of the model is .215 and considered to be medium, describing a fair amount of variance in the dependent variable creativity. The PLS algorithm was used to determine the path coefficients, using a bootstrapping procedure with 5,000 subsamples to test for significance (Hair et al., 2011). A strong and highly significant, direct effect was found for social media self-efficacy on the active and passive job related social media use ($\beta = .650$, $t = 13.755$, $p < .001$; $\beta = .633$, $t = 14.422$, $p < .001$). Hence, hypotheses 1a and 1b are supported. In addition, a significant direct effect was found for the variable collective social media efficacy on active job related social media use ($\beta = .186$, $t = 3.273$, $p < .001$). These results support hypothesis 2a,

whereas hypothesis 2b is rejected as no significant effects of collective social media efficacy on passive use of social media at work were found.

To test for the mediation effects of connectivity on creativity, the direct effect of active and passive job related social media use was assessed first. A significant, direct effect was found for the active job-related use of social media on creativity ($\beta = .318$, $t = 2.998$, $p < .001$), whereas the direct effect of passive use of social media was found to be insignificant ($\beta = .027$, $t = 0.374$, $p > .05$). Hence, hypothesis H3a is supported, whereas hypothesis 3b is rejected. Secondly, the mediation effect of connectivity is measured. The direct, large effect of connectivity on creativity is significant ($\beta = .350$, $t = 4.356$, $p < .001$), while connectivity is significantly affected by passive social media use ($\beta = .206$, $t = 2.036$, $p < .05$). The effects of active use of social media on connectivity are insignificant ($\beta = -.041$, $t = .508$, $p > .05$) while the direct effect of active social media use on creativity remains ($\beta = .278$, $t = 3.685$, $p < .001$). Although our data does not support hypothesis 4a, we do find support for hypothesis 4b. The complete path model including coefficients and t-values is shown below in Figure 2.

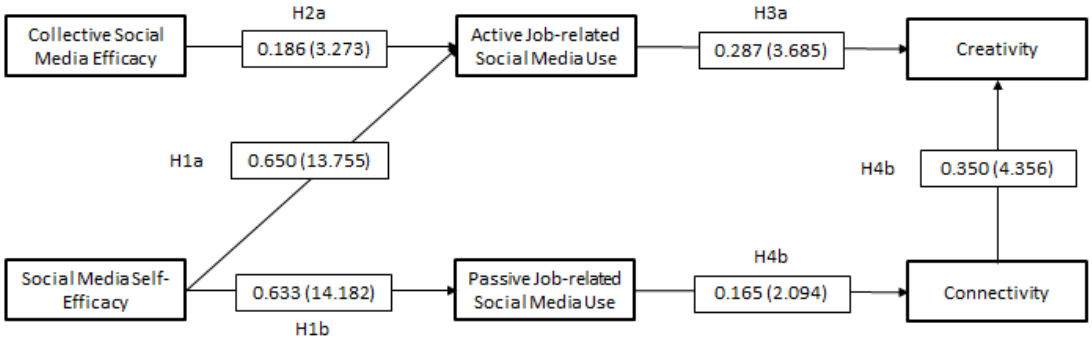

Figure 2: Significant path coefficients and t-values

Social media use in the private context is strongly driven by the age of the users (Bolton et al., 2013; Chaffey, 2016; Correa et al., 2010; O'Keeffe and Clarke-Pearson, 2011). To test for this heterogeneity effect in our sample, we divided our sample into two distinct age groups, namely Generation Y (and younger) and Generation X (and older), as previous research shows that these two generations differ in terms of how they actively (generating content) and passively (receiving and evaluating content) use social media platforms (Leung, 2013). We follow the definition of Howe and Strauss (2009) who defined Generation X as born between 1961 and 1981 and Generation Y as born between 1982 and to 1997. Splitting our sample into these two groups results in 39.2% of the sample being in the 'Gen Y' condition and 60.8% in the 'Gen X' condition. We estimated two separate PLS path models using Smart PLS Multi-group Analysis (MGA) to account for the continuous moderation effect of the variable at hand (Sarstedt et al., 2011; Vinzi et al., 2010) .

Comparing our two models, the R2-value of creativity in the Gen Y model is .295, whereas the Gen X model's value is lower at .169, yet a parametric test shows that these differences are not significant ($t = 1.041$, $p > .05$). Comparing the path coefficients among the two models revealed several notable differences. First, the PLS-MGA indicates a significant difference between Gen Y and Gen X on the path from collective social media efficacy to active job-related social media use (β diff. $= .525$, $p < .001$). Examining the paths for the different models shows a positive and strong effect of collective social media efficacy on active job-related social media use for Gen Y ($\beta = .404$, $t = 4.837$, $p < .001$), whereas for Gen X the relationship is weak and negative ($\beta = -.121$, $t = 1.659$, $p < .05$). Second, the relationship of social media self-efficacy on active job-related social media is significantly different (β diff. $= .295$, $p <$

.01) in such that for both generations the relationship is positive, but for Gen X (β = .740, t = 15.524, p < .001) it is significantly stronger than for Gen Y (β = .446, t = 4.558, p < .001).

Third, similarly we observe differences among the two generation for the relationship between passive job-related social media use and individual connectivity. The PLS-MGA results in a significant difference for this relationship across both models (β diff. = .563, p < .001), due to the fact that for Gen Y this relationship is strong and positive (β = .425, t = 3.973, p < .001), whereas for Gen X the relationship is weak and negative (β = -.138, t = 1.677, p < .05). All other path coefficients are significant as in the initial model but did not differ significantly across the two generation models. Overall, these results show that there is a difference among the two generations and how their social media use is affected as well as how it influences their individual connectivity and creativity.

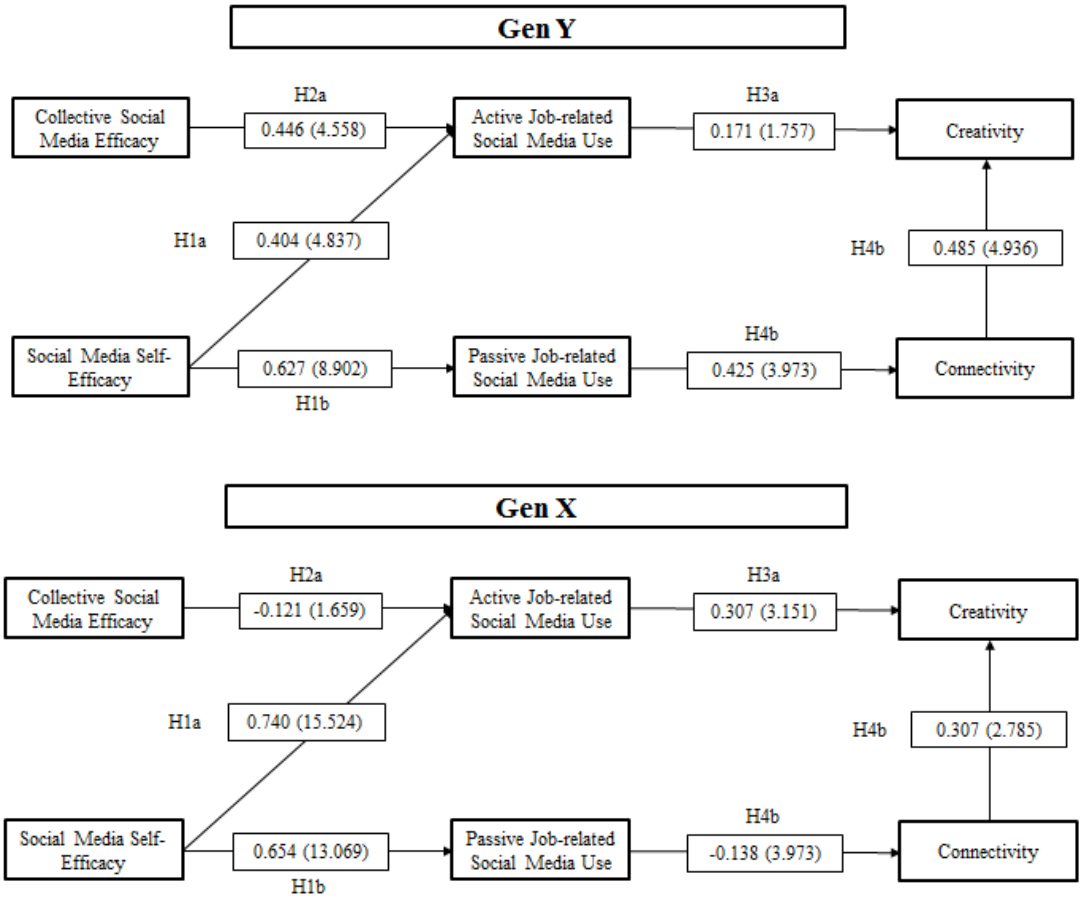

Figure 3: Significant path coefficients and t-values for the Gen Y and Gen X model

The findings support and build on prior results on the relationship of social media self-efficacy on the active and passive job-related social media use, confirming a significant, positive relationship, which was exclusively tested for private social media use in prior studies (Hocevar et al., 2014; Krämer and Winter, 2008). Furthermore, the collective social media efficacy in the department of procurement professionals has a positive impact on the active social media use but does not affect the passive use. Our model shows a positive direct relationship between active use of social media and creativity and this relationship is, in contrast to our hypothesis, not mediated by individual connectivity. The direct effect on creativity is only present for the active use of social media, while passive use of social media indirectly positively affects creativity through connectivity. Connectivity is only significantly affected by passive social media use.

The positive impact of job-related passive use of social media on creativity produces essential implications to procurement professionals from several perspectives. Firstly, many companies still suppress the use of social media at work via codes-of-conduct or technically blocking social media platforms, due to the perception that it reduces individual productivity and job performance. Our research finds evidence against this common belief. Procurement professionals do report more creativity when companies allow them to actively and passively use social media for work purposes. Secondly, from a recruiter's or manager's perspective, knowing the positive effects of social media use, social media self-efficacy, and collective social media efficacy should be tested when hiring new procurement employees or assessing the procurement department's creativity climate. In addition, it might be desirable to design a job environment in which procurement professionals have a certain freedom of deciding on how their daily tasks and projects are undertaken, as one positive result could be the use of social media to enhance creativity.

The MGA analysis shows different finding for Generation X and Y. Collective Social Media Efficacy increases Active Job-related social media use for Generation Y but decreases it for Generation X. Potentially, Generation Y feels encouraged to use social media actively if they believe the collective has strong skills. They 'adapt' to their environment. Generation X however feels threatened by the collective skills; therefore rather does not engage in the unknown territory of social media Social Media Self Efficacy's effect on Active Job-related Social Media Use is significantly stronger for Generation X than for Generation Y. Generation X seems to use active social media more if they believe that their individual efficacy is high, independent on what the collective/team is doing. For Generation X, self-efficacy is the main driver, whereas for Generation Y both, self and collective efficacy, are the drivers for active use. Passive Job-related Social Media Use increases Connectivity for Generation Y but decreases for Generation X. Generation Y uses passive social media to stay connected and have constant updates about their peers, while Generation X most likely uses other ways to stay connected and feels rather threatened by using passive social media

CONCLUSION

The theoretical findings of this study contribute and extend current research in the fields of social media and procurement while differentiating between the types of social media use and assessing the mediating effects of individual connectivity. Firstly, consistent with previous research (Chuang et al., 2015; Hocevar et al., 2014; Wang et al., 2015), social media self-efficacy is positively associated with the use of social media. However, this study extends current research and proves that the positive relationship, which holds for (any) private use of social media, is also present when using social media in a work context for job-related purposes and furthermore confirms the relationship for active use (i.e., producing content) and passive use (i.e., consuming content). Secondly, this study contributes to our knowledge on the relationship between collective social media efficacy and social media use at the workplace, which has not been researched up until today. Thirdly, the positive relationship found between active job-related social media use and creativity shines light onto an vital tool that procurement professionals can use to enhance their creativity, and through that increase their job performance (Cao et al., 2012; Jue et al., 2009; Paniagua and Sapena, 2014). It is proven that the effect is partially an indirect effect. For the passive use, the effect is mediated by individual connectivity, which implies that the plain, passive use of social media, in the context of procurement only enhances creativity when the procurement professional is well connected to his procurement team or department.

Despite the insightful findings of this research, several limitations need to be mentioned. First, the sample size of 149 valid responses needs to be considered when generalizing the results of this study. Additionally, the sample did not control for differences in industries or managerial

positions due to the small sample size. Research with a larger sample size needs to be conducted to ensure generalizability. Second, the study was conducted and controlled for data collected at one point in time. Hence, this cross-sectional research does not allow to measure causal effects appropriately. This issue could be overcome with a longitudinal study, which elaborates on the impact of job-related social media use over time, as well as measuring the effects of job-related social media use on job performance from a time-dependent perspective.

Next to the abovementioned limitations, several directions for future research can be derived from this study. To begin with, the underlying sample mainly had a European background (85% European, 6% North America, 9% other), with a strong focus on Western Europe nationalities (49% Dutch, 15% Swedish, 12% German, 5% British), thus future research could investigate the generalizability across different nationalities and other controlling variables, as internet use in the a country, education level or innovation index. This research focused on factors influencing the use of social media at work for procurement professionals. However, it is assumed that there are additional factors that could be examined to deepen our understanding of job-related social media use in the procurement context. Next to individual connectivity as our single mediating variable, we believe that more research is necessary to fully understand other potential mediators when trying to understand the antecedents of creativity in a procurement context.

Thus, additional research is necessary for developing a broader theoretical and practical understanding of the relationship between social media use and procurement creativity in the 21st century.

Abstract

This paper presents empirical insights into the dynamics of a complex inter-organizational network as it develops over time. We take a 'whole network' perspective to show that actors in networks use and develop social capital – individual, organizational, relational and network social capital– as the glue holding networks together as they change dynamically over time. The role of the hub organization also changes through the phases of development of the network. It continually works to orchestrate the flow of network resources, but over time these orchestration actions move between coping, adapting, planning and controlling activities.

Keywords

Inter-organizational network, orchestration, longitudinal case study, social capital

Introduction

Research in complex inter-organizational networks seems to fall into one of two camps. The first, often associated with Complex Adaptive Systems (CAS) and IMP Network Theory, is an emergent view of networks where actors are conceived as adapting and reacting, whilst the second takes a more directed view of networks and actors are conceived as proactively orchestrating network resources, in line with Resource Orchestration Theory (ROT), developed from Resource Based View (RBV).

To date there has been limited empirical research that takes a 'whole network' (involving all the key network actors) and longitudinal perspective in order to unveil the dynamics at play in the development of complex networks. We lack research that sheds light on the way in which diverse actors come together in these networks to address complex challenges. The unfolding and leveraging of network relationships is fundamental to the success of a network (Galaskiewicz, 2011), yet the difficulties of conducting whole network studies have acted as a barrier to expanding our knowledge in this area.

In this paper, we contribute in this direction through an empirical study of a complex whole network in healthcare, spanning public and private boundaries and bringing together actors to increase the uptake of innovation in local health systems.

Conceptual foundations

Inter-organizational network social capital

Inter-organizational networks are capable of addressing complex problems and sharing scarce resources to achieve network goals (Keast et al., 2004, Bryson et al., 2006, Weber and Khademian, 2008, Hoberecht et al., 2011). They can improve efficiency, legitimacy, power and help manage uncertainty arising in complex settings (Isett and Provan, 2005, Pesämaa, 2007, Hoberecht et al., 2011, Isett et al., 2011). They have been shown to improve service delivery, advance innovation, support risk distribution and share accountability (Pesämaa, 2007, Hoberecht et al., 2011). A more holistic, whole system perspective provided by working in inter-organizational networks enables key managers to understand bigger, more sustainable solutions (Hoberecht et al., 2011) that individual organizations and managers cannot achieve independently (Provan and Kenis, 2008, Weber and Khademian, 2008). In particular, wicked problems such as poverty and global warming, and reform of complex services such as education and healthcare, cannot be solved by single agencies, organizations and even sectors (Huxham and Vangen, 2005, Hoberecht et al., 2011). These complex problems facing societies and economies provide a "moral imperative" to collaborate across organizations and sectors (Popp et al., 2013).

Public services are provided through complex inter-organizational networks involving government departments and agencies, public procurement offices, private sector providers of goods and services, industry representative bodies, regulatory bodies and a range of other stakeholders. Whilst the importance of understanding dyadic relationships within public management networks is recognised, (Isett and Provan, 2005, Provan and Lemaire, 2012), the provision of health and social care services are viewed as particularly suited to inter-organizational networks as a mechanism (Reid, 1995, Berry et al., 2004).

A public management inter-organizational network typology identifies three main types of networks in the public sector - policy networks, collaborative networks and governance networks (Isett et al., 2011). All three types are present in public management (Popp et al., 2013), but collaborative networks are the most common type of networks found in healthcare (Eisingerich et al., 2009). Collaboration in these inter-organizational networks may involve suppliers of goods and services, government departments and agencies, not for profit

organizations, community representatives and members of the public (Bryson et al., 2006, Rethemeyer and Hatmaker, 2008).

Social relations in inter-organizational networks lead to connections that can be used – sociologists term these 'ties' (Granovetter, 1973, Granovetter, 1983, Granovetter, 1985, Collet, 2003, Burt, 1983, Burt, 2000, Burt, 2009, Walker et al., 1997) and their exploitation can give rise to benefits, termed social capital. It is only relatively recently that academic scholars have sought to understand how social networks work; previously managers have communicated to promote collaboration without necessarily understanding the workings of the social network involved in that collaboration and the potential outcomes. Within organizations it has been observed that social networks are deliberately used to assess strategy execution, improve strategic decision-making in top leadership teams, integrate across core processes, ensure integration post large scale change such as merger, and develop communities of practice. More recently, academic interest has focused on the use of social networks in supporting partnerships, alliances and the management of inter-organizational relationships (Cross and Parker, 2004, Kilduff and Brass, 2010, Galaskiewicz, 2011). Some social networks form for the purpose of interacting but others are deliberately formed to solve complex problems (Ryan, 2011). Social networks and inter-organizational networks have largely been studied separately, with some authors highlighting the value of seeing them as distinctly different. However, some attention has been paid to the interaction between social networks and inter-organizational networks, observing that sometimes social networks lead to the formation of inter-organizational networks, and vice versa (Brass et al., 2004, Harryson et al., 2007, Kenis and Oerlemans, 2008, Gulati et al., 2011, Larimo and Vissak, 2009, Voinea and Stephan, 2009). Actors in a social network can be individuals, teams, organizations, regions, or countries (Liebowitz, 2007), and communications technology development from telegraph, radio, telephone and internet has allowed social networking to occur more easily over any distance (Churchill and Halverson, 2005), thereby easing network formation and development.

Time and network development

The concept of time is a central, yet often implicit, dimension in organizational and management research. In recent years increased attention has been paid to the temporal dimension of organizational studies (Reinecke and Ansari, 2015), with authors arguing that it constitutes a meta-dimension of management (Chen and Miller, 2011). Temporality has been particularly central to process research (Langley et al., 2013) that has focused on theorising processes of organizational change. Methodologically, while time is not always explicitly mentioned, studies that embrace longitudinal designs provide insights into the evolution of organizational events and structures over time. This aligns with a process-orientated or qualitative perspective on time, where "there is no beginning or end of time, only unfolding moments and ongoing transformations" (Reinecke and Ansari, 2015: 261). In this perspective, time flows and resides not in the clock measure, but in the unfolding of organizational life.

Interestingly, network studies have a relatively long tradition of embracing time and temporality as core dimensions, particularly in their attempts at making sense of and theorizing the evolution of network structures and inter-organizational ties (Lorenzoni and Lipparini, 1999). Several studies adopt longitudinal designs to study phenomena at the network level (Provan et al., 2007). This is certainly a reflection of the complexity of networks and their dynamics, and therefore it is necessary to study them empirically over a period rather than cross-sectionally in order to be able to draw reasonable conclusions about their nature and processes. Nonetheless dominant network theories still seem to offer very static frameworks.

Supply chain management research on the other hand, remains primarily cross-sectional and has shied away from engaging with ideas of temporality. Klassen and Hajmohammad's (2017)

recent contribution is a notable exception, offering multiple perspectives on time in relation to sustainability and competitiveness. Supply chain management activities and problems are by nature related to processes; sourcing and relationship development are themselves processes that happen over time. Hence there exist opportunities to offer more longitudinal and temporal frameworks of supply networks.

We embrace time in our process of theorising as we see it as a core dimension of the development of networks taking place at the tensions between control and emergence. A temporal view of network development and social capital orchestration in this context allows for a richer and more accurate conceptual framework.

Methodology

Empirical whole network studies

One of the challenges in researching inter-organizational networks is bounding the network being researched; so called 'whole network' studies (Provan et al., 2007) contain key organizations involved in the provision of a product or service that is the focus of the research question being asked. The most simplistic approach to bounding a network is including within its boundary all the organizations with membership (Valente et al. 2008; Alvarez, Pilbeam, and Wilding 2010). Alternatively, membership might be taken as a starting point and then certain member organizations might be excluded on the basis of empirically evidencing whether the organization actively participates in the network, or are just being considered to be a member as a formality (Human and Provan 2000). On the other hand, in some studies network boundaries have been expanded beyond membership, since, after snowballing, key informants thought other organizations were relevant to be included in the study (Robins, Bates, and Pattison 2011; Morrissey, Johnsen, and Calloway 1997).

In other studies of inter-organizational networks, network 'membership' has not been quite so explicit. For example, a study on supply networks in the automotive industry set boundaries based on a specific assembly (Choi and Hong 2002) and which organizations were centrally involved in the supply of components for this assembly. In another example, level of turnover, if they were legal persons and if they could compete for public works were criteria used to include and exclude organizations for the network to be researched (I. Castro, Galán, and Casanueva 2009). In a study focused on lean, researchers chose to include organizations in the network who used lean practices (Bortolotti et al. 2016).

The challenges and limitations of network bounding criteria have been recognised (Henry, Lubell, and McCoy 2012); it was observed that researchers' choice of who they included impacted on responses of network organizations to interview questions. When researchers did not specify organizations in their questioning, interviewees responded only about those whom they had strong relationships with and omitted those with weaker relationships. When researchers specified organizations, interviewees did not consider other organizations with whom they had strong relationships.

A set of elements for researchers to consider when examining inter-organizational networks has been provided (Halinen and Tornroos 2005). They propose that the objective and research question should determine the particular theoretical perspective to be taken. Inter-organizational networks are complex multi-dimensional systems (Raab, Mannak, and Cambré 2015), making choice of theoretical perspectives to be taken a complex decision for the researcher.

However, overall, most research to date on inter-organizational networks has emphasized the organizational level; there is little evidence of research that considers effects at the network level.

Research approach and context

The findings are drawn from case study research with embedded sub-units. A five year longitudinal study and a cross-sectional study of health care networks were examined, representing two embedded sub-units within an overarching case of a large regionally based healthcare network. An embedded case study was selected as a suitable methodology because it enabled detailed investigations of organizations and organizational processes to be conducted whilst capturing the contextual factors and social embeddedness of the phenomenon under study (Yin, 2003, Miles and Huberman, 1994).

Data collection and analysis

A total of 41 interviews were conducted with multiple respondents within the networks. These were digitally recorded and later transcribed. This data was complemented with documents and participation and note-taking in meetings. In conducting the analysis, we were interested in how the network developed over time, and the role of the hub organization in this development in facilitating action and the achievement of network goals. The data analysis process was based on the principles of abductive reasoning whereby the researchers engaged in a to-and-from method between the empirical and the conceptual, in order to make sense of the phenomena under study (Ketokivi and Choi, 2014).

Findings

In the case the network is formed around a non-traditional hub organization – a social enterprise spanning the public and private sector with a mandate to facilitate and affect change at the levels of individual practitioners, health organizations, health systems and the wider community. The network has been formed, in part, to increase the uptake of innovation in the local health system and provide a route into the health system through forming temporary supply chains connecting innovations to those with purchasing power and at times directly to end users (practitioners and patients).

Social capital in a healthcare innovation supply network

In this context social capital, at an individual, organizational and network level, was a key resource leveraged and developed by the hub organization and valued as an outcome by members. The hub organization's pattern of connections to the local health community, the extent to which its values reflected those of potential network members and its reputation, as well as the subsequent trust this engendered, supported its position of influence. However this static view of social capital as a resource for the hub organization did not sufficiently capture the role of social capital in network development and through the course of this study the dynamic nature of social capital has become apparent.

The extent to which a network represents a context in which social capital is leveraged (bridging social capital) versus one in which it is developed (bonding social capital) changes over time. (Ansari et al., 2012). The beneficial outcomes of the leveraging and development of social capital can move between the individual, organization, network and community levels. The extent to which different individuals and groups can use their social capital to gain an advantage in the context of the network changes over time. The impact of the different dimensions and forms of social capital on the network also change over time. The relational dimension of social capital is a more emergent property, whilst cognitive and structural dimensions both emerge and can be controlled or orchestrated. Network social capital represents the social capital in the network that has been activated and developed and is therefore the form of social capital most available for orchestration.

Role of orchestration in network development over time

Over the course of our observations, both over time and between the two embedded sub units, the role of the hub organization in the developing network changed. The network went through four phases of development; initiation, formation, initial collective action and maturing collective action (Harland et al., 2017). During the different phases the hub organization worked continually to orchestrate the flow of network resources, but over time these actions moved between coping, adapting, planning and controlling activities. As social capital was a significant resource for this network the extent to which the hub organization could orchestrate this for the benefit of the network was an important factor in its development. Further, the dynamic nature of network social capital meant that its changing form, position and availability influenced the ability of the hub organization to cope, adapt, plan and control. To this end the degree to which network properties emerged, with the hub organization merely coping with the outcome of this, or were fully orchestrated was a function of timing (i.e. phases) and activation of different parts of social capital across different areas and levels of the network. Figure 1 summarises our ongoing conceptual development of these phenomena.

Discussion

This study has highlighted the importance of factoring time into our understanding of networks and the variables under observation. Network structure, activities, goals and roles change over time, however this additional demonstration of how multi-faceted network variables such as social capital move around the network structure, mutate form and change utility over time adds to the understanding of how time significantly shapes understanding of relationships between variables in networks. Social capital and its different facets and forms do not develop and mutate at the same rate within the network context. For example structural connections form earlier than the cognitive dimension of developing a shared understanding. Relational elements such as trust based on reputation are high during the initiation of the network, reduce during formation as expectations based on reputation are challenged and then increase through joint working and development of shared understanding.

Time also plays a role in the availability of bonding and bridging social capital; in the early stages bridging social capital is more highly available as new connections are most abundantly available and over time the potential to create bonding social capital increases as a stronger network identity or shared language is developed. However the utility of these two forms of social capital also changes over time, moderated by changing network goals and activities. During formation, investment in developing bonding social capital is emphasised as network purpose and structure are refined, however in the later stages being able to utilise bridging social capital to diffuse, distribute and publicise the network's activities becomes increasingly important. This shift in emphasis between bridging and bonding social capital and the dynamic nature of this over time appear to be important for network development

In this context the hub organization attempts to play a number of different roles over time. However its ability to influence the network via the forms of hierarchical power used in a traditional organization structure is significantly limited. One factor shaping its source of influence was the pattern of resource availability. At an organizational level it had a high level of social capital but less access to other resources. Significantly other resources available to the hub organization, such as knowledge and financial capital, are frequently deployed in order to develop further organizational social capital and network social capital as either a primary or secondary outcome. The hub organization's access to social capital supports its ability to orchestrate network activities, and yet a significant portion of these orchestration activities are concerned with the mobilization and development of social capital across the network.

Over time tensions form within the network as the development of bonding social capital decreases the uniqueness of the social capital available to the hub organization and therefore reduces its ability to influence the network. This is countered, to some extent, with significant efforts of the hub organization to maintain centrality within the network. However, it is also important to note that over time the need for central control also varies particularly as the network moves into more mature collective action; in this phase there are more clearly defined goals, roles and high levels of bonding social capital supporting network processes. At this later stage the resilience of the network can support a form of network coping and adaptation up to a point without significant central planning and control. However the underlying plan remains in place and monitoring for deviation from the plan that is jointly owned, but centrally organised, acts as a form of more subtle control. These joint metrics reinforce bonding social capital as they contribute to a shared language and understanding, and the transparency with which they are shared adds to the level of trust across the network.

This study has taken a whole network approach and whilst we have frequently observed orchestration from the perspective of the hub organization, which undoubtedly plays a pivotal role, in seeking to understand the role of social and network social capital in orchestration processes we begin to see how orchestration is a function of the whole network. Individual organizations at different times are able to exert more or less control over the network's activities, but this is shaped by their own social capital, the social capital within the network and time. Consequently we can see that orchestration is not a top down process and over time network development can appear to take on an emergent quality. However the ability of a hub organization to mobilize social capital can enable it to take control at pivotal moments particularly related to managing network boundaries.

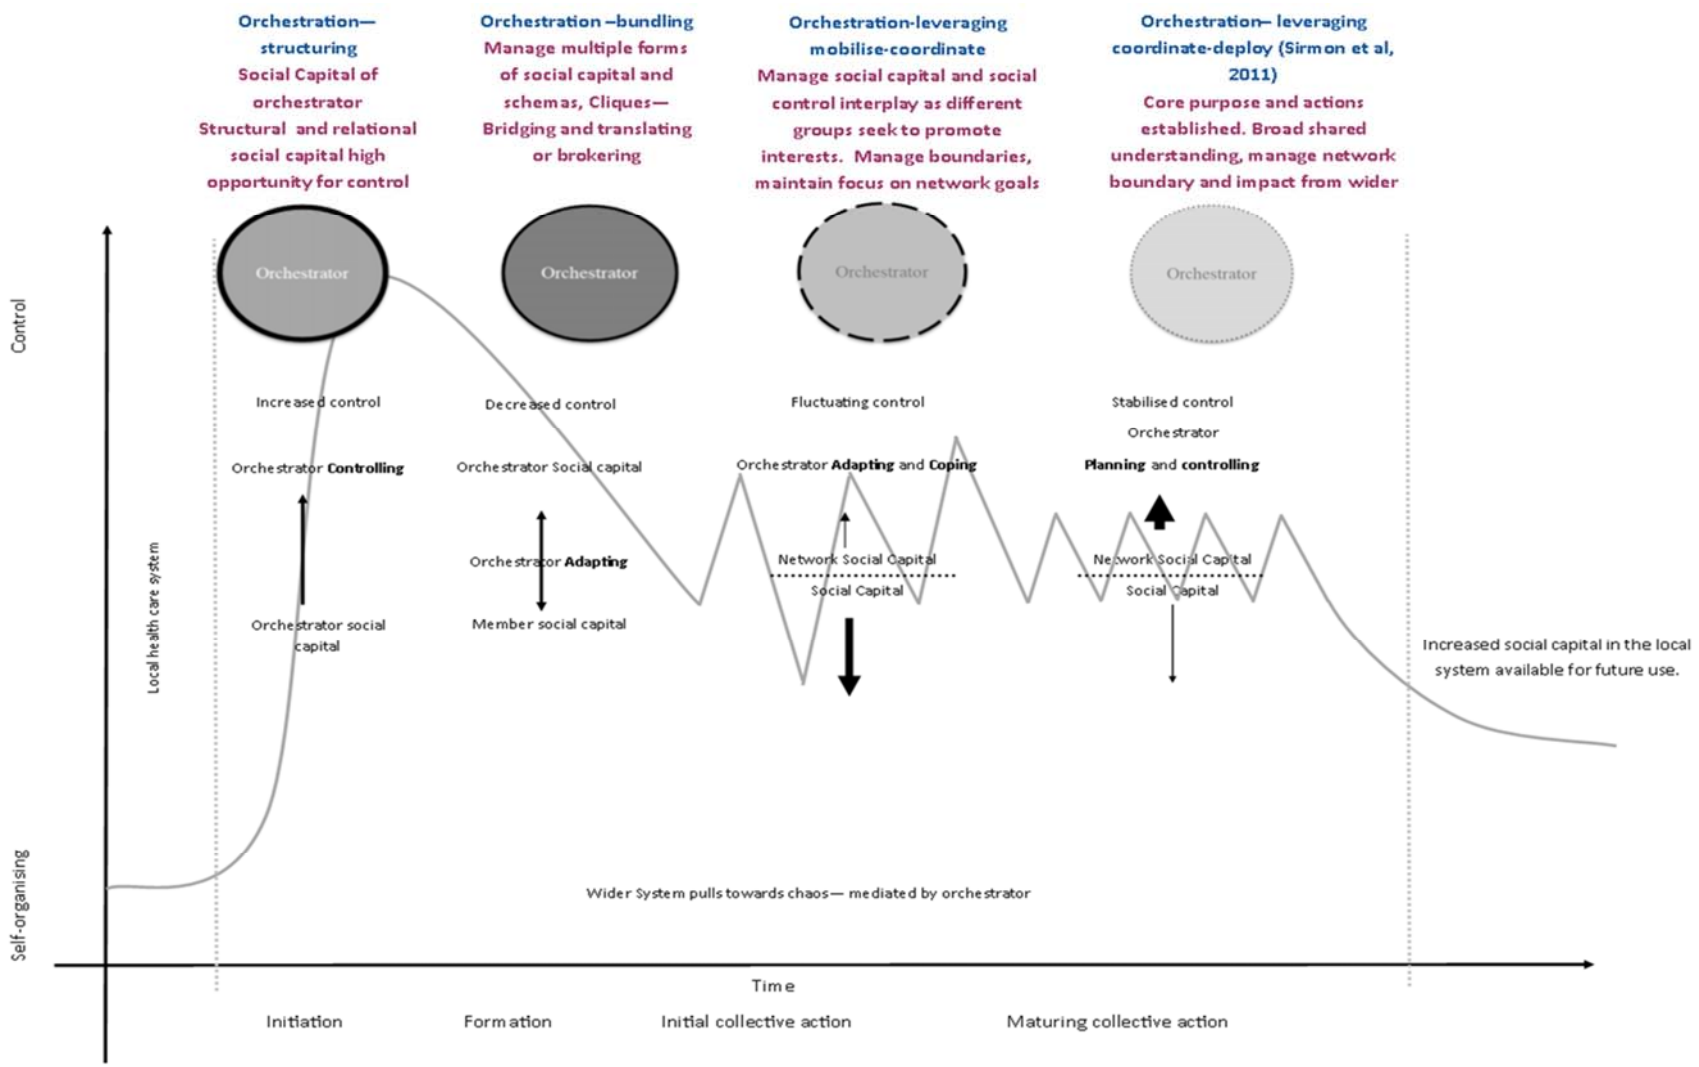

Figure 1. Orchestrating and coping through phases of network development

Conclusion

Via an extensive longitudinal study of two embedded subunits within an overarching case of a large regional health network, our study investigates how the hub organization orchestrates its network for desired economic and social outcomes. We find that network orchestration is a dynamic and complex process. Unlike commercial networks, the hub organization in our case does not occupy sufficient power to 'enforce' network development practices, however social capital is found to be the key conduit to shape the dynamics between organizations and support inter-organizational collaboration. Our study also finds that social capital is continually deployed by the hub organization during the different development phases of the network, but over time the emphasis was shifting between coping, adapting, planning and controlling activities. We contribute to the literature by developing and articulating the concept of network orchestration via the theoretical lens of social capital. Our study also offers insights into the dynamic and complex interplay between members and the hub organization of the network. Finally, our research contributes to unveiling the temporality of complex network activities and development.

Towards PSM 4.0

An exploratory discussion on the impact of the Internet of Things on Purchasing and Supply Management

Abstract
Industry 4.0 and the Internet of Things (IoT) are transforming industry architectures, traditional business models and processes. This calls for significant adaptations of the Purchasing and Supply Management Function (PSM). The present article aims at stimulating debates between practitioners and academic on this evolution. It first describes the context by exploring why and how the IoT changes industry architecture and favour some specific governance mechanisms. From this, building on three separate research investigations involving practitioners we explore a scenario where PSM is taking a more strategic role while being more digitized. This scenario aims to describe how PSM would evolve in this context and how PSM can manage this transformation. We conclude by suggesting future research areas.
Keywords: Purchasing and Supply Management, IoT, Digital Transformation

Introduction
Industry 4.0 and the Internet of Things are commonly used terms within industry and academia to describe some of the profound changes of our industrial and business foundations. They play a key role in digital transformations. Industry structures will go through significant changes in the next 20 years. The IoT changes products into product/service hybrids. As more and more "Things" get connected, more data is generated and new digital services and business model innovations take place. The impact of the IoT is important, including sectors that were not data intensive in the past, such as agriculture and mining. This will lead to significant re-configurations of value chain networks. Building on the title of a Wall Street Journal article (Andreessen, 2011) we could say that today both "sensors and software are eating the world". We have only seen the first sparks of a broad transformation that will significantly alter industry architectures and changes how companies compete and collaborate within their business ecosystems. The transformation of industry architectures will change the role of the Purchasing and Supply Management (PSM) Function. It could shift back to a more operational role or it could gain further importance. In the present paper we outline a scenario where, by taking an active role in a company transformation, the PSM functions gain further strategic relevance. We start with a definition of IoT and Industry 4.0 and describe how they relate to digital transformation. Following, we outline why and how IoT changes industry architectures and favour specific governance mechanisms. From this we develop a scenario and describe how

PSM could evolve in this context and how PSM could manage such a transformation. We conclude by suggesting future areas of investigation.

2-Background of the research

The present paper result from the consolidation of three separate research investigations that involved altogether hundreds of practitioners. In 2016 the three authors decided to combine their effort due to the exploratory nature of the topic.

The idea of the Fraunhofer IML and BME pilot study was initially based on the belief that the fourth industrial revolution offers procurement a unique opportunity to meet the demand that it plays a strategic role. The opinions of the surveyed procurement managers and Chief Procurement Officers (CPOs) from a total of 25 companies and two universities, form the core of this pilot study, which is designed to act as a source and starting point for more extensive and detailed investigations into the topic of PSM 4.0. When selecting respondents, the focus was placed on achieving a highly heterogeneous participant structure featuring experts from companies representing different sectors and of different sizes. Companies with headquarters based in Germany, Austria and Switzerland were surveyed as part of the study (For more details see Fraunhofer IML and BME, 2016).

In 2015, The EIPM started a research stream on the IoT with semi-structured interviews conducted with 15 CPOs across diverse sectors. Then 120 purchasing managers were involved in focus groups to explore the likely impact of the IoT on their industry and on different dimensions of PSM. Following this, 6 case studies were documented. The outcomes were published in the 2017 edition of the EIPM Value Creation Observatory.

In Switzerland, an expert group was launched in 2016 to explore the impact of Industry 4.0 on PSM Function and to develop a commonly agreed strategic roadmap transforming PSM. The expert group was an outcome of a broad survey performed with purchasing managers in Switzerland, which indicated, that the upcoming digitalization and disruptive transformation of business models will have a huge impact on organization, roles and competences in purchasing and supply management. Eleven purchasing managers from leading Swiss companies have been working closely together with academic and consulting partners to define and challenge a PSM 4.0 roadmap.

During the three streams of investigation, practitioners were not in a position to share a finalized "set of good practices" they had already developed and tested. They mainly presented anecdotal evidence coming from early stage projects and isolated case studies. This was complemented by their personal insights and views on the implications of IoT for PSM. Therefore, we systematically compared and contrasted our findings and decided to build a scenario that could be further questioned and tested. The purpose of this scenario is to generate discussion amongst practitioners and academics. The value of scenarios lies in their ability to challenge our theoretical model and to lift barriers that limit our creativity (Schwartz, 2007). We have identified two main external trends that could affect PSM. The first trend is that IoT can provide significant opportunities to the PSM function to create access to complementary but distant digital capabilities that will be essential to transform a firm's business model. The second trend is that PSM will be itself impacted by the digitalization of business activities. Based on this, we created one scenario that realizes a combination of these two trends. We have structured our scenario around three dimensions: Organization and Processes, Technologies and Systems and Management of People and Skills. Build on that, our aim is to provide new perspectives while

broadening the range of causal relationships that could be further investigated in the field of PSM practices and research.

IoT, Industry 4.0 and digital transformation: some definition

The Internet of Things goes back to Mark Weiser's work in 1988 at computer science lab at Xerox PARC where he formulated the ubiquitous computing vision and described a world, where algorithms are closely embedded in our daily life (Weiser, 1991). Later, in 2009, the term Internet of Things was coined by Kevin Ashton, RFID pioneer and co-founder of the Auto-ID centre at the Massachusetts Institute of Technology (MIT), which created a global standard for RFID (Ashton K., 2009). The IoT is now defined by the International Telecommunication Union as "the global infrastructure for the information society, enabling advanced services by interconnecting (physical and virtual) things based on existing and evolving interoperable information and communication technologies. The interrelated evolution of science, technology, business and social practices turns this vision into a reality. Algorithms and sensors offer a system of interconnected smart devices, which enable real time and intelligent communication from man to machine, machine to machine and enterprise to enterprise. IoT is a "general purpose technology" (Rousseau, 2017), it pervades many industries, improves rapidly and generates further innovations. More and more technology building blocks (e.g. smart objects and devices) that can be swiftly interfaced to create open or semi-open systems (Kortuem e.a., 2010, Serbanati e.a., 2011). These building blocks are continuously available at lower price and consume less energy. As the building blocks are increasingly used across all sectors, an increasing amount of data is produced and released and more value springs from connecting unrelated devices and capabilities. Data is becoming the most valuable raw material for the future. In other sectors, products are changed into product/service hybrids and business models are transformed. These changes 'who does what' and 'who gets what' within and across industries and new industry architectures emerge (Jacobides et al., 2006). The Industry 4.0 was coined in a document (Kagermann, 2013) that defined a R&D strategy for the German manufacturing sector. Industry 4.0 is the application of IoT to manufacturing activities as it is based on the concepts of Cyber-Physical Systems (a fusion of the physical and the virtual worlds). The technology enablers for Industry 4.0 include mobile, cloud, big data analytics, machine to machine communication (M2M), 3D Printing, Robotics etc... Meanwhile the 4.0 extension is used in almost all economic fields and for all functions to express the significant changes that are expected to come (e.g. Logistics 4.0, government 4.0, health 4.0, etc.). Industry 4.0 and The Internet of Things are encompassed within the broader digital transformation which was defined as the digitalization of analog machine and service operations, organizational tasks, and managerial processes (Iansiti & Lakhani, 2014) to create value for customers and employees (Solis, 2017).

The Transformation of industry architectures

The following examples show the nature and the extent of the transformation of industry architecture we may experience in the coming years across every part of private and business relationships.

For **retail**, IoT offers opportunities in customer experience, the supply chain, new distribution channels and revenue streams. It allows bi-directional, real time interactions of customers, smart stores, smart products and smart logistics (Gregory J., 2015). IoT is the foundation for achieving "same day delivery" and it could enable companies, such as Amazon, to further

disrupt this sector of activities. Drones are only one device within a much broader web of information resp. Internet of Things and logistic services supported by a rapidly evolving business ecosystem.

For **transportation and mobility**, the emergence of self-driving cars forces automotive OEMs to transform their network of suppliers and partners and to access new capabilities such as batteries, connectivity solutions and mobility services. Mobility-as-a-Service becomes widely accessible as the young generation is moving away from owning a car (Stricker u.a., 2011).The evolution of the industry architecture coupled with the evolution of customer habits will challenge the OEMs dominance in the automotive sector (Attias, 2017). They may find it difficult to keep control over the allocation of profit across the mobility value chain networks.

For **consumer goods**, in recent years, many problems have occurred in the control and protection within food supply chains. As a result, public institutions have given food safety a top priority. In order to stay ahead in this protected and controlled market, IoT may play a significant role on food supply chain's effective information, identification and traceability opportunities. Implementing sensors and identification cross over the value chain, from farming to consuming, creates an interlink of geographic, organizational and functional distributed data networks (Xiaorong Z. u.a, 2015).

3-The IoT architecture as backbone of innovative business models

In order to propose a scenario for the development of PSM 4.0, initially we outline how the IoT affects industry architectures (Figure 1). Therefore, we explore how technology is converted into business value using IoT. The underlying framework combines an IoT architecture (Gubbi J. u.a., 2013) with a business model approach (Dijkman, u.a., 2015).

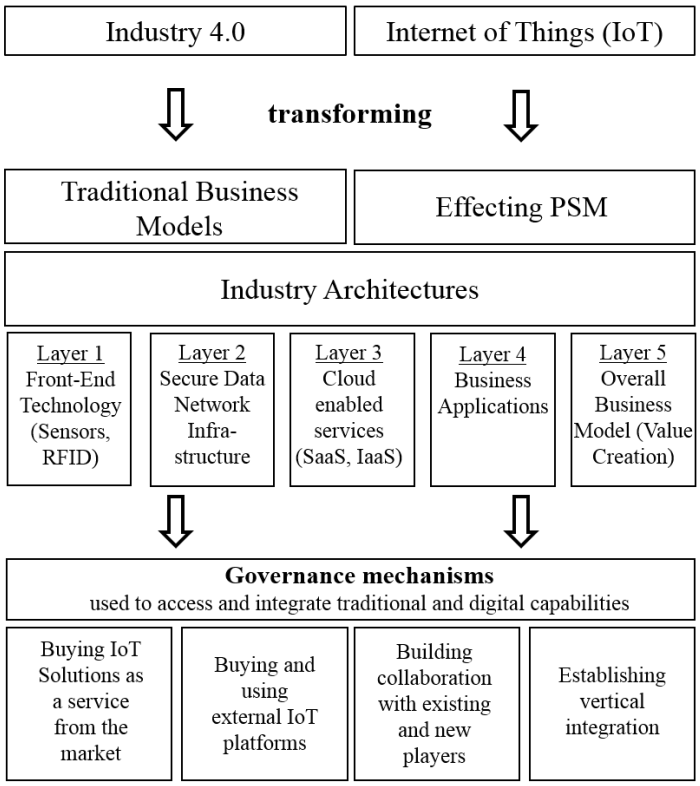

Figure 1: Overview how IoT affects industry architectures

The IoT architecture consists of five complementary layers that transform technology building blocks into new business processes and business models:

- Layer 1 includes front-end technology such as sensors, actuators and RFID embedded in mobile devices or intelligent autonomous objects (e.g. drones, robots, vehicles or smart stores). It creates and processes data anytime and anywhere autonomously. Layer 1 is responsible for the growth of data, conveyed by the Internet in layer 2.
- Layer 2 consists of internal and external communication infrastructures. Networks allow to collect, process, analyse and disseminate valuable information, which were gathered from distributed sources. The required hardware consists of a secure data network infrastructure of scalable nodes (access points, storage) and linkages (wired and wireless).
- Layer 3 represents cloud enabled services that provide SaaS (Software-as-a-Service), PaaS (Platform-as-a-Service), IaaS (Infrastructure as a Service), DaaS (Data-as-a-Service) and more. These software services are available via intranet, extranet or internet. Layer 1, 2 and 3 describe the technologies, which create and process "Big Data".
- Layer 4 encompasses the business applications as customer and supplier relationship management, demand and supply planning and forecasting, SCM risk Management, Track and trace information system, supplier /market scouting and scanning, and more. It improves functional processes and enables new offerings for data driven services. "Big Data" is leveraged to deliver value to customers, employees or other stakeholder. It also improves and accelerate the decision-making process.
- Layer 5 comprises elements of the overall business model. A business model demonstrates how a business creates and delivers value to customers. It also outlines the architecture of revenues, costs, and profits associated with the business enterprise delivering value (Teece, 2009). Technologies grounded in layer 1 to 4 are combined within a business model. Layer 5 therefore transforms information into new competitive advantage.

The proposed IoT architecture shows that companies need to combine traditional and digital capabilities coming from diverse technical and business fields. An IoT architecture is imbedded in a network of partners that provide all necessary building blocks to generate economic value. This integration across one or more layers of the IoT architecture can rely on different types of governance mechanisms used to access and integrate traditional and digital capabilities:

- ***Buying IoT solutions as a service from the market***. Here, an external integrator combines the higher layers of the IoT architecture within its own offerings and business model. Such offerings can then be deployed by the buying firm. For instance, companies can purchase smart logistic services from existing or new suppliers. Airlines purchase aircraft engines by the hour from providers who have extensive capabilities in data led services. Offers come "*as a service*".
- ***Buying & using external IoT Platforms***. Such platforms bring together multiple data service suppliers within a two-sided market. This is relevant for Layer 3 and 4 of the IoT architecture when a broad range of solutions can be aggregated in a platform to match the needs of the buyer. Market places such as iOS and Android allow consumers to access diverse connected devices. Smart factory platforms aggregate and combine diverse data services from multiple sources.

- ***Building collaboration with existing and new players.*** Such collaborations typically aim to combine traditional and digital capabilities to integrate the first three layers of the IoT architecture within a product/service hybrid, an operating model and possibly a business model. The development of Smart Meters for water application by Suez was performed in collaboration with two partners. The three companies worked together on development and sales in order to build an industry standard. Such collaboration can take place between heterogeneous partners where one is a start-up. The Rossignol connected ski for example was developed with PIQ a start-up with artificial intelligence capabilities.
- ***Establishing vertical integration.*** Vertical integration requires to insource and to integrate all necessary capabilities to develop an offering. This can help secure quality and speed while owning the final solution. This creates a path-dependency and requires an important investment, but it can provide a great competitive position, if successful. This is the case of Tesla Motors who, for instance, own their own network of charging stations to make sure that every Tesla driver can charge their vehicle when needed.

The first three modes of governance, presented above, highlight the importance of developing different types of horizontal collaborations. They offer an opportunity for the PSM function to play a key role in the upcoming transformation of their company's business models. PSM can create access to complementary but distant digital capabilities. Furthermore, the digital transformation implies that the roles, tasks, processes and competences of PSM are also affected by the change.

4-Evolving the Purchasing and Supply Management functions

Over the past forty years, the PSM functions in many industries have moved from transactional orientation into a more strategic role (e.g. Weele, Arjan J., Erik M. Raaij, 2014, R. McIvor e.a., 1997). The development of PSM function is often described in evolutionary stages (Schiele, 2007). The PSM Organisation evolves to respond to corporate goals and to react to an ever changing environment. A broad number of Industry partners, in each of our three research streams, expect that the IoT will accelerate and initiate transformations for the PSM function. They see PSM in a unique position to help companies taking advantage of the current industry transformations by gaining visibility on opportunities associated with the IoT.

To summarise our combined findings, we will look at the operational side of PSM stages of evolution as well as at the strategic stages of evolution. Our industry partners recognised that they have to achieve more than a linear extension of what was already done before. For example, the traditional attitude of PSM with a lower level towards risks and standardisation needs to evolve radically to gain advantage from business model innovation. And most importantly, it is not about simply replacing existing practices by new ones but about adding new options. Both, operational and strategic activities will remain relevant and will go through significant evolutions.

On the operational side, the focus of PSM is on efficiency, cost and performance. Our industry partners recognized that IoT and digitalization will transform the way they operate. By further automating the PSM processes, leveraging market-places and data led services from suppliers they expect that internal efficiencies, cost optimisation and further performance enhancement will be achieved. Their challenge is to understand how to set priorities within an uncertain and speculative context.

On the strategic side, the focus of PSM is on innovation, renewal and growth. This is essential to leverage opportunities associated with the Internet of Things. As PSM facilitates access to relevant IoT capabilities, companies are able to redefine their market position and to find profitable spots in the emerging division of labour. Our industry partners expect to help their company either maintain or gain new market shares. On the innovation side, they emphasize the importance of horizontal collaboration as a mean to understand innovation needs and the opportunities so they can help access relevant external capabilities. They also emphasize the need to strengthen their ability to scout for innovative solutions and to strengthen their attractiveness. Early supplier involvement is expected to remain important but to evolve for the forthcoming transformation. Some of our industry partners expect that external partners with IoT capabilities will contribute to transform the core businesses and the business models of their company. Smart meters have been incorporated into the core business of utility companies through collaborations with external partners. Now, they work with external data scientists to build new business models. Here, some of our industry partners see the value of looking well beyond existing suppliers, within the business ecosystem, to identify complementary and distant capabilities of value for the future. Some of them have started to explore how they can work in more agile ways to manage the relationship with innovative suppliers including start-ups and to support early experimentation activities. This section has outlined some of the changes that our industry partners expect. It also establishes the foundation for the scenario presented underneath.

5-A scenario for the transformation of the PSM function

Building on the previous analysis and on the three research streams, we have decided to develop a scenario structured around two hypotheses: First, the IoT can provide significant opportunities to the PSM function to create access to complementary but distant capabilities that will be essential to transform a company business model. Second, PSM will be itself impacted by the digitalization of business activities. We have structured our scenario around three dimensions: Organization and Processes, Technologies and Systems and Management of People and Skills.

Looking at ***Organisation and Processes***, industry experts expect that PSM teams will further diversify their practices to improve their strategic fit between organization and the requirements they face. Most of our industry partners assume that the future PSM organisations become more ambidextrous. While building on digitization opportunities for business-as-usual-situations, they will adopt new ways of working to contribute to a company's transformation. While some processes will be systematic and automatized, others will be more experimental and innovation focused. Classic efforts in terms of standardization will co-exist with flexible and swift forms of work that will respond to the business transformation imperatives.

Processes will be capable of tackling different levels of uncertainty and complexity. The contingency theory (Lawrence & Lorsch, 1967; Burns and Stalker, 1961) suggests that organizations operating in turbulent and uncertain environments are more effective when they use organic, informal, decentralized, organizational structures. Organizations operating in stable environments tend to use more mechanistic, formal and centralized structures to gain efficiency.

In our scenario, PSM needs to do both concurrently. The following framework helps us to reflect this challenge. In line with the contingency theory, the proposed purchasing organization

landscape considers two contingent factors: speed of change on demand side and speed of change on the supply side. The Y axis represents the level of turbulence on the demand side. Environmental turbulence is characterized by high speed change, rapid innovation and growing levels of complexity. As the IoT offers opportunities to rethink offerings and business models, it generates such turbulences. The X axis represents the level of turbulence on the supply side. Environmental turbulence is characterised by high speed of change, rapid innovation and increasing complexity. IoT generates such turbulences on this side as companies need to access and integrate new and distant complementary capabilities. On the bottom left, mechanistic structures will dominate while on the top right we will witness more organic structures. Six approaches have been identified.

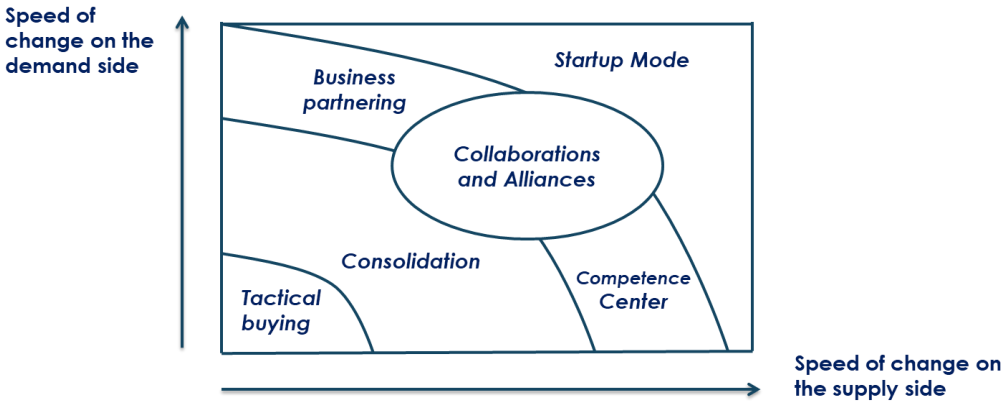

Figure 2: The purchasing organization landscape

I) On the bottom left, the absence of turbulence allows to implement highly *efficient tactical teams*. Using standard processes, they buy standard offerings that match the needs of everyone within the company. Such teams ensure that price and transaction costs are kept at a minimum by using adequate technologies. Tactical purchasing will be increasingly digitized and will be measured by its efficiency.

II) *Consolidation* is performed by Category Management Teams. Their role is to reduce complexity and diversity while maintaining or improving the current levels of performance. Such teams serve the needs of multiple business units, projects, sites or countries. They aspire to consolidate needs on the demand side and to standardize offerings on the supply side. As consolidation is achieved, tactical teams can take over. Buying IoT solutions as a service to cover all needs of a business will fall in this structure. Consolidation focuses on improving the economic performance of the company.

III) *Business partnering* typically arises as an advanced category management practice. Buyers focus on maintaining strong relationships with their business partners to cater for the diversity of needs and the rapid evolutions on the demand side. They do this either through regular direct interaction with them or thanks to a network of contacts within the different business groups. Business partnering is essential when the pace of change is high on the demand side and when the current supplier base can support the business. Suppliers can integrate IoT capabilities to offer easy to deploy solutions that respond to the diverse needs of the business. The purchase of Facility Management solutions typically fall into this category. IoT offers new solutions for managing and servicing buildings effectively. Business partnering aims at offering the best value from the market for the best price to different units with different needs. Performance can be measured by a combination of economic indicators complemented by operational performance measures shared with the business partners such as user satisfaction.

IV) *Competence centres* are an advanced Category Management practice. As turbulences occur on the supply side, buyers continuously keep abreast of the rapid changes that take place in the

broader environment. They advise the business on emerging solutions that could enhance the business performance or offer some differentiation opportunities. As new building blocks for the Internet of Things are put on the market, buyers will need to spot them and develop a clear and early understanding of how they could bring value to the business. Helping the business with taking the best decision at the right time is the role of competence centres. Performance can be measured by assessing the ability to balance risk, cost and innovation.
V) *Managing collaborations and alliances* is required when different building blocks need to be integrated and when architectural knowledge needs to be developed. This is a requirement in many IoT initiatives. Such purchasing teams manage long term relationships with strategic and critical suppliers who bring sometime distant complementary capabilities. The job is about facilitating cross company collaboration by working closely with all parties. This requires the use of the relevant cross company governance mechanisms, joint collaboration frameworks and shared communication tools. The objective is to contribute to the achievement of the business goals shared by all parties. In terms of IoT we saw that one of the governance mechanisms consist of building collaboration with existing and new players which fit within this structure.
VI) Our research also indicates that PSM teams increasingly work in *Startup Mode*. Business projects are handled by small multifunctional teams that combine diverse expertise and operates through rapid loops of visioning, development and validation. They have full freedom to pursue a new idea. When purchasing is involved in such a team, its role is to assemble innovative solutions from external partners that deliver value to the business and to clients. Innovative marketing and sales campaigns that leverage smart packaging or smart displays for instance, can fall in this category. Because resources are limited, it is essential to plan when and how to integrate such teams best possible. From a performance point of view the focus is on time, innovation and final user satisfaction for a given budget base.

The challenge for PSM teams is to develop their ability to use the different structures and approaches presented above concurrently, depending on the level of uncertainty and the nature of turbulences. This requires moving away from the application of a detailed standard process to gain flexibility. The framework presented above is also dynamic in nature. As dominant designs emerge on the demand and supply side, interfaces become more and more standard and PSM can revise its plan and adopt a new structure and approach for a specific purchasing segment.

Looking at ***Technologies and Systems,*** our expert groups indicated that PSM will benefit from being a new technology adopter. Using Big Data, Smart Analytics and the upper IoT layers, PSM can elevate itself to another level of performance. By combining a broad array of internal and external data PSM may act in real-time and become more flexible. Horizontal collaboration and the digitalization of the internal processes help PSM make quick and relevant decisions. PSM systems and tools will be further developed, interconnected and simplified by using bots, natural language and artificial intelligence. We believe that adopting digital and IoT solutions for PSM requires a solid understanding of the problems that are worth solving. Focusing blindly on automating tasks will not be enough. We expect that leading PSM teams adopt broad and forward-looking perspectives on digitalization, so both creativity and end-to-end performance will be unlocked.

Recent publications show that several firms are tapping into the need to harmonize product and financial flows among supply chain partners reaching beyond the traditional horizon of PSM. For such an integrated financial supply chain management cross-functional integration with finance/treasury internally and participating external suppliers is essential (Wuttke et al., 2013a). Such initiatives involve short-term working capital optimizations to leverage credit

rating differentials between OEMs and their upstream suppliers as well as long-term focused lending to suppliers to support their involvement in PSM innovation projects (Wuttke et al., 2013b) or the early stages of joint-product development projects (Wynstra et al., 2010). In order to leverage the full potential of such an inclusive supply chain finance initiative, digital technologies have to be considered in future PSM research. Besides IT techniques such as cloud computing (e.g. Bruque-Cámara et al., 2016), very recently, the blockchain technology and its potential for the field of SCM have been profoundly discussed. It offers a shared, reliable, public register of transactions, that all actors can examine, but no actor can control. As a result, the blockchain offers a virtual room to store value, identities, property rights and agreements. With their ability to keep track of every transaction through a decentralized mechanism of ownership, blockchains offer transparency and accountability of information. Hence, they are likely to affect the sphere of sustainable supply chain management. For example, materials, components and even minerals could be traced back and verified. It could have potentially prevented recent sustainability scandals on conflict mineral or the horse meat scandal from 2013 (Hofmann et al., 2015).

In terms of ***Management of People and Skills***, the adoption of a more diverse set of practices will logically drive PSM to adopt a situational leadership paradigm and to manage paradox effectively (Lewis, Andriopoulos & Smith, 2014). Purchasing teams will be bound together by common ambitions and practices while they need to exploit a diversity of internal capabilities that can be combined and recombined effectively depending of the context. It will be the ability to operate multiple approaches effectively at the same time, which will make the difference for future PSM leaders.

This calls for new skills and extended collaboration capabilities. Depending of the context and of their focus, PSM professionals will work across different structures and approaches. The optimization of work processes by digitalization will lead to a redistribution and change of existing tasks on operational and strategic level. PSM will perform more sophisticated task with less manpower. There will be fewer buyers with a higher level of qualification. PSM teams will increasingly be constituted by small groups of powerful and strategically oriented entrepreneurs. The optimal combination of technologies, processes and people will differentiate leaders from followers. To support the digital transformation PSM has to gain a broader understanding of issues and opportunities related to data, security, IP matters, system integration and business model innovation. Horizontal collaboration will be key in the forthcoming transformation and it requires open collaboration skills. Since technological progress is rapid, the limitation actually lies within the human factor. Therefore, human abilities and ways of thinking should be developed and adapted to the working environment 4.0.

5-Managerial and academic conclusion

As the Internet of Things and Industry 4.0 unfold, we observe that industry architectures are re-invented. For most companies, this means that some suppliers and some existing collaborations need to be abandoned while new ones need to be developed to gain access to valuable distant complementary capabilities. In this context, companies will need to empower PSM to develop their ability to simultaneously explore and exploit new territories and unfamiliar knowledge fields. Integrating different streams of knowledge to generate new offerings, new processes and new business models will be essential. Due to financial constraints and high level of uncertainty, collaborations amongst new players will be a popular vector of change. PSM has a unique opportunity to play here. Therefore, PSM needs to see the IoT as an opportunity. Regardless of whether it acts as an active influencer or as a driving force, the role played by PSM will be

important. PSM leaders need to outline their strategic relevance in this emerging context. The main risk lies in 'doing nothing', 'sitting back and waiting', which will cause PSM to become a follower. PSM leaders can initiate the change and shape a vision that establishes PSM and its ability to leverage IoT opportunities at the core of the strategy. They need to evolve their practices on both operational and strategic matters. They need to experiment with new forms of organisation and develop a culture where failure is accepted as a milestone on the way to success. PSM leaders will also need to ensure that their teams and external partners are properly informed, involved and prepared for the future.

On the academic side, PSM scholars will face some opportunities to broaden their investigations and to address new research questions that relate to PSM and the Internet of Things. This includes studying the transformation of industry architectures, the development of new PSM capabilities and the management of vertical and horizontal collaborations. At the same time, some fundamental questions related to PSM organisation, process and performance will need to be revisited. For instance, we need to study how PSM manages the paradox of being more efficient and innovation focused at the same time. Both practitioners and academics can expect exciting times ahead.

Preparing for public tendering:

With or without national templates for organizing interaction

Abstract

The preparation phase of public competitive tendering has for long been acknowledged as important. However, how interaction takes place in this phase has been given little attention. We use explorative multiple case studies conducted in Finland and Norway to study how interactions in the preparation phase can be organized. We rely on process theories (deliberate and emergent strategies) to compare the design of activities in preparation phases, and supply- and knowledge sharing network research to analyze how interaction is organized in the process. We conclude that the interaction can take different forms, and include various types of information exchange.

Key words: public procurement, preparation phase, interaction

Introduction

Public procurement is a multi-objective policy, which simultaneously aims to achieve economic, sustainability, and social goals, and on top of that facilitate innovation to take place through the procurement process (Uyarra and Flanagan, 2010). Interaction with the market in the preparations for public tendering has been acknowledged as important to facilitate innovation and procurement of better goods and services for public use. Early interaction with the market can provide public buyers access to industry knowledge, increase the chances of finding solutions for cost savings, and create an environment of trust that can facilitate realization of opportunities (Uyarra, 2010). However, EU directives and national procurement law restricts the forms of interaction and emphasizes equal treatment of all participants (Arrowsmith, 2014; Lenferink, Taede and Arts, 2013). In this paper, we describe how interaction can take place in the preparations for public tendering in which it can facilitate innovation and lead to better procurements. Thus, our study relates to 'innovation-friendly procurement', which is a term that has been used to denote that, in terms of the procurement process, markets can be expanded and accommodated for new solutions to be developed, or new actors can be invited (Knutsson and Thomasson, 2014, Uyarra and Flanagan, 2010).

In this paper we explore; How can interaction be designed and organized in the preparations of regularly tendered services? Furthermore, how does innovative procurement programs instigated at the national level enable and constrain the manner in which interaction is organized? As a method, we use explorative multiple case studies conducted in Finland and in Norway. The study of interest is, however, how interaction can take place when preparing for competitive tendering in public procurement rather than on country specific differences. Theoretically, we rely on (1) Mintzberg and Waters' (1985) concepts of deliberate and emergent strategies to describe and compare the process of activities in different preparation phases, and (2) supply network and knowledge sharing network research (e.g. Dyer and Nobeoka, 2000; Holmen, Håkansson and Pedersen, 2003) to analyze how interaction takes place during this phase. We conclude that the interaction in the preparation phase can take different forms and include various types of information exchange.

The paper is organized as follows. First, the theoretical framework used for analysis will be presented and discussed. Second follows a discussion of the method applied and a presentation of the empirical material. The third section presents an analysis of the cases. The final section concludes the study.

Theoretical framework – public procurement process and knowledge exchange

In general, the public procurement process can be divided into three stages: the preparation, tender and post tender phase. The preparation phase (also known as pre-procurement or pre-tender phase) is the the process prior to the competitive tendering process where fewer regulations restrict the forms of interaction with suppliers. To describe the activities in preparation phase of public procurement, we use the concepts of deliberate and emergent strategies (Mintzberg and Waters, 1985). Some strategies are intended and intentions are formulated in plans for them to be realized and to set direction and control, often referred to as 'planned strategies'. On the other hand, sometimes strategies emerge more as patterns based on actions and choices taken along a path by employees or other actors, without following predefined plans and intentions, which can facilitate 'strategic learning' (Mintzberg and Waters, 1985, p. 270). Moreover, Mintzberg and Waters (1985) argue that strategies are never purely deliberate or emergent but fall somewhere in between the continuum of the two externalities, and contains some deliberate and emergent elements.

Knowledge-sharing between firms is seen to promote more rich and diverse knowledge compared to the knowledge-sharing within a firm (Hardy, Nelson and Lawrence, 2003), benefiting thus both the buyer and supplier (Dyer and Nobeoka, 2000). Suppliers can possess knowledge that can be useful for the firm, and knowledge-sharing can give firms valuable information (Lorenzoni and Lipparini, 1999). In creating knowledge sharing networks, three dilemmas have to be managed; (i) getting actors to participate and openly share knowledge, (ii) prevent 'free riders', and (iii) share knowledge effectively within the network (Dyer and Nobeoka, 2000). Knowledge can be either (i) explicit or information, and (ii) tacit or 'know-how' (Grant, 1996). Explicit knowledge can be regarded as easily coded and transferable for example in a group setting. Tacit knowledge is encoded and inherent knowledge in the firm, and it is transferred through closer and more intensive interaction in small groups (Dyer and Nobeoka, 2000). Moreover, organizations learn by collaborating with other organizations and by sharing tacit information (Kogut and Zander, 1992). Regular communication, interpersonal connections and commitment help to share knowledge and create shared perspectives (Granovetter, 1973). Prior studies have shown that informal socialization tactics, such as face-to-face communication, are important to the level of knowledge sharing within collaborative product development teams (Lawson, Petersen and Cousins, 2009) and strategic alliances (Oxley and Sampson, 2004). Barriers for knowledge-sharing and collective learning may exist when there are differences in norms, values, technical language and fundamental concepts between individuals or organizations (Rashman, Withers and Hartley, 2009). In public procurement context, competition between public organizations or punishments for failure may inhibit knowledge-sharing (Vince and Saleem, 2004). However, relatively little research has been devoted to the ways by which public organizations create, transfer, share and apply knowledge (Rashman et al., 2009).

Method

To show how interaction can be organized in the preparation phase of public procurement, we have followed an embedded multiple case study design consisting of four cases. Two of the cases are taken from a Finnish context, where no innovative procurement program has yet been established at the national level. Two of the cases are taken from a Norwegian context where a national innovative procurement program (NP) was set up more than a decade ago. In empirically describing the cases, we aim to present different activities in the preparation phase and capture how the interaction between procurers, suppliers and other parties can take place.

We adopted an exploratory approach. The Finnish study (Case 1 and Case 2) was a part of a three-year long research project (2014-2017). The main data sources were in-depth semi-structured interviews with potential suppliers and unstructured interviews with Procurement Unit (PU) that was responsible for the municipalities' tendering. Furthermore, we observed interactions between the suppliers and the PUs and studied several documents related to the tendering, for example, the initial and final RFQ, and material prepared for the interactions with the potential suppliers. We arranged also workshops with the personnel involved in the procurements.

The Norwegian study (Case 3 and Case 4) was part of a one and a half year long research project (2016-2017). Data was collected through semi-structured interviews with representatives from the procurement and function units responsible for the procurements, potential suppliers and a sub-supplier. Further, a number of different documents related to the preparation phase and competitive tendering was studied (i.e. invitations to information session, RFQ etc.). Workshops were held with the representatives from the procurement and function units, the NP and researchers to discuss and have common understanding of the procurements.

Case descriptions

In all the four cases, the value of procurement contract exceeded the EU-thresholds, and competitive tendering was organized according to the EU Directives and national law of public procurement, and applying the open tendering procedure.

Case 1 (*Care catering*) and Case 2 (*Hospital Catering*) concern a Finnish municipality's two different catering services procurements. Collective supply contracts are used in all the Municipality's units. In 2014, the Municipality started an outsourcing process of all its catering services, which previously had been provided in-house. *Care catering* concerned meal deliveries for special groups, i.e. persons with disabilities, senior citizens and drug addicts. Preparations started in the autumn 2014, and the Contract Notice and Request for Quotation (RFQ) were published in the spring 2015. *Hospital catering* involved municipality's hospitals, including catering services for patients, staff restaurants, and hospital cafeterias. The preparations started in the autumn 2015, and the Contract Notice and RFQ were published in the beginning of the year 2016. The PU was authorized to take care of the preparations for the tendering. The intended duration of both the contracts was three years. In both the cases, the Welfare unit was the customer, which, in turn, is responsible for providing catering services for its customers, i.e. hospitals and care homes. The end customers were the inmates, patients, visitors and stuff in the hospitals and care homes.

Case 3 (*Ferry service*) and Case 4 (*Education service*) concern two county municipalities' procurements of services. The *Ferry service* involved a procurement of ferry transit services with a two-year contract. Normally, the contract duration are eight to ten years, but the procurement was adjusted for a future procurement of two sections in one tender. The preparations for tender started in autumn of 2014 and the RFQ was published in the start of 2015. The county municipality was the customer and is responsible for the planning of local and regional schedule for transportation and in this case, a county municipality owned organization (CMO) performed the procurement based on a mandate issued from the county. The end customers were travelers using the ferry transit service. The *Education service* concerned procurement of follow-up services for young people with risk of falling out or fallen out of upper secondary education. The county municipality had not offered a similar service earlier. The preparations for tender started in late summer 2015 and the RFQ was published late autumn 2015. The preparations and procurement was performed by a project group (PG) consisting of representatives from the follow-up service and procurement unit, and the end customers were young people fallen out or with risk of falling out of upper secondary education. In the *Ferry* and *Education services*, the NP was involved and suggested to use a designed process of activities in the preparation phase.

Activities in the preparation phases

The *Ferry* and the *Education services* followed a designed process of activities proposed by the NP. In the *Care* and *Hospital caterings*, the processes were inspired by other tenderings. All the four preparation phases started with internal service specification and needs assessment, and a draft of the specifications were developed in advance of the market dialogue activities. Catering services had earlier been provided by a limited company owned by the municipality. Therefore, the internal needs assessment was extensive. Different interest groups were engaged: the PU engaged the Welfare unit, and several other internal units. In addition, a market search was done to map potential suppliers. The *Hospital catering* preceded the *Care catering*, and was conducted by the same PU. In the *Education services* as well, the internal needs assessment was extensive and long.

In all the cases, information sessions were organized, where the suppliers were informed about the forthcoming tendering and the tentative plans regarding the content of the service. In the *Care* and *Hospital caterings*, the organizer was the PU, and the sessions were open for all interested actors. An additional aim for these sessions was to provide the suppliers an opportunity to create relationships so that also the small suppliers would be able to participate the tendering. However, no partnering relationships were formed. In the *Ferry service*, the information session was organized by the CMO, and the NP, a municipality, and the shipping association attended, in addition to the potential suppliers and one sub-supplier. For the *Education service*, the information session was organized by the PG, and potential suppliers, the NP and head of education attended the session. After the information session, several suppliers started talking to one other about delivering a solicited offer.

In the information sessions, the potential suppliers were invited to book a time for a face-to-face technical dialogue in all the four cases. In all the technical dialogues, confidentiality was underlined, and all suppliers were given equal amount of time. The issues discussed concerned mainly technical details. In the *Care* and *Hospital caterings*, the customer was invited to these dialogues; however, the customer was present in three dialogues out of five and in the *Hospital catering*, there was no customer representation.

The feedback from the information session and technical dialogues were used to improve the RFQ and to finalize the tender documents. As a final activity, the RFQ was distributed for comments in writing and suppliers could comment in writing in two of the cases: *Care catering* and *Ferry service*. The purpose of this activity was to clarify aspects in the specifications. Figure 1 shows the timelines of the activities in the preparation phase for all the cases.

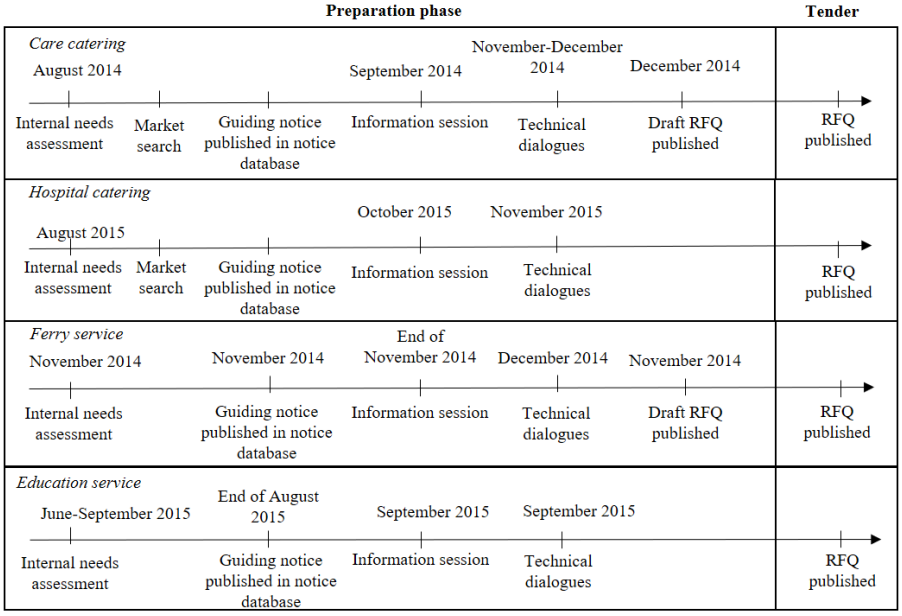

Figure 1: Timelines of the preparation phases

Analysis of interactions and processes

This section analyses the results of each case. The first issue addressed for each case is how interaction was organized and designed, and the type of information exchanged. The second issue addressed is how the process of activities in the preparation can be viewed as emergent or deliberate.

Case 1 – Care catering

The *Care catering* procurement consisted of one internal activity and three activities to facilitate interaction with potential suppliers. The interaction at the information session reflected one-way explicit information exchange of technical information from the PU to the potential suppliers about the forthcoming tender. The PU expected the suppliers to comment about the plans but due to presence of other potential suppliers, none of the suppliers asked or commented on the information that were given, which demonstrates the difficulties in creating networks of relationship where knowledge could be shared openly, as noticed by Dyer and Nobeoka (2000).

In the technical dialogues, the PU and suppliers had an opportunity to interact on a face-to-face basis and to exchange information without the suppliers' competitors' presence. The information was mainly related to the details of the purchased services and goods, i.e. the information exchanged was explicit knowledge. In addition, the buyer learned about the suppliers´ resources and capabilities, and both parties equally recognized the importance of meeting face-to-face and coming to know one another. The dialogues were well prepared with pre-readings that were sent to the suppliers beforehand and the suppliers could prepare. Furthermore, longer time was allocated to the dialogues (1,5 hours) and the suppliers perceived that the dialogues created better conditions for potential cooperation. However, a barrier for the buyer for deeper interaction and sharing implicit knowledge was the required equal treatment of the potential suppliers. For the suppliers, this requirement of equal treatment caused the fear of knowledge spillover to competitors. Therefore, the technical dialogues did not help in developing the tender specifications, and the dialogues resulted only in minor modification in the preliminary RFQ, for example, correcting some mistakes in the calculations. The most significant change was mitigating the sanctions related to the providers' expected performance.

When the RFQ was distributed, the comments were used to make the last adjustments prior the announcement of the competitive tender. The information exchange was written and two-way. The suppliers found written commenting difficult and unproductive. There was a time pressure with tight deadlines and reading took a lot of time due to the length of the RFQ. However, some faults were corrected with the help of the suppliers' comments.

Moreover, the process of activities in the preparation phase of the *Care catering*, the activities did not follow a predefined path of activities proposed by an external actor. The PU followed mainly the same practices that have been used in the context of other large tenderings in the municipality, for example in facilities tendering. Hence, the process of interaction activities can be regarded as an emergent process with hints of deliberate elements as the PU was inspired by other large tenderings.

Case 2 – Hospital catering

In the *Hospital catering*, the interaction at the information session was one-way exchange of explicit of technical information about the forthcoming tender from the PU to the potential suppliers. As in the *Care catering*, the PU expected the suppliers to comment but none of the suppliers asked or commented on the information given. In the technical dialogues, the information exchange had the same features as in the *Care catering* case. However, the *Hospital catering* preparations were featured by tight timetable and lack of sufficient resources. The technical dialogues lasted for one hour and the suppliers were not given pre-readings before the dialogues. As in the *Care catering*, for the buyer a barrier for deeper interaction and sharing implicit knowledge was the required equal treatment of the potential suppliers. For the suppliers, this requirement of equal treatment caused the fear of knowledge spillover to competitors (Dyer and Nobeoka, 2000). Therefore, the dialogues resulted only in minor modification in the preliminary RFQ, for example, correcting some mistakes in the

calculations. The most significant change was mitigating the sanctions related to the providers' expected performance. During a later phase when the service was implemented, it was noticed that the commenting of RFQ would have been important, because several misunderstandings and lapses of memory were discovered. These faults had to be corrected, which prolonged the implementation and impeded daily deliveries.

The preparation phase in the *Hospital catering* was emergent with hints of deliberate elements. as it was not based on a predefined process model but the PU followed the same procedures as in the *Care catering*.

Case 3 – Ferry service

In the *Ferry service*, the interaction at the information session was one-way explicit information exchange with traces of dialogue. Information was exchanged from the CMO, the NP and municipality to the potential suppliers and the shipping association. The traces of dialogue were apparent through the questions some suppliers asked, however, these were general clarifications. The attending suppliers reported that the information session made it easier to understand the need and requirements for the tender, since the duration of the contract was shorter than normal ferry transit contracts.

The technical dialogues involved face-to-face explicit information exchange between the CMO and the suppliers, where technical details about the forthcoming tender was discussed. Moreover, the suppliers were in the technical dialogues more open to exchange information. The suppliers experienced that the technical dialogues gave them more insights about the risk and uncertainty of the forthcoming tender in which helped them price and develop the tender documents more precise when the RFQ was published. The CMO got inputs from suppliers on several aspects regarding the specifications in which also resulted in changes e.g. time of departure of ferry was changed to time of arrival based on inputs from the suppliers. In addition, the CMO got more insights to the suppliers' capacity and views on the ferry service, which was valuable for future tenders.

The preparation phase in the *Ferry service* followed a processes of activities proposed by the NP. Thus, the preparation phase can be regarded as a deliberate process of activities. However, the NP proposed what the content in the different activities could be but the CMO was responsible for what was done.

Case 4 – Education service

The interaction at the information session in the *Education service* can be regarded as one-way explicit information exchange with few traces of dialogue. There were very few comments from the suppliers, but the PG was prepared for this as the NP had informed them in advance. The PG experienced the information session as valuable because they got to inform suppliers about the need and aim of the service. The information session also resulted in establishments of relationships between suppliers.

The technical dialogues involved two-way information exchange between the PG and the suppliers, and the suppliers presented a proposal for the service. Several suppliers attended the technical dialogues in groups of two or three as a result of the relationships established after the information session. This was to draw on each other's strengths and due to suppliers' capacity limitations. The input from the suppliers were perceived as valuable by the PG as it gave them insights to suppliers capability of providing the service and inputs on the specifications and service. The suppliers experienced that their feedback was used to improve the specifications e.g. adjusting the economic model for payment. Based on the information session and technical dialogues, the PG felt that it was created a 'sense of community' for the

need and aim of the service, meaning that the PG and suppliers were working towards the same goal.

The *Education service's* preparation phase followed the designed process model proposed by the NP and can be regarded as a deliberate process, but with hints of emerging elements. The emerging elements came to light by that not all the activities the NP proposed was used in the preparation phase i.e. the written procedure.

Cross-case analysis

In this section, we recognize that interaction during the preparation phase takes different forms (or framing modes, see Holmen et al., 2003) and different actors are involved. We focus on how information flows and forms of interaction in the different activities.

One-way information exchange

Different actors were involved in the activities of the four preparation phases. In all the cases, the information flow in the information sessions were characterized by one-way exchange with traces of dialogue in the *Ferry* and *Education services*. The public buyers expected the suppliers to comment about the plans but due to presence of other suppliers, some comments were only raised in the *Ferry* and *Education services*, and none in the *Care* and *Hospital caterings*. This demonstrates the difficulties in creating networks of relationship where knowledge could be shared openly, as noticed by Dyer and Nobeoka (2000). The absence of interaction and dialogue between the public buyers and suppliers at information session can be linked to sharing information in plenary sessions with the risk of revealing business secrets and lack of trust. This is also illustrates the 'free rider' problem in knowledge sharing networks (Dyer and Nobeoka, 2000). Creating mutual trust in the preparation phase is not consistent with the competitive situation the suppliers are part of in public procurement and, therefore, it is difficult to create trust-based and fruitful interaction at the information session.

For the *Care* and *Hospital caterings*, the PU was the only actor informing suppliers at the information session, while in the *Ferry* and *Education services*, other actors also informed the suppliers. While the interaction set-up in *Care* and *Hospital caterings*, can be regarded as 'one-to-many' i.e. PU to many suppliers, the interaction was organized as 'many-to-many' in the *Ferry* and *Education service* i.e. public buyer and other actors to suppliers. Figure 2 illustrates the forms of interaction at the information sessions. The attendants at the information session for the *Care* and *Hospital caterings* were the PU personnel and potential suppliers, while in the *Ferry* and *Education services* other actors also attended i.e. the NP, shipping association, head of education etc. In the *Care* and *Hospital caterings'* preparations, the suppliers noticed the absence of the customer, and they would have preferred discussing some issues, for example logistic details, directly with those dealing with the daily practices. In the *Ferry* and *Education services'* preparations, the NP supported the CMO and PG in the preparations for the information session and technical dialogues.

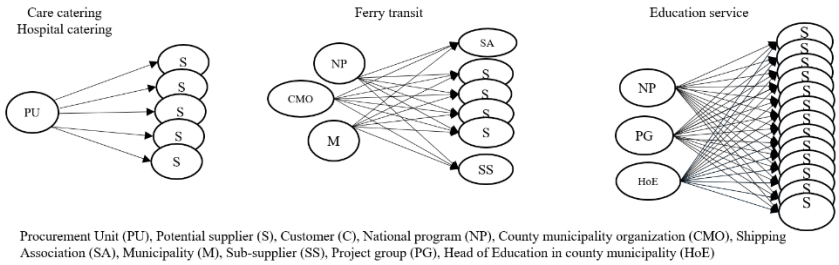

Figure 2: Information exchange at information sessions

Two-way information exchange

In the *Care catering* and *Ferry service*, two-way information exchange took place at the technical dialogues and in the written procedure to comment the RFQ. The form of set-up for the technical dialogues in the *Care catering*, were 'one-to-one' in two dialogues i.e. PU to one supplier and 'many-to-one' in three dialogues i.e. PU and customer to one supplier. In *Ferry service*, the technical dialogues were organized as 'one-to-one' i.e. CMO to one supplier. Moreover, more detailed information was shared at the technical dialogues since competitors were not present, but tacit knowledge was not shared.

In the *Hospital catering* and *Education service*, two-way information exchange were organized at the technical dialogues. Due to limited time, the written procedure was not done in these preparations. In the *Hospital catering*, the interaction was organized as 'one-to-one' i.e. PU to one supplier. In the *Education service*, some suppliers formed relationships after the information session and participated the technical dialogues together. This was also an additional aim in the *Care* and *Hospital caterings*, but no relationships were formed. The interaction in the *Education service*, reflected a 'one-to-many' set-up in three dialogues i.e. PG to many suppliers and 'one-to-one' in two dialogues i.e. PG to one supplier. Figure 3 illustrates the forms of interaction in the four cases.

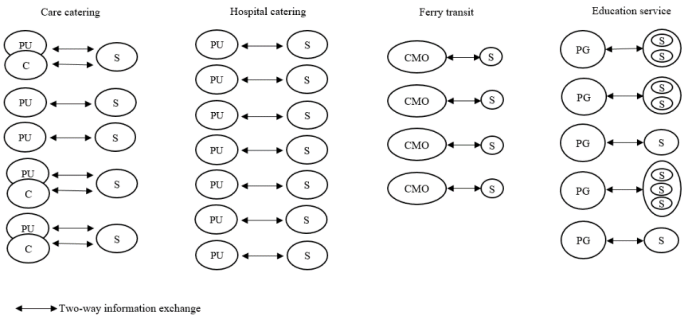

Figure 3: Information exchange in technical dialogues

Discussion/conclusion

From the analysis of the cases, we conclude that the process of activities in the preparation phases are similar with some variations. However, the forms of interaction, outcomes of the preparation phase, and how the processes of activities were instigated, differs. In terms of the processes of activities, information sessions and technical dialogues were used in all the cases, while the written procedure were used in the *Care catering* and *Ferry service*. In the *Care* and *Hospital caterings*, the suppliers were mapped prior to the information session, aiming to get as many potential suppliers as possible to tender. This was not done in the *Ferry* and *Education services*. As it follows from the analysis, the activities of the preparation phase can be regarded as deliberate – following a predefined model of activities instigated by an external actor, or emergent – not following a predefined model for activities. However, the deliberate processes shows hints of emergent elements as seen in the *Education service* where the written procedure was not done due to time pressure. The vice versa is also the case for the emergent processes, containing deliberate elements, shown in the *Care* and *Hospital caterings*. This follows Mintzberg and Waters' (1985) argument that processes cannot be completely deliberate or emergent.

Moreover, the forms of interaction in the activities and outcomes of the preparation phases for the specifications differs. The interaction form in the information sessions, were organized as 'one-to-many' and 'many-to-many', involving one-way information exchange in informing about the service needs and procurement plans. Further, the technical dialogues opened up for more interaction and were organized as 'many-to-one', 'one-to-one', and 'one-to-many', which illustrates different forms of interaction . Furthermore, the outcome of the preparation phases

illustrates differences in how feedback from potential suppliers were used to improve the specifications. In the *Care* and *Hospital caterings*, the feedback from suppliers was mainly used to mitigate sanctions, and the specifications for tender were very detailed. On the other hand, in the *Ferry* and *Education services*, the feedback from the suppliers were used to improve the specifications in order to make it possible for suppliers to deliver on the tender based on their capacities. A possible explanation for this could be because the *Ferry* and *Education services'* preparation phases followed a predefined model by the NP, and the NP assisted the public buyers in the preparations contributing with expertise. The role of the NP resembles what Edler and Yeow (2016) describes as intermediaries in which the intermediary could help to tackle some of the known procedural and capability failures in public procurement of innovation.

From the analysis, we see that interaction with the market in the preparation phase is not only used in relation to innovation and when procuring new goods and services. Interaction activities in the preparation phase can be used to get inputs from suppliers on ways of delivering the good and get insights to suppliers' capability and capacity in delivering the tender, when the public buyer is outsourcing a service which earlier has been provided inhouse, or when the service is new to the public buyer.

ABSTRACT
The aim of this paper is to explore how cooperative public purchasing is organised within the context of security organisations.The literature review outlines the different forms of cooperative purchasing, the context of public purchasing and the agency theory. The empirical part identifies the different forms of cooperative purchasing and the incentives of cooperation through eighteen interviews with purchasing professionals. This article contributes to the current state of scientific knowledge on cooperation purchasing and the enhancement of cooperation between different purchasing organisations. This is accomplished by demonstrating the rationale of choosing different forms of cooperative purchasing.

Keywords: cooperative purchasing, public purchasing, security

INTRODUCTION

The economic situation in Europe, and especially in Finland, has led to extensive budget reductions. Security organizations in particular with fewer resources had to response to incidents like the crisis in the Ukraine, the immigration crisis and the increasing level of terrorism. Even though the appropriations distributed to the Finnish Defence Forces, the Police of Finland and the Finnish Border Guard have nominally increased by 20% in 2007–2017, their level has, however, remained relatively unchanged when adjusted for inflation. At the same time salary costs in the public sector have increased 16% quicker than the rate of inflation. During the past ten years, the number of personnel in the Finnish Defence Forces has decreased by 23%, in the Finnish Border Guard by 13% and in the Police of Finland by 12% (Ministry of Finance, 2007 and 2017).

In an effort to meet economic demands, the Finnish Government has focused on the development of procurement activities, such as collaborative procurement, as means to respond to the challenges driven by fewer resources and changes in the security environment. One way is to collaborate with other similar organisations beyond national borders, such as purchasing defence material from the NATO Supply and Maintenance Agency. Another is to collaborate with other public organisations, such as security organisations. Collaboration with the private sector, in the form of a private-public partnership could also be fruitful. Finally, the need of multiple purchasing of the same material could be eliminated altogether by appointing an official responsible for each security material, who will be able to provide administrative assistance that will enable material borrowing across security organizations within country.

Finland's public procurement strategy aims to expand collaboration and centralise procurement (Ministry of Finance, 2009). The Finnish Government has defined in 2006 the products and services that must be acquired through a centralised procurement process that includes electricity, fuel, office furniture, regular IT equipment, expert services, mobile

phones and occupational healthcare services. In accordance with the procurement strategy, Hansel Oy, a central procurement unit, is responsible for arranging the bidding processes for commodity-type products and services. Its activities, as a central procurement unit, are defined in the legislation In 2016, the Ministry of Finance proposed the monitoring of the consumption of cooperatively procured products and services and promoting the overall use of cooperative procurement in line with the goals set to be adopted as common goals for public procurement (Ministry of Finance, 2016).

This article discusses the opportunities for collaborative procurement between Finnish security and rescue organisations. The article also evaluates different forms of cooperation between security authorities including centralised procurement through Hansel Oy. The aim is to answer the following questions:

- What types of items are suitable for collaborative or centralised procurement projects in the context of public purchasing and what are not?
- How collaborative procurement of Finnish security organisations is currently organised and how it is reflected through theory?

There are quite a few differing definitions of cooperative purchasing. For example, a narrow one by Tella and Virolainen (2005: 162) "independent organisations that pool their purchases in order to achieve various benefits" and a broad one Schotanus and Telgen (2007: 53) "the cooperation between two or more organisations in a purchasing group in one or more steps of the purchasing process by sharing and/or bundling their purchasing volumes, information and/or resources". In this article, we follow the broad definition where cooperation in its simplest form may only involve the exchange of information.

The article presents the background of public procurement and its legal context as well as the different types of items. The Agency theory is discussed in order to highlight the conflicting goals between the principal and the agent and describe the governance mechanism that limits the agent's self-serving behaviour as suggested by Eisenhardt (1989) on the public procurement and collaboration. It continues with the different forms of organising collaborative procurement following the Schotanus and Telgen (2007) model. Then the interview results are presented and the article concludes by drawing conclusions and discussion of the results

LITERATURE REVIEW

Public procurement

Public procurement in Finland is governed by the Act on Public Contracts (1397/2016), which is based on the EU public procurement directive 2014/24/EU and the Act on Public Defence and Security Contracts (2011/1531) consistent with the EU defence and sensitive security procurement directive 2009/81/EC. According to these acts, purchases that exceed a specific monetary value threshold must generally undergo a bidding process as defined in the legislation. However, the national security derogation in article 346 of TFEU leaves the trade of military material as well as the disclosure of information, essential to security interest, outside the jurisdiction of the EU. Because of this national security derogation, the defence procurement directive has not been extensively used. European Commission (2016) estimates that only 8.5% of defence procurement was carried out on the basis of its provisions.

According to Schapper et al. (2006), public procurement has three types of principal goals. In addition to the most affordable results and effective management, these goals include the maintaining of general trust in public procurement activities through transparency, equality and sustainability and the aiming to fulfil other general political goals, such as regional balance and eco-friendliness. For example, maintaining general trust, through openness and monitored use of assets, is possible by means of laws and decrees. This leads to different procedures compared to a situation where only affordability and efficiency are required. The regulatory system, which is also called bureaucracy, is not in line with the goals of flexibility and efficiency.

The Kraljic (1983) model is widely used in procurement management to divide the purchases of industrial companies into four categories according to the importance of each product and the risk of availability. These categories are strategic, bottleneck, leverage and non-critical items. The procurement volume should be regarded as a criterion for importance, in the simplest sense, and the lack of alternative suppliers or substiute products can be regarded as an availability risk. Different goals and operating methods can be applied to various categories. Van Weele (2005) recommends supplier cooperation for high-volume products and products with an uncertain availability but, if the risk is low, a strict bidding process should be used. Correspondingly, routine products of a low volume and risk should be procured effectively with minimal administration but, if availability is uncertain, it is important that availability is secured. According to Schapper et al. (2006), public procurement is divided, in most countries, into processes involving a low unit price and a high volume and into processes involving a high unit price and a low volume (e.g. investments). Of the five main procurement groups defined by Iloranta and Pajunen-Muhonen (2012), this definition corresponds to investments and indirect procurement, as the other groups, such as intermediated items or production purchases, do not exist in the public sector. According to them, these different groups differ from one another in terms of goals and operating methods. The fundamental idea of the Act on Public Contracts is competitive bidding which is automatically assumed to reduce prices (Kalima et al., 2007). However, the Kraljic model recommends that bidding processes are only applied to high-volume and low-risk products. Even though controlling the availability risk is not necessarily a central factor in public procurement for security organisations, at least in terms of regulation, it is important to deal with high-volume products with low unit prices. With regard to these, the aim is to reduce the amount of administrative work. Iloranta and Pajunen-Muhonen (2012) define these as indirect purchases that, according to them, are often decentralised and poorly monitored.

Agency theory

The core of agency theory is the differing goals of the principal, who contracts the work to be performed by the agent, and the agent who does the work and receives a reward. This leads to issues involving lack of effort by the agent (i.e. moral hazard), misrepresentation of ability (adverse selection), because of the principal's inability to verify ability, and the actual effort or outcome (Eisenhardt, 1989). There are ways to mitigate these challenges through e.g. procedural control (Soudry, 2007), monitoring, bonding (i.e. sanctions, punishment), oversight (Yukins, 2010) and economic incentives to align interests of the principal and the agent through outcome-based rewards (Eisenhardt, 1989).

Agency theory has its origins in the organizational works of Mitnick and the economical agency theory developed by Ross both published in 1973 (Mitnick, 2013). Since then there is

an abundance of applications of agency theory within different contexts. For example, Fayezi et al. (2012) found 19 papers in the field of Supply Chain Management. Flynn & Davis (2014) identified the substantial role of agency theory in public purchasing, even though they concluded that public purchasing in general has been under-theorized. Agency theory, as McCue and Prier (2008) suggest, may shed light also on cooperative public purchasing in particular.

Cooperation means mutual effort for a common goal and implies mutual benefits. In agency theory, however, the agent receives a reward that might be based either on behavior (e.g., salaries, hierarchical governance) or outcome (e.g., commissions, market governance) (Eisenhardt, 1989). The meaning of cooperation is the opposite to being vertically compelled in cooperative public purchasing, where mutual benefits would flow to independent parties deciding to cooperate i.e. have enough independent power to make decisions concerning participation. McCue and Prier (2008) recognize multiple layers of agency (the government, purchasing units, individual purchasers) involved in any public purchase and that vertical agreements (or contracts) are different from horizontal public purchasing agreements. The goals of purchasing units could be at cross-purposes so that there may be times when cooperative public purchasing is not mutually advantageous (McCue and Prier, 2008). Mutual benefits imply a win-win relationship between cooperating parties (e.g. purchasing units), at least ex-ante. A win-win relationship may not be assessed in each cooperative transaction when taking a long-term relationship view, although case-by-case assessment may dominate. Maverick buying, as discussed by Karjalainen et al. (2009), is also an agency problem where a purchasing unit or a purchaser is seen as an agent that is compelled by a superior principal, but because of hidden information, compliance cannot be fully monitored by the principal, leaving the door open to maverick buying i.e. noncompliance. However, this is not true independence to make purchasing decisions, but goal incongruence between a principal and an agent.

In cooperative public purchasing, multiple parties arise both from, by definition, more than one principal in cooperation, and multiple levels of agency in public administration. Levels of agency in public purchasing make cooperation more complicated than in the private sector where two private enterprises are independent while in the public sector, different purchasing units of a state are subject to national government. Only the participation in intergovernmental cooperations, such as NATO Support and Procurement Agency, is from this viewpoint, comparable to cooperations between private enterprises. McCue et al. (2015) state that problems of common agency, referring to multiple and conflicting principals utilizing a common purchasing agent, appear to be unrecognized in the current literature. The national government level may set up a purchasing vehicle, such as Hansel in Finland, charged with the task of procuring some items for all purchasing units. This kind of arrangement can still be viewed as purchasing cooperation in Schotanus and Telgen (2007) model but not as cooperation between independent units, as it is mandated by the principal, the Finnish Government. As the level of application ascends from two to three parties the number of articles investigating the identified relationship variables descends, indicating a gap in the literature (Fayezi et al., 2012).

Organisation of cooperative procurement

When a purchaseing unit transfers purchase agreement to another using the same definitions, terms and conditions or carry out a procurement process on behalf of another without the other party having any impact on the specification or terms and conditions, is this form of

cooperation called by Schotanus & Telgen (2007) as **hitchhiking**. This form of cooperative procurement means that one organisation is responsible for the entire procurement, but other joining organisations are able to report their volumes for the specific project. Hitchhiking can be an effective way to benefit from low prices without needing to carry out any procurement-related work. However, the party preparing the agreement has no direct incentives, unless the hitchhikers pay compensation or significantly increase the total volume. Considering the recuirements of procurement directive, it is sufficient, to state that other procurement units, specified in the procurement notice, may be involved in the final agreement based on their offer (European Commission, 2008).

Cooperative procurement may be carried out by a third party. To cover the costs of the third party, the participating organisations can collect membership fees. As the participants cannot have much impact on the implementation of cooperative procurement or the specification of the product Schotanus & Telgen (2007) call it **bus service**. According to this option, the participants have few cooperating and influencing opportunities, which also allows the number of participants to be high.

Responsibilities for cooperative procurement can also be implemented on the basis of the lead buyer concept. Schotanus & Telgen (2007) refer to this form of cooperative procurement as a **carpooling**. This cooperative procurement method cannot be applied to one-time procurement or a single item because there must be many products and the operations must be continuous, at least to some extent, so that the responsibilities for different product groups can be distributed among participants. This requires a higher amount of administrative work than the bus service and hitchhiking. Each participant is able to increase their expertise within their own area of responsibility, but they will, correspondingly, lose it in other areas.

For large and significant project procurement the procurement unit might not even be able to carry out such procurement without the cooperation of other parties with similar needs. Schotanus & Telgen (2007) refer to this type of cooperative procurement as a **convoy**. Here, the expertise of all different parties can be utilised in cooperative procurement. This means extensive cooperation and many negotiations, for example, when specifying the requirements and selecting suppliers. For a one-time project, it can be difficult to build trust and evenly distribute responsibilities.

When all parties participate and have a shared impact on many or all procurement phases Schotanus & Telgen (2007) call this kind of cooperative procurement as an **F1 team**. Responsibilities and influencing opportunities can be defined in the agreement but, if there is strong mutual trust, a formal agreement may not be necessary. Cooperation involves the specifications of technical requirements and commercial aspects as well as testing and acceptance, even if purchase agreements are often separate. Some functions may be outsourced to parties that do not take part in the product procurement process, for example, the preparation of commercial agreements. Unlike in carpooling where procurement of each product group is a responsibility of one participant, in an F1 team participant organisations are involved in the procurement process of a same product, just as in a convoy. Compared to a convoy, an F1 team operates continuously, which enables a more permanent and thorough form of cooperation than a project organisation.

Schotanus & Telgen (2007) present how different forms of cooperative procurement can be placed in a matrix where one dimension presents the number of shared activities and the other dimension shows the intesinveness of participation in group's activities by individual

members. Activities cover, for example, the exchange of information, the definition of requirements, the selection of suppliers, the preparation of agreements and the shared use of personnel resources. Intensiveness refers to the depth and intensity of cooperation, such as number of benefits, shared meetings, influencing opportunities and commitment.

Schotanus & Telgen (2007) suggest that the model is beneficial especially during the initial phases of the cooperative procurement group, when it can be used to pick the best mode of cooperation with respect to the operating environment. However, the selected form of cooperation influences the depth and intensity of cooperation and the number of shared functions are influenced by the mode of cooperation and they are not merely independent environmental factors. The product is not part of the model, even though project-type procurement includes much more work and, therefore, offers more opportunities for shared activities than procurement of standard products. The European Commission (2008), in contrast, presents only two cooperative procurement models. The first one, the full cooperation model, is divided into a centralised lead buyer option, which is suitable for standard products, and a decentralised option which is suitable for more complex products, with all parties working closely together during all phases. The second model is identical to the Schotanus & Telgen (2007) hitchhiking model.

A Critical review on cooperative purchasing litterature

The broad definition (e.g. Schotanus and Telgen, 2007) counts as cooperative purchasing even when two organisations end up purchasing different products from different sources, if only some kind of information exchange, maybe just a phone call, takes place. Broad and differing definitions of what exactly is cooperative procurement do not help in building common theory and make comparing contributions more difficult. In their comprehensive literature review Glock and Hochrein (2011) identify 15 contributions from 1967 to 2009 in collaborative procurement, so the overall volume of research in this topic is rather limited. Of these, 12 are from the public sector which reflects its relative prevalence there. As why it is prevalent in the public sector, similar processes, the lack of competition and mutual trust are mentioned by Walker et al. (2007) while the legal restrictions of competition law in private sector appears unidentified in the literature. Glock and Hochrein (2011) identify the impact of public procurement on the structure of public purchasing as an unresearched topic, albeit from a literature survey that doesn't include any law journals.

In terms of research topics, both Schotanus and Telgen (2007) and Cagnazzo et al (2009) identify the following research themes in cooperative purchasing literature: advantages and disadvantages, enablers and preconditions, coordination structure, development over time and finally, formation of groups in electronic marketplaces. The theme of agency theory specifically in cooperative purchasing is discussed by McCue et al. (2015) and McCue and Prier (2008) and more generally in purchasing e.g. by Yukins (2010) Karjalainen et al. (2009) and Soudry (2007). For each theme, however, there is a limited number of contributions so there is little confirmative research.

There are rather few contributions in terms of what kind of products are suitable for purchasing cooperation. Walker et al. (2013) suggest that collaborative purchasing clearly benefits standard routine items where economies of scale can be achieved. Karjalainen (2009) writes that many nations have set up centralized purchasing units that purchase commodities. As to why commodities could be suitable for centralized purchasing, one reason is that there is no need for requirements specification, just choosing among commodities from frame

agreements. In terms of the Schotanus and Telgen (2007) model, centralized purchasing could be seen as bus ride-type of cooperation as it is close to a third party with low intensiveness and strategic importance. However, when this centralization is mandated by the principal, it is not cooperation in the sense of mutual benefit, at least, not necessarily.

Non-commodities, on the other hand, require specifications. In security organization, these can relate to the core mission of the organization. While end user satisfaction is important, it is not the only criterion that defines the best value. The soldier in the field, for example, is seldom satisfied with the equipment bought as "best value"—which points out a divergence of interests between stakeholders and principals (Yukins, 2010). The specifications determine the price and there is no easy way to enable end users to determine specifications because this may not result in the best value from the principal's point of view. McCue and Prier (2008) take an example where a cooperative is used to purchase police vehicles. During the vendor selection process, the purchasing agent in the cooperative may acquire information about a vendor who might satisfy the local preferences of some (or all) principals, but given the nature of the cooperative, the agent does not divulge this information to the cooperative principals. Thus, the principals may end up with an inferior vendor being selected by the cooperative.

INTERVIEWS AND A THEORY-BASED ANALYSIS OF THE CONTENT

In the study, we interviewed eighteen people who work in the field of public procurement. The interviewees are referred to as I1–I18. Five people work in the Finnish Defence Forces, four in the Finnish Police, six in the Finnish Fire and Rescue Services and three in the Finnish Border Guard. The interviewees represented the middle management or administration, and they had 2–20 years of experience in material projects. The names, positions or organisations of the interviewees are not presented in this article to protect the privacy and secrecy of the interviewees. This approach has encouraged a fruitfull discussion and openness.

The interviews were carried out as semi-structured thematic interviews where the interview themes were based on the literature. The interview themes were modified in two phases. During the first phase, we discussed the interview themes at a meeting, and we also proposed how they could be developed. At the second meeting, we ensured that the proposals had been fulfilled. We sent the interview themes to each interviewee in advance. The average duration of a single interview was one hour. Fifteen interviews were conducted in the facilities of the interviewees' organisation and three by using a videoconferencing system. All interviews were recorded and transcribed. We used text and theory-based content analysis as research method. The analysis and codes are based on the the different forms of Schotanus and Telgen (2007) model. The theory-based content analysis proceeded in three phases where the material was simplified, grouped, categorised and conceptualised. In the simplified phase we transcripted all the interviews. Notes representing cooperative procurement material, end user and forms of cooperative procurement were thus not created in advance but as the they emerged in the analysis of the transcripts. All notes were created during the analysis of the first eight interviews. By this time all the themes were emerged from interviews. In the last ten, coding was done using already existing nodes, meaning they only repeated and enriched current notes. This is a solid indication that theoretical saturation was achieved within the eighteen interviews (Eisenhardt, 1989)

Table 1. Operating costs per year in millions of Euros. Average of 2015 and 2016. Source: Netra, reporting service of the State Treasury and Fire and Rescue Services.

Expenses	Border Guard	Police	Defence Forces	Fire & Rescue
Material, supplies and items	14	33	250	22
Personnel expenses	167	570	881	228
Rent	20	69	186	45
Purchased services	28	114	687	42
Other expenses	8	18	376	3
Total	237	804	2,380	340

The expenses of the Finnish Defence Forces were roughly 2.4 billion EUR , those of the Finnish Police were one third of this amount, all the Fire and Rescue services comprise of one seventh of this sum and those of the Finnish Border Guard one tenth (Table 1). Personnel expenses accounted for about 70% of all the costs of the Finnish Border Guard, the Finnish Police and the Fire and Rescure services, whereas personnel expenses made up only 37% of all the costs of the Finnish Defence Forces., The Finnish Defence Forces has by far both the largest budget and the largest share of purchases compared to the other security organisations.

INTERVIEW RESULTS

The Finnish Defence Forces, the Finnish Police, the Finnish Border Guard and Finnish Fire and Rescue Services all use cooperative procurement as a procurement method. Every interviewee was able to name at least one public procurement process which involved at least two security organisations. On the basis of the interviews, the tasks performed by a single organisation or the cooperative procurement group include agreement negotiations, requirement specifications, commercial management, technical management, overall project management, exchange of information, testing, acceptance inspections, customer complaint processes and shared resources.

A cooperative procurement network has operated under the administration of internal affairs since 2014, and it has expanded to form the network of Finnish security authorities. Members of the cooperative procurement network hold annual meetings, at which they present their competitive bidding calendars. On the basis of these meetings, organisations that identify shared needs or are interested in future projects of other organisations start detailed preparations for cooperative procurement. Many interviewees stated that this cooperation is challenging because, in practice, the network is an expert body. It may not have any official or recognised position in cooperating organisations. For example, in more difficult cooperative procurement processes where one organisation is responsible for testing the procured material, there may be problems in leadership as commands cannot be issued across organisational boundaries. In the worst-case scenario, this leads to a situation where planned testing needs to be interrupted and a new project partner needs to be acquired. As a result, the procurement process slows down. During the interviews in early 2017, the interviewees representing the Finnish Border Guard and the Police of Finland revealed that the upper management did not fully understand and support the activities of the cooperative procurement network.

Material suitable for cooperative procurement

All the interviewees were able to name suitable items for cooperative procurements. The most commonly cited products for cooperative procurement were the so called commercial-off-the-shelf (COTS). This refers to materiel that does not need user-specific modifications, it

is the same for all users and does not need a requirements definition other than agreeing on the purchase criteria.
” When you buy materiel goods, i.e. COTS, which doesn't need tailoring”. I3“Bulk products such as Hansel can offer. Uniforms and all that stuff which meets your needs. When the product is clearly defined, and the need is very similar to each other. "(I17)

The second most commonly cited materiel suitable for cooperative procurement were items used by multiple authorities. It is natural for the security authorities to use similar, if not even the same, pieces of equipment. The Finnish Defence Forces, the Finnish Police and the Border Guard all use very similar protective equipment and firearms. Another example would be the Fire and Rescue Service, the military Fire and Rescue units and the Border Guard Fire and Rescue personnel as they all use similar fire-fighting equipment.
” All materiel that has more than one user. Weapons, equipment, vehicles etc.” (I1)
” All authorities that have dogs would probably benefit from tendering the purchase of dog collars cooperatively”. (I9)
“In the case of rescue vehicles, it would be possible for all the Finnish rescue vehicles to be procured through the same project and the same deal could then be used by other security operators as well”. (I16)

One interview mentioned that a cooperative procurement could also be a platform, such as a vessel where different authorities may install their own systems.
”Such projects that have space and opportunities for various kinds of missions. Boats and ships are then platforms that we can mount different equipment on. (I7)

Material unsuitable for cooperative procurement

According to the interviewees, there are only few types of procurement projects that are unsuitable for cooperative procurement between security and rescue organisations. Six interviewees could not name any unsuitable projects. The most common reason for not procuring something cooperatively was materiel related to each organisation's unique activities, where the other organisations were seen as not having the need for procuring this equipment.
” Procurements are meeting our own functional requirements. Those that are a part of our own powers or jurisdiction”. (I3)
"Customized Products. For example, the command and control vehicle for the Fire and Rescue Service. Helsinki had quite different requirements from Vantaa. One reason was the tram lines that set their own demands on the vehicle. "(I13)

In two interviews, other reasons for not doing cooperative procurement surfaced. One interviewee saw that when the goal of the project is top performance, other organisations are not wanted because in that case compromises will have to be made on the performance or capability of the project. The same interviewee also said that when procuring is an urgently required capability, a cooperative procurement is not wanted because it causes delays. Only in one interview it was suggested that the organisation should guard rigorously its capabilities and procurements, and therefore avoid any collaborations with other organisations in procurement projects, in order to prevent future compromises.
” Niches and things related to your own special activities. Where compromises endanger your own needs. Or then a capability that is temporally limited or narrow in terms of the scope of the capability but extremely finely tuned. If one wants top capability, then you don’t want any distractors.” (I7)

"*Probably certain pieces of kit for Special Operations Forces. That are classified anyway. Protecting your capability is one of the most important ways to keep your procurements away from the limelight. If it's done as cooperative procurement, there are risks"*. (I9)
"We do not want compromises, only the best possible product or service."(I18)

End user in purchasing project

In all interviews it was stated the importance of the end user in a purchasing project. End users were mainly involved in the process by outlining the technical requirements. This is a logical solution because in the end purchased products and services are used by the end user. If this basic need is not fulfilled it might lead to a situations where organisations or individuals not using the product. In two interviews, it was reported that one security organisation didn't continue the cooperative procurement process because their needs were in danger of not being fulfilled. In one interview, it was stated that fire and rescue organisations made a contract about the fire helmet without an end user opinion regarding the technical specifications. The outcome was that the Fire and Rescue department did not purchase those helmets because there end user needs were not fulfilled.
"We just finished our long cooperative procurement project, a lightweight bulletproof vest. However, the police forces exited from project, cause their end users did not accepted the compromises in technical issues." (I9)
"The firefighter helmet project was carried out in the north. In the end nobody bought the helmet. Not a single Fire and Rescue Service. There were not end user requirements in the project, they used only some standards and that was the root reason why helmet acquisition failed." (I13)
*"The disadvantage of cooperative procurement may be the non-fulfilment or abandonment of own specific needs. Compromise can mean not satisfyingthe user requirements and this can put reputation at risk." (*I2)

In some cases even differenent end users may have different requirements from the same product. The reason can be the usage of the product in different environments or the multiple ways of using same product. The end user was conceptualized in two ways. The majority of the interviewees saw that the officer who works in the field is the end user. But in one interview the security organisation can also be the end user. In this case the end user was defined as the owner of the technical understanding of the product.
"If we speak about firefighter suits, we use them more than any other Fire and Rescue Service. That's why we emphasize user requirements related to maintenance and washing. For example, can we use industrial washing, how the suits can be repaired? I18)
"The helmet for the motorcycle and snowmobile drivers was a good cooperative project because it was suitable for the police and the border guard, and so the volume of helmets was increased. At the beginning of the project, users were having different views on what they needed from the helmet. Views were different in the Northern part of the country and coastal areas. "(I8)
"We had cooperative procurement of bulletproof vests for the Border Guard, the Police and the Customs. This kind of product may have technical requirements that the Hansel can not understand. The Hansel can handle simple cases, but not special cases. Because then the technical understanding should come outside the Hansel and whether it makes sense to spin it through." (I8)

Forms of cooperative procurement

All interviewees identified hitchhiking as a possible form of cooperative procurement in their organisations. They did not regard hitchhiking as a poor alternative, but as an opportunity to carry out cooperative procurement processes. In particular, the interviewees considered that simple material, i.e. off-the-shelf material, is highly suitable for hitchhiking. While hitchhiking is possible with different volumes, its alternative is that two or more organisations maintain a long-term arrangement. This means, for example, that whenever specific material is procured, the same hitchhikers are involved in the process. In general, hitchhiking requires two organisations. In some cases, the organisation that holds the primary responsibility can carry several hitchhikers.

"When someone has already done the acquisition, is there a point of doing the same job again? Better is to save the resources and take the fruits. We just inform them what is our quantity and pay the fee if its needed."(I16)

"Recently, we have started to use more Hansel. We want to take full advantage of its framework agreements." (I18)

Four interviewees pointed out that, even if an organisation is only involved in indicating the volume they need, the participating organisation must pay for their share of project costs. In some cases, the costs can be divided based on the required volumes or evenly across participants. The bus service model has one organisation that bears the primary responsibility, and there can be any number of organisations participating with any specific volume.

"Usually, we require that participants must have some input. Especially if we use external consultation, such as commercial experts or legal counsels, these costs are divided between all participating organisations, evenly above all else, regardless of volumes. We have also made compromises so that we have covered the largest proportion of these costs." (I2)

The security organisations, where the interviewees work, specialise in different official duties. The Finnish Defence Forces is in charge of external security, and it specialises, for example, in material projects for military defence. The Finnish Police is in charge of internal security, and it requires equipment for criminal investigations, speed limit enforcement and driving condition enforcement. The Finnish Border Guard aims to safeguard Finnish borders, and it requires equipment related to the fulfilment of this mission. In addition, cooperative procurement processes are divided between these security organisations in accordance with the aforementioned missions. However, carpooling allows the participating organisations to share their expert resources. For example, the procurement unit may obtain experts from another organisation for testing or specification requirements, while the procurement unit is responsible for the overall procurement and its results. In some cases, it is possible that requirements are defined together, after which each organisation carries out their own procurement process (Schotanus & Telgen, 2005).

"Procurement processes often demand substance-based requirements that are defined by the organisations who have the necessary experts. For example, we carry out the bidding process, because we have that kind of expertise. Then again, if the aim is to acquire something completely different, it's also possible that we act as the receiving party." (I3)

"In fact, we carried out a bidding process for the procurement of protective vests for the Border Guard and Customs." (I8)

Two interviewees mentioned a material project in which several different organisations were involved in the requirements specification and bidding processes. One of these interviewees pointed out the interest of an external organisation in the project, as its involvement would have significantly increased the total procurement volume. The other interviewee stated that, even though a few organisations had made the preparations required for the material project,

they would have allowed other security organisations to join the process. On the basis of these interviews, a convoy is not a pre-planned operating model, but rather an exploitation of opportunities that open up along the way. Neither of the two interviewees recognised the convoy model as an existing or planned option. According to these the interviews, the involvement of new organisations in a convoy by volume only is related to personal relationships and the resulting exchange of information.

"We had a Nordic ammunitions project, in which we carried out the requirements specification and testing processes together with the police of Sweden, Norway and Denmark. Norway was responsible for commercial preparations and the bidding process, while we were in charge of requirements specification, product testing and scoring. When the project was about to close, the National Gendarmerie of France was interested to take part in the project with their volume. This would have multiplied the number of ammunitions by five. However, their involvement wasn't possible due to the French procurement legislation which prevents cooperative procurement with other countries." (I1)

"We prepared specifications for protective vests together, and launched a bidding process for several security organisations. We could have included the police in the offer." (I8)

All interviewees recognised the existence of an F1 team in cooperative procurement. The interviews revealed that the most common way is that a project is divided into commercial and technical parts. The primarily responsible organisation is in charge of both parts. Project teams include representatives of all organisations. One interviewee mentioned an example in which the commercial part was outsourced to an external organisation.

"We can distribute tasks between different parties. For example, a single party can define the specifications for the procurement. (I7)

"It's important to set technical and/or performance requirements. However, considering cooperative procurement, it's equally important that a specific party coordinates the requirements prepared by different organisations and fits them. It's challenging to prepare shared requirements." (I8)

"We bought the commercial part and the agreed consulting services from Hansel, but otherwise we prepared the specifications and tested the products together with the Border Guard." (I3)

Two interviewees mentioned a form of cooperative procurement that Schotanus & Telgen (2007) have not identified. In this form, at least one organisation takes part in the requirements specification without covering any costs. The requirements specification may concern the entire procurement or an independent system which is part of the whole process. A ship offers an example where the ship is the object of procurement in which several different systems can be installed. In this case an external organisation or the external organisations do not cover the costs arising from their requirements. This operating model requires support and control from the management of both organisations in order to succeed. This operating model can be applied to nationally significant projects.

"I'd like to mention a special case in which an external organisation defines the specifications and sets the requirements for procurement without covering any costs. Costs are covered by granting higher appropriations to the procurement unit. Another example is a case in which the performance level of a project is increased by acquiring oil spill equipment, monitoring equipment or anything else." (I1)

"It's possible that we acquire the equipment which is then installed on a platform. It's also possible that one organisation defines the specifications, and another one acquires the equipment." (I7)

Table 2. Inteview (n = 18) themes and their interaction with organization form.

Themes relating participation	Themes relating to procurement items
• Volume benefits (Hitchhiking 18 and Bus ride 18). • Fee (Bus ride 18). • Providing resources (Carpooling 18, Convoy 18 and F1 18). • Divided purchasing project (F1 18). • Outsourcing some parts of project (F1 5). • Technical requirements, no compensation (Politically mandated F1 team 2) • End user participation (Carpooling 18, Convoy 18 and F1 18)	• Commodities / COTS (Hitchhiking 18, Bus Ride 18). • Non-commodities (Carpooling 18, Convoy 7, F1 7). • Top performance (Carpooling 3, Convoy 3, F1 3). • Functional requirements (Carpooling 7, Convoy 7, F1 7)

The interaction of the interview themes relating to item and participation, like paying a fee or providing resources with orgnaisation form is shown in table 2 where the number indicates in how many interviews this theme was mentioned in connection to each organisation form.

DISCUSSIONS OF THE RESULTS

In general, all interviewed persons had a positive attitude towards the purchasing cooperation between security and rescue organisations. One interviewee added a concern that the cooperation needs to be mutual. According to the participants the main purpose of procurement in security and rescue organisations is to fulfill the needs of the end user. However, some of the purchased items are commodities, where the end user's opinion and needs are not crucial for carrying out purchasing. In this category of material and services, security organizations don't have special needs. Such materials can be procured centrally through Hansel Oy, the Government procurement organisation.

The somewhat self-evident fact that procurement collaboration is possible only when the purchasing need is not unique but shared with some other security organisation also came up in the interviews. But with some kind of purchases, security and rescue organizations do have special needs. In these cases collaborative procurement projects could be arranged among security organizations with end user involvement in defining the requirements. When the need of the end user is not fulfilled and it is possible that the end user chooses maverick buying in order to fulfill the required needs. If the principal fails to identify the agent special need it might lead to purchasing material which agents don't use. The interviews pointed out two examples of how the principal-agent roles and their different goals can have an effect on cooperative purchasing projects. The uniqueness of the need arises from the performance requirements of the equipment that is spefic to that organisation. However, there was also a statement on maintaining secrecy and avoiding cooperation with other organizations with respect to Special Operation Forces equipment.

According to the model of Schotanus & Telgen (2007), there are five different forms of cooperative procurement. On the basis of these interviews, we were able to confirm the existence of these forms in cooperative procurement processes between the Finnish security organisations, with the exception of convoy. None of interviewees had any experience with the convoy model in cooperative procurement processes. However, it was recognised as a possible form of collaborative procurement, albeit a one not used in practice. A possible reason why convoy is so little used could be that Finland has only few security organisations

and people, who are involded in purchasing, know people in other organisations. When organisations start a cooperative purchasing project they involve all possible organisations from the beginning because of the existing network. So there is no need for any security organisation to later join a project. But Convoy could be a useful form of cooperative purchasing in projects which are multinational, as mentiond in one interview. On the other hand, it was also possible to identify a new form of cooperative procurement based on two interviews, a politically mandated F1-team. As such, it is a fairly rare form of cooperative procurement. In this novel procurement form there may be collaborating organisations giving their own requirements for the project without covering the costs that these requirements cause to the organisation that is purchasing the equipment. Instead, they are covered by other participating organisations. In practice, such a form can exist only in the public sector where it can be understood through the levels of public administration as presented by Mccue and Prier (2008). Such a form makes sense only from the perspective of the overall principal, the Government, for whom it may be the most affordable operating method where a particular agent ends up paying the costs of minor relevance. Such a model is applicable only for major purchases that reach the Government level. We found that the forms of hitchhiking and bus ride are is associated with commodity-type items as shown in table 2 which is not explicitly discussed by Schotanus and Telgen (2007). In a few interviews we also found evidence that the agent and the principal roles and their level of participation might depend on the chosen form of cooperation.

Schotanus & Telgen (2007) identify free-riding as a disadvantage of cooperative procurement. None of the interviewees, with the exception of one, did recognise this disadvantage. Free-riding was identified, but it was not regarded as a problem if each organisation allows other organisations to take a free ride in turn. On the basis of these interviews, we can state that, if organisations, who take part in cooperative procurement, have mutual trust achieved through years of cooperation and it is apparent that their partnership will continue in the future, free-riding is not a problem in cooperative procurement processes. The interviewees stated that standard equipment is an advantage of cooperative procurement, as it produces savings in the areas of maintenance, training and operations. Schotanus & Telgen (2007) perceive harmonisation only as a disadvantage. This conflict between the interviews and the literature could be easily explained since harmonisation is considered to lead to compromises over performance requirements, whereas the interviewees stated that products used by security organisations are often so similar that cooperative procurement processes do not put performance at risk. One interviewee pointed out that cooperative procurement does not always produce savings in procurement resources; instead, the need for resources increases. Schotanus & Telgen (2007) also make this observation. Nevertheless, cooperative procurement processes do not only produce benefits for individual organisations. In particular, when looking at such processes from the perspective of taxpayers and the public administration, the increased workload of individual organisations can produce overall savings and improve the efficiency of resources.

CONCLUSIONS

Security and fire rescue organisations provide standard public goods for which markets do not provide the optimal level of welfare. Because the principal's ultimate goal is to minimise the need for such organisations (e.g. prevention of crime), output-based (e.g. number of indictments) contracts would align interests less than perfectly. Outcome-based contracts that mitigate the agency problem, as recommended by Eisenhard (1989), are not as simple to implement in purchasing because minimising purchasing costs does not take into account the

end-user value. In public purchasing, behaviour-based contracts appear to be the only viable possibility, as their objective is to maximize the cost-effectiveness, through the reduction of the total cost, while raising the hard-to-measure end user satisfaction, unlike in e.g. sales where the incentives of principal and agent are easy to align. When behaviour-based contracts are used, the principal tries to minimize the agency problem through rules-based control, accountability, oversight and bonding (i.e. punishments) that comes in the expense of efficiency. Soundry (2007) writes that a fairly stringent rule-based approach deprives procurement agents of the amount of flexibility needed in order to achieve the best economic results; especially in cases where contracts are more complex.

The cooperative purchasing forms of Schotanus and Telgen helped to identify different forms of cooperation. This study can confirm tis model within the specific context of security organisations and at the same time identify a novel form of cooperative purchasing, the politically mandated F1-team. However, the operationalisation of the dimensions of intensiveness and number of activities and, therefore, the identification of the most suitable form, needs some judgement as there are no clear-cut criteria for the dimensions. In this study, the low intensive cooperation forms where those with the commodity-type items purchased through a centralised unit (Hansel Oy) that, at the same time, is serving also all other government organisations, while the more intensive forms (lead bying, and both F1-teams) were the subject of cooperation between security and rescue organisations.

Cooperative procurement in public sector can be examined from the perspective of individual purchasing organisations or the entire public administration, highlighting the existence of multiple agency levels identified by McCue and Prier (2008). This became apparent both in the case of centralized purchasing conducted by Hansel, from where the Government mandated commodity-type items to be purchased by security organisations and in the case of larger purchases where some organisations could participate by setting their requirements. This and other instances show that agency theory can provide, as Yukins (2010) claims, “a versatile prism” view of issues associated with cooperative public purchasing. However, cooperation is not a principal-agent relationship and important themes like mutual trust needs to be complemented with other “prisms”.

Overall, the experience of cooperation was positive and from the Governent’s principal point of view; it is a recommendation for Finland’s public purchasing strategy. Then why it is not more common? One reason is the lack of common equipment needs while this could be also a topic for future research. Cooperative procurement between security organisations dealing with specialized equipment would benefit from the support of the upper management. The cooperative procurement network of security authorities has not received this type of support, as its activities were limited to the collaboration among experts.

Barriers to Strategic Supply Management
– a top management perspective

Abstract

In the general management literature flaws and distortions of managerial decision making have been devoted increasing interest during the latest decennia. This paper elaborates theories on managerial cognition within SM context. During two-three decennia the strategic orientation of SM has increased, but top management insight of the strategic SM in firms has grown slower than expected. This paper suggests explanations for this slow top management adaptation to the grown importance of external resources and SSM. We have integrated frameworks from cognitive psychology with empirical findings from top management teams of three case companies and five SM-related change projects within them.

Keywords: strategic supply management, framing, case study

Introduction and motivation

Rationality is an attribute connected to the purchasing and, more generally, operational management literature (Barratt, Choi, & Li 2011). The drivers and rationale of new and more strategic approaches to SM have been described well in the literature since the 1980s (e.g. Kraljic 1983; Leenders et al 1988; Cox et Lamming 1997; Trent 2007; Tanskanen et al 2012; Laiho 2015). Much of the related research is limited to rational benefits, operationally optimal solutions, and best practices; however, implementation and human resource issues have received less attention (Fawcett, Magnan & McCarter 2008; McCarter, Fawcett & Magnan 2005). Barriers and behavioural hindrances to SSM seem to be especially weakly covered (Moberg, Speh & Freese 2003) and the more recent literature does not seem to fully cover this gap.

Fawcett et al. (2008) addressed barriers to successful SC collaboration, an important dimension of SSM. They suggest that the primary barrier to collaboration is human behavior in different forms: "organizational culture and structure, functional conflicts, lack of managerial commitment, conflicting and non-transparent processes, policies, and procedures, performance measurement, information sharing, lack of trust, resource constraints, and complexity of SC networks". All the issues are inherently such that top management will be involved, with their activities impacting on the issues.

Koen Vandenbempt and Paul Matthyssens (2005) studied barriers to strategic innovations and suggested that the barriers have both cognitive and structural dimensions. The cognitive dimension relates to the mental models of individual executives, based on perceived outdated cause-and-effect relationships. With time the cognitive barriers have become embedded in the structures, routines, and cultures of firms (Vandenbempt & Matthyssens 2005). Their paper offers relevant views to our phenomenon of interest, because a change from operational PSM to strategic SM can be seen as a company's internal strategic innovation, suggesting changes in resource allocation, organisation, and processes.

This paper is focused on barriers to top management cognition of strategic opportunities through effective utilization and management of external resources; that is, SSM. The following question addresses both the individual level and top management team level:

What are the potential barriers and hindering mechanisms to top management cognition of the strategic importance and opportunities of supply management and external resources?

Theoretical foundation

To understand the real reasons for some issues being recognised as important and worthy of action, or why decisions are made or not made, requires the evaluation of individual decision makers' complex mental processes. This paper is build on two basic concepts, namely that of bounded rationality by Herbert Simon (1997(1945)), and contextual framing and anchoring put forward by Gregory Bateson (2000(1972)), Amos Tversky and Daniel Kahneman (1981). Based on further managerial cognition literature, we also develop a model of an issue's rise to top management's attention.

Bounded rationality

Herbert Simon suggested that traditional economic theories contain a hidden expectation of an "economic man" who makes rational decisions and has unlimited wisdom and capabilities (Simon 2010, p. 99). Simon's conclusion was that an executive can never be fully "rational" in decision making as, in a complex world, he/she can never know everything that influences the premises of the decision. He described the individual weaknesses of decision making as bounded rationality: "the pattern of human choice is often more nearly a stimulus-response pattern than a choice among alternatives. Human rationality operates, then, within the limits of the psychological environment." (Simon 1997, p. 117).

Framing and anchoring

Gregory Bateson (1972) developed a concept of psychological framing, proposing that a frame (around an issue) means that different thinking should be applied to an issue within a frame than outside it. He suggested that any message that defines a frame (explicitly or implicitly) also factually gives the receiver instructions as to how to interpret and understand this message. This frame is anchored in cognitive frameworks that guide interpretations (Bateson 2000). The concept of framing has been further developed and applied within psychology (e.g. Minsky 1975) economics (e.g. Tversky & Kahnemann 1981), sociology (e.g. Young 2010), strategic change (Kaplan 2008) and also supply management (Tokar, Aloysius, Waller, & Hawkins 2016). Referring to Tversky et al, Bendoly et al. (2010) argue that a key source of flaws in operational decisions is inappropriate framing through inadequate adaptation to the situational context.

Factors raising an issue to management's attention

In the complex and continuously evolving business environment, members of top management can be regarded as information workes, spending their time in absorbing, processing, formulating, and deploying information on issues, problems, and opportunities (Walsh 1995). They cannot scan every aspect of an organisation or its environment. An executive's perceptions are limited as a result of his/her selective perception of only some of the visible phenomena. Further, the information selected for processing is interpreted through a filter of cognitive bias and values (Hambrick et al. 1984; McKenney et al. 1974).

Raw signals from the environment are not devoted attention, until executives interpret their causal relationship with the firm's activities. Attention focus is linked to an executive's causal logics (mental models, personal constructs) describing his/her understanding of how the world works; that is, the causal relationships between different phenomena in the business

environment. Together, attention focus and causal logic filter and shape the responses of individual executives and management teams to environmental changes (Nadkarni et al. 2008).

Nadkarni et al. (2008, p. 1399) propose that individual executives focus their attention on environmental changes that seem to be potentially important for the performance of their areas of responsibility and ignore environmental signals concerning changes and phenomena perceived as 1) less relevant for themselves, 2) usual or 3) expected. (These views are integrated into a model which is presented with empirical findings in *Picture 3.)*

Dominant logic and the management team's agenda

Joint discussions and interpretations develop joint beliefs in relationships between environmental events and a company's strategic concepts. In the long term, this common causal logic is argued to be the primary basis for decision making (Nadkarni et al. 2008). Prahalad and Bettis employ the term "dominant management logic" (Prahalad et al. 1986) to describe "a shared understanding of the factors relevant to the business's strategy and the relationship between these factors" (Bettis et al. 1995).

Kamann et al. use contagion as a term describing the process of the homogenisation of views and mental models, i.e. the development and strengthening of dominant logics within a team or organisation, but also within industry networks (Kamann et al. 2004). Within a network the socially leading actor or group of actors set the network's way of doing things, the socially negotiated network order. The evolution of dominant logics happens in two ways: both through the selection of actors who appear desirable (showing desirable attributes) to the network and through contagion (conditioning) to discourage deviating behavior (Kamann et al 2004).

Research methodology

Through studying individual perceptions, we will be able to create a broad understanding of the factors driving firm-level behavior related to SSM, including individual perceptions and common dominant logics. In this study, we have focused on the cognitive framing of top management team members who make or influence SSM-related decisions.

Ontology and epistemology

We adopt constructionist epistemology as the philosophical basis for this research. A constructionist perspective rests on the assumption that human beings impose their internal perceptions on the external world and, in so doing, actively create their individual realities based on their individual experience (Kelly 1963). This philosophy has also been termed constructive alternativism, which "is the idea that, while there is only one true reality, reality is always experienced from one or another perspective, or alternative construction. I have a construction, you have one, … even someone who is seriously mentally ill has one. Yet no-one's construction is ever complete -- the world is just too complicated, too big, for anyone to have the perfect perspective" (Boeree 1997).

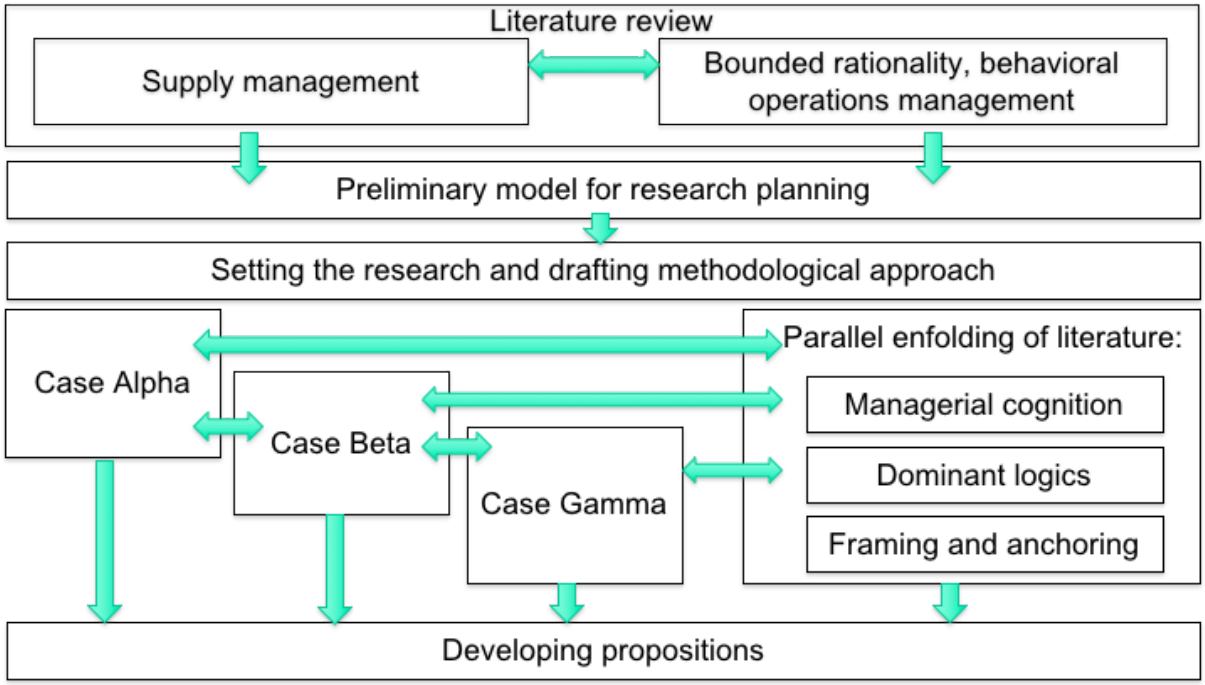

Figure 1. An overview of the research process

Selection of the cases

A preliminary study on perceived strategicity of purchasing (Aminoff et al. 2008) was based on interviews with selected top-level supply executives in large industrial companies. In one of these companies the apparent conflict between the high relative share of the purchased spend and the perceived purely operational role of PSM seemed to be obvious. The phenomenon of interest should thus be clearly visible within that organisation, which would be an optimal selection as the first case (Alpha).

The second case was purposefully sourced utilising a clear criterion: to enable reasonable cross-case comparability, it should be contextually similar to the previous case company in as many dimensions as possible: an industrial company, operating internationally and facing international competition. Preferrably, it should operate in a different industry to avoid potential hidden implications of industry features. To give richer insights into the mechanisms of missing top management cognition, an optimal company would not have invested anything in PSM training or development. A nearby optimal company, a mid-sized high-technology company (Beta), was identified and contacted.

To explore deeper the mechanisms influencing top management cognition of PSM, we endeavoured to identify a company in which a recent radical change in the top management's attitudes had occurred, witnessing a visible recognition of SM. Gamma was selected purposefully to shed light on the process, what happens before and after top management's nascent cognition of the importance of SSM.

These three companies represent different industries. Alpha and Beta represent two very different high-technology industries, both focusing on high-quality branded goods in global markets, also being market leaders in their national markets. Gamma represents a more slow-moving industry with relatively simple technologies. All the three companies were high performers, both in the short and long term, with highly appreciated management. Each case company enjoyed a leading position in its respective national market within its industry/main

business. Each case company had an international frame of performance. Each of them also had experiece of direct sourcing activities in LCC's. Each case company faced global competition, both locally and internationally.

Alpha and Beta represent highly R&D- and marketing-focused businesses. Especially in Alpha, product development projects were expensive and lengthy, handled as long-term investments by management. Margins were high because of successful R&D; however, so too were the risks relating to R&D projects' long time spans. In Beta, the key drivers of success were technological leadership and a top-quality product brand. In both Alpha and Beta, purchased cost or supply market analysis played a minimal role in the R&D process. Once a supplier was selected to deliver a component or service for a product, they were seldom changed over the product's lifecycle. Purchasing was more an internal service function, a supplement to production. The top management's focus in both companies was heavily on R&D issues and global marketing. In Gamma, the management's focus was on the economic performance of local BUs that were running similar businesses across the country. R&D and marketing played minor roles, although intimate sales and customer service were important success factors. The role of purchasing had changed radically towards SSM as a result of its newly-born recognition by top management.

In all of the case companies, earlier SM-related change initiatives was identified. The first initiative in Alpha (Alpha 1) had occurred five years previously. It had been limited to the centralisation of fragmented purchasing functions, new resources, and professional training as an internal exercise within the purchasing organisation. Two years before this research another development intiative (Alpha 2) covered all the purchasing and SCM organisation, focusing on total cost thinking. Although the project had noteworthy economic results, the consequences and cognition remained functional. In Beta, the exercise (Beta1) had focused on a new plant streamlining production and supply chain, but did not question existing supplier relations nor lead to top management cognition of SSM. In Gamma the first cross-organisational training exercise (Gamma 1), had occurred five years earlier, had led to significant economic results but did not lead to top management cognition of SSM. Another hands on training project on SM (Gamma 2) was organised six months before this study's interviews. During this process, visible CEO cognition of SSM had occurred, leading to e.g. immediate CPO nomination, demanding targets on SM and weekly discussions in the top management team (TMT).

Data collection

The primary scope were the top management teams of industrial companies. We interviewed 28 top management team members and two purchasing managers (PM's), as well as 6 mid level executives in Gamma to hear non TMT viewpoints on the change:

1) Alpha: previous CEO, CEO, 9 TMT members, PM
2) Beta: CEO, 8 TMT members, PM
3) Gamma: 2 previous CEO's, CEO, 5 TMT members (incl CPO), 6 mid-level executives.

Numerical data and deeper understanding were gathered through repeated discussions with the Purchasing Manager (Alpha), PM and VP SCM (Beta) and newly nominated CPO (Gamma). The findings were tested through their presentation at top management team meetings and discussions with CEO's. The interviews were tape-recorded, and transcribed by a research assistant. In Alpha the interview notes were handwritten by two participating senior researchers, the notes integrated and possible corrections asked from the interviewees within two days.

The interview questions

The key interview question was an open bid to elicit a description of the evolution of SM in the company as perceived by the interviewee. This should enable the full richness of the real perceptions to be best heard in the stories. The interviewer endeavoured to avoid any indication of preliminary propositions and did not address them during the interviews to avoid causing biases, distortion, or framing in the answers.

Complementary questions on drivers for and barriers to SSM were employed as necessary to cover all the issues wished: perceptions of SM's strategic potential and its relative importance and also evolutionary perspectives on the future were asked in varying order, depending on the flow of discussion.

The last set of questions was designed to gain the interviewees' insights into and practical knowledge of the tools and methods of SSM and to evaluate their preparedness to identify alternative differentiation opportunities and participate in related decisions.

The analysis process

In analyzing the interview records we utilized the causal mapping techniques as presented, for example, by Miles and Huberman (1994). Causal mapping is a generic technique for describing interdependencies between issues and/or events. As a general tool, it is appropriate for structuring messy and complex data and for managing large amounts of qualitative data (Ackermann et al. 1992). It can be employed to integrate individual perceptions of a situation into an evolving overall mental map of the researcher (Miles & Huberman 1994, p. 152).

Figure 2: An example of causal mapping of an individual interview in Gamma. The interviewee spontaneously separated the issues related to first (left) and second development project (right), as well as their backgrounds and reasons for outcomes and consequences. (The numbers are only for coding purposes.)

Causal mapping was in the first phase employed to describe the reasoning of the interviewees for perceived causal relationships concerning SM; that is, their perceptions of what is caused by which issue, activity, perception, or phenomenon. Through causal mapping technique, we captured the individual reasoning of the insights through drawing causal maps for each interview, one of which is shown below (just to visualize the idea), as well as summarized the dominant logics of each management team and the reasons and consequences of development projects. In addition to causal map-based issue identification and categorization, the chapter-, sentence-, and even word-level coding of the interviews was also used.

Abductive reasoning

Finally, we conducted trials to dig deeper and search for potential underlying root causes of the most important cross-case patterns. For this, we employed abductive reasoning (Douven 2011). The idea of abductive reasoning is to find the most probable explanation for a set of observations. It is reasoning from effects (findings) to causes or explanations (Lamma, Mello, Milano and Riguzzi 1999). The explanation should be sufficient, but not necessary cause of the observations. This thinking was first introduced by Charles Sanders Peirce (1839-1914) with the term "guessing" and it has been regarded as "a deliberate and creative part" of the abduction process (Tschaepe 2014). Abductive reasoning applies earlier theoretical knowledge, e.g. frameworks from other disciplines, to explain the empirical observations, to "match" the observations with appropriate frameworks (Spens & Kovács 2006). The process is thus one of continuous iteration between the observations and potential theoretical frameworks, constituting a learning process (Dubois & Gadde 2002).

Findings

Through the interviews, participant observation and other data, a good visibility of five development initiatives involving SSM was gained in the three companies, each more or less successful. Of these five development projects, only one, Gamma 2, had led to immediate behavioral changes at the top management team level. Three projects were purely functional, Alpha 1 and Alpha 2 being internal to purchasing and Beta 1 extremely production flow-oriented, and one project (Gamma 1) just did not awaken management's broader recognition after the project, despite cross-functionality, management participation, and convincing results.

Within all the case companies, the expected phenomenon was clearly visible: the share of the external spend was high, exceeding 70% of the cost structure, but supply-related issues were on the top management team's agenda only as operational issues, either as routine reporting of operational figures or relating to some sort of problem. The perceived content of the purchased spend was limited to direct, production-related purchases and neither its relative importance nor differentiation opportunities were recognized. The strategicity of SM was not visible on management teams' agendas, strategy processes nor organizational role.

Perceived strategicity

SM was not perceived as strategic by the CEO's or TMT's. "Supply management is not so important for us, because we are a high-quality technology leader in R&D-driven business" (VP, Beta). SM-related issues arose in the company's strategy process only through the production-focused SCM organization's operational strategy process flow (i.e. Alpha and Beta) or hidden in operational plans and budgets (i.e. in Gamma before the change). In Alpha, SM-related issues were perceived as being on the top management team's agenda irregularly, "only

when there is a problem". Supply- related issues were presented to the management team by VP Supply Chain (SC), focus being on quality and logistical efficiency, capital employed and availability. In Beta, VP SCM presented purchasing and supply management related issues, if needed, when something "special" occurred; for example, "supplier delivery or quality problems". In Gamma, SM-related issues before the change were perceived as being local business issues and were seldom discussed by the management team. "The management did not have any idea of supply management's potential as a source of competitive advantage, the methods of effective supply management, nor the efforts needed" (CEO A, Gamma).

Perceived economic importance

The management team members in Alpha and Beta did not know the relative share of the externally purchased spend, but underestimated it, most about to the level of the direct spend, the external part of the Bill of Material (BOM). Because the indirect spend in all the companies was remarkable, the estimated relative share was roughly at the level of half of the real share.

Perceived opportunities for differentiation

McKenney et al (1974) suggest, that consistent modes of thought develop through training and experience. For the purposes of this research, we have selected knowledge of the methods of modern SSM as a proxy for the identification of strategic opportunities through them. We expect that opportunities to differentiate oneself from one's competitors depend on the capability to understand different methods of SSM. If a broad set of methods are understood, then the opportunities achievable through them can also be identified.

Only one interviewee, the CPO in Gamma, had a university education in modern SM. No other interviewee had undergone SM-related school or university education. Only one interviewee (in Alpha) had been working in a firm with developed SSM. Most of the interviewees in Alpha and Beta somehow confessed their weak personal knowledge of the methods that PSM has to improve the company's performance. Their answers to questions concerning methods varied widely, which can be interpreted as meaning that there have been no common discussions of these issues. Nobody in Alpha or Beta mentioned e.g. the (strategic) segmentation of the purchased spend or total cost thinking, which can be regarded as the two basic frameworks of SSM. On the other hand, the interview records indicated that Gamma's management had well understood tools and means of modern SSM. Within the second initiative in Gamma all the top and middle management had participated in an intensive training and hands-on learning exercise, developing and implementing category strategies in cross-organizational teams.

Proposition 1: An individual executive's limited education and experience path, without exposure to the strategic utilization of external resources, are barriers to cognition of the strategic potential of SM and external resources.

Production-focused reporting on external spend

The total use of the externally purchased spend was not reported as an entity, but in all the cases fragmented under different cost headings in the profit and loss statement. In Alpha and Beta, the total sum and content of the indirect spend in a broad sense had never been calculated. A Bill of Material contained externally purchased materials, components, and services, but they are seen and evaluated from the production point of view. Only the production-related direct spend was visible in top management reports as purchases. This makes it understandable that the management team members clearly underestimated the size of purchased spend and never recognized the relative share of total external spend. Management reporting can be regarded as

playing a role in limiting or enabling understanding of both the content and relative importance of the external spend.

Proposition 2: Fragmented and production-oriented management reporting of the external resource spend creates a barrier to recognizing the economic importance of SM and external resources

Inward-oriented dominant logics

There were prevalent strong dominant logics within the management teams of each case company. In Alpha, the dominant logic emphasized the importance of long-term R&D projects and regarded production costs and PSM as less important. In Beta, the dominant logics emphasized high-quality branded products, for which PSM might even cause quality risks. In Gamma, the dominant logics emphasized full independence of Business Units, which is in conflict with SSM's ideas on coordination. The strategic supplier selections and decisions were actually made by either R&D or local BU's, without adequate education or experience on modern SM. Suppliers or external resources were only exceptionally discussed in management teams ("only when problems").

Proposition 3: Inward-oriented dominant logics of top management teams create a barrier to recognizing the strategic potential of SM and external resources.

Transactional framing through terminology, operational role

Although the interviewer systematically formulated questions using broader terms (procurement, supply management), the terminology employed by the interviewees was traditional and transactional (buying, purchasing). This seems to reflect the general vocabulary regarding these issues: broader terms were relatively new, and not broadly established in the common company languages. The transactional terms used seem to indicate that purchasing is perceived as having only a marginal influence on prices (e.g. Alpha: "routine discounts", "bargaining", "routine negotiations", and "secretary or purchasing department"; Beta: passive "inquiry about prices", and Gamma: "fiddling the prices", "air in the prices" (that is, there is a "correct" price). These repeatedly employed wordings suggest that the speakers regard the potential results of the PSM function's participation as relatively negligible.

PSM was given only an operational role in Alpha and Beta, but in Gamma an insight of strategicity was evolving. Interview observations and other data in each case company indicate that PSM had been expected to have only a marginal influence on costs; for example, only transactional measures employed on external resources, late involvement of purchasing in supplier selections, and localization of purchasing.

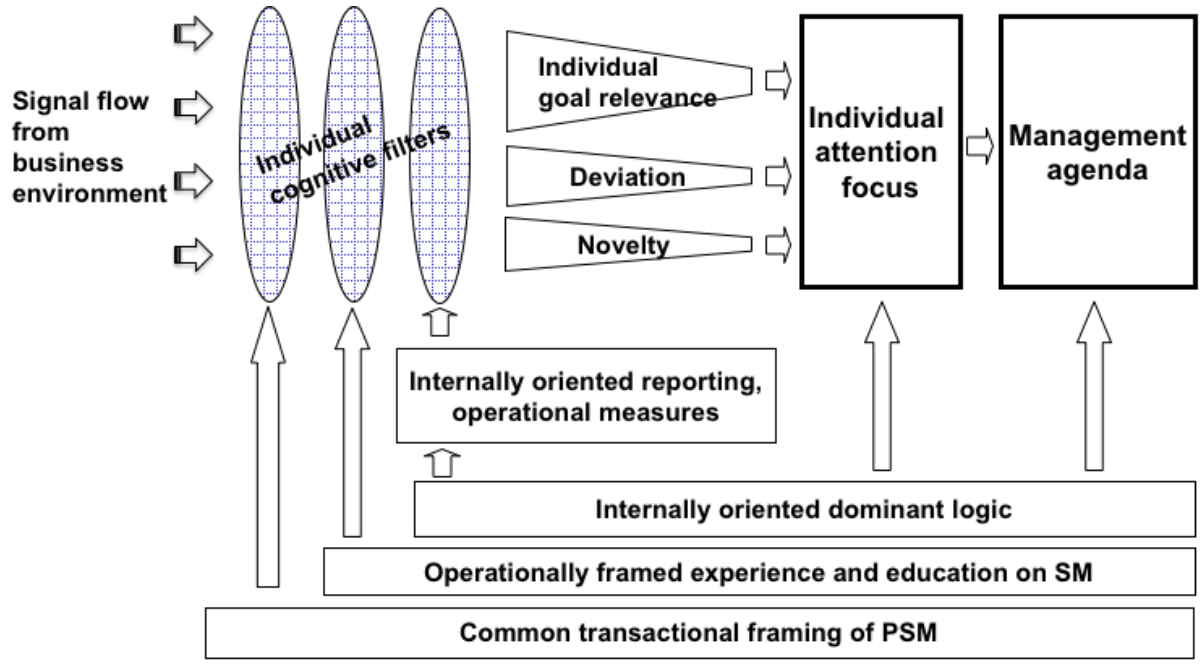
Herbert Simon refers to "hammers" of the decision maker, based on his/her history and experience (Simon 1997, pp. 298-302). In the case firms, "routine" negotiations (Alpha), passive inquiry about prices (Beta), and empty bargaining (Gamma) seemed to be perceived as the "hammers" of PSM.

PSM-related norms in the case companies, PSM-related terminology and habits (practices and processes), and management's expectancies regarding PSM would indicate that in the minds of the interviewees PSM was framed as an operational, transactional activity. The framing of PSM as such leads to external resource related problems being understood and handled as transactional only. Even the new title of CPO in Gamma was understood in practice as Chief Purchasing Officer, still indicating traces of traditional orientation.

Proposition 4: Transactional common terminology frames the role of PSM as operational and creates a barrier to cognition of the strategic opportunities offered by SM and external resources.

Conclusions

The presented propositions are the most probable explanations for the empirical observations in the light of the selected streams of managerial cognition literature. The explanations are sufficient, but not necessary cause of the observations. The propositions are summarized and integrated with the literature-based framework in the following picture 3:



Picture 3. Detailed model of issues influencing an SSM-related signal's rise to management's attention. Empirical findings are integrated with a model based on Hambrick et al. 1984, Nadkarni et al. 2008 and other literature on management cognition. Modified from Iloranta 2016.

Signals from environment are filtered through individual cognitive filter, which frames all PSM-related issues as transactional / operational. As such they are not identified to influence on individual goals nor deviate from usual. The transactional framing is based on general transactional terminology and framing of PSM, transactionally and operationally framed education and experience on PSM, internally oriented dominant logics of management, maintained through fragmented, internally oriented reporting.

Discussion

The supply management literature suggests that supply management has a natural strategic role within an industrial company because of the strong influence on a firm's performance (e.g. Axelsson 2005; Chen, Paulraj & Lado 2004; Gunasekaran, Patel & McGaughey 2004; Hughes, Day, & Hughes 2005; Hall 2000; Laseter 1998; Rajagopal & Bernard 1994; Giunipero, Handfield & Eltantawy 2006; Schiele 2007; Trent 2007; Iloranta & Pajunen-Muhonen 2008/2012/2015; Hoffmann 2010). Previous literature further maintais that top management

understanding, support and commitment are crucial for the successful transformation of purchasing's role towards that strategic role (Rajagopal & Bernard 1994; Hughes et al 2005; Schiele 2007; Trent 2007). However, it is still arguet that executives do not fully recognize SM's link to the firm's long-term performance, i.e. cognition of the strategicity of SM (Hofmann 2010, Hughes et al. (2005).

This paper addresses this problem and identifies several mechanisms that create barriers to top management cognition of SM's strategic opportunities and more generally the strategic role of external resources.

The novelty of this research lies firstly in the top management perspective on SM, and secondly in the cognitive views on supply management-related decision making. The existing supply management literature does not offer frameworks for these issues. Even the most fresh managerial textbooks on SM tend to maintain a functional (and rational) view although emphasize the increasing strategicity of SM (e.g. Chick and Hanfield 2015). Bendoly, Croson, Goncalves, and Schultz (2010) pointed out that case studies on cognitive psychology are rare within operations management. Approaching cognitive barriers through analysis of top management's perceptions of SM will thus contribute to filling also this broader gap.

Linking cognition literature with SSM related decisions of top management opens also broader tracks towards behavioral PSM and external resource management. Education and experience constitute the background of any human decision in any position, heavily influenced by common world views, industry beliefs and the organization's dominant logics, which have born for very different environments. International reporting norms and practices seem still to be based on production oriented concepts of a firm, which can be questioned in our globally networked business environments. It would also be interesting to learn, how generalizable the suggested mechanisms are as barriers to any adaptation to evolutionary changes in business environment, especially adaptation to slow changes like the underlying driver of the studied change, the growth of the share of a firm's external resources compared to internal (from 20% to 80% during hundred years).

The explanatory suggestions of this paper should be further tested and validated in broader contexts. The empirical part of this research was made during years, when the phenomenon to be studied was still clearly visible in midsize and even large industrial companies. The situation in the business environment generally as well as in the case companies has evolved remarkably since the interviews for 8 years ago. However, the key contribution of this paper are plausible potential explanations for the top management's slowness in recognition of SSM, which is still today very visible in many organizations.

The role of Supply Chain Information Integration in building Supply Chain Resilience

Abstract

Through the usage of the CRBV of the firm, this study aims at analyzing the relationships between resources (strategic information sharing and information technology), capabilities (formative resilience elements) and performance (supply chain resilience). In addition, supply base complexity is adopted as a moderating factor. The theoretical model has been tested and survey data has been collected from 235 companies. The obtained results suggest that the bundle between resources leads to the development of resilient capabilities. Of these, only two enhance resilience in the supply chain. Regarding supply base complexity, only scale complexity has shown to have moderating effects.

Keywords: Supply Chain Resilience; Supply Chain Information Integration; Contingent Resource Based View

Submission category: Competitive paper

1. Introduction

The last disastrous events occurred in recent years have changed the concept of "business as usual" for many companies (Christopher and Peck, 2004). Disruptions have severely damaged the capability of the firms to produce and deliver their products, but have also highlighted the need for developing more effective supply chains (SC), able to cope and quickly recover from these events. Even relying on the most controlled internal processes, modern supply chains depend on different players spread across different countries or even continents in the world. The flows of information and products go through the nodes of these networks that link firms, industries and economies (Christopher and Peck, 2004). This spatial complexity (Choi and Hang, 2002), together with the adoption of practices aimed at increasing the cost efficiency (e.g. lean manufacturing initiatives or single sourcing policies) without leaving spare capacity for unexpected events, establishes the basis for a high supply chain risk as well as a key precursor for severe disruptions (Tang, 2006). Despite firms cannot completely avoid the likelihood of disruptive events whose consequences can seriously affect performance (Blackhurst *et al*. 2005), there are some actions that could be implemented to reduce their probability as well as the vulnerability to risks. In this highly complex context, the idea of building resilient supply chains, defined as "*the ability of supply chain to return to its original state or move to a new, more desirable state after being disturbed*" (Christopher and Peck, 2004, p.2), has gained support (Brandon-Jones *et al.* 2014).

Despite the complex environment, that has underlined the importance of building resilience, there are other practices, mostly adopted under "normal" conditions, whose outcome could support supply chains in facing disruptive events. One of these is supply chain integration. Many authors have expressed diverging opinions regarding the relationships between supply chain integration and resilience. In this regard, the aim of this study is to make clearer this connection by focusing on the Supply Chain Information Integration dimension in its two components of strategic information sharing and information technology (Prajogo and Olhager, 2012), whose effects will be studied in relationship to supply chain resilience and its formative elements. To achieve this purpose, this study will be drawn on the Contingent Resource Based View (RBV) of the firm (Barney 1986,1991), whose usage is aimed at addressing the issue of "context insensitivity" (Ling-yee, 2007, p.370) of the RBV. In particular, the vision of complementary relationship between resources (Amit and Schoemaker, 1993) will be adopted. Therefore, following the CRBV schema, the relationship between resources (strategic information sharing and information technology), capabilities (the four resilience capabilities identified by Juttner and Maklan (2011)), performance (supply chain resilience) and contingencies (supply base complexity), will be analysed.

By extending the findings of Brandon-Jones et al. (2014) and by empirically investigating the relationship between IT and strategic information sharing, this study aims to deeply analyze the outcome given by the complementarity between these two resources in terms of the resilience

capabilities identified by Juttner and Maklan (2011). The model obtained from this analysis could be used as a blueprint for future studies concerning the impact supply chain information integration in terms of supply chain resilience. In this way, it would be possible to advise managers in creating an information sharing culture where the exchange of meaningful information magnifies the value of IT, while the connectivity, enabled by technological infrastructure, supports coordination by providing supply chain partners with right and timely information, once needed. The remainder of this paper is organized as follows: Section 2 describes the theoretical background; Section 3 depicts the theoretical framework together with the developed hypotheses; Section 4 describes the applied methodology; results are analysed in section 5; finally, Section 6 depicts the main conclusions and directions for future research.

2. Theoretical Background

Supply Chain Information Integration and Supply Chain Resilience

Flynn et al. (2010, p. 59) define the Supply Chain Integration *as "the degree to which a manufacturer strategically collaborates with its supply chain partners and collaboratively manages inter and intra-organizational processes"*. The Literature on this topic is characterized by several dimensions and definitions (Van der Vaart and van Donk, 2008). One of these identifies the existence of two flows along the chain: goods and information (Pagell, 2004). The first is related to the concept of Logistics Integration while the latter flow is linked to the Information integration, which deals with the share of key information throughout the supply chain network by means of information technology (IT) (Prajogo and Olhager, 2012). The concept of supply chain integration has been mostly focused on the achievement of the performance of the firm under normal conditions, without considering its potential implications on the dimension of supply chain resilience. However, some studies have started to debate about the role of integration in case of disruptive events and its relationship with supply chain resilience. On the one hand, some authors state that integrated chains are more vulnerable since a disruption in one node may affect the entire network; on the other hand, some studies state that tightly coupled chains could better react to disruptive events (Scholten et al., 2014). Wieland and Wallenburg (2013) analysed the interaction between three relational competences (communication, cooperation and integration) in relationship to the supply chain resilience. Their findings underlined that the combined effects of communication (transmission process and flow of explicit information (Modi and Mabert, 2007)) and cooperation (process by which individuals interact and create psychological connections for gaining mutual benefits (Smith *et al.*,1995)), would have concealed the effect of integration as enhancer of resilience. The reasons were that mutual dependencies, tied-up resources and restricted flexibility would have neutralized the positive effects of integration. However, the results of Wieland and Wallenburg (2013) were affected by a too broadly perspective of integration. Indeed, as stated by the same authors, other aspects of the concept could have given different results. Starting from this consideration, this study adopts, as a reference, the specific dimension of Supply Chain Information Integration (SCII) (Prajogo and Olhager, 2012). Its two components, information technology and information sharing, have been mostly studied separately in relationship to supply chain resilience. For example, Christopher and Lee (2004), through the usage of the "risk spiral", stated that information sharing was the key to improve supply chain visibility, seen as a crucial element in reducing risk exposure. However, despite the quality, accessibility and accuracy of information (Cao and Zhang, 2011), the support of technological means for ensuring the effective delivery and processing of data is required (Fawcett *et al.*, 2007). Regarding the role of information technology, Blackhurst *et al.* (2011) underlined that the presence of technologies, able to increase the visibility in the supply chain, would have represented an enhancer of supply chain resilience. These contributions from the existing literature have given rise to the following research question to which this study aims to answer: *should be the effects of information sharing and information technology analysed separately in relationship to supply chain resilience or the impact could be enhanced through their integration?*

The complementary perspective in the RBV

According to the Resource Based View (RBV), organizations can achieve a superior competitive advantage by combining strategic resources and/or capabilities with certain characteristics (Barney, 1991). In particular, the creation of competitive advantage starts from bundling resources that are valuable, rare, imperfectly imitable and non-substitutable (Grant, 1991). Focusing on IT, some authors argue that these technology assets are unlikely to respect all the aforementioned characteristics (Mata et al., 1995). However, within the RBV it is possible to notice a specific view regarding this topic. If the firm owns IT resources that do not constitute a distinctive source of competitive advantage and if these resources are instead used to leverage the full competitive advantage of valuable, costly to imitate and rare non-IT resources, then IT can be considered an enhancer of the competitive advantage of the firm. This last view is in line with the notion of complementary relationships. Complementarities represent an increase in the resource value and arise once the resource produces a greater outcome in the presence of another resource than it does alone (Mishra and Shah, 2009). Many authors have been influenced by the complementarity perspective, due to the idea that co-specialization among complementary resources may have beneficial effects (Teece, 1986). For example, Powell and Dent-Micallef (1997) stated that the sole usage of IT does not explain a distinctive variance in the competitive advantage achieved by the firm, whereas the firms can be analysed by their ability of combining explicit technological resources (IT) with other human or business resources to gain competitive advantage. These last resources are represented by strategic information sharing defined as "the willingness to make strategic and tactical data available to other members of the supply chain" (Mentzer, 2001, p.8). This study aims to be aligned with the previous perspective regarding the complementary role of IT but at the same time it wants to go beyond the simple recognition of the potential positive effects of IT over no-IT resources. Indeed, addressing Black and Boal (1994), the need to open the "black box" of organizations is pointed out in order to examine the bundle in which IT resources are included and more precisely the nature of the relationships among resources that make up the bundle. Finally, this bundle of resources and its intrinsic relationships will be considered under the broader notion of Supply Chain Information Integration (Prajogo and Olhager, 2012). Indeed, this concept enhances the fit (a term that has been largely used in the literature as synonymous of complementarity) between the exchange of strategic information and the information technology. It has to be remarked that these types of resources need to be jointly considered in order to fully understand the competitive advantage generated. The adopted dimension of integration will be the external rather than the internal one, and in particular, within the external integration, the focus will be mainly on the supplier side.

The usage of the Contingent Resource Based View (CRBV)

Kraaijenbrink et al. have argued that "*the moment in which we try to explain or predict the firm's actual performance, the RBV turns out to be incomplete since it ignores the material contingencies' of the firm's situation*" (2010, p.365). This means that the theory is not able to identify the conditions in which both resources and capabilities may be optimised (Ling-yee, 2007). In this regard, the contingency theory states that both external and internal conditions may influence the way in which an organization or supply chain is managed (Grotsch et al.,2013). Hence, also the resources and capabilities needed for driving the performance of the supply chain in certain circumstances may be affected (Brandon-Jones et al., 2014). Many scholars have suggested that the static nature of the RBV can be addressed by the usage of a contingent RBV (Brandon-Jones et al., 2014). The adoption of this view could help to recognize to which extent resources and capabilities may create value (Aragòn-Correa and Sharma, 2003), to enhance the usefulness of the RBV (Brush and Artz,1999) and lastly to identify the conditions that affect the utility of certain resources and capabilities (Brandon-Jones et al., 2014). The contingencies adopted in this study are represented by supply base complexity factors.

3. Theoretical Framework and Hypothesis Development

Supply Chain Resilience

Ponomarov and Holcomb (2009, p.131) defined supply chain resilience as "*the adaptive capability of a supply chain to prepare for unexpected events, respond to disruptions, and recover from them by maintaining continuity of operations at the desired level of connectedness and control over structure and function*". Within this definition, it is possible to notice three distinct phases. The first phase deals with the period before the disruption, once some proactive strategies need to be implemented, such as the development of collaborative activities with supply chain actors as well as the building of capabilities aimed at increasing visibility in the supply chain. The second and third phases deal with responding to and recovering from a disruption that has hit the supply chain. In this case, the implementation of reactive strategies is needed. These stress the need of velocity, thus the need of less time and highly efficient practices to quickly recover from the disruption. Furthermore, the willing of "maintaining continuity of operations" enhances the need of flexible resources, while "the control over structure and function" can be ensured through the continuous exchange of information with supply chain partners. To summarize, this definition clearly identifies several underlying elements of supply chain resilience during the distinct phases of preparation, response and recovery. In addition, these elements are captured at a capability level (Ponomarov and Holcomb,2009; Juttner and Maklan, 2011).

Despite in the literature no conceptual differences are evident among the phases in which the supply chain resilience is operationalized, the perspective on the resilience formative elements is still affected by some overlaps (Juttner and Maklan, 2011; Scholten et al., 2014). The concepts of efficiency, redundancy, collaboration, flexibility, velocity, visibility and robustness are used in relationship to supply chain resilience (Christopher and Peck, 2004; Sheffi and Rice, 2005; Ponomarov and Holcomb, 2009; Pettit et al., 2010,2013; Blackhurst et al., 2011; Juttner and Maklan, 2011; Wieland and Wallenburg, 2012,2013). Among the previously identified strategies, supply chain visibility, flexibility, velocity and collaboration are the most commonly mentioned and the ones that better capture the essence of all the consideration regarding the resilience formative elements (Juttner and Maklan, 2011). Therefore, in line with Juttner and Maklan (2011), this study has considered these four as the formative elements of resilience. In this regard, supply chain resilience is seen as a performance outcome of these capabilities. The line of reasoning, can be formulated as follows. The aforementioned four capabilities, which stem from complex interactions between resources, are the mechanisms that mitigate the impact of disruptions. Their development and exploitation before or after a disruption, can significantly reduce its overall impact that can be measured in terms of supply chain resilience. Therefore, by considering resilience as a performance with its consequent measures, it is possible to state to which extent the exploitation of capabilities could protect or create value. The longer the time the supply chain takes to develop these capabilities, the more the disruption impact grows and negatively affect supply chain. In this regard, resilience performance has been measured at the operational level in terms of the time required to return to the original state of operating performance or also the time taken to restore the flow of materials after a disruptive event. This is in agreement with other authors, such as Blackhurst et al. (2011) and Brandon-Jones et al. (2014), who also adopted the RBV in their research and considered resilience as a performance outcome.

The impact of Supply Chain Information Integration on Supply Chain Resilience

Frequently in literature, there has been a lack of a clear distinction between the concepts of information sharing and visibility (Barratt and Oke, 2007). While information sharing is related to the quality, accessibility, strategic relevance of the information exchanged between the supply chain actors (Cao and Zhang, 2011), visibility is predominantly concerned with information flows in a given time in terms of: inventory levels both upstream and downstream in the supply chain, demand and supply conditions, and production and purchasing schedules (Christopher and Peck, 2004). Visibility contributes to have a clear view of all the aforementioned factors, thus allowing the supply chain to be more transparent (Christopher and Lee, 2004). The continuous exchange of accurate information

between supply chain partners, contributes to increase supply chain visibility (Chirstopher and Lee, 2004); the type of information shared (e.g. inventory, orders, market trends etc.), its frequency and the direction play a fundamental role in the achievement of this capability (Scholten et al., 2015). Naturally, in order to ensure information sharing, organizations need to create the right technological linkages across the supply chain aimed at enhancing visibility in their operations (Mabert and Venkataramanan, 1998). In this regard, information technology systems, which are related to the tangible resources, provide the platform for enhancing supply chain visibility (Brandon-Jones et al., 2014). Information Technology provides real-time information regarding the inventory level, the delivery status, the production planning and scheduling, thus enabling the firms to improve the management of their activities (Prajogo and Olhager., 2011). The availability of this information in a timely manner, by means of technological infrastructure, contributes to increase the transparency in the supply chain and thus visibility. Furthermore, some studies have highlighted that IT positively contributes in enhancing the level of integration between supply chain partners (Soliman and Youssef, 2001). In turn, this integration inhibits the presence of "functional silos" and further enhances the free flow of strategic information between organizations (Christopher and Peck, 2004). This information integration, in which the exchange of meaningful information is supported and improved by the technological infrastructure, represents an integrated bundle which improves the impact on the visibility of the two resources that constitute it. By developing supply chain visibility, firms are able to reduce both the likelihood and impact of disruptions (Christopher and Lee, 2004a) and therefore to enhance resilience (Juttner and Maklan, 2011). This is confirmed by several authors who have underlined the role of supply chain visibility in developing supply chain resilience (Blackhurst et al., 2011; Juttner and Maklan, 2011; Wilding, 2013; Brandon-Jones et al., 2014). For example, Tang (2006) states that visibility can enable supply chain partners to create a common demand forecast that, associated with the proper restoration rule, could ensure the return to normal levels of inventory after a disruptive event. Therefore, especially in the case of disruptions, the supply chain can return to its normal state of performance if all its members have the proper visibility. In the light of what stated above, the following hypotheses may be formulated:

H1a: Supply Chain Information Integration has a positive effect on Supply Chain Visibility
H2a: Supply Chain Visibility is positively related to Supply Chain Resilience

Through investments in information technology, it is possible to create an important enabler for a unique collaboration between supply chain partners. Indeed, the partners are tied together and thus are more willing to send signals about unexpected changes in the supply chain as well as to improve both their own and joint processes (Wieland and Wallenburg, 2012). This mutual dependency has been shown to positively affect the degree of collaboration between supply chain actors (Scholten et al., 2015). However, following the RBV perspective, a collaboration capability is rare, valuable and hard to replicate (Fawcett et al., 2007; Richey et al., 2010). The building of productive relationships is the basis for an effective collaboration between supply chain partners and the strength of these supply chain relationships is enhanced if information technology and the willing of sharing strategic information simultaneously exist (Frohlic and Westbrook, 2001; Min, Mentzer and Ladd, 2007; Fawcett et al., 2011). In this regard, by jointly considering the effects of strategic information sharing and information technology from the perspective of supply chain information integration, the benefits in terms of long-term collaboration may be enhanced. Indeed, information integration provides not only the availability of information in a timely manner (Wong et al., 2011), but also the transparency of decisions, a key factor in the development of a long-term collaboration. The development of collaborative activities between organizations makes the network integrated and contributes to have a holistic approach, essential for building supply chain resilience (Scholten et al., 2014). Indeed, collaboration plays a fundamental role not only before a disruptive event but also after it, in order to share, among the parties, the experiences useful to increase the ability of the system to deal with future threats (Juttner and Maklan, 2011; Sheffi, 2005). Given the above, in the case of disruptions,

supply chain resilience cannot be achieved without the strict participation of the supply chain members who are called to collaborate and respond in a synergistic manner (Juttner and Maklan, 2011; Ponomarov and Holcomb, 2009).Therefore:

H1b: Supply Chain Information Integration has a positive effect on Supply Chain Collaboration
H2b: Supply Chain Collaboration is positively related to Supply Chain Resilience

In order to achieve velocity, firms need to reduce the so-called "end-to-end" pipeline time that is the time required for moving products, materials and information from one side of the supply chain to the other, being able to react to upwards or downwards changes in the demand. Through investments in integrated systems, the interchange of data, and consequently processes, can be accelerated. As a consequence, the time-based performance of supply chains may be positively affected by the implementation of an information-intensive IT platform (Jayaram et al., 2010). These benefits provided by IT may be used in leveraging the ones resulting from the continuous exchange of strategic information between supply chain partners. Indeed, the prompt exchange of both tactical and strategic information in a timely manner, positively influences the event readiness of each member of the supply chain thereby increasing velocity and making the supply chain more resilient (Juttner and Maklan, 2011). According to Manuj and Mentzer (2008), three main dimensions of velocity can be identified: the rate at which a risk event occurs, the rate at which losses happen and finally the rate at which the risk event is discovered. The fourth dimension is added by Juttner and Maklan (2011) who identify velocity, in the context of supply chain resilience, as the capability to recover and respond to a disruption. This final dimension underlines the importance of velocity before, during and after a disruption and further stresses how supply chain velocity is a fundamental element in order to increase supply chain resilience, given its contribution to increase the speed of recovery from a disruption (Mandal et al., 2015).

H1c: Supply Chain Information Integration has a positive effect on Supply Chain Velocity
H2c: Supply Chain Velocity is positively related to Supply Chain Resilience

The real-time connectivity enabled by technological infrastructure may provide less-tangible benefits such as the managers' capability to predict possible environmental trends and inflection points (McGee, 2004). By being capable to detect changes in demand, requirements or even (potential) disruptions in the supply chain, companies could, for example, react through changes in the product mix, or more generally act upon these changes (Swafford et al., 2008). Therefore, the presence of IT enhances the capability to alter the product flows of the firm, which in turns leads to a higher degree of readiness to potential disruptions and thus increase supply chain flexibility. However, the reliance on technology without the willing of sharing information related to supply chain activities will make firms not meaningfully integrated and thus not capable of achieving superior performance (Prajogo and Olhager, 2012). Information sharing within the supply chain may create flexibility, but it has to be accurate and timely (Jarrell, 1998). This is in line with Scholten et al. (2015) and with Chan et al. (2009), who found that receiving the right information too late could negatively affect the flexibility dimension to face upcoming disruptions. The underlying reason was that if information is received too late, the production schedules are already fixed and the level of stocks are already set, thus enhancing the impact of disruptions. Therefore, the achievement of flexibility is enhanced by the integration of strategic information sharing and information technology. The development of flexibility is related to the organic capability that helps the supply chain in detecting potential disruptions and emergency plans (Sheffi and Rice, 2005). In this regard, it can also be defined as the ability to have different positions and rapidly face potential changes in the supply chain (Lee, 2004). Having flexibility has been detected by many authors (Tang, 2006) as an enhancer of SC resilience. Very often supply chain flexibility and velocity are grouped under the broader concept of supply chain agility (Christopher and Peck, 2004b). Despite the speed of recovery is important, much more

important is the knowledge of the potential configurations that guide the recovery process and thus the flexibility of the system (Mandal et a., 2015). What stated above leads to the formulation of the following hypotheses:

H1d: Supply Chain Information Integration has a positive effect on Supply Chain Flexibility
H2d: Supply Chain Flexibility is positively related to Supply Chain Resilience

The moderating effect of Supply Base Complexity on Supply Chain Resilience
Supply base complexity is linked to the complexity that arises in the upstream part of the supply chain. Three main dimensions have been adopted in this study: scale complexity (number of suppliers), delivery complexity and geographical dispersion of the supply base.
A supply chain characterized by a high number of suppliers is more exposed to unreliable deliveries (Choi and Krause, 2006). Smith et al. (1991) showed that scale complexity reduces the level of responsiveness, as the transmission of information between the actors of the chain becomes delayed or even blocked. Since the movement of physical goods is strictly related to the flows of information, delay in the latter may expose firm to disruptive events. Together with the number of suppliers, supply chains that experience long lead time or high unreliable suppliers' delivery are exposed to a high supply base complexity. This in turn may cause more frequent disruptions due to less rapid responses to changes in end-customer demand (Simangunsong et al., 2012) and less transparency along the chain (Brandon-Jones et al., 2014). Finally, a geographically dispersed supply base creates the basis for a truly global supply chain (Brandon-Jones et al., 2014). Global sourcing is often related to increased uncertainty and less transparency caused by trade restrictions, custom barriers, exchange rate fluctuations and institutional differences (Wagner and Bode, 2006), if compared to sourcing from local or domestic markets. Once the geographical distance increases, the coordination of activities between the buyer and its suppliers becomes costly and difficult.
Each dimension of complexity contributes in creating more uncertainty along the chain and therefore additional opportunities for resilience capabilities to benefit managers. Indeed, the uncertainties created by supply base complexity could enhance the effects of long-term collaboration, visibility, flexibility and velocity in reducing the likelihood of disruptive events and increasing the speed of response. For example, supply chain visibility improves supply chain information processing capacity and thus positively contributes to better information collection, flows and accuracy (Tushman and Nadler, 1978). The benefits of visibility are particularly helpful when there is a high degree of scale complexity, due to the increase in the information to be processed as the number of actors within the network increases as well. Accordingly, the benefits of long term collaboration may be enhanced by the presence of a high degree of complexity. Both market and technological issues may be effectively dealt through specific long term partnerships where supply chain actors share information regarding unexpected events and developments (Verwaal and Hesselmans, 2004). Furthermore, the collaborative communication between partners positively contributes in reducing behavioural uncertainty (Wuyts and Geyskens, 2005). Finally, the sensing of supply chain disruptions, that is one of the major characteristics of supply chain flexibility (Sheffi and Rice, 2005), may be fully exploited once the transparency along the chain is obscured by a high degree of supply base complexity. Firms can improve their ability to sense disruptions through activities such as monitoring, auditing and certifying suppliers. If the complexity of the supply base is high, the return from such activities is particularly enhanced.
Therefore, the following hypotheses can be formulated:

H3a,b,c,d: Supply base complexity positively moderates the relationship between SC visibility, LT Collaboration, SC velocity, SC flexibility and supply chain resilience: the higher the complexity, the greater the beneficial effects on resilience

The following image (Fig.1) depicts the theoretical model with all the hypotheses previously explained.

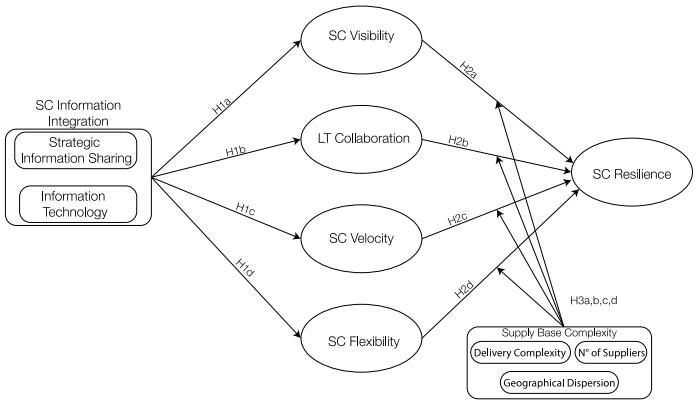

Fig.1: Theoretical model

4. Methodology

Sample and Data Collection

The data collection has been carried out through a survey which was developed by a group of students and academic experts of the University of Groningen, covering the topics such as supply chain complexity, resilience capabilities, supply chain resilience and supply chain integration. proper respondents have been identified within these professional figures: CEO, plant director, supply chain director or any other actor directly involved at a managerial level in the supply chain field. The companies involved in participating to the research project come from the manufacturing sector. In particular, the following sectors characterized by these NACE codes were involved: C.10-11, C.13, C.20, C.23, C.27, C.29-30.

A presentation letter has been prepared, in which the main topics and objectives of the research were concisely described. It was underlined that each respondent would have received the results of the research once completed. For the fulfillment of the survey, the period of time between the beginning of January and the beginning of March (10 weeks) was granted. In many cases, it has been necessary to make reminders through emails or phone calls (every 2 weeks). Once the survey was fulfilled by the companies, it has been sent an email of thanks for the participation to the project. A total of 107 Italian responses were received, accounting for a response rate of 20%. These were then added to the already existing database containing 129 responses from Chinese (95 responses) and Dutch (34 responses) respondents. All the proper tests have been pursued to validate that no differences were present among the Italian, Chinese and Dutch data.

Measures

This study uses the following constructs: information sharing, information technology, long term collaboration, supply chain visibility, supply chain flexibility, supply chain velocity and supply base complexity. The survey questions pertaining to these constructs were derived from valid and reliable extant research.

Information sharing and information technology were respectively measured by five and six items and were adapted to this work from Prajogo and Olhager (2012). The items of Information Sharing, limited to the supplier side, measure to which extent the exchange of information occurs between supply chain partners. Information technology items, always limited to the supplier side, measure to which extent information technology is adopted in the relationship between the focal firm and its supplier. The items used to measure supply chain visibility, flexibility and velocity were adapted to this work from Pettit et al. (2013). The items for supply chain visibility state the capability of the focal firm to know the status of the operating activities and the environment at one point. The items for supply chain flexibility are related to the capability of the firm to make changes in terms of order quantity, delivery time and production volume. The items for supply chain velocity were measured

in terms of "recovery", underlining the ability to return to the operational state rapidly and efficiently after disruptive events. Finally, the items used for measuring the supply base complexity were adopted from the work carried out by Bozarth et al. (2009). The selected items relate to the number of suppliers, the percentage of purchases made in the home country and the variances of supplier lead-time and supply reliability. A high level of these variables indicates a high level of supply base complexity. The survey items are developed by using the Linkert-scale, with values ranging from 1 ("strongly disagree") to 5 ("strongly agree"). To ensure the consistency of scaling, the items used for measuring supply base complexity are reversely recorded, so that the range goes from 1 (less complexity) to 5 (more complexity).

5. Analyses and results

This section describes the methodology adopted for conducting the statistical analysis of the data sample. Partial Least Squares – Path Modeling (PLS – PM) has been used for statistically validating the relationships between factors and variables; its development has been carried out through the package plspm of the software R.

Measurement model

In this study, the relationship between the latent variables (e.g. strategic information sharing, information technology, visibility, collaboration etc.) and their block of manifest variables has been considered reflective. The idea behind the reflective measurement model is that all the reflective indicators, also known as the block of manifest variables, are measuring the same latent variable and thus are the expression of the same construct. To evaluate the reflective measures, three aspects have to be considered: the unidimensionality of the indicators (Crobach's alpha, Dillon-Goldstein's rho, first eigenvalue), verify if the indicators are well explained by its latent variable (loadings and communalities) and finally assess the degree to which a given construct can be differentiated from another construct. The unidimensionality of the indicators has been confirmed by the outstanding values of the Cronbach-alpha and the Dillon- Goldstein' rho, both higher (for each construct) than the acceptable threshold of 0.7. Also the first eigenvalues, that in case of unidimensionality of the construct should be greater than one, were considered highly acceptable. Finally, all the factor loadings were closer to 0.7 or even higher, thus resulting to be acceptable. However, in order to make stronger the analyses conducted, it has been assessed the average variance extracted for all the constructs. For each latent variable, the AVE value was in excess of 0.50 thus supporting the convergent validity. The obtained results underline that each block of manifest variables was highly represented by the latent variable to which they are associated.

Structural Effects

This section shows the estimation results of the complementary effects of strategic information sharing and information technology, grouped under the concept of supply chain information integration, on the formative resilience elements as well as the impact of long term collaboration, velocity, flexibility and visibility on supply chain resilience.

The supply chain information integration, which comes from the interaction between strategic information sharing and information technology, has been estimated through the usage of the two-step approach (Agarwal and Karahanna,2000; Henseler et al. 2007). Figure E.2 shows the single effects of strategic information sharing and information technology over the formative resilience elements.

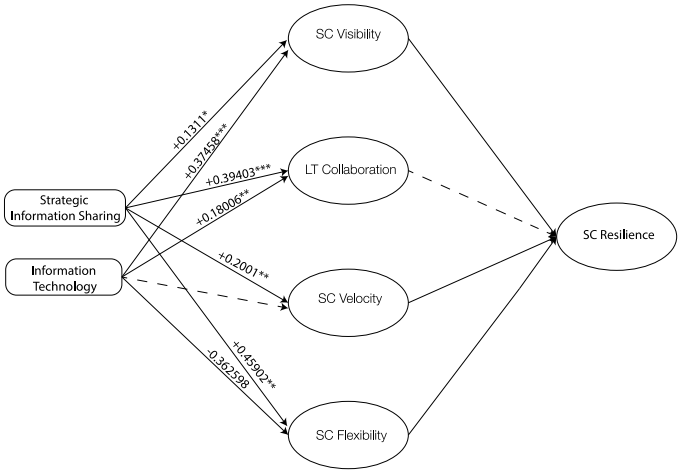

Fig.2: Impact of the single effects (significance at *p< .05, **p< .01, ***p< .001, p< .10)

When testing H1a,b,c,d the path coefficients for the interaction term (Strategic Information Sharing x Information Technology) and the formative resilience elements were all positive and significant, as it is showed in the Figure 3. This result was already anticipated in the first-step of the methodology in which the effects of the single resources turned out to be both positive and significant for most of the relationships. In the light of what stated above, the previously mentioned positive effects provide support for H1a,b,c,d.

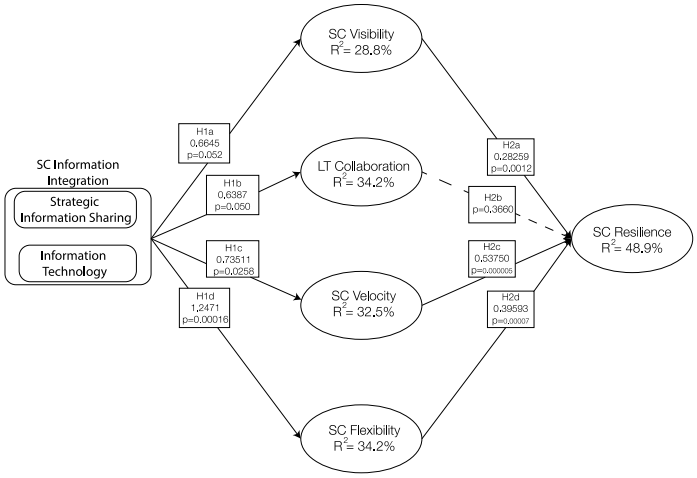

Fig.3: Impact of Supply Chain Information Integration

Turning to H2a,b,c,d, regarding the effects of the formative elements on supply chain resilience, it may be noticed that the p-values are all significant with the exception of H7 (p-value >0.1). Therefore, from the results obtained it can be stated how supply chain visibility, flexibility and velocity are positively related to supply chain resilience, while the same cannot be stated for long term collaboration.

When testing the proposed moderating effects between supply base complexity and the formative resilience elements in relationship to supply chain resilience, the product indicator has been applied (Busemeyer and Jones, 1983; Kenny and Judd, 1984). Each of the supply base variables (number of suppliers, geographical dispersion and delivery complexity) have been multiplied for each capability (visibility, flexibility, velocity and LT collaboration), thus obtaining 12 different terms. It was hypothesized that the formative resilience capabilities would have been enhanced in case of supply base complexity and, as showed by results, this was confirmed only in two cases. Indeed, the positive impact of supply chain visibility on supply chain resilience was slightly higher for high scale complexity (p-value:0.0475; coeff.:+0.325). A high degree of delivery complexity negatively affected the relationship between long term collaboration and supply chain resilience. In other words,

the impact of long term collaboration on resilience is low when delivery complexity is higher (p-value: 0.04; coeff.: -2.569).

6. Discussion of the results and directions for future research

Some important considerations could be deduced from the obtained results. Supply chain information integration helps firms in conducting not only the day-by-day business activities but also helps in the development of resilient capabilities. Indeed, the sharing of strategic information between the actors is strongly supported by the proper technological infrastructure, thus making possible the availability of strategic data in a timely manner. In turn, this allows to constantly control the supply chain, to forewarn possible threats in one node and to speed up the measures to be adopted in case of disruptions. All these outcomes are positively related to resilient capabilities and underline that specific forms of integration may enhance resilience in the chain, as also suggested by Wieland and Wallenburg (2012). This result is even more interesting by considering that survey data has been used to test these hypothesized relationships, making this study one of the few in empirically contributing to the literature on supply chain resilience. Firms need to understand the importance of sharing both strategic and tactical information that could magnify the returns from investments in the scope of IT applications and, consequently, develop capabilities for overcoming or recovering from disruptive events. Inability in recognizing complementary interactions, hardly discussed in the RBV, may lead to unnecessary overemphasis and could dampen the net impact of some investments. Therefore, managers should include these considerations into their decision-making process and, moreover, should also understand that resources typically used for the daily business activities (e.g. strategic information sharing and information technology) may be integrated for making the supply chain more resilient.

In terms of capabilities, the obtained results suggest that the effects of information integration, in its two components of strategic information sharing and information technology, are positively related to supply chain resilience capabilities; most of them were the positively related to SC resilience. Through the transparency (due to the exchange of strategic information) and the fast elaboration of strategic data mixed to systems able to monitor events along the chain (due to the technological infrastructure), it is possible to improve reactions, take effective decisions and all the necessary interventions in managing a risky event. These elements represent the foundation of supply chain visibility and their positive connection to supply chain resilience has been demonstrated by several authors (Blackhurst et al., 2011; Juttner and Maklan, 2011; Azadeh et al., 2014).

Supply chain information integration, as well as its principal components, has been shown to be positively related to long-term collaboration. Indeed, sharing information increases transparency and trust (Bhamra et al., 2011) that are considered enhancers of long-term relationship and cooperation across partners in the chain (Faisal et al., 2007). Furthermore, if this information is supported by technological platforms that allow the real-time exchange (Boyson et al., 2003), the collaboration is further enhanced as every actor can efficiently and effectively receive relevant information efficiently and effectively (Mandal, 2012). However, the capability resulting from the integration among resources, turned out to be not statistically significant in relationship to supply chain resilience. The reasons of this result, rely in the choice of the construct used for measuring collaboration and, in particular, in its aspect of using fewer suppliers over a longer period instead of maintaining a large supply base (Helper, 1991). This element could positively contribute to enhance the relationship between the focal firm and its suppliers but, at the time of a disruption, the choice of limiting the supply base could negatively affect supply chain vulnerability (Cavinato, 2004; Choi and Krause, 2006; Svensson, 2004). In this regard, future studies could investigate the role of long-term collaboration as an antecedent of the resilient capabilities identified by Juttner and Maklan (2011).

With regards to supply chain velocity, while the willing of sharing strategic information has been positively related to speed, the same did not happen for the only presence of information technology.If information technology supports the early sharing of strategic information among the actors, the integration among these two resources enhances the lead-time in responding but it also allows to have

enough time for developing countermeasures in case of disruptive events. The negative impact of information technology has been found in the case of supply chain flexibility, similarly to supply chain velocity. This is in line with the findings of Wieland and Wallenburg (2013) who considered information technology infrastructure as integrated systems able to accelerate the interchange of data. The authors found that tight coupling of resources and integrated systems would have impeded a quick reaction to unpredictable events that would have required, for example, the change of suppliers. Nevertheless, as also stated by the authors, the concept of integration adopted in their research did not consider the communication among the actors, which was intended as the formal and informal exchange of meaningful and timely information. By jointly considering strategic information sharing and information technology, grouped under supply chain information integration, the benefits in terms of supply chain flexibility are enhanced. Indeed, information technology provides the platform for accelerating the flow of strategic information. This enhancement in flexibility derived from information integration, is measured along two dimensions that, in turn, affect the supply chain resilience. The first deals with the capability of rapidly meeting new demands (in terms of product type and quantities), whereas the second is instead the ability to reconfigure the supply chain by flexibly taking decisions in terms of switching supplier, change delivery times etc. By knowing exactly what is happening in each node of the chain in terms of production conditions through constant and fast flows of information, the focal firm is able to better manage internal changes as well as timely switch the supplier in case of disruptive events.

Many hypotheses have been rejected due to the non-significant moderation influence of supply base complexity on the direct relationships between the formative resilience capabilities and supply chain resilience. The only exceptions are represented by two interactions. The first deals with the positive and significant effect of supply chain visibility on supply chain resilience in case of a high degree of scale complexity (number of suppliers) (p-value=0.0475; estimate=0.325). For firms operating in this context, it has been shown that investments in supply chain visibility would have given a superior outcome in terms of supply chain resilience. Scale complexity might lead to more frequent disruptions due to a higher number of nodes in the supply network and, therefore, an increased likelihood of propagation of disruptions. In turn, disruptions are events that limit the ability to work in a pre-determined manner (Craighead et al., 2007) and increase the information processing requirements of an organization. In this regard, the creation of greater visibility in the supply chain would contribute in enhancing the information processing capacity of the organization. The second significant interaction is related to the negative impact of delivery complexity on the relationship between long-term collaboration and supply chain resilience. Delivery complexity is associated with more frequent disruptions due to the greater distance to be travelled (Stecke and Kumar, 2009), demand amplifications effects (Lee et al., 1997) and less rapid responses to changes (Simangunsong et al., 2012). In addition, as suggested by Brandon-Jones et al. (2012), long lead time supply chains may be characterized by having less transparency and thus being subjected to more frequent disruptions. These elements can explain the obtained result. Among all, the lack of transparency in the chain could cause uncertainty. This, in turn, is viewed as one of the underlying determinants of high transaction costs (Williamson, 1975) that undermine the relationships among actors. Building long-term relationship with a reduced number of suppliers does not affect the development of resilience, but if this limited group is also characterized by a high delivery complexity, then the management of disruptions will be even negatively affected. Finally, supply chain velocity and supply chain flexibility have not been affected by any supply base complexity factors in relationship to supply chain resilience. This could mean that these capabilities are always helpful in any work condition in which the firm works since they effectively help in reducing both time and cost of disruptions and, thus, enhancing supply chain resilience. For this reason, future studies could investigate new contingency factors and their moderation in the effects of resilient capabilities.

Coordinating model of working capital management: developing economic sustainability from the inside

Anastasiia Ivakina and Nikolay Zenkevich

St Petersburg State University, Russia

Summary
The paper is devoted to development of a working capital management model providing optimal levels of working capital (WC) to all individual business partners in a supply chain (SC) through collaborative actions of capital reallocation. As such, we suggest the tool of WC optimization through financial terms and cash flows verified on Russian collaborative SC data. Mathematical modeling is suggested as a method to upgrade existing collaborative cash conversion cycle (CCC) model (Hoffman and Kotzab, 2010) by optimizing it for a three-stage SC. The application of the suggested optimization model to focal SC provided significant acceleration of individual CCCs and investments in WC by combining the extension of days of accounts payable, reduction in days of inventories and reduction in days of accounts receivable in different proportions for SC participants. The theoretical contribution consists of integrating collaboration and WC concepts, adding a holistic perspective to extant working capital management (WCM) models. The suggested model illustrates financially the motivation of SC partners to cooperate in order to simultaneously achieve target levels of WC investments and improve individual financial performance through collaborative operations.

Keywords
Supply Chain Finance, Working Capital Management, Supply Chain Coordination

Introduction and area of investigation

Supply chain finance (SCF) and working capital management (WCM) are increasingly recognized as important means of liquidity and profitability improvement, specifically in terms of globalization and growing competition between supply chains (SCs) (Deloof, 2003; García-Teruel and Martínez-Solano, 2007; Lazaridis and Tryfonidis, 2006). The physical product and information flows have long been addressed by researchers and practitioners, unlike the upstream and downstream flows of money (Gupta and Dutta, 2011; Kouvelis et al., 2006; Weiss, 2011; Wuttke, Blome and Henke, 2013), although rising financial risk in SCs stimulated management to recognize that the financial side of supply chain management (SCM) is a promising area for improvements. Nevertheless, companies still focus on their individual SC issues and take their own interests into account rather than understanding the whole SC and coordinating with their partners.

As business environment is swiftly changing and competition levels rise, Gupta and Dutta (2011, p.47) emphasise that “for an effective supply chain system, the management of upstream flow of money is as important as the management of downstream flow of goods”. From this perspective, working capital management (WCM) as an essential element of

financial supply chain management (FSCM) has gained a lot of attention (Deloof, 2003; García-Teruel and Martínez-Solano, 2007; Johnson and Templar, 2011; Matyac, 2015; Protopappa-Sieke and Seifert, 2016; Shin and Soenen, 1998; Viskari et al., 2011; Viskari et al., 2012; Viskari and Karri, 2012;) since the financial crisis of 2008. WCM is stated to be a way to accelerate the cycle time of working capital and increase the profitability and liquidity of the company in respond to spreading volatility in business environment and enacted Basel II restraining external financing from banks and in turn increased demand for capital from within the SC (Hofmann and Kotzab, 2010; Talonpoika et al., 2016). For this reason, importance of effective WCM increased dramatically, especially for SCs from emerging markets, that matter-of-factly faced difficulties with access to capital, limited financial infrastructure and legal, regulatory and accounting uncertainties in the first place (ACCA, 2014). Apart from that, the focus of the study on emerging markets is as well prompted by the fact that SCs stretch across the globe with a diverse range of suppliers in emerging markets, and it is failure of a supplier that can impact most severely the whole production process putting viability and continuity of a whole SC at threat. So, WCM is increasingly transcending boundaries of mature markets and has potential for economic stabilization, however most emerging market companies have not yet fully realized its benefits.

Likewise, coordinating mechanisms of WCM in SCs have received little attention due to the fact, that the role of financial coordinators (financial service providers, banks, FinTech companies and other financial intermediaries) as core participants in facilitating and enabling SCF has only recently been identified in academic literature (Silvestro and Lustrato, 2014). Along with that, the research is motivated by the call for more holistic approach to SCM on the grounds of merging financial and operational SC measures as existing literature either considers them separately or does not give insights on financial flows (Protopappa-Sieke and Seifert, 2010; Kroes and Manikas, 2014).

Authors address these gaps and develop coordinating WCM model aimed at minimizing total financial costs associated with each SC stage on the grounds of collaborative actions of SC players using SCF solutions (Reverse Factoring and Inventory Financing). The model is further verified on the grounds of the combination of mathematical modeling and case study of Russian distributive SC from ICT industry. The suggested model introduces holistic perspective to WCM and provides financial illustration for the motivation of SC partners to cooperate in order to simultaneously achieve target levels of working capital investments and improve individual financial performance and as a result strengthening whole SC competitiveness and value.

Methodology and model development

In compliance with the research aim of working capital optimization for all SC business partners and following the tradition (Talonpoika et al., 2014; Wuttke, Blome and Henke, 2013; Hoffman and Koztab, 2011; Randall and Farris, 2009; etc.), the core of the research methodology is based on quantitative methods. The research is based on the combination of mathematical modeling and case method. Mathematical modeling is suggested as a method to upgrade existing CCCC model (Hoffman and Kotzab, 2010) by optimizing it in terms of minimization of total financial costs associated with each SC stage.

The fundamental metric of WC is cash conversion cycle (CCC), which is a composite measure of “average interval between the time cash expenditures are made to purchase inventory for use in the production process and the time that funds are received from the sale of the finished product” (Schilling, 1996, p. 4-5). Farris and Hutchinson (2002) state this

definition to be "the most commonly accepted definition currently found in the literature". The CCC concept applicability was further extended from intra-organizational level of WCM to inter-organizational one by Hofmann and Kotzab (2010), who introduced collaborative CCC model (CCCC) as SC-oriented approach of WCM. CCCC is actually a sum of individual CCCs, but internal payments among the participants do not affect it and are not counted (Hofmann and Kotzab, 2010).

For the purposes of our research, we consider a simple three-stage SC consisting of a single supplier, distributor and retailer, what is actually a simplifying assumption. For this SC structure, we define collaborative cash conversion cycle (CCCC) as the sum of every CCC for all participants (1):

$$CCCC = \sum_{l=1}^{3} \sum_{k=1}^{K_l} CCC_l^k,$$
$$CCC_l^k = DIO_l^k + DRO_l^k - DPO_l^k, \quad (1)$$

where $l = \overline{1,\ 3}$ (1 – supplier stage, 2 – wholesaler stage, 3 – retailer stage),
$k = \overline{1,\ K_l}$, $K_l = \begin{cases} N, & l = 1, \\ 1, & l = 2, \\ M, & l = 3. \end{cases}$
$DIO_l^k -$ days of inventory outstanding for company k at stage l,
$DRO_l^k -$ days of accounts receivable outstanding for company k at stage l,
$DPO_l^k -$ days of accounts payable outstanding for company k at stage l.
Following this simple SC structure, we have constraints on CCCC elements (Eq. 2). The rationale behind these constraints is straightforward: it provides SC-oriented approach to CCC evaluation as duration of the internal payments among participants is excluded.

$$DRO_l^k = DPO_{l+1}^k, \quad (2)$$

where $l = \overline{1,\ 2}$, $k = \overline{1,\ K_l}$.

The total financial costs minimization is of common interest for all SC members; however, the rationale behind such collaboration is that each participant's financial costs are not worse than performing individually. We will evaluate financial costs associated with each SC stage with formula (3) introduced by Viskari et al. (2013):

$$FC_l^k\left(DIO_l^k, DRO_l^k, DPO_l^k, INV_l^k, AR_l^k, AP_l^k\right) =$$
$$= INV_l^k\left[\left(1 + c_l^k\right)^{\frac{DIO_l^k}{365}} - 1\right] + AR_l^k\left[\left(1 + c_l^k\right)^{\frac{DRO_l^k}{365}} - 1\right] - AP_l^k\left[\left(1 + c_l^k\right)^{\frac{DPO_l^k}{365}} - 1\right], \quad (3)$$

where $l = \overline{1,\ 3}$, $k = \overline{1,\ K_l}$,
c_l^k – annual cost of capital for company k at stage l,
$DIO_l^k, DRO_l^k, DPO_l^k$ – elements of CCC for company k at stage l,
INV_l^k – level of inventory at year-end for company k at stage l,
AR_l^k – level of accounts receivable at year-end for company k at stage l,
AP_l^k – level of accounts payable at year-end for company k at stage l.
Collaborative financial costs (CFC) function sums financial costs of all supply chain participants:

$$CFC = \sum_{l=1}^{3} \sum_{k=1}^{K_l} FC_l^k, \quad (4)$$

where $l = \overline{1,\ 3}$, $k = \overline{1,\ K_l}$.

We denote FC_l^{0k} as known beginning-of-the-year financial costs values (before optimization) for company k at stage l. Firstly, financial costs FC_l^k should not exceed values FC_l^{0k}, or:

$$FC_l^k \leq FC_l^{0k}, \quad (5)$$

where $l = \overline{1,\ 3}$, $k = \overline{1,\ K_l}$.

Secondly, we assume that each company in a chain has individual constraints on rate of inventory turnover:

$$DIO_l^k \geq DIO_l^{up}, \quad (6)$$

where $l = \overline{1,\ 3}$, $k = \overline{1,\ K_l}$,

DIO_l^{up} – target levels of days of inventory outstanding for company k at stage l.

Thirdly, following Garanina and Belova (2015) we denote CCC_l^k to confine to recommended industry specific stability interval providing favorable return-liquidity trade-off (Eq. 7). As such, we suppose a company is pursuing moderate approach to working capital management ensuring company's current ratio is higher than the industry average rate of return and at the same time, is below the value at which the relation between liquidity and rate of return becomes inverse (Garanina and Belova, 2015).

$$CCC_{low} \leq CCC_l^k \leq CCC^{up}, \quad (7)$$

where $l = \overline{1,\ 3}$, $k = \overline{1,\ K_l}$,

CCC_{low}, CCC^{up} – targeted lowest and highest levels of CCC for company k at stage l.

We incorporate the inward-looking approach to the problem of CCCC optimization (Hofmann and Kotzab, 2010), so for optimization we only use elements of CCCC that are immediately within the specified perimeter of a SC. As such, values of DPO_1^k and DRO_3^k after optimization should equal their values before optimization:

$$DPO_1^k = DPO_1^{0k},\ k = \overline{1,\ N},$$
$$DRO_3^k = DRO_3^{0k},\ k = \overline{1,\ M}. \quad (8)$$

Furthermore, we suppose elements of CCCC (1) to be nonnegative and continuous:

$$DIO_l^k, DRO_l^k, DPO_l^k \geq 0, \quad (9)$$

where $l = \overline{1,\ 3}$, $k = \overline{1,\ K_l}$.

Finally, we construct the optimization model as follows: to minimize CFC (4) under constraints (2), (5) – (9). The objective function and constraints are separable functions. As such, for this nonlinear separable programming problem we employ gradient general nonlinear algorithm (Stefanov, 2013).

The theoretical model is further tested on the grounds of case study of collaborative SC from ICT industry, that is generally characterized by an integrated business environment and fast technology development. It is service-oriented, and has a large variety of end products and

customers. Besides, even though individual companies in the ICT industry have been used in many case studies, and the SCs of single products or companies have been examined, the ICT networks at the industry level have been studied relatively little (Lind et al., 2012; Pirttilä et al., 2014). The focal company in a chain is a Russian public telecommunication services provider, holding licenses for local, long-distance and mobile telephone services, data, TV and value-added solutions to residential, corporate and governmental subscribers and third party operators. The company operates across all regions of the Russian Federation, Europe and Asia.

The data concerning the supply chain business partners was retrieved from semi-structured interviews with middle-level operations managers, that was further triangulated with secondary data sources (annual financial reports downloaded from Thomson Reuters Eikon).

Findings

In this section, we present our findings by illustrative numerical example. The choice of a numerical analysis of SC operating in information and communication technology (ICT) industry is motivated by the fact that it is characterized by a highly integrated business environment and fast technology development (Pirttilä et al., 2014). It is service-oriented, and has a large variety of end products and customers. Besides, even though individual companies in the ICT industry have been used in many case studies, and the SCs of single products have been examined, the ICT chains at the industry level have been rarely studied (Lind et al., 2012). For simplicity, we consider a chain consisting of a single supplier, wholesaler and retailer.

The model parameters we consider are based on data (Tab. 1) retrieved from the Wholesaler's Annual Report and interviews with Supplier's and Retailer's financial managers.

Table 1. Year-beginning data (before optimization)

l	***Supplier***	***Wholesaler***	***Retailer***	***Total (SC)***
INV_l^0	1,342.0	11,593.0	972.0	13,907.0
AR_l^0	1,374.0	816.2	119.0	2,309.2
AP_l^0	901.0	2,896.2	85.0	3,882.2
WC_l^0	***1,815.0***	***9,513.0***	***1,006.0***	***12,334.0***
$COGS_l^0$	6,345.0	22,981.0	5,528.0	X
$Revenue_l^0$	7,419.0	29,792.0	6,588.0	X
c_l	0.0818	0.0474	0.0338	X
DIO_l^0	77.2	184.1	64.2	X
DRO_l^0	67.6	10.0	6.6	X
DPO_l^0	51.8	46.0	5.6	X
CCC_l^0	***93.0***	***148.1***	***65.2***	***306.3***
FC_l^0	***32.5***	***258.1***	***5.7***	***296.3***

The results in Table 2 contain elements of CCC and financial costs FC for all supply chain business-partners at the end of the planning period as well as the relative change in CCCC model elements after optimization.

Table 2. Results of CCCC modeling (year-end, after optimization)

l	*Supplier*		*Wholesaler*		*Retailer*		*Total (SC)*	
INV_l^0	132.4	-90.13%	12,802.6	10.43%	972.0	0.00%	13,907.0	0.00%
AR_l^0	1,989.6	44.80%	578.6	-29.11%	119.0	0.00%	2,687.3	16.37%
AP_l^0	901.0	0.00%	6,163.0	112.80%	107.4	26.35%	7,171.4	84.73%
WC_l^0	*1,221.0*	-32.73%	*7,218.2*	-24.12%	*983.6*	-2.23%	*9,422.9*	-23.60%
DIO_l^0	7.6	-90.16%	203.3	10.43%	64.2	0.00%	X	X
DRO_l^0	97.9	44.82%	7.1	-29.00%	6.6	0.00%	X	X
DPO_l^0	51.8	0.00%	97.9	112.83%	7.1	26.79%	X	X
CCC_l^0	*53.7*	-42.26%	*112.5*	-24.04%	*63.7*	-2.30%	*229.9*	-24.94%
FC_l^0	*32.5*	0.00%	*258.1*	0.00%	*5.7*	0.00%	*296.3*	0.00%

The illustrative example results depict the decrease in CCCC by 24.94% without further financial costs. The acceleration in the cash conversion cycle is mainly a consequence of CCC decrease for the Supplier and the Wholesaler (- 42.26% and -24.04% respectively, Table 2).

The CCCC boost is achieved based on decreasing days of inventories for the Supplier (-90.16%, from 77.2 days to 7.6 days) and reallocation of a major part of inventories to the Wholesaler. Moreover, the Supplier faces increased DRO (by 44.82%, from 67.6 days to 97.9 days). This target is achievable due to ICT industry specifics: ICT suppliers often render only services, and thus they do not need high levels of inventories, but have a long DRO instead. The long DRO in turn can be explained by the fact that ICT suppliers in most cases give their customers time to test the new system before the customer has to pay the final installment. The Wholesaler's optimal behavior is granted with DRO declining (-29.00%, from 10.0 days to 7.1 days) as well as 112.83% (from 46.0 days to 97.9) increase in DPO. This may signal that the Wholesaler is in a position to provide financing to other SC participants using various forms of SC financing solutions (approved payables finance, advanced inventory financing, trade-credit, factoring, reverse factoring, and supplier subsidy) alleviating their high working capital requirements. Ii is as well prompted by the fact that most financial service providers focus on large, international companies and generally lack the established means to approach small and medium-sized enterprises and their alternative financing needs. In contrast, financing 80-100 percent of their receivables or payables from an experienced partner involved in a collaborative supply chain can be achieved at a very low cost. The Retailer in its turn achieves a significant increase in DPO (26.79%, from 5.6 to 7.1 days) that gives him the opportunity to reinvest his working capital or at least decrease his requirements by 2.23%. From the SC perspective this definitely fits the customers' side objectives for the financial flows as does not imply acceleration of payments. Moreover, extended payment terms can increase customer satisfaction.

Discussion and conclusions

The main goal of this paper was to develop a model of working capital optimization in collaborative supply chains and to describe how companies can benefit from collaboratively managing their financial flows at the supply chain level. The study indicates that companies do not yet use of available opportunities adequately. By identifying possible ways of implementing CCCC optimization, the research illustrates approaches for companies to overcome existing challenges. The research contributes to existing SCM literature by focusing

on financial flows and studying its optimization. The research integrates financial and supply chain perspectives on the involvement of WCM on the supply chain level.

Managerial actions towards working capital in collaborative supply chains are critical at the operational level for such operations as supply chain management, production, procurement and finance. The companies have gained knowledge how to assess the cycle time of working capital at the intra-organizational level, but estimation of this at the inter-organizational level still causes difficulties for the companies involved in collaborative supply chains. This paper provides insights into collaborative evaluation of CCC using an optimization CCCC model by accurately assessing the length of the cycle time of working capital and the total financial costs associated with it.

There are two main theoretical implications of the paper that correspond to the main objectives justified by the empirical study. Current studies outline the importance of working capital management in supply chains because companies need to adjust their operations to the volatile economic and financial environment. Firstly, the gap in research that connects the CCC approach and the three-stage collaborative supply chains is filled by the development of the CCCC concept. Secondly, the authors contributed to an improvement in the methodology of working capital assessment in collaborative supply chains by introducing the optimization CCCC model that provides a holistic view to the collaborative supply chains. The developed methodology is suitable for a threestage collaborative supply chain and is applicable for usage for business, consultancy, 3PL or bank as an intermediary or the decision maker.

Future research should seek to extend the context of this paper by investigating the possible imputation options for gained costs reduction on the grounds of cooperative games with coalition structure as there is power asymmetry among players leading to possible lack of motivation to cooperate in the process of collaborative working capital management.

IKEA: Global sourcing and sustainable leather initiatives

Summary
Aims: The aim of this teaching case is to illustrate the Sustainable Global Sourcing (SGS) practices of IKEA influenced by its Global Sourcing (GS) strategy and structure aspects through a case study of the sustainable leather initiative.
Scope: This study is developed though 20 face-to-face interviews with IKEA managers in both Sweden and China, covering all the major SGS-related departments i.e. purchasing, sustainability, IWAY, and competence center (sustainable project team).
Contribution: We provide a benchmark of SGS for other multinational companies and allows for a thorough discussion of a sustainability initiative in a GS context. The case can be used to teach graduate/postgraduate in agricultural economics, MBA and executive students on sustainable supply chain management and corporate social responsibility.
Keywords
Global sourcing strategy; global sourcing structure; sustainable leather initiatives; teaching case
Submission category: educational paper

Introduction

In a sunny afternoon, Peter Agnefjäll, the President and CEO of IKEA Group and the Group Management team members sat in the meeting room, summing up the results of the past year and discussing the following reorganization issues that Group is facing in the next.
IKEA Group is a leading retailing company and has been engaged in sustainability for many years. In nowadays business environment, MNCs sourcing globally face pressures from consumers and Non-Governmental Organizations (NGOs) of not addressing environmental and social concerns sufficiently. IKEA constantly performs well in integrating social and environmental sustainability into its Global Sourcing (GS) activities.
Peter Agnefjäll concluded that FY16 was a remarkable year for them in many ways. The sales grew to EUR 34.2 billion. Together with the rental income from the shopping centre business (IKEA Centres), total revenue increased by 7.4% to EUR 35.1 billion. Meanwhile, On 31 August 2016 they sold their product development, supply chain and production companies to Inter IKEA Group. Together, they also created a movement, meeting and bringing people together around food in new ways. And they made the food served and sold in their stores more healthy and sustainable. Peter Agnefjäll highly affirmed the past achievements and proposed the questions run through his mind.
He indicated that, in next the Group plans to implement a sustainable initiative for the leather supply chain, and it requires the transformation of their organizational structure to better fit its sustainable global sourcing (SGS) strategy. However, implementing such an initiative is complicated due to the various factors involved, such as long distances of transportation, overseas suppliers, resources investment and cultural differences, among others. To carry out this initiative, Peter Agnefjäll proposed the following questions emerged for Group Management team to consider. IKEA aims to restructure the way of GS by category, so what appropriate GS strategy and structure is needed in order to enable the sustainable initiative e.g. sustainable leather initative? How do GS strategy and structure shape a sustainable leather initiative? What processes could IKEA use to implement a sustainable leather initiative?
These questions bother the Group Management team members, especially for the lead of Purchasing Group and Sustainability Group at IKEA Sweden. They wonder how to deal with these problems and work together to implement the sustainable initiative. To answer these questions, we first provide IKEA's overall background followed by a detailed explanation of

IKEA's GS strategy and structure. Then, the leather initiative is elaborated in light of the GS strategy and structure. In this teaching case, we explore SGS influenced by IKEA's GS strategy and structure through its sustainable initiatives on leather supply chain.

Company and organization background

IKEA is a multinational group, headquartered in the Netherlands, designs and sells ready-to-assemble furniture, kitchen appliances and home accessories. IKEA received €11 billion in sales revenue and more than 1.1 billion euros in net profit, becoming the world's largest furniture retailer in 2003. Founded in Sweden in 1943 by the then 17-year-old Ingvar Kamprad, the company's name is an acronym that consists of the initials of Ingvar Kamprad, Elmtaryd (the farm where he grew up), and Agunnaryd (his hometown in Småland, southern Sweden). The company is known for its modernist designs for various types of appliances and furniture, and its interior design work is often associated with an eco-friendly simplicity. In addition, the firm is also known for its attention to cost control, operational details, and continuous product development. These corporate attributes have allowed IKEA to lower its prices by an average of 2-3% over the decades to 2010 during a period of global expansion. All of these are well summarized in its business strategy, i.e. "to offer a wide range of well-designed, functional home furnishing products at prices so low that as many people as possible will be able to afford them" (IKEA website).

The groups of companies that form IKEA are all controlled by INGKA Holding B.V., a Dutch corporation, which in turn is controlled by a tax-exempt, not-for-profit Dutch foundation. The IKEA trademark and concept is controlled by a series of corporations that can be traced to the Netherlands Antilles and to the Interogo Foundation in Liechtenstein. INGKA Holding B.V. owns the industrial group Swedwood, which sources the manufacturing of IKEA furniture, the sales companies that run IKEA stores, as well as Purchasing and Supply functions, and IKEA of Sweden, which is responsible for the design and development of products in the IKEA range. INGKA Holding B.V. is wholly owned by the Stichting INGKA Foundation, which is a non-profit foundation registered in Delft, Netherlands. The European logistics centre is located in Dortmund, Germany, and the Asian logistics centre is located in Singapore. Inter IKEA Systems B.V. in Delft, owns the IKEA concept and trademark, and there is a franchising agreement with every IKEA store in the world. The INGKA Group (not to be confused with INGKA Holding B.V.) is the biggest franchisee of Inter IKEA Systems B.V., the latter not being owned by INGKA Holding B.V., but by Inter IKEA Holding S.A. registered in Luxembourg, which in turn is controlled by the Interogo Foundation in Liechtenstein. Ingvar Kamprad has confirmed that he and his family control this foundation. The company, which originated in Småland, Sweden, distributes its products through its retail outlets.

As of December 2016, IKEA owns and operates 392 stores in 48 countries, 22 pick-up and order points in 11 countries, 41 shopping centres in 15 countries and 38 distribution sites in 18 countries. In FY16 (financial year 2016, from September 2015 to August 2016), IKEA had 783 million store visits and 425 million shopping centre visits, and sold €34.2 billion worth of goods, representing a 7.1% increase over FY15. Meanwhile, the IKEA website contains about 12,000 products and is the closest representation of the entire IKEA range. There were over 2.1 billion visitors to its websites and €1.4 billion online sales across 14 IKEA Group markets in FY16, an increase of 9% compared to FY15 (IKEA Group Sustainability Report FY16).

IKEA has a long tradition of embedding sustainability in its operations. The company is keen to show leadership in integrating sustainability across its business. As Steve Howard, the Chief Sustainability Officer of IKEA Group said in his TEDTalk (talk videos from expert speakers on education, business, science, tech and creativity),

"Sustainability has gone from a nice-to-do to a must-do. It's about what we do right here, right now, and for the rest of our working lives…. If you're a business leader, if you're not already weaving sustainability right into the heart of your business model, I'd urge you to do so."

The vision of IKEA is to create a better everyday life for many people and it adopts a People & Planet Positive strategy to work towards this vision. The strategy focuses on three aspects: inspiring and enabling millions of customers to live a more sustainable life at home; striving for resource and energy independence; and taking a lead in creating a better life for the people and communities influenced by its business. IKEA sets minimum requirements on environment, social and working conditions throughout its supply chain, i.e. IWAY (the IKEA way on purchasing products, materials and service). IWAY is the IKEA supplier code of conduct, which ensures a mutual understanding on sustainability with its suppliers. IKEA transferred the responsibility to IWAY to visit suppliers and monitor their compliance with the code of conduct. IKEA has been adopting IWAY since 1999 to ensure that products are made to an environmentally and socially acceptable standard. Furthermore, IKEA pays particular attention to vulnerable groups in its supply chain, such as migrant workers and home-based workers, to ensure that they can access decent employment including wages, working conditions and labour rights (IKEA Group Sustainability Report FY16).

IKEA global sourcing strategy and structure

IKEA global sourcing strategy

GS within IKEA has always been an important contributor to realizing the Vision and Business Idea. IKEA comes from a trading organization that delivers excellent results based on internal competition and a strong focus on manufacturing in low cost countries. This has generated cost savings when moving volumes from Western Europe to Eastern Europe and Asia. However, this way of working has also left room for improvements related to better cooperation and increased transparency within IKEA.

To take full advantage of the economies of scale and competence, IKEA decided to develop its GS strategies based on categories (product lines). This led to the product-based strategy and a common agenda towards suppliers. The product-based strategy contributed to the Supplier Development Process and a clear way of working with suppliers. With the Supplier Development Process, IKEA now has a more concentrated supplier base, reducing the number of suppliers from 2,000 to 1,000 in FY16. Meanwhile, IKEA has set a common agenda with suppliers and works together with them under a common agenda. In this way, IKEA optimizes the whole value chain and obtains good products at low cost. Regarding consistent excellent performance, IKEA will continue its GS works with a product-based strategy and its way of developing suppliers.

IKEA's GS strategy is characterized by Three Cornerstones, i.e. lower total cost from material to customer, IKEA supplier – partners for growth, and one IKEA purchasing – simple and professional.

Lower total cost from material to customer

By working together to optimize the whole value chain, IKEA makes better products and provides services at a lower total cost. The total cost approach empowers the IKEA organization to make decisions closer to reality. IKEA strives to connect suppliers to customers' needs and expectations. Optimizing the whole value chain from material to customer is only possible by integrating the internal functions and external stakeholders, from an end-to-end perspective. It starts with the design of the product, from the choice and use of sustainable materials and techniques, to design for efficient manufacturing (cost and quality), logistics, the buying process and customer use. By using standard solutions, components and platforms, IKEA develops its offering at a faster speed as well as a lower cost.

IKEA shares its business model with suppliers, and purchasing volume is the foundation for this. The large purchasing volume helps IKEA obtain a high bargaining power and save costs. Meanwhile, it can further ensure IKEA is involved in some suppliers' choices, such as buying machinery and developing technologies. Furthermore, the large purchasing volume also makes it possible to invest in more efficient industrial production set-ups and to drive industrialization of new industries, which leads to better quality and lower cost. IKEA develops material and components strategies by focusing on affordability, accessibility and sustainability.

IKEA suppliers – partners for growth

To offer better products that are affordable for the many and to develop a more successful IKEA, a diverse and concentrated supplier base is required to meet the needs of businesses and customers. Partnerships are built on a shared business model and values, which IKEA calls strategic fit.

IKEA has developed a diverse but concentrated supplier base, which can handle more products and service with a higher flexibility as well as a faster reaction speed. It reacts to customers' needs with speed and accuracy. The IKEA supplier base is also concentrated. It has a smaller number of suppliers and an integrated way of working, which contributes to the development of products, standard solutions, components and platforms.

IKEA positions itself as a preferred business partner, both for existing suppliers and new potential suppliers. IKEA's partnership is characterized by mutual respect, trust and transparency. Based on shared business plans and common goals, IKEA creates the conditions for suppliers to be able to take full responsibility for performance. The allocation of responsibility to suppliers helps IKEA move its focus from controlling to business development, and in this way, suppliers are more proactive in following IKEA's plans and goals.

One IKEA purchasing – simple and professional

IKEA develops GS strategies for categories and action plans with suppliers using the Purchasing Development and Supplier Development processes. The work is based on and contributes to IKEA's leadership. IKEA develops a business intelligence platform and has a common framework for defining, communicating and mitigating risks, leading to one view on trade barriers, market, political and sustainability risks as well as volatility in currency and raw materials. To deliver results IKEA takes the required measures to implement its strategies and action plans, by organizing the key initiatives as projects (e.g. cotton project and leather project).

To enable professional GS, IKEA has a simple and efficient organization, with a shorter distance between customers and suppliers, and fewer people involved. This leads to an agile and empowered organization, where IKEA takes leadership and gives clarity about where and by whom decisions are made and who is accountable. The principle is that IKEA acts as One IKEA Purchasing for the core processes, with all functions and people contributing directly towards the business objectives. The business needs set the agenda for the allocation of resources, regardless of function or location.

IKEA global sourcing structure

IKEA has three processes: product range (product development), supply (including purchasing and logistics) and sales (retailer). Transportation has been outsourced but warehousing is operated in-house. IKEA implements GS with Range & Supply organizations and a total of 6,800 co-workers around the world. IKEA Range & Supply consists of two units: IKEA of Sweden AB (range) and IKEA Supply AG (supply).

IKEA Range & Supply

IKEA Range is the organizational structure for product development and innovation. IKEA of Sweden AB is structured into 10 Business Areas, i.e. Livingroom & Workspace; Bedroom &

Bathroom; Kitchen & Dinning; Children's IKEA; Lighting & Home Smart; Textiles; Cooking, Eating & Decoration; Outdoor, Storage, Organization & IKEA Family; Free Range; and IKEA Food. IKEA Range is the core of the IKEA business. It is developed to inspire people and provide solutions to everyday home furnishing needs. Each year, IKEA introduces approximately 2,000 new products to the IKEA stores. The complete IKEA range consists of almost 10,000 products.

IKEA Supply AG is the main wholesale company. It owns the goods in the distribution centres and is responsible for cross-border flows and replenishment, and goods to various IKEA Retail Companies (and to local wholesale companies in Russia and China). The way IKEA works within its supply chain has always been an important contributor to realizing the IKEA vision and business idea. By taking an interest in efficient production and constantly working to lower logistics costs, IKEA strives to be the strong link between suppliers and customers. The goal of the IKEA Purchasing & Logistics organization is to take the lead in optimizing the total value chain, contributing to the goal of providing better products at lower prices.

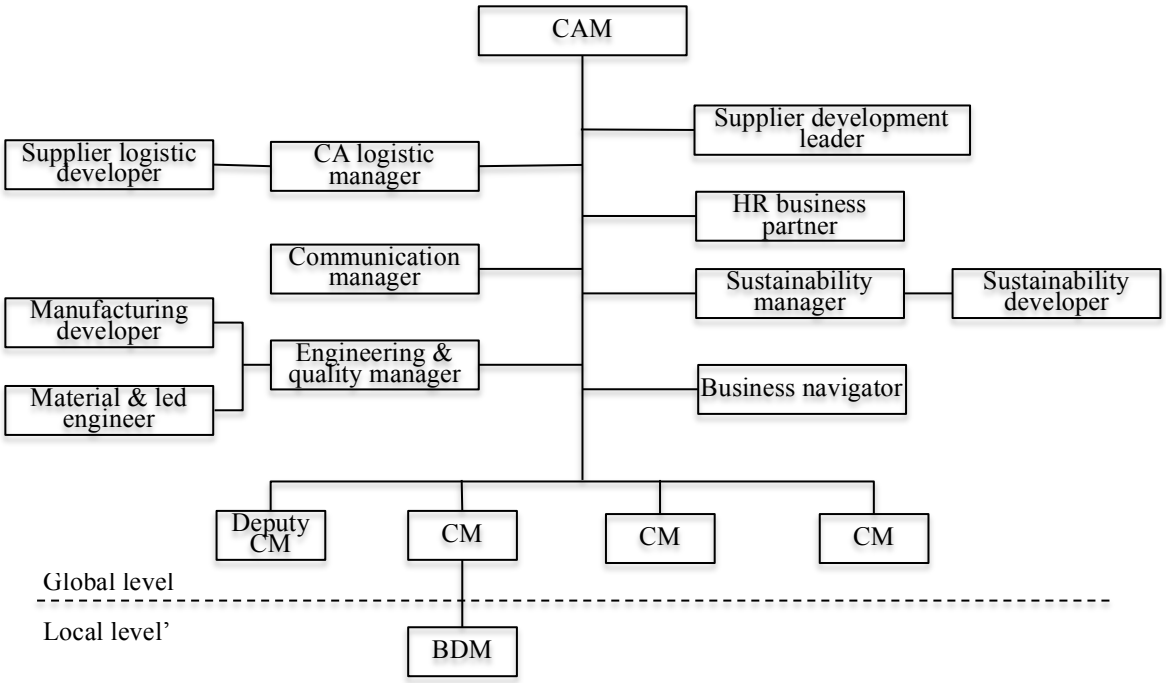
IKEA Purchasing development is divided into seven category areas (CAs): 1) Flatline, 2) Wood & Fibres, 3) Comfort, 4) Textiles, 5) Electronics, 6) Metal, Plastic and Float Glass, and 7) Specific Home Furnishing Business (stearin, tableware, green plants, etc.). Logistics in the Inter IKEA Group includes Global Distribution Network Design, Global Goods Flow and Capacity Planning, Global and Regional Transport Purchasing and Operations, Regional Supply Teams (Europe, Asia Pacific, and North America), Regional Quality Support Centres, and Customs Service Centres.

IKEA purchasing development and logistics works are organized geographically as Purchasing and Logistics Areas (PLAs), of which the predecessor was trading areas. PLAs are internal trading companies but are centrally funded. There are 9 PLAs with 24 offices in IKEA, i.e., South Europe, South East Europe, North Europe, North East Europe, Central Europe, Americas, South Asia, South East Asia and East Asia. China belongs to the East Asian PLA and has 4 offices i.e. Qingdao, Shanghai, Shenzhen and Taipei. Suppliers are selected based on their competitiveness, including price, capacity, innovation capabilities and sustainable performance.

Centralized GS planning

IKEA GS work is centrally planned and organized by category area. There are four GS levels with each level contributing in different ways. According to Echo Ye, the Deputy Category Manager at the Shenzhen IKEA trading office,

> *"When planning GS, the first level is 7 category area managers (CAMs) in global, who are responsible for the 7 CAs respectively and directly lead the work of category managers (CMs); the second level consists of CMs also located in global, who are in charge of drawing up the 5 years GS strategic plan; the third level is made up of CMs and business developing managers (BDMs), who are working together to make the 2-3 years tactical plan according to the 5 years GS strategy; the fourth level is BDMs in local, who take charge of working out the 1-2 years operational plan according to the 2-3 years GS tactics, and directly lead the business team (BT) which is organized for interface with suppliers in local."* Shown in Figure 1.



(Source: summaries from interviews by authors)

CAM: category area manager
CA: category area
CM: category manager
BDM: business developing manager

Fig. 1 IKEA GS structure

From global to local level, GS activity is structured as a BT. Daniel Xu, the Business Developer at the Qingdao IKEA trading office claims that one BT usually consists of three staff: business developer, supplier planner and production engineer. Sometimes there is also a product engineer, who supports more than one BT at a time. Usually a BT is established according to the GS products.

Matrix management and support functions

IKEA GS is centrally planned with matrix management. IKEA Range & Supply also consists of several matrices and a number of support units. One example is the IKEA Sustainability Management Group. The Chief Sustainability Officer (CSO), Steve Howard, is a member of Group Management and reports directly to Peter Agnefjäll. The CSO chairs the Sustainability Management Group, which brings together sustainability managers from the main business areas. Together they review performance against the targets and make strategic decisions on sustainability in the IKEA Group. Progress towards the goal is reported to Group Management and the Supervisory Board every three months. In FY16 the Sustainability Management Group comprised the Heads of Sustainability Policy & Compliance, Sustainability Innovation, Sustainability Communication, and sustainability managers from Range & Supply, IKEA Industry and Retail & Expansion. From September 2016, the Sustainability Management Group comprises the IKEA Group Chief Sustainability Officer, the Heads of Sustainability Integration & Development, Sustainability Policy & Compliance, Sustainability Innovation and Sustainability Communication, and sustainability managers from IKEA Centres, IKEA IMS, Customer Fulfilment and IKEA Property.

In addition, there are several other functions/units and legal companies operating in IKEA Range & Supply, such as IKEA Components, Regional Supply teams, Logistics Development, Sales & Supply planning, Transport, Purchasing operations, Quality Support Centres, IKEA communications AB, and Product Development Centre (China).

IKEA sustainable global sourcing

IKEA responsible sourcing

IKEA's sustainability agenda is integrated into its GS strategy across both governance and business aspects. The People & Planet Positive strategy makes the company groups work closely together to ensure the sustainability efforts across the whole value chain. IKEA's goal is for SGS to have a positive impact on people and the planet. Stefan Karlsson, the Sustainability Compliance Manager at IKEA Purchasing Service (China) Co., Ltd., said:

> *"The long-term is being close to the market where we are to source more environmentally friendly products. We consider five dimensions of our democratic design, form, functionality, quality, sustainability and low price. Of course, the price is very important. The sustainability aspect is regarding what kind of materials do we use, what kind of processes do we have in our production, to become more sustainable. We identify critical materials, because they can be recycled in the supply chain, cotton is one of them, leather is another one. It's not only about the sustainability in terms of environment, but also about people in our supply chain, like the working conditions."*

IKEA implements responsible sourcing by going beyond the supply chain to ensure sustainable resource management across the industry. Sustainable resource management is protecting the raw materials that go into IKEA products and ensuring a sustainable supply chain (SSC), which is vital for the long-term viability of the business. The raw materials include wood, cotton, palm oil and leather By June 2015, the IKEA Foundation has implemented programmes to promote children's rights, fight child labour and create opportunities for families living in the cotton supply chain communities in India and Pakistan, and leather supply chain communities in Brazil.

By August 2015, 100% cotton used in IKEA products is sourced from sustainable sources, and IKEA continuously investigates complementary fibres with improved sustainability performance compared to cotton. By December 2015, 96% palm oil (Candles 100%, food approximately 50%) currently used in home furnishing products comes from certified segregated sustainable sources or is substituted with more sustainable alternatives. By August 2016, 61% of wood comes from sustainable sources. By August 2020, IKEA aims to source 100% of its wood, paper and cardboard from more sustainable sources.

By August 2015, 100% of the leather IKEA sourced is chromium-free, and from September 2015 onwards all IKEA's leather is produced using 'wet-white' tanning or other alternatives to chromium, which is highly polluting. By August 2016, IKEA has achieved traceability of cattle leather and hides back to slaughterhouses. By August 2017, IKEA has secured traceability of all leather back to slaughterhouse level and has developed and started to implement requirements to secure social and animal welfare issues. Next, the sustainable leather initiative is used to illustrate the SGS practice influenced by IKEA's GS strategy and GS structure.

Motives for IKEA responsible sourcing

IKEA has been committed to sustainability for many years. According to Peter Agnefjäll,

> *"Urgent action is needed to tackle climate change – communities across the world and the success of business depend on it. That's why IKEA Group is going all-in to be part of the solution. We see action on climate change as a driver of innovation, investment and renewal."*

IKEA Group welcomes Sustainable Development Goals (SDGs) as a catalyst towards achieving a more sustainable and equal world. It will use the goals to guide and inspire itself in developing a sustainability agenda. IKEA has mapped its People & Planet Positive strategy against the goals, and identified seven in particular, where it can make the greatest contribution. The seven goals for excellent achievements are: *gender quality*, *affordable and clean energy*, *decent work and economic growth*, *reduced inequalities*, *responsible*

consumption and production, *climate action*, and *life and land*. Responsible sourcing is the main strategy regarding the *life and land* goal. Following this strategy, IKEA sources its key raw materials, such as cotton, wood and leather, from more sustainable sources.
Meanwhile, to find the most competitive supply market and suppliers, IKEA also considers a list of factors including total cost, quality, availability, sustainability and preferred partner. According to Stefan Karlsson,

> *"IKEA is a big global company and we have stores almost around the world. Global sourcing is of course important and I think the sustainability agenda actually emphasises that, knowing where we need to have suppliers because some products are very bulky, being too far away, not only for the cost perspective or killing the products' speed, it's not going to be competitive to deliver to stores all over the world. So one direction is of course from the costs perspective. The second that we are also very much looking into is sources from the environmental perspective, for example, if you deliver or transport products over long distances, it will cause additional CO_2 emissions, so it's also in our way of thinking when setting up new suppliers."*

In particular, as China is the largest single supply market with a 26% share of the supply (IKEA Group Sustainability Report FY16), the motive to open the Greater China trading area includes not only the reasons stated above but also to collect supply market intelligence.

IKEA sustainable leather initiatives

IKEA leather profile

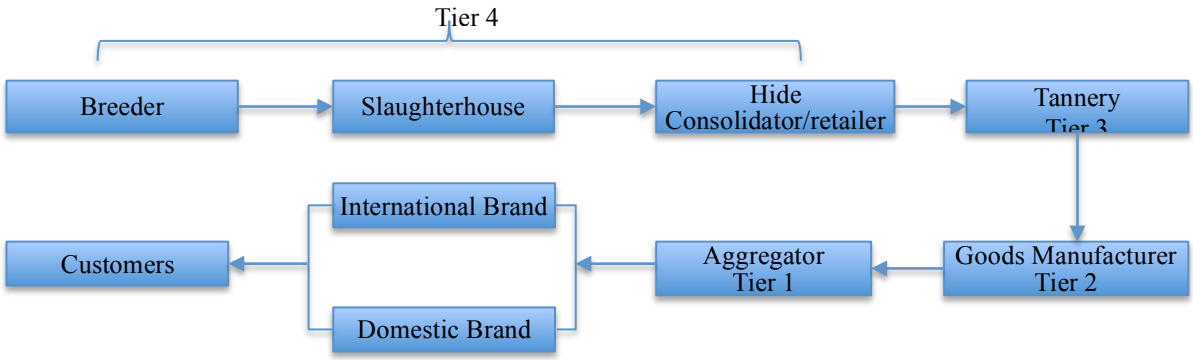
Every year IKEA uses about 3 million m^2 of leather in its home furnishing products, including sofas and rugs. This comes from eight leather suppliers and three hair-on-leather suppliers. Brazil supplies around half of the leather and sheepskin IKEA uses annually. However, at present, the retailers from major business districts and international brands are facing the requirements of knowing the product sources and production conditions requested by consumers and NGOs, so retailers and brands need to ensure that the sources of leather are legal and in line with the Convention on International Trade in Endangered Species of Wild Flora and Fauna. In recent years, the leather industry has been questioned by human rights organizations, environmental organizations and animal protection organizations, as they believe that the leather industry is in violation of the relevant laws in aspects of work conditions, environmental controls and animal welfare. In response to these statements and to prove that the leather supply chain is open and transparent, more and more brands and retailers are trying to introduce a traceability system for the leather supply chain. In the era of globalization, traceability of the leather supply chain industry has become increasingly complicated. Throughout the whole process from the transaction of raw hides to leather production and sales, mixed participants from different parties around the world are involved. The leather making process also uses many physical-chemical processes, which makes monitoring each hide or skin a challenge (ITM, 2017).
In respect to this, IKEA works closely with its partners to address the environmental and social issues that are common in leather supply chains, such as forced labour, chemical pollution and cruelty to animals. For example, IKEA has been working with suppliers and a number of chemical companies to find ways to reduce chemical use, and the carbon and water impacts of the tanning process. IKEA has met the chromium-free leather target, now the company is focusing on continuing to improve leather traceability. IKEA sets minimum social, environmental and animal welfare standards for its direct suppliers, including a requirement that leather does not come from suppliers linked with deforestation in the Amazon. IKEA's goal is to ensure animal welfare in its supply chain – whether animals are treated humanely, and with the opportunity to express natural behaviours. Over the past year IKEA has developed the IKEA Farm Animal Welfare position to drive progress on animal welfare for

all animals in its supply chains. IKEA commits to protecting animals' health, physiological and behavioural needs. This is important for animal-derived raw materials used as food ingredients, or in its home furnishing range, such as leather. It applies at all stages of an animal's life, and within all tiers of its supply chain.

IKEA leather supply chains

Generic leather supply chains

The key supply chain entities in the leather sector can be divided into four tiers or levels: tier 1 consists of exporters or retailers; tier 2 is the finished product manufacturers; tier 3 is tanneries and tier 4 is raw hide suppliers including breeders, slaughterhouses and hide consolidators/retailers. The leather industry value chain is shown in Figure 2.



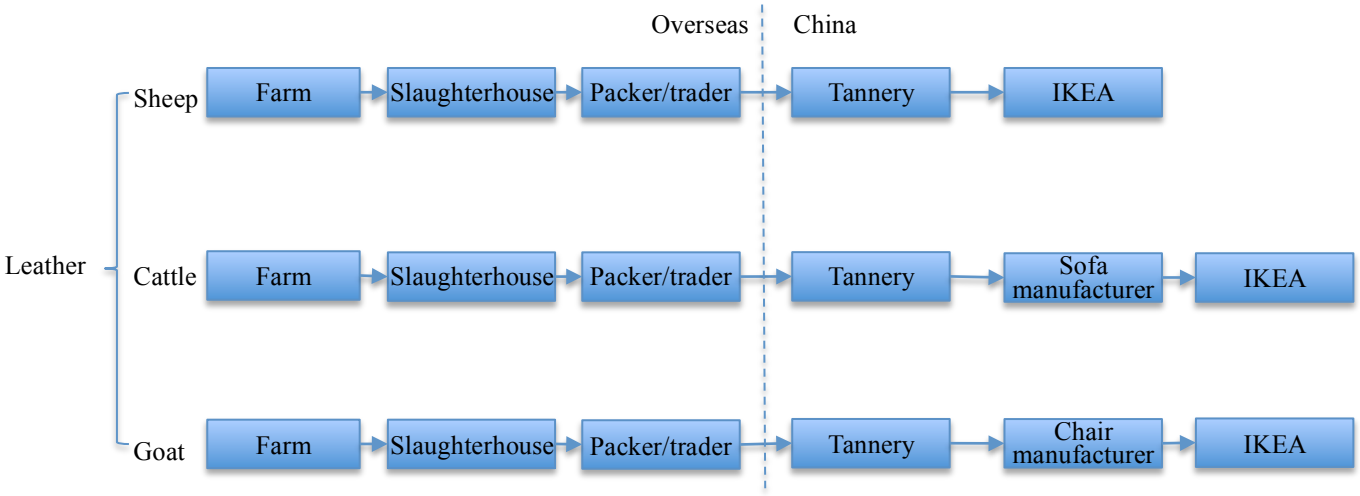
(Source: KPMG, 2013)

Fig. 2 The leather industry value chain

The leather supply chain entities listed above are summarized from the general situation of the leather industry. Thus, there may also be various combinations in which product flow happens between the different tiers and all steps may not necessarily be followed. In some cases, tiers 1 and 2 operations may be conducted by a single organization (KPMG, 2013).

IKEA's leather supply chains

IKEA's leather supply chain includes cattle farms, slaughterhouses, tanneries and finishers. According to Frank Ouyang, the Leather Competence Center Manager (LCCM) from IKEA China, the IKEA Leather Competence Center (LCC) in China is responsible for sourcing three kinds of leather globally, i.e. cattle, sheep and goat. The reason for GS is the lack of resources in the China market. Due to the Chinese meat consumption habits, there are many pig breeders in China, so the large volume of raw hides are pigskins and the volume of cattle skins and sheepskins are very small. Thus, for the tanneries located in China even in Asia, cattle skins and sheepskins are almost all imported. IKEA has three leather supply chains corresponding to the three kinds of leather, as shown in Figure 3. Leather from cattle is purchased mainly from South America, North America, Europe and a little from Africa, the major GS countries include America, Brazil, Germany, the United Kingdom, Australia and France; leather from sheep is sourced from Australia and New Zealand, a little from Britain and Argentina; and leather from goat is procured mainly from Australia.



(Source: summaries by author)

Fig. 3 IKEA's three leather supply chains

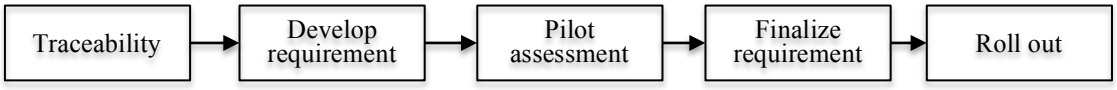
According to Frank Ouyang, IKEA's three types of leather supply chain begin at farms, which may include several different kinds of farms. For example, a beef cattle farm keeps the cattle newborns with their mothers until weaning; then a cow-calf farm buys the calf from the beef cattle farm and continues to raise the calves until they are young beef cattle; after that, the young beef cattle are usually sold to a feedlot to be raised for meat. All these kinds of farms are seen as one tier in the leather supply chain, and finally the cattle are sold from the feedlots to slaughterhouses. It is also possible that there is no feedlot, and the cattle are sold directly from a cow-calf farm to slaughterhouses. This depends on customer demands, such as cattle breeds, ages, grades, etc.

After the slaughterhouse, there are various packers and traders involved before the tanneries. The packers, who are mainly responsible for sorting and salting the leather, sort the leather first according to several criteria, such as size, quality, scar area, etc. Meanwhile, the leather also needs to be salted to avoid rotting. After sorting and salting, the leather is distributed by traders to tanneries, which are local suppliers in the example of China.

After the tanneries, there are three paths of supply: leather from sheep is sold direct to IKEA stores; leather from cattle is sold to sofa manufacturers and then to IKEA stores; and leather from goat is sold to chair manufacturers and then to IKEA stores. The reason for this is that there are two kinds of leather usage in IKEA. One is called Carpet leather (i.e. leather from sheep), which is sold direct to IKEA stores after being bought from the tannery. The other kind is Upholstery leather (i.e. leather from cattle and goat), which needs to be finished for sofas and chairs after being bought from the tannery. In this case, the tier 1 supplier for IKEA is sofa manufacturer and chair manufacturer.

Five steps of the sustainable leather initiative process

The leather supply chain is complex and IKEA conducts sustainable initiatives for each part throughout the whole chain. According to Frank Ouyang, IKEA has already traced down to the slaughterhouse level, and continues to work towards having traceability to the farm level. Furthermore, IKEA has also developed a requirement for leather traceability, and within 2017 – up to August 2017, IKEA aims to test this requirement in the leather supply chain. That means IKEA goes out to suppliers to check if the requirement works and whether IKEA has the right requirement set. By the end of 2017, all of the leather IKEA uses will be fully traceable and produced according to standards that help protect forests and respect animal welfare. For IKEA, good animal welfare means that all animals in its supply chain live a life worth living, which is achieved through the protection and promotion of good health, physiological and behavioural needs. IKEA endeavours to uphold the Five Freedoms, i.e. that all animals in its leather supply chain have freedom from thirst or hunger, freedom from discomfort, freedom from pain or injury and disease, freedom to express natural behaviours, and freedom from distress. There are five steps in the IKEA sustainable initiative for its leather supply chain, as shown in Figure 4.



(Source: summaries of interviews by author)

Fig. 4 Five steps of IKEA sustainable initiative for leather supply chain

Supply chain mapping

The first step is traceability, which refers to supply chain mapping. To have a clear picture on the existing leather supply chain, IKEA first conducted a supply chain mapping exercise. The leather supply chain is notoriously complex as the production involves many steps. Because of this complexity, IKEA had to revise its traceability target. Instead of securing a chain of

custody back to the farm by August 2017, it aimed to trace leather back to the slaughterhouse by the same date, while keeping the long-term ambition for a full chain of custody. In FY16, IKEA had already collected information on almost all of the slaughterhouses in its leather supply chain – one year before the target. That means it is very possible for IKEA to meet the goal by the middle of FY17. Frank Ouyang claimed that,

> *"To date, IKEA has the traceability in place - down to the slaughterhouse level, and what is ongoing is to have traceability to the farm level, which is more difficult but it is something being worked on during this year."*

IKEA mainly traces to the direct farm at the farm level, which is the first farm after the slaughterhouse level. During the rest of FY17 IKEA will continue to focus on securing a chain of custody verification routines and setting clear social, environmental and animal welfare standards.

Requirements development

The second step is developing IKEA Slaughterhouse & Transport Requirements. According to Frank Ouyang, IKEA has produced a traceability specification for the leather supply chain, which is IOS-MAT-0093, IOS is short for IKEA of Sweden, and MAT is short for material. This specification has been issued by Leo Chen, who is the Global Leather Engineer at the Leather Competence Center of IKEA. According to Leo Chen, this specification describes the traceability requirements for leathers used in IKEA articles, and the requirements are based on IKEA's commitment to social and environmental responsibility around the world. This specification addresses the manufacturers of domestic cattle leather and cattle hair-on-leather. The requirements for leather/hides originating areas are broken down into Brazil and the rest of the world. This is because Brazil is located in the Amazon region, which involves the forest conservation and biodiversity problems. With regard to Brazil, this specification particularly describes the requirements for protecting the Amazon Biome, which is mainly related to the issues of farms and slaughterhouses in this region. For both Brazil and the rest of the world, this specification describes the requirements for farms, slaughterhouses and manufacturers as well.

Pilot assessment

The third step is pilot assessments at selected slaughterhouses. Frank Ouyang said that,

> *"As now we have already traced back to the slaughterhouses of cattle, sheep and goat, the next step is that we are going to do the assessment of slaughterhouses. For example, in early August this year, we select 4 to 5 slaughterhouses in Australia to assess our requirements, including standards for animal welfare and transport, how to deal with the welfare of animals and how to solve the transport issues. In this assessment, we believe we will have lots of findings and learnings, which will help us to finalize the specification with a good improvement."*

There are three parties who will attend the pilot assessment, i.e. IKEA IWAY auditors plus one representative from the business team, representatives from tanneries, and animal welfare experts from the Food Animal Initiative (FAI). This step is the assessment of the developed requirements instead of a pass/fail audit for suppliers.

Finalize requirements and roll out

By the middle of 2017, the first and second steps have been achieved; the third step is what is ongoing now; the fourth step – finalizing requirements and an implementation plan and the fifth step – roll out, will be carried out later on. Based on the lessons learnt in the pilot projects, IKEA will finalize the requirement and roll out the programme to cover all supply chain partners.

Sustainability driven GS strategy and structure for leather

Peter Möller, the Category Area Comfort Sustainability Manager of IKEA of Sweden AB – Inter IKEA Group, stated that the goals for sustainable leather initiatives are 1) to have a traceability supply chain; 2) to set the requirements in the supply chain; and 3) to secure IKEA's requirement in this transparent supply chain. Peter further commented,

> *"When it comes to the requirements, it is of course about the animal welfare in the supply chain, but also about the workers welfare as well in the supply chain. Securing the animal and workers welfare in the supply chain is not so much to do with what kind of process that is used in the supply chain, it is more about the animal welfare in the supply chain. And regarding the workers welfare, it is mainly about ensuring the compliance of environmental section in IWAY within upstream supply chain. …"*

GS strategy for leather

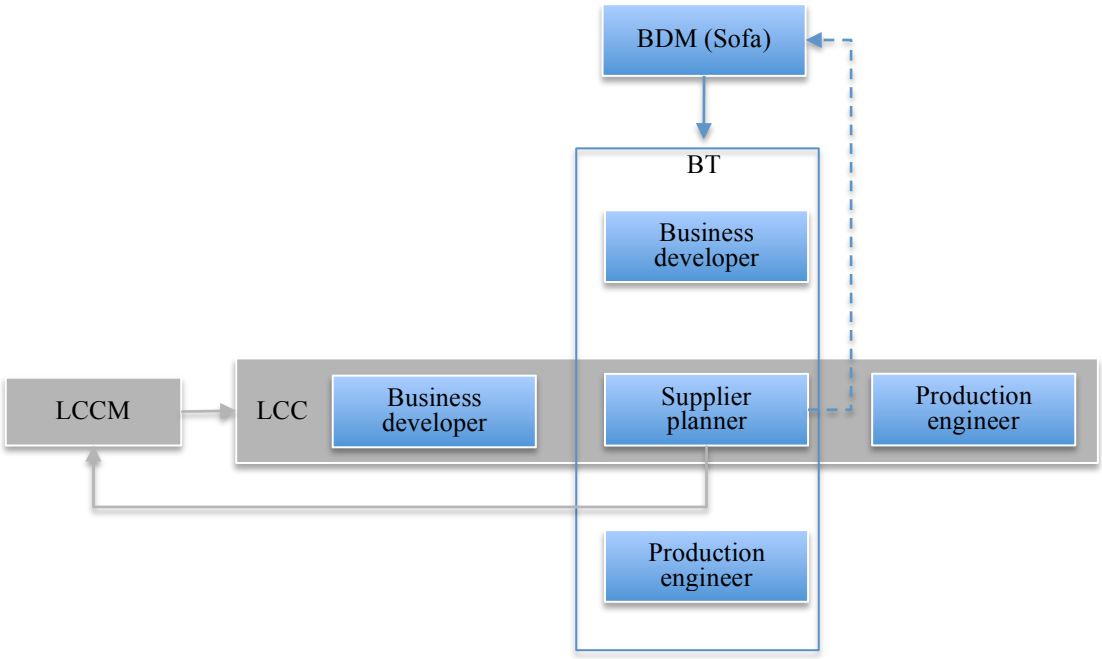
All the leather in IKEA is sourced globally by following the overall sourcing strategy. To enable a simple but professional leather SGS process, IKEA has a Leather Competence Center (LCC) that actually purchases all animal leathers. The home for leather GS in China is Shanghai LCC and the lead for the leather project is Frank Ouyang. The goals for the leather GS strategy include not only resource seeking and cost reduction, but also sustainability. According to Frank Ouyang,

> *"We purchase leather in the global scope, we have a lot of pre-conditions for leather global sourcing, for example, our raw hides of leather cannot come from the Amazon, because in some of its region, herdsmen deforest the forest for grazing, which will have a negative impact on not only the local indigenous peoples, but also the entire ecological chain; meanwhile, our raw hides also cannot come from the primeval forest area, even if it is not the Amazon region, because cutting down the forest in this area will also cause the destruction of the entire environment. Thus, we don't use the raw hides coming from these regions. Another point is that our raw materials are by-products, this is to say, animals are fed for meat instead of raw hides, after animals are slaughtered and meat is taken, the rest, i.e. raw hides is what we use. Furthermore, we don't use the raw hides coming from rare animals, this is a clear point in our pre-conditions. IKEA has three kinds of leather, cattle, sheep and goat, all of them are by-products."*

The main product in slaughterhouses is meat sold to meat-processing companies, e.g. McDonald's, which have high bargaining powers. IKEA has low bargaining power in their relationship with slaughterhouses as animal skins are a by-product and are sold with low value. In this case, it is not easy for IKEA to persuade the slaughterhouses to collaborate in the implementation of sustainable leather initiatives.

GS structure for leather

IKEA's leather GS work is highly internally integrated and is led by the LCCM with centralized planning and following a matrix management structure, as shown in Figure 5.



(Source: summaries of interviews by author)

LCC: leather competence center
LCCM: leather competence center manager
BDM: business developing manager
BT: business team

Fig. 5 Leather GS structure (matrix)

The Shanghai LCC is led by the LCCM – Frank Ouyang, and consists of a business developer, a production engineer and a supplier planner. The supplier planner also belongs to the sofa business team, which is led by the BDM of the sofa category. Differently from the typical matrix structure, which consists of *an operational* and *a functional line of reporting*, the GS of IKEA's leather follows a matrix structure composed of two reporting lines, both of which are based on products. For leather products, the supplier planner *line reports* to the LCCM; for sofa products, the same supplier planner *dotted line reports* to the BDM of the sofa category. In this approach, decisions can be made based on themes that are common to each product and costs can be cut as the supplier planner is able to perform cross-leather or cross-sofa activities. Moreover, besides the cross-product working groups, there are also other cross-organizational working groups covering topics such as energy, waste, circularity, community involvement and sustainability reporting. The cross-organizational working groups provide leadership, best practices, research and support on sustainable leather initiatives. With these two kinds of internal working groups' integration, IKEA's leather GS work is organized efficiently and economically.

Meanwhile, the GS of IKEA's leather also includes external integration with NGOs and suppliers. As IKEA sustainable leather initiatives are mainly focused on animal welfare and workers' welfare, when interfacing with suppliers, the LCC works together with the Food Animal Initiative (FAI) – a British NGO committed to better farming practices – and aims to provide knowledge about animal welfare to slaughterhouses and further to ask slaughterhouses to ensure animal welfare of their own suppliers – farms; while workers' welfare is the responsibility of the IWAY group, who check the IWAY of tier 1 suppliers and ask them to communicate and audit IMust requirements with nominated sub-suppliers, by using this approach until the end of the leather supply chain.

Conclusion

The implementation of SGS has led to several improvements for IKEA sustainability performance, including not only economic performance but also social and environmental performance. IKEA has achieved successful expansion in the global market and established close and long-term relationships with suppliers, performing global leadership through its sustainability agenda. The matrix structure has successfully followed the SGS strategy and allows a fast responsiveness and knowledge sharing within IKEA. The sustainable initiative for the leather supply chain illustrates that IKEA's strategy and the structure of SGS performs well in a complex global supply chain and represents a key lever that is useful to improve the general impact on sustainability in all Groups' compartments. Although until now the leather project is still on track, it is anticipated that IKEA will implement more sustainable initiatives and achieve a fully sustainable leather supply chain in the end.

For the future, what IKEA worries about are the limitations of the matrix management. There may be a conflict of loyalty between line managers and dotted line managers over the allocation of resources; projects may be difficult to monitor if teams have more independence; and employees may be confused by the roles that are played in different teams. Meanwhile, due to the low bargaining power IKEA has in leather GS, implementing sustainable leather initiatives still faces some challenges, such as how to persuade slaughterhouses to comply with the IWAY standards and with animal welfare, what the role of multi-tier suppliers is in auditing the IWAY standards across the leather supply chain, and how FAI transfers the knowledge of animal welfare to slaughterhouses and farms; these could be the directions for future studies.

Analysis of operational efficiency of a halal meat processing supply chain

Jerin Varghese John, Balan Sundarakani, and Ioannis Manikas

Purpose:
The purpose of this paper is to analyse the factors affecting operational efficiency for a meat processing supply chain. The paper focuses on the operations take place in a slaughterhouse. The results obtained by testing a simulation model and the related factors mentioned are used to analyse the operative effectiveness..

Design / Methodology / Approach
The study takes place in the MENA region and in particular the UAE thus takes into account the Halal approach for meat processing. The ARENA software has been used to develop a process simulation model of a real time slaughterhouse processes scenario along with factors such as waste disposal, government regulation and Islamic Halal procedures that are also taken into account.

Findings:
The simulation model analysis shows that the current operational efficiency of the slaughterhouse processes is too low, as compared to the standard industrial operative efficiency. In the ARENA based process simulation, the parameters were varied and new resource utilization was obtained. By testing the new values into the relationship it was found that the operative effectiveness has improved to the initial results from 0.2193 to 0.2612. This study implies that there is room for improvement in the slaughterhouse facilities to achieve sustainability, and eco-friendliness by increasing the operative effectiveness.

Research limitation and implications:
Even though there is enough literature on operational efficiency of meat supply chain (Fattahi et al., 2013), very few researchers have focused on the slaughterhouse operations and the relevant supporting processes. Further refinement based on the factors that can affect the slaughterhouse operations needs to be studied. The data collected reflect the general aspects of the operations that are easily accessible; a study on the complete process carried out in the slaughterhouse supply chain would possibly support a better understanding of the factors and thus develop a better view of the operational efficiency of the slaughterhouse.

Practical Implications:
The analysis of the operational efficiency of the slaughterhouse may improve the slaughterhouse management practices to increase the performance. The managers and strategic decision makers need to decide on the appropriate mix of factors that would contribute to the improvement of slaughterhouse's operational performance. This study brings to light the improvement needs of the slaughterhouse facilities operate in this region in order to meet the food requirements of the consumers with utmost quality and by reducing the impact on environment which is a growing concern at present.

Originality / Value:
Although few researches have studied the aspects of waste disposal, government regulation, and resource utilization of a slaughterhouse facility, this paper investigates the operational efficiency of a slaughterhouse by considering all the aforementioned aspects by creating a

relationship among them which makes it a unique contribution to the meat industry. This study provides an insight on the operation aspects of the slaughterhouse and the common practices carried out in this industry thereby considering the dimensions and factors that can improve the targeted operational efficiency.

Keywords: slaughterhouse, halal meat supply chain, operational efficiency, ARENA simulation.

Introduction

Supply chain is a very broad term in the business world. It is generally defined as a network of facilities that deal with the supply and demand of the product and services. The network consists of people, activities, goods or services from one end to the other to meet the demand of the customer. The food industry over the past few years has been struggling to meet the expectancy in quality due to various reasons. With the increase in population, the need to meet the requirement for the large mass increased. This has had a very bad impact to keep the market responsive to the demands. There are various inhibitors that contribute to this decline in the food industry, such as government regulation on quality, processing ineffectiveness, infrastructures, distribution channels, poor handling, and customer practices. In such crucial time where the industry finds difficulties to meet the demand, cope up losses and reduction in wastages are affecting the world economy, overall environment and hunger levels. Thus attention to the shelf life of these perishable units play a very important role in the meeting the industry requirement. Food loss and wastage occurs at the pre-consumption and consumption stages. Hence, the need to improve to operating model is essential to have a good business model that can help to survive the current drop in the industry. Figure 1 illustrated a three stage comprehensive meat supply chain, which starts from farming and ends at the consumption.

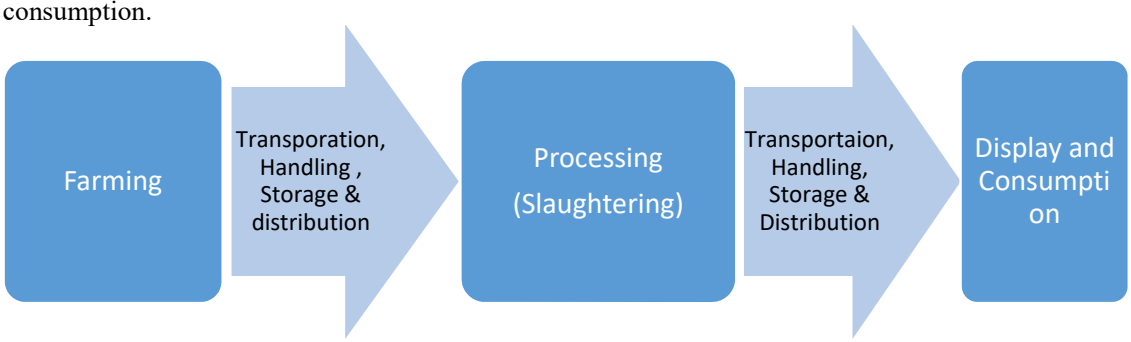

Figure 1: Three Tier meat Supply Chain

In the case of meat supply chain, livestock production and processing is the least efficient process with losses of more than 40% of food loses in the post-harvest and processing phase while in industrialized countries more than 40% of the loses and wastage are seen at the retail and consumer level, according to Gustavsson et al. (2011). With the increase in population, meeting demands could affect the environment by causing loss of diversity. To achieve effectiveness, the need for control system is required in the food industry. To gain maximum profitability, technology needs to be utilized efficiently in the food supply chain to stay aligned with the business expectation. Concentrating into the production section, which has the most implications in the supply chain, De Burgos et al. (2001) discussed the effect of operation objectives linking with environmental performance and supply chain issues. For example, in the food industry, customers are very keen on purchasing high quality products due to the potential health implications, apart from the government regulations, quality can

also be taken into consideration during the production time as this is the key area where the chances of quality degradation are found to be high. As estimated, in an average wastage of food accounts to 35% of the total output (Prafitt et al. 2010).

Literature Review

As per the international consumer research on meat-related requirements the quality related attributes be categorized into three areas; a) the meat quality as perceived by consumers b) meat safety as per the consumer attitude and c) mandatory quality and safety certification schemes of the meat supply chain (Krystallis et al. 2006).

Other important crucial factors to be considered in addition to the above mentioned three factors in food consumption are the religion and culture. Research has shown clear evidence in the past that religion as well affects the consumers' choices and eating habits (Delener, 1994). Some religions have direct clear instructions on how and what food can be consumed for example some pork meat is forbidden in Islam and Judaism or pork and beef in Hinduism and Buddhism except for Christianity that has no restriction on food (Sack, 2001).

This study takes place in the MENA region and in particular the UAE thus takes into account the Halal approach for meat processing. Halal is a credence quality attribute, an intangible feature of the food product that cannot be assessed by the consumer, even at a pre or post consumption phase (Grunert, 2005). Halal certification addresses the nature, origin, and processing methods of meat, applying similar approaches for sustainability and animal welfare as organic food production methods (Bonne et al., 2008).

The number of people requiring such credence quality attributes to be followed in food processing affects the consumption and requirements that shall be adhered to in the globalization arena which puts no limits or borders on the movements of food, goods, services labour or capital. All these complexity and inadequacy has dramatically increased the price for quality meat around the world and has attracted worldwide attention. (Sahin.et al, 2014) Presently the trends in meat consumption is changing at a rapid pace, this has resulted in the increased provision of meat products. The history of meat consumption is dated to prehistoric times; despite the meat industry is one of the most complex and problematic area concerning human diet. Over the past century, meat was considered as a luxury food product accessible to the elite class. The impact of Second World War and the overall increase in the global economy has led to the increase trend of meat consumption from early 1970s (Charlebois et al, 2010). This trend has led to increased demand and the global pressure for meat demand has propelled the price of meat products in various part of the globe.

Livestock products contribute to 33% of the protein consumption worldwide, globally it has been forecasted that by 2025 demand for meat products likely to increase rapidly (Rosegrant et al 2009). With the aspects of hygiene taken into consideration, the functioning of slaughterhouse s became vivid. Slaughterhouse function is meant for the production of edible portion of slaughtered animals to meet the meat protein demand for human consumption. Despite form other production unit, the level of hygiene is of prior importance. Such complexity would always lead to production inefficiencies. Therefore, understanding the process model and thereby measuring the efficiency of the processing unit of various operational processes seems to be imperative in the modern meat supply chain, especially places like the UAE where extreme temperature prevails during summer.

Research methodology

Phase 1:

Data collection from slaughterhouse operations:
In this step the slaughterhouse is visited and the procedures and process carried out and the data's regarding the time taken for the entity to pass from one process to another, the tine taken for an entity in a single process and human resource allocation for each process and the time over all time taken were observed in Figure 2.
Modelling and detailing of the process in simulation arena software.
The data's collected and the framework of the process carried out in the slaughterhouse facility are used as the input to the model created in the Arena simulation software. The analysis of the operations and the flow of products are modelled and then the data fed into the model and run over the replication of 10 times from a span of 12 hours a day.
Obtaining the report from the model and analysing the result.
The model is then tested and the output is obtained from the report generated by the software. The report would assist in assessing the factors that hinders the best performance of the overall process mentioned in the model. Also the alternatives that are required to make improvements in the operation cycle are analysed.

Phase 2:

Searching the literatures for factors affecting operative effectiveness
An extensive search through the literature review is carried out see the other core factors that impact the operations of the slaughter house are listed for further analysis.
Selection of key factors affecting slaughterhouse process
For a system, there are macro and micro environment factors that affect its operations, from the literatures the most critical and important factors are selected.
Calculation of contribution based on the secondary data
From the secondary data available from the literatures and online-published sources, the proportion of selected factors affecting the operations are calculated. Further, by the impact of the selected factors and their interdependencies the effectiveness is found which the sole purpose of this study is.
Simulation methods have always been used by manger as a management tool for production and processing environments to implement changes at strategic and operational levels. In this study, the simulation of the model represented in the below section is based on Arena simulation software prepared by Rockwell Inc. Discreet event simulation helps to understand the process with unique, specific events in time. These are mostly activity based modelling methods that are capable to accommodate flexibility in processes and simulate almost any processes in the industry. It provides a range of implications of the decisional changes before its practical application in the unit, thus reducing the uncertainties that would impact as a consequence on the operation dues to new changes implemented.
This would also help mangers in the industry to combine the layout, utilization of resources and space orientation to facilities in the production floor. The software allows users to enter data and design the features of the process intuitively with the following:

1. Real time decision making.
2. Addressing bottlenecks.
3. Increased reliability.

Data collection

In this study, data were collected from field measurement and observation of activities during the animal slaughter operation at a slaughterhouse located in Al Qusais was considered for the analysis. The research takes into account the whole process and activities occurring in the slaughterhouse facility. For understanding the various processes in the slaughterhouse

operations, an exploratory visit to the slaughterhouse was made and the measurement of time and the number of employees required for the different process in the slaughterhouse was observed. The model was created based on the field operation in the simulation software with the parameters and input variables observed from the field. The parameters include the time taken by an entity *(cattle)* to be processed through the various processing units across the production centre, time taken by employees to perform their function, the number of employees at each work stations; the resources employed for the business operations were gathered.

The second part of the analysis calculates the effect of the parameters selected based on the secondary data available and correlating it to the relation and there by formulating a formula based on the relationship and calculating the effectiveness of the operations.

The literature review depicts the various factors that would determine the effectiveness of the operations in an slaughterhouse facility. Among the various factors this study looks into the key aspect that affects its operation especially for slaughterhouse s that follows Islamic regulation for slaughter of animals for human's consumption.

1. Government regulation and Islamic laws
2. Human resource utilization for efficient productivity
3. Waste disposal

In accordance to mentioned factors in the earlier sections of this paper a model has been designed and the diagrammatic representation is as mentioned in Fig 2, each of these nodes represent the factors that contribute to the effective operation of an slaughterhouse facility based on the knowledge acquired from the various literature review. The arrows in the network of model also depict the causal relationship among the variables. The values for the mentioned factors are calculated for the factors and are depicted in the below section.

Data analysis

(i) Waste disposal:

Even with the existence of the state of the art technologies, waste disposal is one of the key areas that need attention with the rise of pollutant from the Slaughterhouse s due to huge investment behind it. Apart from the waste generated from the carcass there are lot of air pollution due to the contribution of Ammonia, Sulphur compounds and other effluents from the rendering process. When considering the statistics of live meats parts only 35 -55% seems to be edible rest of the portion needs to discarded as waste (Petrovic, et al , 2015)**.** The details regarding the statistics of cattle by percentage of weight typically for slaughtering are depicted in Fig 3. Animals that are slaughtered in the slaughterhouse include cow's sheep's, goat's, camels and veal's.

As mentioned earlier in the literature review with environment impact is of the highest concern around the globe, eco efficiency is being introduced to various industries. In the meat industry the requirement of safe environment is of highest factors due to rising risk of environmental changes that are encountered in the recent year. According the existing statistic, only the dung or manure is used for treatment process in sewage plants that contributes to 10% of the total waste products from goat.

(ii) Government Regulations and Islamic law

From the various literature reviewed in this article a set of factors were listed (Cost of the product, operations management in the slaughterhouse, waste management, location, implementation of halal slaughtering) and their requirement for 100% compliance were analysed and tabulated in the *table 1*. Further the percentage of contribution of government regulation on the slaughterhouse s operating effectiveness was calculated based on the number of factors that needs to undergo 100% compliance with the regulations. Also due to the lack secondary data's and journals regarding all the factors mentioned, a generic approach of analysis is selected for the analysis of the Government regulation factors. The analysis of this factor is based on the calculation of percentage of the effect of these represented sub factors by government regulation. The conclusion to these factors is based on review of government regulation on slaughterhouse management and halal food regulation.

Table 1 Contribution of factors

Factors requiring 100% compliance to Government regulation	**Yes or No**	**Percentage**
Costing of the product	NO	57.14%
Operations management in the slaughterhouse	NO	
Waste management	Yes	
Location	Yes	
Hygiene management system	Yes	
Design and Equipment	No	
Implementation of halal slaughtering process	Yes	

It is clear from the above table, based on the analysis it was found that 57.14% of the operation in the slaughterhouse are in accordance to the government regulation.

(iii) Human resource allocation and utilization

The model was created in Arena simulation software; the parameters are taken from the real life observation. The observation are based on time recorded by a sheep through the entire slaughterhouse process until the product, consumable meat is processed. For this observation, the slaughterhouse was visited and real time data's were collected. The parameters and their observations recorded were noted and were analysed to figure the inputs to the software. The following are the key fundamental blocks constituting the model of a functioning slaughterhouse:

Table 2 Process Involved

Sl No	**Process involved:**
1.	Sheep arrival dock

2.	Preparation for Halal slaughtering
3.	Slaughtering process
4.	Meat processing section
5.	Cleansing unit
6.	Slicing process
7.	Packaging process

Initial model

The mentioned process and the data's observed for the parameters are modelled using the software and the model as shown in Figure 2. The simulation model was tested and run for a period of 12 hours per day at a replication of 10 number. From the model, we can understand that many of the resources are utilized for system performance. For example in the cattle preparation area, a massive amount of water is used for the cattle preparation and cleansing of blood substrates from the meat to make the product hygienic and edible for human use. It is estimated that a sheep would require 100 -150L of water per animal from the simulation report. In this software the key main function used is process function with the triangular time function with minimum, most likely, and maximum. Since the arena software that is used is restricted to student version the use of advanced process and advanced transfer such as conveyors machines etc. could not be employed in this simulation model analysed for the study. For the conveyors in the original facility routes and station were used in the model as mentioned.

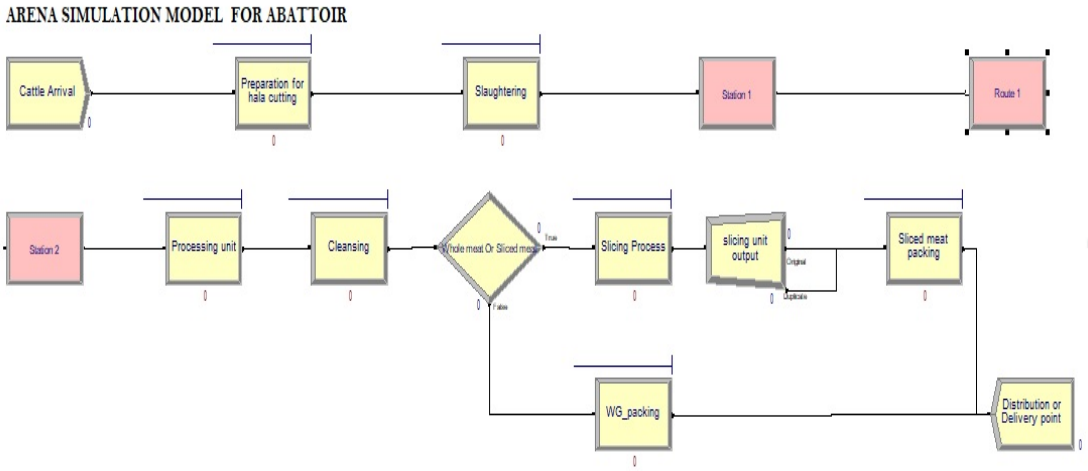

Figure 2: Arena Model for the slaughterhouse

Simulation and analysis of result

Based on the above assumption the model was created and the report was generated. The model was run for a replication of 10 with the working hours of 12 hour per day. From the result, it was found that in the system a lot of queue was observed at the following areas:

1. Preparation of halal cutting.
2. Processing unit
3. Sliced meat packing unit

The result was evaluated in minutes for the entire testing of the model. It helped to conclude that the average value time for a sheep was found to 10.5 minutes and the overall time a sheep would in waiting time to be 46.8 minutes, in depth analysis of the report has provided the time consumption of an average entity (sheep) in queue through the various processes in the system. In addition, the report showcases that at an average rate there are about 20 sheep's in the processing centre and 18 at the sliced meat packing section in queue from the testing carried out. The resource usage in this analysis has recorded highest utilization of resources at the processman_1 and SPacker_1 with 98.8% and 87.4% while the least utilization of resources' were cleaningStaff_1, resource manpower, and WGPAcker_1 with 10%, 16%, and 15%.This is being represented in the graph below. Since this study focuses on the operative effectiveness of the slaughterhouse functioning, many flaws can be identified in the process flow related to the functions. From the field observation, the area that was least focused on the simulation but plays an important role to elevate the effectiveness of the slaughterhouse .as mentioned in the earlier sections is the bio coding mechanism. It is a tracing techniques employed in many places but difficult to trace throughout the process due to the vast number of handling and process across the supply chain by the time the product reaches the slicing unit. Also the tracking and traceability is found to be poor after the slicing of the meat is carried also when the sliced product are packed the degree of traceability is very low. At this point, there seems to be no traceability as the number of sliced parts that are produced. Hence, apart from resource utilization there needs to an efficient tractability management and feedback system that can improve the quality of the quality of operation in the slaughterhouse.

While interviewing the workers in the line it was found that the processes in the meat processing unit have not changed from its beginning. The changes that they observe in the facility are the management's steps to maintain quality by repeated quality checks. The report from the arena simulation has provided the insight that resource utilization is partly been into effectiveness that is the processing unit and the cleansing unit. As the process involved in the process unit cannot be tailored due to the risks involved, the only way to increase the output is by structuring the process layout and optimizing the resource utilization.

When it comes to operation of any process related business model the needs for proper utilization is necessary. For this, the result from the arena modelling discussed above is analysed on the human resources utilization from the resource utilization. The result of the percentage of various resources employed in the operation line are as mentioned in the below table 6.

Further, based on an assumed scenario, the model was run to see the impact of human resource allocation and utilization in the arena software. With the variation based on the data received from the slaughterhouse the following changes mentioned in Table 3 were altered in term of the number of resources assigned were altered and tested to verify the usage of the human resources employed at each of the processes involved in the facility.

Resource name	Capacity
Slaughter_1	2
Process man_1	10
Cleaning staff_1	2
Butcher man _1	2
WGPacker_1	1
Spacker_1	5
Water	1
Resource manpower	2

Table 3 Tested values for resources

Testing the model with the above-mentioned resources for the same number of replication and length as of the original case test-run parameters were carried out and the result was obtained. By analysing the two reports the usage of with the changes have increased compared to the original case scenario and the outputs of the original case and the crested scenario from 38.39 to 45.72%. It is clear that the number of products produced remained the same for both the cases; this proves that there is scope for improvement in the resource utilization in the slaughterhouse facility as contrasted in the table 4.

Resource names	**Percentage of utilization**(Original condition)	**Percentage of utilization**(Scenario condition)
Butcher man	38.78	58.16
Cleaning staff	10.4	15.61
Process man	98.8	98.8
Resource manpower	16	39.91

Table 4: Comparison of results

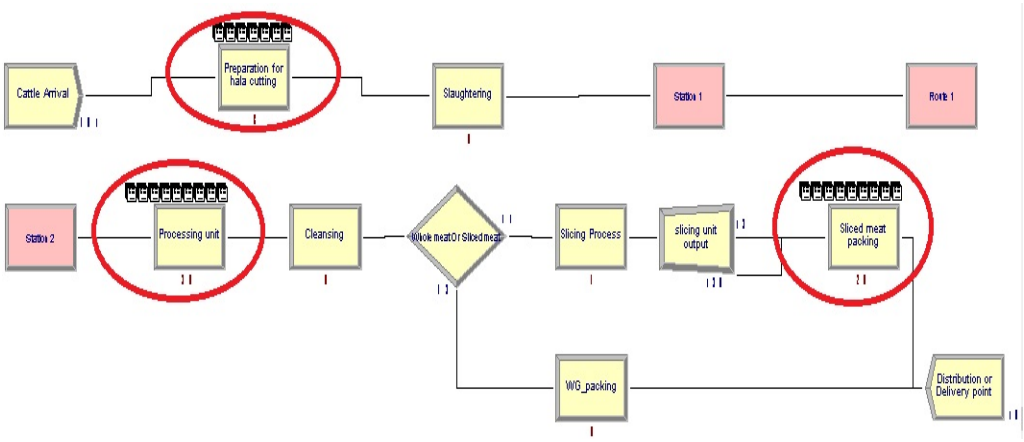

Figure 3 Revised model

From The revised model mentioned in Figure 4 above, the factors contributing to the effectiveness is measured based on the Overall Operational Effectiveness (OOE).

$$O.O.E = (Performance) * (Availability) * (Quality)$$ **.....(Eqn 1).**

The relation is formed from the basics that the overall effectiveness of system is the probability of success that the factor influence on the operations. In general, for a system the operations are influenced by these factors: Performance and Availability and Quality.

Conclusion

The proposed method of analysing the operational effectiveness using Arena simulation software, the parameters were varied and new resource utilization was obtained. By testing the new values into the relationship it was found that the operative effectiveness has improved to the initial results 0.2193 to 0.2612. This study thus implies that there is room for improvement in the slaughterhouse facilities to achieve sustainability, and eco-friendliness by increasing the operative effectiveness.

The managers and strategic decision makers are required to decide on the appropriate mix of factors that would contribute to the improvement of slaughterhouse operational performance. This study recommends improvisation of slaughterhouse facilities in this region thus able to meet the food (meat) requirements of the residence with utmost quality and by reducing the impact on environment from such facilities which is a growing concern at present.

Abstract
This study answers to the following questions: can the availability of social capital in the supplier-buyer relationship explain supplier's solution provision performance, what is the importance of different forms of social capital in supplier's solution provision performance? The empirical data of this study consists of 662 survey responses which are analyzed with partial least squares (PLS) structural equation modelling. The results demonstrate the importance of social capital in obtaining the optimal solution from suppliers and the role of different dimensions of social capital especially in diagnosing customer needs.

Keywords: social capital, solution offering, supplier capability

Introduction

Supplier capabilities are increasingly important for the competitive advantage of companies (Hunt and Davis, 2012). Buyers and customers are seeking for means to identify the most skillful suppliers with the willingness to provide the best possible offering. Increasingly the most skillful suppliers can select the customers to whom they invest their best resources and provide their best solutions. This is the case especially with complex solutions, such as problem-solving for the customer or tailored combinations of products and services. Customers need more understanding on the antecedents of effective provision of offerings by suppliers. This challenge has been discussed in the field of value creation research stating that the optimal solutions and value are created through interaction between supplier and customer (Aarikka-Stenroos & Jaakkola, 2012). Thus, in solution business, it is critical to identify what improves the supplier capabilities and suppliers' value creation potential.

Earlier research has emphasized measurable technical characteristics (Ho, et al., 2010) of suppliers, such as certificates and delivery performance, but is also known that the collaborative attitude of the suppliers is essential (Schiele, 2006). A more balanced approach to examining the capabilities of suppliers in their solution provision is needed. Earlier research has identified that interaction between the supplier and the customer will develop joint understanding on what kind of solution creates optimal value, but it has not paid sufficient attention to the practices of suppliers' solution provision (Aarikka-Stenroos and Jaakkola, 2012). Our study aims to contribute to the existing literature by emphasizing the processual nature of solution delivery, i.e. it comprises different phases such as designing and delivering the solution (see e.g. Tuli et al. 2007; Aarikka-Stenroos & Jaakkola, 2012) Literature on solution business (e.g. Hakanen and Jaakkola, 2013; Jaakkola and Hakanen, 2013) has analyzed how solution provision should

be managed or solution elements integrated or customized. By this far, the factors improving the supplier's solution provision (Tuli et al., 2007) and especially its processual practices have not yet been analyzed. Therefore this paper focuses on the antecedents of suppliers' solution provision, particularly from the perspective interaction in the buyer-supplier relationship.

This study approaches the issue by taking social capital approach in the investigation. Social capital is a promising theory for supply chain research (Krause et al. 2007) and it has gained increasing attention in the last decade in the literature of business relationships (Lawson et al., 2008; Tsai and Ghoshal, 1998). The basic assumption is that the positive requirements for resource exchange between companies depend on the development of social capital in business relationships (Hughes and Perrons, 2011). However, the complex value creation through social capital in buyer-supplier relationships is still a topic requiring more attention (Hughes and Perrons, 2011). Many of the existing studies demonstrating the benefits of social capital in supply relationships concentrate on company or relationship performance benefits (Krause et al., 2007; Lawson et al., 2008; Villena et al., 2011) leaving the benefits in the form of practices applied by the actors with less attention. More studies can be found regarding the enablers of supplier's solution provision, e.g. social capital can enable the collaborative environment between companies (Leana and Pil, 2006). Social capital has been investigated in customizing the offering for the customer (Madhavaram and Hunt, 2017) but with focus only on the use of social capital in the internal interaction within a company when developing a solution for a customer problem. We begin with an assumption that social capital facilitates interaction between the supplier and the customer in solution business and thus contributes also to value creation potential of the focal solution. We therefore examine particularly social capital with relation to the supplier's capability to design and provide optimal solutions.

This study aims to understand the relationship between different dimensions of social capital and the performance of a supplier in its solution provision that realizes via interaction between the supplier and the customer. It seeks answers to the following research questions:

RQ1. Can the availability of social capital in the supplier-buyer relationship explain supplier's solution provision performance?
RQ2. What is the importance of different forms of social capital in supplier's solution provision performance and the different phases of solution provision?

The empirical data of this study is collected with a survey addressed to the suppliers of four large customer companies. The survey was sent to 1630 supplier companies and 662 usable responses were received resulting in a response rate of 41 %. Partial least squares (PLS) structural equation modelling (SEM) is used to analyze the data.

The results demonstrate the importance of social capital prevalent in supplier-buyer relationship in solution provision by a supplier. They provide understanding on the role of different dimensions of social capital in the phases of supplier's solution provision. The study utilizes a detailed view on the content of solution provision by differentiating the diagnosis of customer needs, solution design and solution implementation. The results demonstrate that different types of social capital have different influence on the phases of solution provision.

Defining solution provision and social capital

A general conception is that a solution is customized and integrated combination of goods and services which meets the business needs of a customer (Davies et al., 2006). Different viewpoints to solutions may prevail between suppliers and buyers: suppliers easily see solutions as a sum of products and services while customers highlight the importance of relational processes in the offerings including activities of customer requirements definition, customization of goods and services; and their implementation (Tuli et al., 2007).

Aarikka-Stenroos and Jaakkola (2012) identify five value co-creation activities by a supplier. This study concentrates on the three main activities: diagnosis of customer needs, designing a solution and implementing a solution. Since customers often lack a proper understanding of their needs, well performing suppliers may support customer in identification of needs for products and services. This is the case especially with inexperienced customers requiring support from suppliers for articulation of their problem (Aarikka-Stenroos and Jaakkola, 2012). Designing a solution involves specification of the problem and negotiation between supplier and buyer in order to reach a resolution. There is indication that this phase is the most important in creating optimal value in the relationship and also the most time-consuming and challenging (Aarikka-Stenroos and Jaakkola, 2012). Implementation of a solution mean the implementation or launch of outputs in the solution design process and it can support a customer to utilize the solution in the most efficient and effective way.

Social capital is an umbrella concept used in a variety of disciplines. The term social capital can be defined as "the sum of the actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or social unit" (Nahapiet and Ghoshal, 1998, p. 243). Thus social capital theory captures various dimensions of relational settings where companies co-create value and exchange resources (Nahapiet and Ghoshal, 1998). Social capital has been found to facilitate interaction, lubricate operations between actors and improve efficiency, and to glue actors together (Nahapiet and Ghoshal 1998). It represents the social ties between actors (both individuals and organizations) supportive to achieving certain benefits from these ties (Portes, 1998). Social capital captures the ability of companies working in networks in obtaining benefits such as access to knowledge, resources, technologies, markets and business opportunities (Inkpen and Tsang, 2005). Social capital can be used to analyze buyer-supplier relationships which include complex social processes where partners interact, exchange information, solve problems jointly and form interdepend relationships (Horn et al., 2014). Social capital has found to be a relevant antecedent for exchange of resources in such relationships (Hughes and Perrons, 2011).

Three dimensions of social capital have been identified: cognitive, structural and relational capital (Nahapiet and Ghoshal 1998). *Cognitive dimension* consists of shared interpretations such as codes, goals, norms and attitudes supportive to the social system (Horn et al., 2014; Tsai and Ghoshal, 1998). Shared culture and interpretations of the relationship and joint goals are important components of cognitive capital (Inkpen and Tsang 2005; Villena et al., 2011).

Structural dimension relates to the impersonal formation of linkages and existence of connections in a social structure (structural links) (Nahapiet and Ghoshal, 1998; Villena et al., 2011). Structural dimension can refer to the density of interactions and the number of connections in a social system facilitating the exchange of resources (Zaheer and Bell, 2005). Structural dimension and its benefits are ensured through frequent interaction at different examination levels and functions (e.g. marketing and purchasing) (Villena et al. 2011). The *relational dimension* relates to the relationships developed between persons during the time through interactions (Nahapiet and Ghoshal, 1998). Trust and commitment are important embodiments of relational component in social capital (Carey et al., 2011; Horn et al., 2014).

Hypotheses formulation

Previous literature indicates that different forms of social capital may be interconnected. Especially, there is evidence in the literature that cognitive and structural capital result in relational capital (Horn et al. 2014; Inkpen and Tsang, 2005; Tsai and Goshal, 1998). Common values between companies are supportive to the development of trust and avoiding of opportunistic behavior (Panayides and Venus Lun, 2009). Structural capital in the form of

information flows is supportive to the creation of relational capital (Carey et al., 2011). Social interaction ties developed over time are also important for relational capital (Horn et al., 2014).

Structural capital enables more frequent and diverse communication between companies (Krause et al., 2007; Lawson et al., 2008). In turn, communication can create value through driving problem solving (Stuart et al., 1998) and mutual understanding (Leuthesser, 1997), setting of priorities and coordinating activities between organizational parties (Mohr et al., 1996) which all can be seen essential enabler's for suppliers capability to provide solutions.

Cognitive capital consists of shared language between actors represented in shared goals, visions and values (Bolino et al., 2002). These in turn enable relationship partners to easier exchange their works (Inkpen and Tsang, 2005) and resources (Tsai and Ghoshal, 1998) arguably reflected in the supplier's willingness to invest in providing its best solutions. In turn, incongruent goals and values can lead to misinterpretations (Inkpen and Tsang, 2005) potentially harmful to supplier's solution provision.

Relational capital facilitates more intense and rich information exchange (Spekman and Carraway, 2005). Trust as a key embodiment of relational capital is supportive to open information exchange between actors (Ireland and Webb, 2007) and it can inhibit opportunism in business relationships (Liu et al., 2009). There is also indication in the literature that the presence of relational capital in buyer-supplier relationships can lead to higher investments in supplier development (Krause et al., 2007; Carey et al., 2011; Villena et al., 2011). These efforts by a buyer can in turn motivate suppliers in improving their solution provision.

Earlier research makes us suggest that social capital inherent in supplier-buyer relationships is supportive to supplier's ability to provide solutions. We provide the following hypothesis:

H1 Social capital and its sub-dimensions are positively related to supplier's solution offering performance

- Hypothesis 1a Structural capital is positively related to supplier's diagnosis of customer needs
- Hypothesis 1b Cognitive capital is positively related to supplier's design of a solution
- Hypothesis 1c Relational capital is positively related to supplier's implementation of a solution

Solution provision includes different phases, which have partly different characteristics. It has been presented that the understanding of customer needs requires that suppliers are close enough to customers in order to understand customer's value chain (Ravald and Grönroos, 1996). Suppliers need to ask the right questions and contact several actors in the customer company (Tuli et al., 2007). Development of solutions may benefit from inherent relationship with a customer (Rowley et al., 2000) while solution implementation also often requires interaction between companies due to, e.g. additional modification needs to products or services (Tuli et al., 2007). Tuli et al. (2007) proposed that solution effectiveness depends on both supplier and customer variables. As examples, a supplier's documentation emphasis and articulation of processes for solution development and in turn a customer's adaptation of its routines and processes to supplier's goods and services and provision of information and guidance of its operations to a supplier, can have a positive effect on solution effectiveness.

It is suggested that different forms of social capital may be needed in the phases of solution provision. This suggestion stems from the finding that different dimensions of social capital can have unique effects depending on the goals (Krause et al., 2007). Structural capital represents the structure of relationships between the actors while relational capital refers to the characteristics of these links (Hartmann and Herb, 2014). Close connection between customer

and supplier typically improves supplier's understanding of customer needs. Structural capital represent the relational ties while relational capital capture the strength of those ties (Krause et al., 2007). According to Moran (2005), structural capital is more important in execution-oriented managerial tasks whereas relational capital is important in innovation-oriented tasks. While diagnosis of customer needs and designing of a solution appear as innovation-oriented tasks, implementation of a solution is more execution-oriented task in solution provision.

Cognitive capital is important in achieving joint understanding of means to improve (Krause et al., 2007) and aligning objectives of interest. It is expected that shared goals and values support the supplier's understanding of customer needs as it enables the supplier better to diagnose the customer problem in order to design solution that fits to the customer problem (see also Aarikka-Stenroos & Jaakkola, 2012). They may also be supportive to the supplier's ability to design and implement solutions. We formulate the following hypothesis:

H2 Social capital dimensions are related to the different phases of supplier's solution provision

- Hypothesis 2a The sub-dimensions of social capital are positively related to supplier's diagnosis of customer needs
- Hypothesis 2b The sub-dimensions of social capital are positively related to supplier's design of a solution
- Hypothesis 2c The sub-dimensions of social capital are positively related to supplier's implementation of a solution

Earlier qualitative research has identified different phases in supplier's solution provision (Aarikka-Stenroos and Jaakkola, 2012; Tuli et al., 2007) and suggested that these phases are processual and inter-connected (Tuli et al., 2007). Solution design may benefit from good understanding of customer needs and good solution is required for its implementation. The prevalent understanding is that the phases are linked in a linear fashion while contrasting observations have also been identified (Aarikka-Stenroos and Jaakkola, 2012). In order to test the logic of the models in previous research, the following hypothesis is set:

H3 Phases of supplier's solution provision are positively related to each other

- Hypothesis 3a Diagnosis of customer needs is positively related to designing of a solution
- Hypothesis 3b Diagnosis of customer needs is positively related to implementation of a solution
- Hypothesis 3c Designing of a solution is positively related to implementation of a solution

Several control variables are used. Customization level of supplier's offering can have an impact on supplier's performance in providing solutions. More customized offerings may require more sophisticated practices for solution provision. Length of the buyer-supplier relationship may also have a role in the hypothesized relationships. Longer business relationships are characterized by trust (Lawson et al., 2008) and may drive a supplier to offer its best solutions. The company size may also explain the investigated relationships. Larger companies have often more sophisticated practices for their relationships. Finally, the importance of a customer as perceived by a supplier is a factor which may affect the supplier's willingness to invest its best resources in solution provision.

Methodology

A survey was directed to the key suppliers of four buyer companies. The four customer companies are large Finnish companies operating mainly in business-to-business markets. Two companies represent manufacturing and the two others service industries. Hence, the unit of

analysis of this study is the specific supplier-customer relationship between the respondent's company and one of the customer companies, from the perspective of the supplier.

The whole survey had four main themes: collaborative process, characteristics of the supplier-customer relationship, information sharing and performance and value creation. In this study, the sections of the study related to social capital dimensions and supplier's solution offering performance were utilized including 23 statements measured in 7-point Likert scale from 'strongly disagree' to 'strongly agree'. In addition, background information was collected concerning the respondents' employer companies. The survey instrument (see Appendix) was based on an extensive review of the literature. Existing survey statements were utilized when available. In some cases, the viewpoint of the question was switched from a buyer to a supplier. Also new statements were designed. The survey structure was piloted and tested with the intended population and fellow scholars. This led to small changes in wordings of the statements in order to avoid misinterpretations and to provide precise answers for measured aspects. Also some changes to the order of questions and subtitles in the survey were made.

The questionnaire was executed as a web-based survey. The survey was open for 3 weeks in May-June 2016. Two reminder messages were sent to the respondents. The test for non-response bias was done by dividing responses into three groups as follows: initial invitation, first reminder or second reminder (Leslie, 1972). T-test was performed to the research constructs and no statistically significant differences were found, indicating that non-response bias is not problem in our study. In total, the questionnaire was sent to 1,630 suppliers. 662 usable responses were received resulting in a response rate of 40.6%. The respondents of the survey were suppliers' contact persons (key account managers, CEOs and senior managers) in the relationship with a specific customer and thereby well knowledgeable on the particular customer relationships. Hence, there were typically only one response per supplier. Table 1 gives an overview of the respondents and their employer companies.

Table 1 Demographic information of the respondents' companies

Sample size	662
Company size in annual revenue 2015	Less than 2 million Euros 19.0%; 2 million - less than 10 million Euros 22.5%; 10 million - less than 50 million Euros 23.0%; 50 million - less than 100 million Euros 7.3%; 100 million - 500 million Euros 10.3%; Over 500 million Euros 16.0%;
Length of supplier-customer relationship	Less than 1 year 0.8%; 1 year - less than 3 years 6.2%; 3 years - less than 5 years 10.7%; 5 years - less than 10 years 15.7%; 10 years - 20 years 31.6%; More than 20 years 34.0%;
Key supplier status	Key suppliers 28.7%; Other suppliers 71.3%

The survey data was analyzed using the statistical software IBM SPSS Statistics 24 and SmartPLS 3.0. Partial least squares (PLS) structural equation modeling was applied to test the hypotheses. PLS SEM is a component based estimation method, which maximizes the amount of variance explained. It does not make assumptions regarding data distributions. PLS-SEM is specifically useful when the research focuses on prediction and explaining the variance of key target constructs. This study utilized PLS due the following reasons. First, PLS-SEM is purposeful in testing models with latent variables when the theory is less developed and the intention is to develop theory instead of testing one, such as in the case of our model (Hair et al., 2011). Second, PLS-SEM is an appropriate choice when models investigated are complex. Third, PLS-SEM can be used even if the variables are non-normally distributed. This study

used SmartPLS 3.0 to obtain the estimates. A bootstrapping procedure with replacement of 5,000 rounds was used in the analysis. According to the proposal by Peng and Lai (2012), we also tested the robustness of PLS results by applying OLS regression to the average values of the items in each construct. No differences in the main results (Tables 3 and 4) were identified.

Number of missing values varied between 5-15% in the statements used. Casewise (listwise) deletion was applied dropping the sample size to 460. Common-method bias was tested by 1) Harman's single factor test and 2) a test with a common method factor (Podsakoff et al., 2003; Liang et al., 2007). In Harman's test no single factor was accountable for the majority of variance in the data. The unmeasured common method factor test was conducted by following the approach presented by Liang et al. (2007). A common method factor was added including the indicators of all the constructs. The variance of each indicator was investigated in relation to its principal construct and the common method factor. The substantive variance of principal constructs was on average 0.660 while the average variance in the method factor was on average 0.006. The ratio between of substantive variance to common method variance is around 102. Further, most of the common method factor loadings were insignificant. Based on these tests we conclude that common method bias is unlikely to be a problem in our study. Table 2 summarizes the characteristics of the data used in this study.

Table 2 Characteristics of the data

Constructs	**Mean (s.d.)**	**Correlations**					
		1.	2.	3.	5.	6.	7.
1.Structural capital	5.05 (1.17)	1.00					
2.Cognitive capital	4.84 (1.14)	0.502	1.00				
3.Relational capital	5.82 (0.95)	0.573	0.552	1.00			
4.Solution offering performance	6.02 (0.73)	0.571	0.498	0.559			
5.Diagnosis of customer needs	6.02 (0.75)	0.512	0.492	0.555	1.00		
6.Designing a solution	5.97 (0.88)	0.532	0.400	0.483	0.636	1.00	
7.Implementing a solution	6.12 (0.82)	0.465	0.430	0.473	0.620	0.685	1.00

All Pearson correlations are significant at 0.001 level

All the constructs in the study are reflective in nature. Internal consistency and reliability were evaluated by using composite reliability (CR) (Fornell and Larcker, 1981), average variance extracted (AVE) and factor loadings (Hair et al., 2014) (results in Appendix). Composite reliability varied between 0.87 and 0.93, exceeding Nunnally's (1978) threshold of 0.7. AVEs varied between 0.56 and 0.72 exceeding the 0.50 cut-off (Fornell and Larcker, 1981) and all the Cronbach alphas were over the limit of 0.7 as proposed by Hair et al. (2014). Most of the survey items exceeded the 0.7 threshold for outer loadings (Henseler et al., 2009). One item with loading over 0.6 was utilized in the study. Cross-loadings for each item were examined by comparing the loadings into different constructs and by using the threshold of 0.2 for the difference. This resulted in the removal of three items in solution provision performance, two items in diagnosis of customer needs and two items in structural capital. Discriminant validity was tested as proposed by Fornell and Larcker (1981). The squared correlations between the

pairs of constructs is always less than the AVE for each individual construct. Multicollinearity was tested by using Variance Inflation Factor (VIF). The VIF values varied between and 1.36 and 2.09 (see Tables 3 and 4), which is well below the cut-off level of 10 often considered as indicator of serious multicollinearity (Duzann and Shariff, 2015).

Results

The first hypothesis regarding the relationship between social capital dimensions in the supplier-buyer relationship and solution provision performance was tested with the model 1 (see Table 3). The results suggest that each dimension of social capital is positively related to the ability of a supplier to provide solutions to its customer. Thereby H1 is supported. In addition, the results suggest that large size of a supplier company is positively related to its ability to provide solutions. The other control variables related to customization level of supplier offerings, supplier's perception of customer importance and long relationship length have no statistically significant relationship to solution provision performance. The model as a whole explains 44.3 percent of the variance in solution provision performance.

Table 3 Results for the hypothesis 1

Path	**PLS SEM analysis results**					**OLS analysis results**		
	VIF	**β**	**t-value**	**Significance (p-value)**	**F^2**	**β**	**t-value**	**Significance (p-value)**
H1a Structural capital→solution offering performance	1.755	0.281	5.674	$p < 0.001$	0.088	0.294	7.029	$p < 0.001$
H1b Cognitive capital→ solution offering performance	1.642	0.180	3.951	$p < 0.001$	0.036	0.161	3.950	$p < 0.001$
H1c Relational capital→ solution offering performance	1.970	0.233	3.952	$p < 0.001$	0.075	0.238	5.377	$p < 0.001$
Control variables								
Large company size → solution offering performance	1.102	0.119	3.783	$p < 0.001$	0.023	0.087	2.616	$p < 0.01$

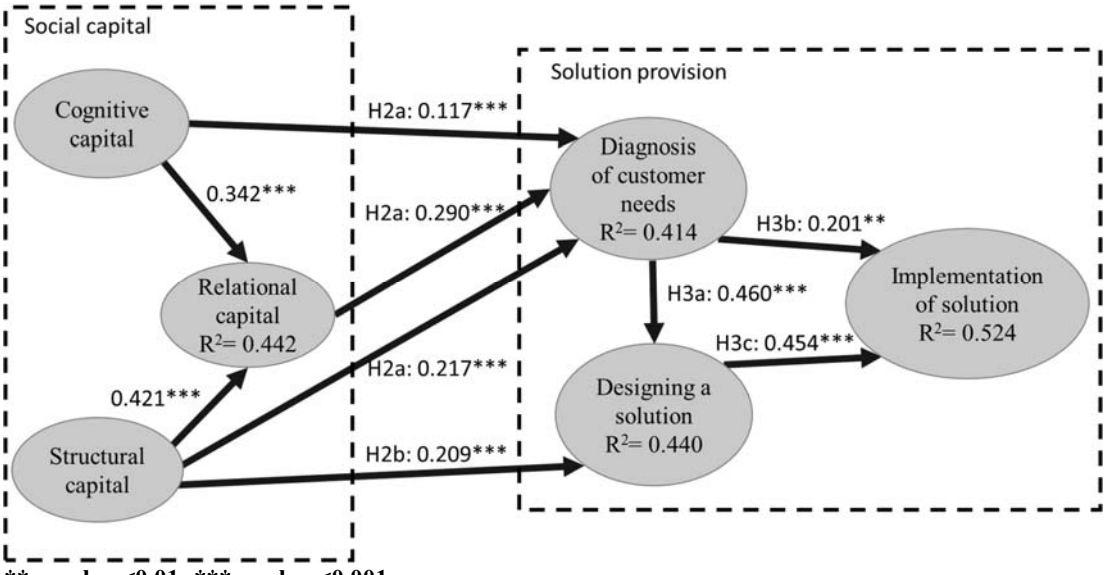
Perceived importance of a customer → solution offering performance	1.353	0.088	1.903	N.S. (0.057)	-	0.115	3.092	$p < 0.01$

Long relationship → solution offering performance	1.086	0.035	1.051	N.S.	-	0.031	0.949	N.S.
R^2		0.443				0.425		
R^2adj		0.435				0.422		
Q^2		0.227						

In line with Hair et al. (2012), the effect size reflecting the relative impact of a specific exogenous latent variable on an endogenous latent variable (elimination of one path at the time) is examined using Cohen's effect size test (Cohen, 1992). The results of F^2statistics indicate that the size of the effect for all paths is small (above 0.02 but below 0.15) (Hair et al., 2014). Further test for predictive relevance of the model was carried out by applying Q^2 statistics through cross-validate redundancy approach (Hair et al., 2014) with satisfactory results.

Further analysis was carried out by applying polynomial regression analysis by comparing the two pairs of social capital dimensions at the time. The main observation of these analysis is that solution provision performance can be high even when one dimension of social capital is high in the relationship while the other is low. Due to the limited space these results are not presented here.

The second, more complex model was used to test the hypotheses 2 and 3. Relational capital appears as a mediator in the relationship between social capital and solution provision performance by a supplier as suggested in the prior literature. Figure 1 presents the significant relationships identified. Hypothesis two regarding the role of social capital in the different phases of supplier's solution provision is only partially supported. As suggested, all three dimensions of social capital are positively related to the supplier's ability to diagnose customer needs. However, only structural capital has a statistically significant positive relationship to a supplier's ability to design a solution. Formal structures and practices for information exchange seem important also in this phase but the result suggest that trust or cultural similarity in the relationship are not important anymore. Further, in implementation of a solution it appears that social capital has even less importance. PLS SEM result provide a weak support to the role of cognitive capital in this phase but OLS regression result is not significant. Overall, we conclude that social capital is least important in implementing solutions.



**** p-value <0.01; ***p-value <0.001**

Figure 1 The model 2 including significant relationships for H2-H3.

The third hypothesis of this study investigated the relationships between the different phases (diagnosis of customer needs, designing and implementing a solution) in supplier' solution provision. The hypothesis is supported. Diagnosis of customer needs has a strong, positive relationship with designing a solution. This suggest that the success in solution design is dependent on the understanding of customer needs. Understanding of customer needs also aids in successful implementation of solutions. Finally, success in designing a solution is positively related to the success in implementing of a solution. The results suggest that social capital contributes to the solution provision especially through its substantial role in supporting the diagnosis of customer needs which is in turn crucial in the other phases of solution provision.

Table 4 presents the results regarding the model 2 in more detail. PLS-SEM analysis suggest that the larger companies are more able to diagnose the needs of their customers and implement their solutions but OLS regression results do not provide support for this observation. The structural model explains 44.2 percent of the variation in relational capital, 41.4 percent of the variation in diagnosis of customer needs, 44 percent of the variation in designing a solution and 52.4 percent of the variation in implementing a solution.

Table 4 Results for the hypothesis 2 and 3

Path	**PLS SEM analysis results**							**OLS results**	
	VIF	**β**	**t-value**	**Signifi-cance (p-value)**	**R^2**	**F^2**	**Q^2**	**β**	**t-value**
H2a Structural capital → diagnosis of customer needs	1.770	0.217	4.258	p < 0.001	**0.414**	0.074	**0.236**	0.139	5.118

H2b Structural capital → designing a solution	1.852	0.209	4.038	p < 0.001	**0.440**	0.042	**0.315**	0.174	5.231
H2b Cognitive capital → designing a solution	1.693	0.002	0.037	N.S.		-		0.005	0.161 N.S.
H2b Relational capital → designing a solution	1.973	0.054	0.868	N.S.		-		0.057	1.289 N.S.
H3a Diagnosis of customer needs → designing a solution	1.704	0.460	8.355	p < 0.001		0.221		0.538	10.473

H2c Structural capital → implementing a solution	1.945	0.031	0.632	N.S.	**0.524**	-	**0.369**	0.010	0.347, N.S.
H2c Cognitive capital → implementing a solution	1.693	0.106	2.401	$p < 0.05$		0.014		0.054	1.943 N.S.
H2c Relational capital → implementing a solution	1.981	0.031	0.521	N.S.		-		0.046	1.191, N.S.
H3b Diagnosis of customer needs → implementing a solution	2.092	0.201	3.112	$p < 0.01$		0.041		0.272	5.483
H3c Designing a solution → implementing a solution	1.785	0.452	6.461	$p < 0.001$		0.241		0.421	11.041
H2 Structural capital → relational capital	1.361	0.421	9.672	$p < 0.001$	**0.442**	0.234	**0.304**	0.342	11.348
H2 Cognitive capital → relational capital	1.361	0.342	7.609	$p < 0.001$		0.154		0.293	9.592

The results of F^2 statistics indicate that the size of the effect for most significant paths is small (above 0.02 but below 0.15). For the path studied for H3 (relationships between the phases in solution provision) the F^2 is above 0.15 indicating medium effect. Only exception is the path diagnosis of customer needs → implementing a solution, which has a small effect. The result of Q^2 statistics through cross-validate redundancy approach suggest that the model has predictive relevance.\

Discussion and conclusions

This study demonstrates the importance of social capital prevalent in supplier-buyer relationship in supplier's solution provision: it particularly reveals how different dimensions of social capital contribute to diagnosing the customer need, designing and implementing the solution. This brings in several contributions.

Firstly, our study contributes to the literature of social capital in supply chains (Hughes and Perrons 2011; Krause et al. 2007; Villena et al., 2011) by unveiling the importance of different dimensions of social capital in the supplier's solution provision. This is one of the first studies examining statistically the antecedents of different phases in supplier's solution provision. Secondly, the study also proves the links between the phases in solution provision (diagnosis customer needs, designing a solution, implementing a solution) as suggested in the qualitative study by Aarikka-Stenroos and Jaakkola (2012). It gives support to the arguments highlighting the importance of understanding customer needs in realizing the innovation potential of suppliers (Larsson et al. 2006). Our study gives empirical evidence that social capital

contributes particularly to customer need diagnosis that determines crucially value creation potential in further phases of designing and implanting a solution. Thus our results build new knowledge particularly on the value creating process of supplier solutions and how different phases of that process are linked. Thirdly, this study contributes to the social capital literature by showing that different forms of social capital can compensate each other. When one dimension is missing the other has to be present in order to gain the desired benefits. This supports the argument by Nahapiet and Ghoshal (1998) highlighting the interdependence on the development of social capital. The study also supports earlier findings on the mediating role of relational capital in gaining benefits from structural and cognitive capital.

Our findings emphasize that the diagnosis of customer needs is the phase most significantly driven by social capital prevalent in the supplier-buyer relationship. This is understandable since diagnosis of customer needs tend to require emotional intelligence and ability to understand the role of a customer (Ravald and Grönroos, 1996). In designing solutions, structural capital remains important while the other dimensions of social capital lose their importance. Earlier research suggests that existence of relational capital may reduce the buyer's dependence on the service provider (Hartmann and Herb, 2014). In the relationships studied, it appears that formal and frequent communication structures are needed during the design of solutions reflecting the supplier's dependence on a buyer. Horn et al. (2014) identified that cognitive capital was more important than structural capital in relationships within a single company while the situation was the opposite in relationships between companies. While in inter-organizational relationships shared targets and values are important, the presence of contact points is even more important. This observation may also partly explain our results. Moran (2005) found that structural capital is more important in execution-oriented managerial tasks whereas relational capital is more essential in innovation-oriented tasks. Villena (2011) also proposed that relational capital may be more important than the other dimensions of social capital when supplier and buyer pursue strategic benefits. This would suggest that designing a solution is a more execution-oriented and less strategic task in comparison to diagnosis of customer needs which is not an easy argument to justify. However, there are varying presentations regarding the nature of solution process in the literature and the process may be affected by the nature of solution.

In the case of implementing solutions, social capital seems to lose its importance. This phase especially is characterized by independent work by suppliers while it is also known that sometimes solution implementation requires more interaction (Aarikka-Stenroos and Jaakkola, 2012) and consequently social capital. However, in our wide dataset of suppliers, solution implementation appears as something suppliers carry out rather independently.

The nature of problem to be solved can affect the characteristics of the solution process (Nordin and Kowalkowski, 2010). The customization level of supplier offerings was a control variable in this study and it was not found to have a significant effect on the findings, although slight indication was found that solution offering performance is higher when solutions are more customized. However, our results might have been different if suppliers with only customized solutions would have been included in the sample. Future empirical research on the relationship between different types of solution processes and social capital is encouraged.

The managerial implications of this study can be assessed from the viewpoints of both customer and supplier. The results give managers with more understanding on the importance of social capital in the supplier-customer relationships particularly in solution business. Our findings suggest that suppliers should analyze their solution provision process and practices, and identify potential means to improve it via social capital inputs. This is important especially in improving the understanding of customer needs. Our paper basing on statistical support advices

also managers to apply social capital along the path of good solution provision comprising the phases of good diagnosis, good solution design and good solution implementation. Traditionally the existence of these different phases has received limited attention and the responsibility for the phases is scattered in the supplier's organization, i.e. customer needs are defined by sales or business development functions while business or customer support functions play part in the implementation of solutions (Tuli et al., 2007). The implication is that the whole process should be taken into account through coordination between the functions. From the buying customer company perspective, the results support in understanding the importance of different supplier capabilities in service provision performance, which is crucial in eventual performance outcomes.

This study is not without limitations. Further research should address in more detail the compensating role of different dimensions of social capital in solution provision. Also the characteristics of a solution should receive more specific attention. This study was carried out with suppliers companies representing different sizes and industries and further study could concentrate on more specific types of suppliers. This study utilized supplier responses and a further study could extend the scope to the buyer company.

Abstract

This paper shows the evolution of traceability management from 1990-2017 using 124 articles. It lists 73 journals by name, classified in 12 fields of science. We find a dominance of food journals, with journals in supply chain management and IT in a stable second and third position. Articles are coded for 9 possible topics and divided into two categories: theoretical and empirical. An increasing Berry index for the 9 topics shows an increased dispersion across the various topics. Out of the 43 case studies, 36 relate to the food industry, although more recent publications also deal with other sectors. Various relevant theories are discussed and observed bottlenecks are discussed as well as future potential, like using Systems Thinking with Big Data Analysis as an enabler.

Keywords: Traceability, Supply Chain Management, Food industry, Literature Review

Supplier relationships with competing customers -
How can purchasers find out who is the preferred customer?

Antonia Kappel[1], Holger Schiele[2], Wolfgang Buchholz[3]

ABSTRACT

Focal companies are embedded in complex supply networks consisting of various suppliers, customers, competitors and complementors. The activities of these actors influence the competitive position of the focal companies. Some customers achieve preferred customer status and gain preferential treatment, others have to restrain to being standard customers getting less privileged services. Consequently, buying companies in such markets have to achieve transparency about the relationships of their suppliers towards their competitors and complementors in order to map them and to analyse their impact. Current literature lacks a holistic approach to capture these relationships. In which sources can the focal companies find the desired information? Which kind of information do they really need? And in which situations is the need for transparency high and when is it low? The aim of this research is to examine these relationships using a World Café method with purchasers for data gathering followed by a Gioia method to structure the qualitative data. The result is a list of desired knowledge covering business, supplier and collaboration details; a set of information sources clustered in published and unpublished sources as well as contingency factors regarding general conditions, changes and particular occasions that require a high supplier relationship knowledge. All answers have been rated by their importance during the World Café. The answers can help to operationalise the mapping of supplier relationships towards competitors and complementors in order to assess the own customer status compared to other customers.

reduction of the amount of competing suppliers. In such a situation, the problem may arise that suppliers do not treat all customers equally, which would also not make any sense from a resource optimisation perspective. Some customers enjoy preferred customer status, while others are treated as standard customers. The ones who achieve a preferred status derive greater benefits from suppliers' resources and capabilities and thus gain competitive advantage (Schiele, Calvi, & Gibbert, 2012). In order to understand their situation, firms need an even better understanding of their attractiveness towards their suppliers. They need to assess, whether they are sufficiently attractive to initially motivate a supplier to start a business relationship with them and at the long term to maintain it by satisfying the supplier. A customer is perceived as attractive by a supplier if the supplier in question has a positive expectation towards the relationship with this customer (Schiele, Calvi, & Gibbert, 2012). Consequently, firms need more supply chain transparency as compared to previous times where large numbers of suppliers were present.
Supply chain transparency is commonly known as the disclosure of information on involved actors (Doorey, 2011). The actors considered in this research are suppliers, customers, competitors and complementors according to the Value Net (Nalebuff & Brandenburger, 1997). Competitors and complementors will be summarised as other customers in the further course of the paper. Previous empirical research among purchasers has shown that the vendors' relationships' transparency as perceived by the buyers contributes to the overall success of a business relationship (Eggert & Helm, 2003). However, the current literature lacks a standard on the required knowledge about the relationships. Only proposals which information to gather exist, such as the suppliers' names and sustainability conditions (Egels-Zandén, Hulthén, & Wulff, 2015).

The analysis of the suppliers' relationships leads to a deep business knowledge in the supply network. This knowledge is useful for focal companies and can confer a competitive advantage on them. Furthermore, an investigation of the suppliers' relationships with competing customers might help to improve negotiation positions or to mitigate strategic risks (Hoffmann, Schiele, & Krabbendam, 2013). On the other hand, research on the complementors' relationships can help to increase sales. Therefore, both actors and their relationships in the horizontal dimension might create value for the focal firm.

In this paper, the World Café Method will be introduced as a suitable exploratory-qualitative research method to examine the knowledge of a focal company's purchasers concerning the relationships of its suppliers with other customers. This method will be complemented by the Gioia Method, which is used to structure the qualitative findings to subordinate constructs. In the end, the authors of this paper will sum up the relevant findings and give an outlook to potential fields of future research.

THEORETICAL BACKGROUND

Business-to-business markets currently face a high competition for resources (Pulles, Schiele, Veldman, & Hüttinger, 2016; Schiele et al., 2012). In many industries the amount and the capacity of the suppliers is limited and can cause bottlenecks in the supply. Especially in expanding or even booming phases of the business cycle, the situation is very serious and the suppliers cannot saturate all the existing demand. Natural disasters as well as the currency, politics, transport and further risks in a globalised world render purchasing activities even more difficult. Ensuring the availability of the ordered parts is the most important target of purchasers in these challenging times.

This development on the markets also leads to changes in the market power: In the past, suppliers fought hard to gain the orders of their customers (Schiele et al., 2012). Most purchasing

organizations had a list of preferred suppliers due to a competitive pricing and a convincing supplier performance. The supply market consisted of a broad range of interchangeable small to mid-size suppliers, whereas the manufacturing companies had a high manufacturing depth and owned most of the intellectual property on innovations. Nowadays, the customers cannot take the fulfilment of their demands as granted anymore due to an oligopolistic market structure (Schiele et al., 2012). The number of suppliers has significantly reduced to a remaining set of big, consolidated and powerful enterprises with a high innovation power and thus a very good negotiation position. Consequently, the customers need to struggle hard in order to become the preferred customers of their suppliers and to obtain preferential resource allocation (Pulles et al., 2016; Schiele et al., 2012).

According to Baxter, a very important determinant for the preferred customer status is the financial customer attractiveness. The supplier satisfaction and supplier commitment mediate this influence (Baxter, 2012). Supplier satisfaction is the buyer's ability to fulfil the expectations of the supplier (Schiele et al., 2012). It is influenced by growth opportunities, reliability and profitability of the relationship (Vos, Schiele, & Hüttinger, 2016). Moreover, Ellis, Henke and Kull state that early supplier involvement and relational reliability positively affect the preferred customer status (Ellis, Henke, & Kull, 2012). A high customer attractiveness can motivate the supplier to invest his limited resources in the common business with this customer (Baxter, 2012). Furthermore, the preferential treatment can be beneficial for product quality, support in the sourcing process, delivery and prices (Nollet, Rebolledo, & Popel, 2012) as well as the supplier's willingness to share new technology with this customer (Ellis et al., 2012). These ways of preferential treatment by the suppliers again increase the customer satisfaction (Bemelmans, Voordijk, Vos, & Dewulf, 2015). However, supplier satisfaction is an antecedent to preferred customer status and preferential treatment, but not an absolute value. Whether a customer receives preferential treatment or not also depends on the alternatives available to the supplier. Hence, for a buying firm it becomes important to understand what its competitors on the supply market are doing.

Consequently, it is very important for the focal companies to be aware of the relevant actors in their supply net and to map how the relationships between them are. The purchasers need to figure out the characteristics of their suppliers' business with other customers. They do not only try to learn more about the products and projects of their suppliers with other customers, but also about the collaboration between both parties. In order to create the desired transparency on supply chains, companies started to develop tools like supply chain maps.

These maps can have a structural or a geographic shape (Lambert, Cooper, & Pagh, 1998; Wilding, 1998). They visualize the material, financial and information flow into all directions of the supply chain and through a firm (Gardner & Cooper, 2003). The maps can show complex, overlapping links, if some actors on a higher level have relationships with various actors on a lower level of the supply chain (Smirnov, Shilov, & Kashevnik, 2006). Nevertheless, supply chain maps only focus on the vertical multi-tier supply chain. They present all sub-suppliers on the supply side and all trade levels on the sales side (Lambert et al., 1998; Wilding, 1998). This paper tries to take supply chain visibility a step ahead. By integrating a horizontal dimension in addition to the vertical supply chain, it considers the whole supply network. According to the value net by Nalebuff and Brandenburger, the important actors in the horizontal dimension are the competitors and complementors of the focal company, as both influence its strategic position on the market (Nalebuff & Brandenburger, 1997).

Once the purchasers know who has a preferred and who has a neglected status for their suppliers, they can define or review their preferred customer strategy and adopt their supplier rela-

tionship management. For this purpose, they can reflect on the reasons for their own (un)attractiveness and try to improve the supplier satisfaction in order to maintain their preferred customer status or to be upgraded to a preferred status (Schiele et al., 2012). They can adjust the supplier classification and focus on those suppliers who treat them as preferred customers. They might stop the collaboration with suppliers who have a trustful relationship with their competitors or intensify projects with suppliers who closely work together with their complementors. Moreover, they can develop another strategy for the suppliers who treat them as preferential customers and try to reduce purchasing costs or to achieve other advantages from them.

To the authors' knowledge, no broad investigation on the information gathering about the relationships between these actors exists yet. That is why this research concentrates on the purchasers' transparency about supplier relationships with other customers. Regarding the preferred customer theory, the aim is to investigate the following research question: How can purchasers assess their own customer status at their suppliers in comparison with other customers?

RESEARCH DESIGN

World Café Method

The World Café is an exploratory-qualitative research method that has been created by Brown and Isaacs (Brown, Isaacs, & Community, 2005). Small focus groups discuss on selected subjects in a café-like atmosphere (Prewitt, 2011; Wibeck, Dahlgren, & Öberg, 2007). Seven core design principles constitute the basis of the World Café method, such as exploring questions that matter or connecting diverse perspectives (Brown et al., 2005; Fouché & Light, 2010; Lorenzetti, Azulai, & Walsh, 2016; Tan & Brown, 2005). The advantages of the method lie in its high output attainable in a short period of time compared to other qualitative research methods such as longitudinal case studies or interviews. In contrast to interviews, an exchange among the participants is possible and desired. Due to the iterative process of the World Café method, a high stability and reliability of data is ensured (Kidd & Parshall, 2000). Varying group constellations enable to achieve rich data and to reduce bias (Fouché & Light, 2010).

The aim of this research is to create a deep and collective understanding on how to assess the customer status by the help of a small group of purchasers. That is why a single case study is suitable to explore the problem instead of a multiple case study analysing the similarities and differences across various cases. The method is applied in an agricultural machinery company, as this firm faces a complex, multi-tier supply network including various suppliers, competitors and complementors and does not carry out a holistic approach to achieve an overall transparency on it yet. In order to form a representative sample of the product-related material purchasing team in this company, five divisions are involved in the World Café session, thereof three manufacturing facilities buying production material, the aftersales division ordering spare parts as well as corporate functions. The heads of purchasing select 14 purchasers, so that at least three buyers and the moderator take part in the discussions at each table.

Important criteria for the selection of the participants are a heterogeneous experience and portfolio among the group. The heterogeneous portfolio enables the authors to examine if the need for transparency depends on the commodity. Represented commodities are assemblies, axles, bearings, belts, cabins, chains, drivelines, electrics, electronics, gearboxes, hydraulics, machined parts, metal sheets, OEM parts, plastics, power train, pulleys, rims, rubber, service provider parts, special tools, tyres and weldments. An average participant of the World Café has worked for the agricultural machinery company since 13.6 years - thereof 11.5 years in strategic

purchasing at this manufacturer – and is responsible for 44 suppliers. With regards to the professional level, nine strategic purchasers, one lead buyer, one head of purchasing as well as three purchasers in corporate functions form the group. The purchasers in the corporate functions are responsible for contract management, product cost optimization and product-related material. Only two participants have taken part in a World Café session previously.

At different stations, the purchasers answer the following questions and change groups after each round. According to the World Café design principles, questions should be powerful and appreciative (Brown et al., 2005; Alexander Schieffer, David Isaacs, & Bo Gyllenpalm, 2004). Questions 1 and 2 are discussed on separate tables regarding competitors and complementors, but lead to similar results, which are presented together in the findings sector.

Q1: ***What*** *would you like to know about your supplier relationships with other customers?*
Q2: ***How*** *do you find out information about these relationships?*
Q3: ***When*** *do you need a high knowledge about these relationships?*

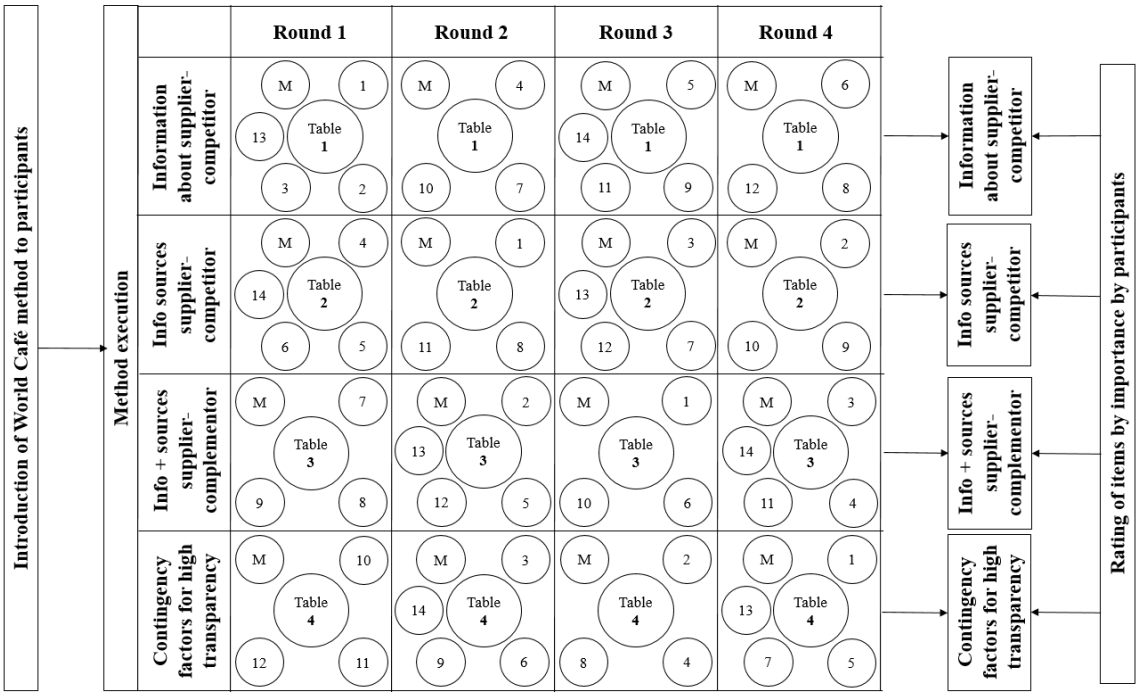

Figure 1: World Café design and application

The numbers in the World Café design in figure 1 illustrate how the participants mix when rotating between the tables in order to maximise knowledge exchange (Chang & Chen, 2015; Prewitt, 2011). The table constellations are announced by the café convenor for each round to ensure that there are new constellations every time and that the participants of the different company divisions mix with each other. In the beginning, each participant draws a number and then changes the tables accordingly. As figure 1 demonstrates, the same participants do not meet each other in the same discussion group more than twice. While the participants move, the moderators remain on their tables. They take notes, make sure that discussions stick to the subject and that every participant can contribute to them. Finally, they sum up the findings for the new group (Hüttinger, Schiele, & Schröer, 2014; Alexander Schieffer, David Isaacs, & Bo Gyllenpalm, 2004). Movable walls and paper sheets are used for documentation (Pumpe &

Vallée, 2016). When noting down the answers, it is very important to use another pen with a different colour for every new round in order to track the progress.

The discussion rounds are recorded, so that no important suggestions are lost due to the tension in lively debates. All audio files are transcribed after the World Café session. These transcripts allow to write a clear definition for every suggested answer listed in the attached glossary. The definitions avoid misunderstandings of the key words on the paper sheets and provide additional explanation. Therefore, they also help to detect overlaps in the answers and to condense them to one single answer.

Four rounds take place each lasting 20-30 minutes, so that a two-hours-time span for the method execution is sufficient (Jorgenson & Steier, 2013). Experience has shown that usually the first session should be the longest and is therefore scheduled with 30 minutes. Most participants have not taken part in a World Café before and they need to get familiar with the questions, colleagues and moderators first. Moreover, there is often a natural resistance to get started with creative techniques. Furthermore, the participants can still mention any aspect that they regard as important, whereas the scope of discussions narrows down from round to round. The second and third round serve mainly to ensuring that all ideas are covered and are thus five minutes shorter. The last round aims at filling the gaps and takes about 20 minutes.

In the end of the World Café session, the participants are requested to fix stickers next to the answers according to the significance of the suggested aspects (Pulles et al., 2016), in order to provide a ranking of the answers collected in the World Café. Another hour is necessary for the evaluation and the closing session. Each participant gets stickers in different colours for the different questions. Six stickers are distributed per question, multiplied by the 14 participants, resulting in a voting of 84 points per question. As there are many answers, all possible ways are allowed for the rating, such as giving all six points to one answer or splitting them up to several answers. Once all stickers are on the paper sheets, the moderators start counting the points per answer. They sort the answers in a descending order by the number of received answers in order to figure out the most important answers for the group. This order can be seen in the ranking tables (figure 3, 5 and 7), which are presented in the findings section. Finally, the moderators present the top responses as the findings to the World Café's participants.

Gioia Method

In order to enhance the qualitative rigor of this inductive research, the World Café is complemented by the Gioia Method. This method is a holistic approach to inductive concept development. The huge advantage of this method is that it clusters the answers given by the participants of the World Café and creates a structure of this qualitative data. This data structure facilitates the integration of the World Café results in the focal company's supplier strategy and supplier relationship management. Although the Gioia Method was developed based on semi-structured interviews, it is just as fitting for the World Café with focus groups, as both methods serve obtaining retrospective and real-time accounts by those people experiencing the phenomenon of theoretical interest (Gioia, 2012).

The analysis of the qualitative data according to the Gioia Method starts with the creation of 1st-order categories by seeking redundancies or high similarities between answers of the focus group. Although the number of categories should be manageable, the effort to merge different categories is still low at this stage. In the next step, several categories are condensed to 2nd-order themes on a more abstract, theoretical level explaining the observed phenomena. In the end of the analysis, these themes are again aggregated to higher dimensions (Gioia, 2012).

In order to build the 2nd-order themes and aggregate dimensions for this research, the posters of the discussion rounds with the purchasers as well as the attached glossary are a big help in order to understand the broader context behind single noted down answers. They give a first indication for the clustering of the answers. A graphic representation for every question in the findings section shows the data structure of 1st-order categories, 2nd-order themes and aggregate dimensions. The dimensions help to generalize from this case study to other manufacturing companies, as the collected insights on the desired knowledge, information sources and contingency factors on supplier relationships are also relevant to other industries.

FINDINGS

The results section describes the data structure according to the Gioia Method followed by the rating of the answers coming from the World Café approach for each question. This structure allows presenting the findings in a logical sequence, although chronologically the results in the World Café were collected first. For the first two questions, most answers regarding the supplier relationships with complementors were the same as already mentioned for the competitors. However, some answers were only given for complementors. These answers are marked by a star (*) in the data structure figures 2 and 4. They give additional insights, as the relationship of the focal company with complementors differs from the relationship with competitors. The answers marked by the star (*) can be looked up in the attached glossary, but are not included in the rating figures 3 and 5.

Q1: Desired relationship knowledge

As illustrated in figure 2, the purchasers are interested in the business that suppliers make with other customers. This business can be expressed best by its commercial facts: Which products are in the delivery scope of the supplier? At which price level? And how much turnover does the supplier make with other customers? Besides this financial perspective, also more background on the business partners is interesting for the purchasers: Are the suppliers unknown for the focal company and consequently new, potential suppliers? How dependent are the other customers of these suppliers? And do they deliver directly to their aftermarket?

Moreover, the purchasers of the focal company would like to find out how other customers deal with suppliers whom they both have in common: How do they handle and manage these suppliers? Assessment-related answers given in the World Café are the supplier classification, evaluation and audit results. Concerning the management of the suppliers, the purchasers would like to know which targets they set for suppliers, how they award projects to and how they optimize processes of the suppliers.

Finally, the buyers would like to discover how the collaboration works between the suppliers and other customers. They would like to know existing legal and logistic agreements like the contract and delivery agreements for the different plants. Furthermore, they are interested in the innovations developed by their common R&D staff as well as the interpersonal exchange: How is the cooperation strategy? How often do they meet? Does the supplier offer an open-book policy for them?

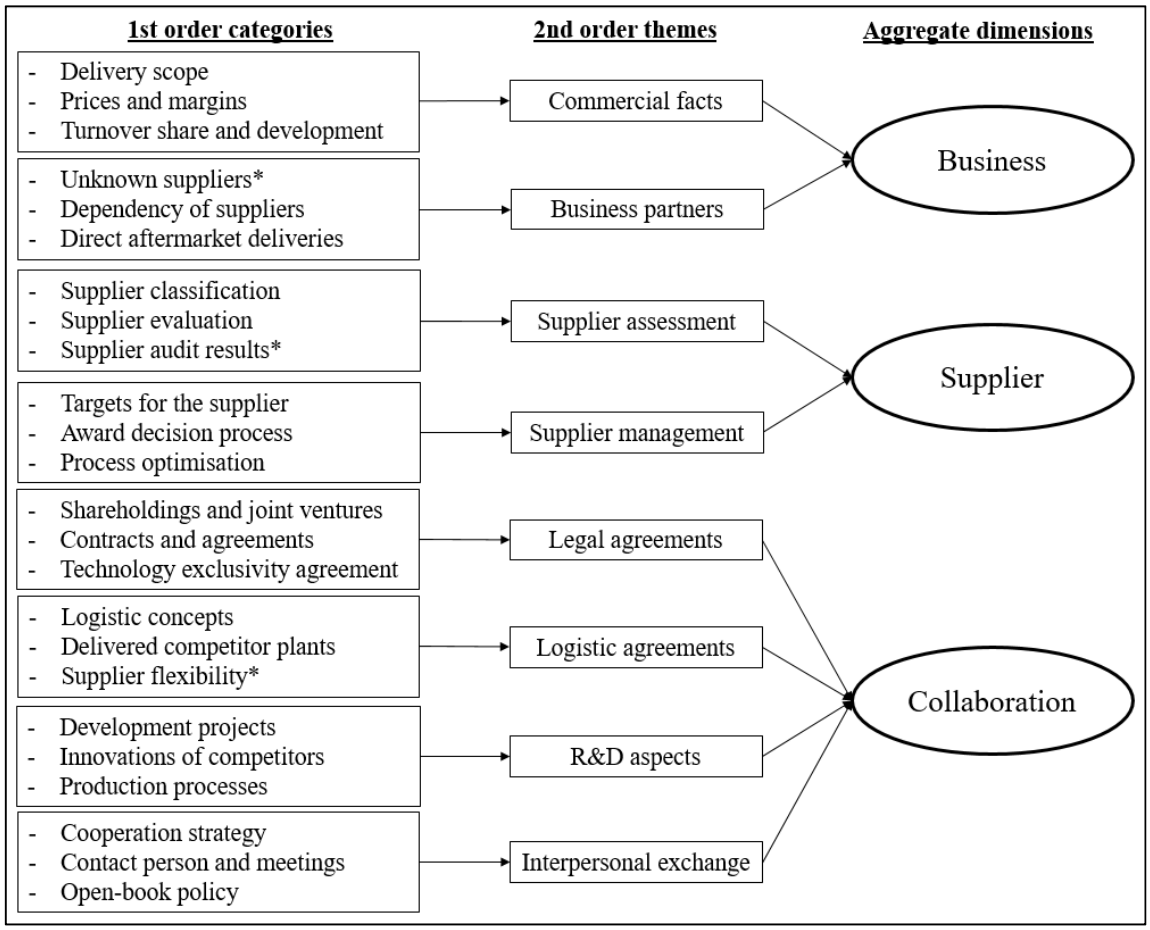

Figure 2: Data structure of desired relationship knowledge

As figure 3 shows, the most desired information mentioned in the World Café are the prices and margins that the supplier grants the competitor. The purchasers placed 15 stickers on this top response. The prices were rated as very important regarding supplier-complementor relationships, as well. However, the aim to figure out this information for the complementors is not the same as for competitors, as it might make sense for complementors to align their prices to each other and to raise or lower them by mutual consent. The managers of an airline would like to know when destination resorts lower their room rates, as the demand for flights will rise. This management of the complementor's relationships describe Yoffie and Kwak as "knowing your friends". (Yoffie & Kwak, 2006).

Another important financial KPI being assessed with 8 points is the turnover share and development that the supplier makes with the competitor. However, not only financial facts are highly important to the purchasers, but also other parameters describing the supplier-competitor business, e.g. if the supplier delivers directly to the competitor's aftermarket (8 points) or if he supplies to his global plants (13 points): Do the supplier and the competitor go local-for-local? If he were willing to implement the corresponding structural and processual changes with other customers, maybe he would agree on the same strategy with the focal company.

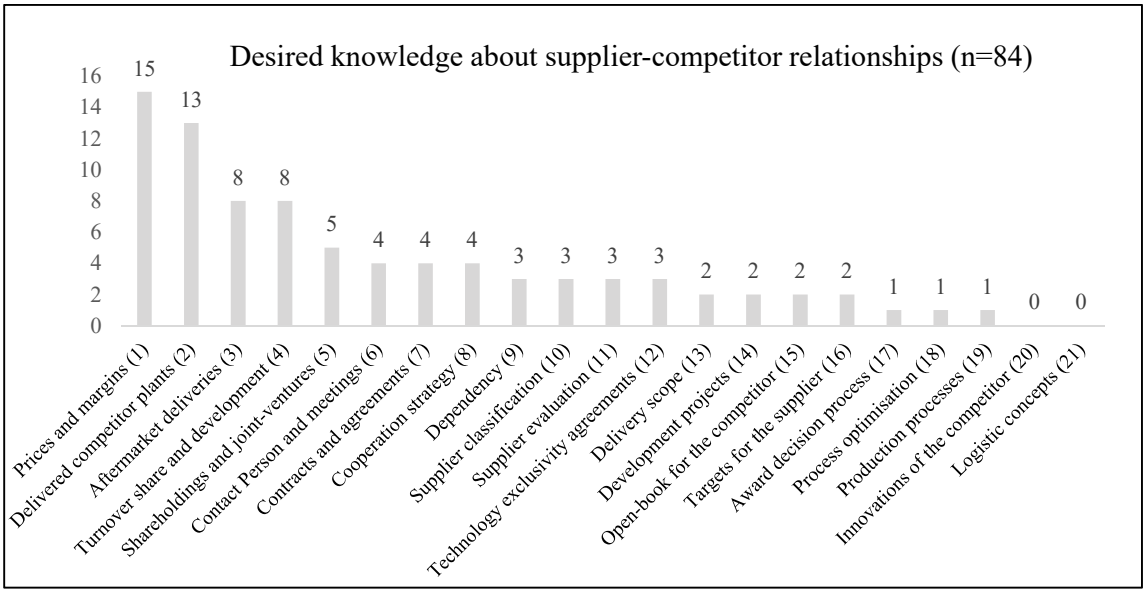

Figure 3: Rating of desired relationship knowledge

The desired relationship knowledge presented in this paper contributes to the current literature examining the different dimensions of customer attractiveness and supplier satisfaction (Pulles et al., 2016). Some mentioned answers correspond to the outcome of the World Café presented by Pulles et al. and thus render the findings of these authors more robust. Other aspects are new and complement the outcome of the previous World Café by valuable additions.

More precisely, the purchasers in this research mention the same following dimensions of customer attractiveness as in the World Café of Pulles et al.: supplier development programs, open-book (providing suppliers access to advanced knowledge), supplier flexibility, top-management interest (which can be derived from the contact person and frequency of meetings), turnover (corresponding to the purchasing volume of the buyer), firm strategy and exclusivity agreements (Pulles et al., 2016). New additional dimensions of customer attractiveness from this research are: prices and margins, direct aftermarket deliveries, process optimisation, shareholdings/joint ventures, contracts/agreements, logistic concepts and delivered plants.

Concerning the dimensions of supplier satisfaction, purchasers in both cases mention: the supplier rating (corresponding to supplier evaluation), the turnover development (equivalent to the growing purchasing volume from the buyer's perspective) as well as joint developments and innovations (Pulles et al., 2016). However, some interesting, new answers from this research can be added to the dimensions of supplier satisfaction: dependency of the customers on the suppliers, supplier classification, supplier audits, targets for the suppliers and the award decision process.

Q2: Information sources

Potential information sources for the supplier relationships with other customers can be differentiated into published and unpublished sources as demonstrated in figure 4. Media belongs to published sources as well as events. Media does not only cover print media in form of specialized press, but also internet search engines and internet-based RfQ platforms. Concerning complementors, the following documents are worth reading: industrial reports (Kumar, Srai, Pattinson, & Gregory, 2013), industry forecasts, scientific reports, annual reports, newspapers, professional magazines, trademark registrations and patents (Ojasalo, 2004). Events are usually

organized by fair organizers and associations. However, sometimes activities take just place on the market and thereby inform third parties about relationships.

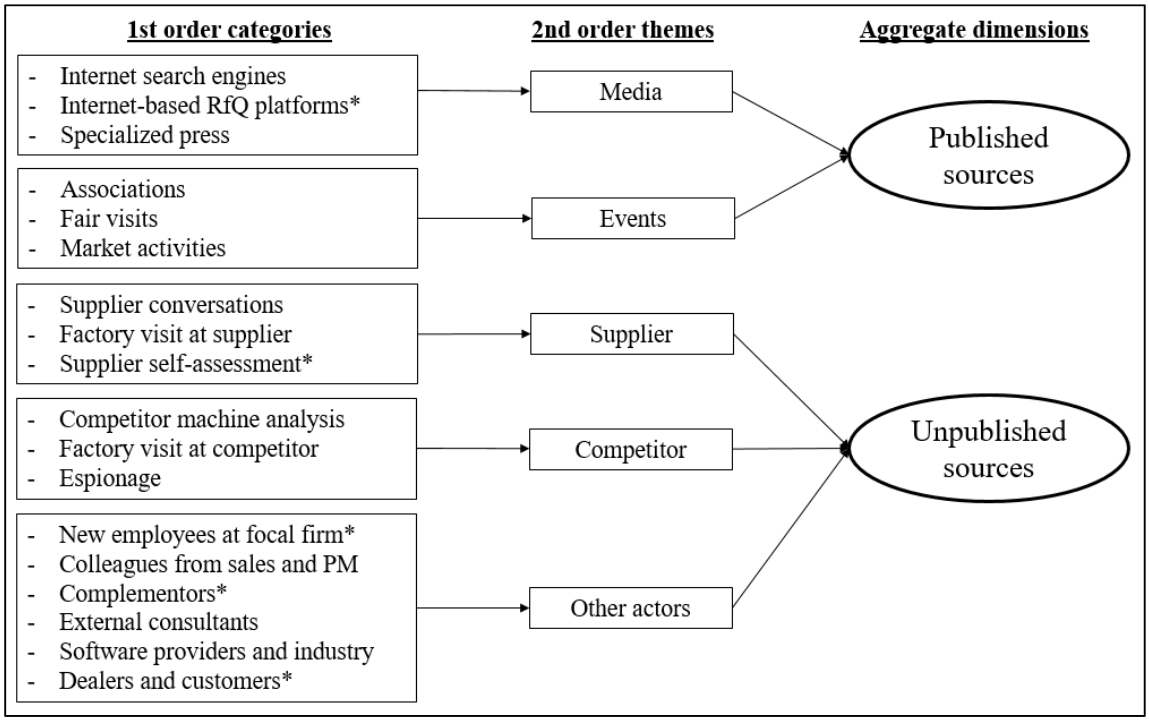

Figure 4: Data structure of information sources

Several actors can be counted to the unpublished sources meaning that they reveal information in an informal, confidential context: The most obvious of these sources is the supplier himself, who either speaks frankly with his contacts of the focal company or who gives information unintentionally during visits at his plant or because he has to do so in self-assessments for the application for new customers. The competitor tends to be more restrictive with his data, yet sometimes his plants may also be visited or one of his products can be analyzed. Espionage is another theoretical way but illegal and therefore excluded for further considerations. Furthermore, it is regarded as helpful to talk to colleagues from other departments or to new colleagues about the suppliers. Complementors, external consultants, software providers and dealers are further promising sources of supplier relationship information.

Rated by 16 points each during the World Café, the purchasers regard both factory visits at the supplier and conversations with the supplier (Ojasalo, 2004) as the most promising information sources regarding relationships with competitors. For relationships with complementors, the score is even higher, as the information policy is obviously more open regarding complementors being considered as friends of the focal company. There are several contact persons at the supplier who might provide the required information: the sales contact, back office employees, the project leader or the responsible engineer.

With eleven points on the second rank, the purchasers regard the exchange with colleagues as highly important. Networking helps to achieve information, team meetings provide also an important platform to exchange with colleagues. The technical approach via a competitor machine analysis is evaluated just as important by the purchasers with eleven points, too.

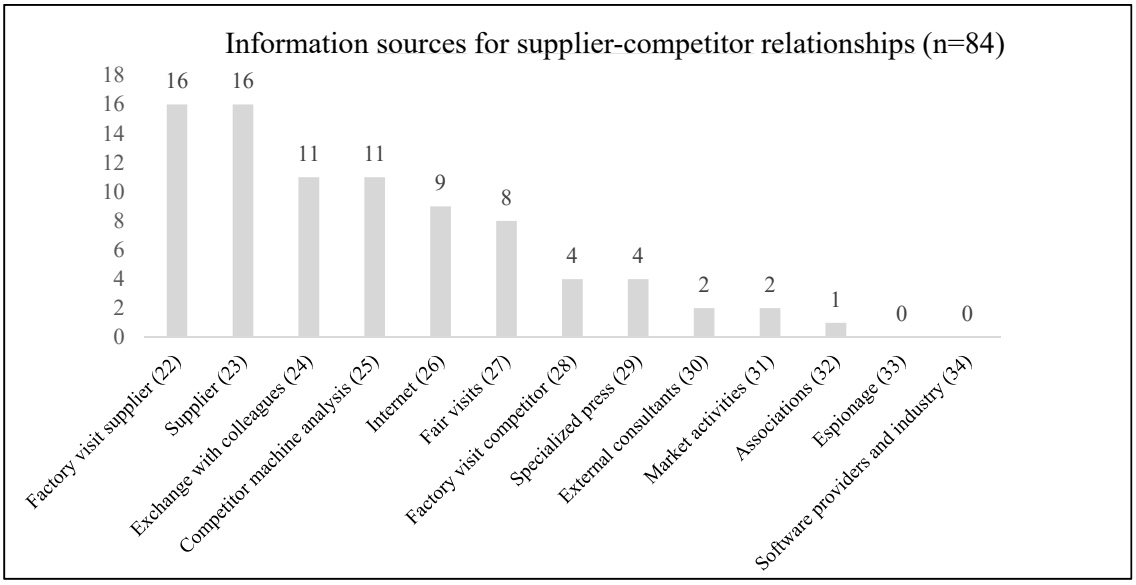

Figure 5: Rating of information sources

Q3: Contingency factors

The contingency factors can be clustered in general conditions, changes and particular occasions as demonstrated in figure 6:

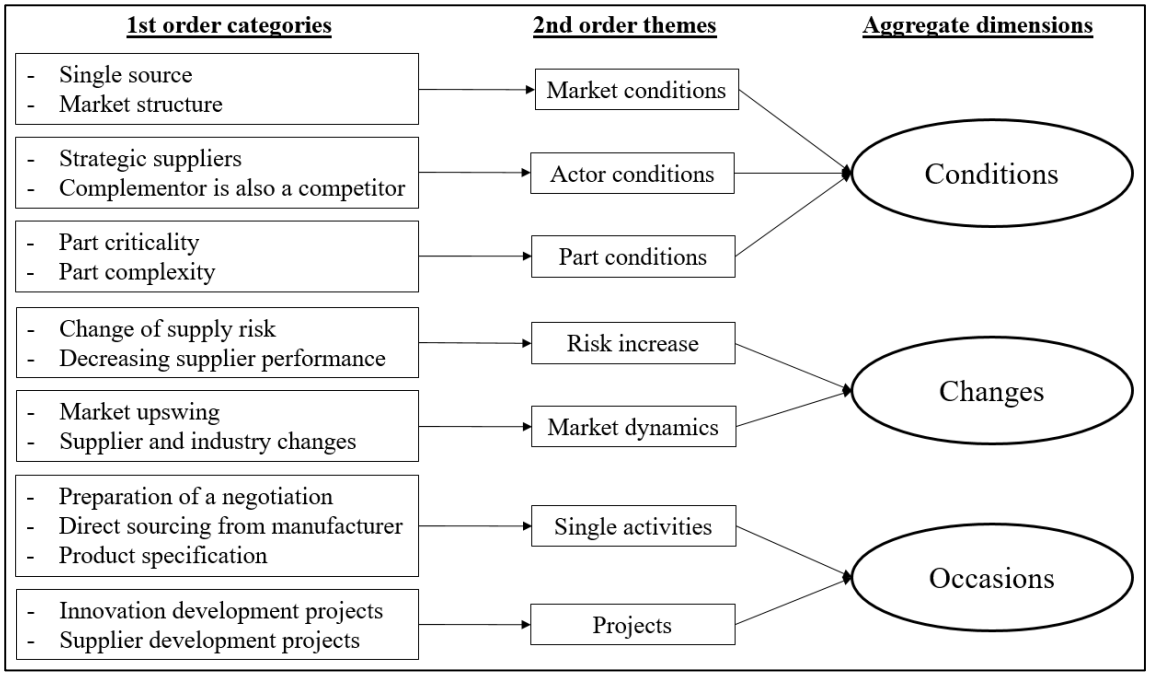

Figure 6: Data structure of contingency factors

The conditions cover the market with his structure and potential alternative sources. The purchasers give seven points to this answer during the World Café. If the focal company is a monopolist, it does not have to bother about relationships that might potentially improve or endanger its situation. However, especially for small and medium-sized enterprises that are not market leaders, it is extremely important to capture its suppliers' relationships. On the one hand for

pricing reasons, but on the other hand also to ensure that there are enough resources planned for the own orders and to secure a beneficial strategic negotiation position even without being the preferred customer (Pulles et al., 2016; Schiele et al., 2012).

Further conditions are the actors like strategic suppliers or complementors who are also competitors at the same time, as well as the part regarding its criticality and complexity. In contrast to parameters requiring a high need for transparency, a low part criticality (six votes) and a low part complexity (four votes) do not justify a high effort to search for information. According to the understanding of this World Café's participants, the part criticality signifies the percentage share of the part of the final product. Thus an A-part like the gearbox or the engine for vehicles endanger the shipment of the final product to the customer in contrast to attachment parts. The technical complexity of a part differentiates assemblies from simple or standard parts.

Apart from these static conditions, also dynamic factors play an important role for a high need of supplier relationship knowledge. Changes can concern the disruption risk which increases (Norrman & Jansson, 2004) or the supplier performance which decreases. Both changes are classified as threatening by the purchasers, as the supply risk on the top rank achieves eighteen points and the decreasing supplier performance still achieves twelve points (see figure 7). According to the purchaser discussions, a high supply risk can be suspected if parts are tool-specific, in case of a supplier insolvency or due to changes in the supplying company's property.

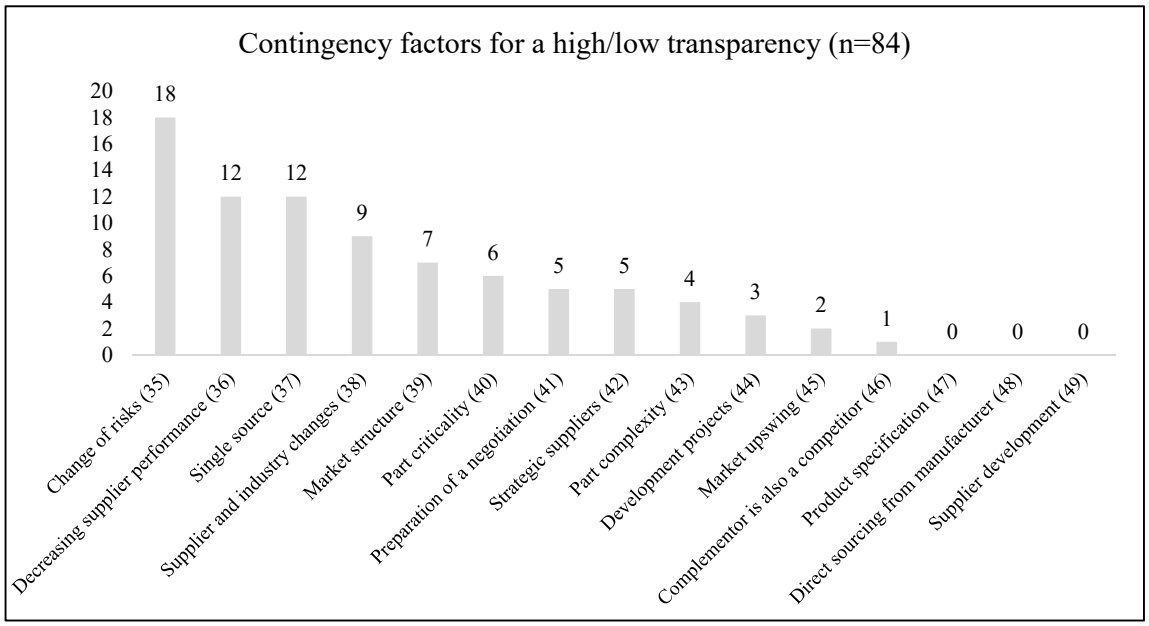

Figure 7: Rating of contingency factors

Apart from risk changes, there are also changes in the market like an upswing or significant changes for the suppliers or even the whole industry. Such trends include e-mobility drive technology, the signature of a contract to extend a business relationship or a change in the supplier's strategy and still achieve nine points by the purchasers during the World Café.

Particular occasions lead to a high need for transparency, as well. Quite often the purchasers have to prepare a negotiation, want to source directly from the manufacturer of a part or need to specify the product before its launch. Apart from these single activities, a high supplier relationship transparency also makes sense in regular innovation and supplier development projects, as this partnership is based on mutual trust.

CONCLUSION AND FUTURE RESEARCH

Contributions

Strategic purchasers of a focal company should know how their suppliers are related to their competitors and complementors. For this purpose, 14 purchasers were asked to participate in a World Café. Their answers have been clustered according to the Gioia Method.

This research leads to the following main theoretical contributions:

This article explains which knowledge purchasers should have about the relationships of their suppliers with other customers. It investigates when and how purchasers can find out how their suppliers work together with other customers. Consequently, this transparency contributes to the assessment of customer attractiveness, supplier satisfaction and the preferred customer status. In particular, this research investigates the different dimensions of customer attractiveness and supplier satisfaction. By increasing the robustness of these dimensions, purchasers are enable to better assess their own customer attractiveness. An increased attractiveness better matches the suppliers' expectations and increases their satisfaction. A standardised procedure to gather information enables companies to react faster. They can assess their status as perceived by the suppliers and in a next step actively influence it to become a preferred customer. This contributes to the literature on the benefits of preferential treatment.

The current literature on supply chain mapping presents the supply chain maps as an output, but neglects the procedure how to create them. This research contributes to the procedure of supply chain mapping. It examines the information gathering phase, which is an initial step before anything can be mapped. It suggests which information should be collected and where it can be found. Furthermore, the current literature focuses on the mapping of vertical supply chains. This article investigates the horizontal mapping of supplier relationships with competitors and complementors. The authors explain when it is important to know and map these relationships. Combining both directions enables the mapping of complex supply networks. While most supply chain mapping literature focuses on the mapping of nodes, this article proposes characteristics of supply chain linkages that should be examined. It also gives ideas how these connections can be quantified. This differentiates the current research from a pure market research on suppliers.

Moreover, this research also contributes to the work of strategic purchasers. The most important practical contributions are:

Strategic purchasers now have a checklist of the most important information that they should collect for a successful supplier relationship management. This information covers knowledge about the suppliers themselves, the business of their suppliers with other customers, and the collaboration between both parties. They profit from a collection of published and unpublished information sources that they can use to gather the desired information. Among the sample of 14 purchasers, they even know which sources these buyers regards as most helpful.

The purchasers know in which general situations and particular occasions this knowledge is important. Moreover, they can create an early-alert-system of severe changes that require a sudden increase of supplier relationship transparency.

Finally, the new knowledge can help purchasers to check and revise their supplier strategies. A well suitable supplier relationship management can again lead to a competitive advantage compared to other customers who do not have as much transparency about the relationships of their suppliers as the focal company. It helps the purchasers to assess their own customer status and to eventually switch it from a neglected to a preferred status.

Limitations and further research

The World Café has been applied in an agricultural machinery company. A generalizability of the results to other industries can be assumed, but requires a subsequent cross-sectional study across e.g. the automotive, electronics, food, construction and textile industry. Such an extension of the single case research design would certainly lead to additions regarding the required information or potential information sources and might lead to further, sector-specific contingency factors concerning the need of transparency on the supplier relationships.

Moreover, all participants in the World Café have come from the purchasing department. However, there are far more services in a company that are in a strategic collaboration with suppliers such as the research and development, material planning or product management department. The opinions of these departments on the required information about suppliers' relationships might lead to helpful additional aspects.

Even if the participants of this World Café have been purchasers with different portfolios, not all product-related commodities of the company have been represented. Maybe additional interviews with the purchasers of the remaining commodities might lead to further required information, information sources and contingency factors for the need of transparency.

Furthermore, a follow-up study with a larger sample of purchasers from different industries should follow to make the evidence generated from this research stronger and more reliable. This study should additionally explore the impact of supplier relationship knowledge on the purchasing performance. This paper has figured out which information is desirable, how it can be gathered and when it is needed. Based on these findings, it is important to further examine which activities purchasers carry out if they have this transparency and how successful they are with these activities. These results will create an additional contribution to decision-making literature. Purchasers should be able to learn from this additional study which information and which transparency-based actions will improve their purchasing performance under which circumstances.

GLOSSARY

(1)	*Prices and margins*	The prices and margins of the supplier achieve 15 votes. This is a cumulated value: 14 points refer to the pricing of identical or similar products towards other customers, while one point is granted to the pricing of the whole supplier portfolio.
(2)	*Delivered competitor plants*	To which plants of the competitor does the supplier deliver his goods? Do the supplier and the competitor go "local-for-local"? This means that the production processes of the supplier are transferred to another country, e.g. a low cost country, if the competitor opens a new plant there.

(3)	*Aftermarket deliveries*	Does the supplier deliver the aftermarket of the competitor directly?
(4)	*Turnover share and development*	How high is the share of the focal company's turnover at the supplier and how has it developed during the last years?
(5)	*Shareholdings and joint ventures*	Does a competitor own shares of the focal company's supplier or even has a joint venture with him? Especially shares of a low percentage are very interesting to find out for the purchasers, as they are not as known as joint ventures, which appear in public media.
(6)	*Contact Person and meetings*	Do the purchaser of the focal company and the purchaser of the competitor have a contact person on the same hierarchy level at the supplier? Do they maybe even share the same contact person? This would be a very difficult situation regarding the exchange of confidential information. Does the competitor achieve management attention from the supplier; is he invited to VIP-meetings? Are there any private relationships on top management-level between both companies? Such close relationships that have existed for years would be very hard to break up.
(7)	*Contracts and agreements*	Not only contracts between the competitor and his suppliers are interesting for the focal company, but also any other kind of agreements, such as logistics and tooling agreements. How are the payment terms and how is the transfer of risk fixed in the incoterms? Is there a forecast for the needs of the competitor?
(8)	*Cooperation strategy*	If a supplier is a cooperation partner, the company exchanges information with him on important topics, such as business strategies or marketing activities, on management level. This cooperation sometimes already has a long history. It is helpful to know this history and the roots of a cooperation. In some cases, the cooperation between a competitor and his suppliers is fixed within a strategic cooperation agreement, which expresses the high mutual importance of the partners. Such agreements may decide, for instance, that referent engineers of the supplier are sent to the customer for a certain period of time in order to push common development projects.
(9)	*Dependency*	Does the competitor have alternative suppliers? A first approach to figure out the answer is to ask the supplier "Who are your competitors?" Each important competitor of the supplier might be a potential alternative supplier to the focal company's competitor.
(10)	*Supplier classification*	Concerning the supplier classification, the participants of the World Café are used to work with an ABCD-classification: A-suppliers are strategic partners and B-suppliers are alternative suppliers to them. C-suppliers describe developing suppliers, while D-suppliers will be phased out after the end of the ongoing project and will currently not get any future business.

(11)	*Supplier evaluation*	The supplier evaluation assesses the performance of a supplier at his customer. Does he show a comparable performance for the competitor as he does for the focal company? Evaluated parameters include among others the supplier reliability, e.g. measured by the ppm-rate, any awards as well as audit results.
(12)	*Technology exclusivity agreements*	If a supplier has an exclusivity agreement for new technologies with one customer, he always has to present his innovation to this customer first.
(13)	*Delivery scope*	Which products does the supplier deliver to the competitor? Are these identical or just similar products?
(14)	*Development projects*	Do the supplier and the competitor have common development projects with HR exchange meaning that the supplier's referent engineer works in the competitor's facility to exchange with his engineers? Who applies for a patent for this development and owns the rights for it - the competitor, the supplier or both?
(15)	*Open-book for the competitor*	Is the supplier willing to provide an open-book calculation to the focal company's competitors? The supplier's willingness to this open communication culture is usually influenced by the relevant customer's market power. However, if a purchaser knows that the supplier refuses an open-book policy to him but practices it with his competitors, he can confront the supplier with this fact and insist on it before signing a deal.
(16)	*Targets for the supplier*	Companies often measure their suppliers by targets without knowing how challenging these targets are in comparison to goals set by other customers. Consequently, it would be interesting to figure out their goals. If the competitors are less demanding regarding the ppm-rate, for example, the focal company might be able to realize higher sales prices as their purchased quality is better. The mentioned targets also involve the reactivity of the supplier to realize more or less volume. It is important to consider the goals set in order to properly compare the supplier's performance result in the supplier evaluation between different customers.
(17)	*Award decision process*	How does the competitor assign a project to his suppliers? Which criteria does he take into consideration and how does he rate price, quality and time to make his decision?
(18)	*Process optimization*	Common process optimisations between the supplier and the competitor in order to decrease the products costs should also decrease the prices of the focal company for the identical products.
(19)	*Production processes*	Does the supplier provide a whole production line and a dedicated team for the competitor? This information can often be achieved during visits of the supplier's production, if the supplier marks the different areas of his production by the customer names.

(20)	*Innovations of the competitor*	Does the supplier offer his innovations with priority to the competitors? The decision which customer to prioritize might be influenced by the volume or the margin that the supplier hopes to realize with this dedicated customer.
(21)	*Logistic concepts*	The logistic concepts used by the supplier for the competitor give important details about their collaboration: Does the supplier use reusable packaging? Is the supplier able to manage the competitor's inventory (VMI)? Did he invest into a new consignment warehouse dedicated to the competitor?
*****	*Unknown suppliers*	Purchasers show an interest for supplier-complementor relationships to learn about new suppliers in the meaning of market research.
*****	*Supplier audit results*	A new supplier has to be audited before he can be released in a focal company. Sometimes he forwards the audit report of another comparable customer, e.g. a competitor or a complementor of the focal company, who has audited him before according to the same standards such as VDA 6.3. After a single case decision, this reference might avoid a new audit.
*****	*Supplier flexibility*	Purchasers are confronted with time pressure, as their sales representatives often have already communicated fix delivery dates to their end-customers. Therefore, the reactivity and flexibility of the supplier regarding his customers is very important. By knowing the flexibility of the supplier towards the complementors, the purchasers of the focal company wish to detect who is the preferred customer for the supplier.
(22)	*Factory visit supplier*	During a factory visit at the supplier, the purchasers shall pay special attention to the production line as well as to the shipping area inside the warehouse in order to find out: To which other customers does the supplier deliver? Labels, a customized packaging or a special container management for one customer might provide this information.
(23)	*Supplier*	The supplier sometimes mentions customers on reference lists on his website or in his company presentations. If not, the purchasers of the focal company can ask the supplier's backoffice staff who knows about delivery dates and quantities of deliveries to the competitor and who maybe has worked with both companies for years. Moreover, the supplier's sales representative might provide the desired information, as he wants to sell his products. Project leaders and engineers at the supplier are further potential contacts. More information about existing relationships can be found in supplier self-assessments with non-disclosure agreements, in which other supplied competitors are a mandatory information, as well as in audit reports by competitors, which are provided by the supplier.

(24)	*Exchange with colleagues*	Networking helps to achieve information, for example, from former employees, colleagues working at the competitors or the own engineers. Team meetings provide also an important platform to exchange with colleagues or rumours can circulate among colleagues in any other way.
(25)	*Competitor machine analysis*	A competitor machine analysis can provide the information which parts supplied by a shared supplier are mounted onto a competitor machine. Usually, either the competitor himself or an independent dealer publish this kind of analysis, or the focal company carries it out in the context of a technical benchmark.
(26)	*Internet*	In the Internet, suppliers publish reference lists containing the names of further customers; search engines display information on projects between different companies; dealer portals list supplier parts and link their original equipment manufacturer references; awards honour the successful cooperation between suppliers and their customers and supplier videos show customer machines working with their parts for marketing purposes.
(27)	*Fair visits*	Purchasers appreciate visiting fairs to examine the exhibition objects of their suppliers, competitors or complementors and to collect information material such as pictures and catalogues.
(28)	*Factory visit competitor*	A factory visit at the competitor would allow to analyse the competitor and to find out about his relationships to suppliers. However, to examine relationships in this direction is less common than a supplier visit on the opposite side.
(29)	*Specialized press*	Specialized press not only includes dedicated test reports and company magazines, but also product recalls appearing in other magazines. Moreover, annual reports indicate the supplier's turnover for each branch. If a purchaser reads in the report that his supplier makes 10 million € of turnover in the agricultural business but he knows that he only purchases 1 million € thereof, he can deduce that the remaining 9 million € must be distributed among others.
(30)	*External consultants*	External consultants provide specific knowledge, e.g. on a specific market like Russia. They might be able to name the top suppliers owing production facilities in Russia and in an ideal case also their turnover with certain customers.
(31)	*Market activities*	Market changes or activities by competitors, suppliers or sub-suppliers are usually reported in the press or presented at conferences.
(32)	*Associations*	Industry associations (e.g. the German associations VDA, VDI or BME) meet regularly on conferences to exchange across different companies about the order situation and similar issues.

(33)	*Espionage*	Espionage is an illegal way to achieve information, yet frequently practiced especially by hackers due to IT security lacks. However, it has also been proposed rather in the sense of observations: The forwarders of the focal company can observe how many loading meters of goods the other forwarders working for competitors or complementors charge at the same supplier.
(34)	*Software providers and industry*	Software providers like SAP or SupplyOn work for various companies and migrate their data. Therefore, they are able to quantify these companies‘ relationships.
*****	*Complementors*	Complementors can serve as an information source in various ways. The achieved twelve points are a cumulated value of eight points given to an organized exchange with complementors, four points granted to the proposal to ask complementors who are willing to provide information and three answers that refer to complementors but achieved zero points each: benchmarking with complementors regarding supplier evaluations, workshops with the complementors and sales statistics of the complementors.
*****	*Internet-based RfQ platforms*	The new RFQ tactic mentioned means an open RFQ process via internet platforms where everyone can see which supplier bids for which projects according to which product specification sheet.
*****	*Supplier self-assessment*	Supplier self-assessments provide information about the suppliers' customers as they contain confidentiality declarations.
*****	*New employees*	New employees who have worked before at suppliers or complementors can provide information. The idea is to implement a standardized process under the responsibility of the HR department, who automatically identify and interview these employees about their former employer's relationships.
*****	*Dealers and customers*	Dealers often offer end-products from a focal company and its complementors in their shops. Moreover, they have to purchase the spare parts for all end-products from the focal company and its complementors. Therefore, they see the branding on the parts and quite often know the suppliers who have manufactured these parts. Sometimes, an end-customer directly disassembles his machine and can also see and provide the same information.
(35)	*Change of risks*	A change of risk, e.g. the supply risk, triggers a high need for information about the supplier relationships. A high supply risk can be suspected if parts are tool-specific, in case of a supplier insolvency or due to changes in the supplying company's property.
(36)	*Decreasing supplier performance*	The performance of a supplier will decrease, for instance, if his products have quality problems. This trend will also result in a bad supplier evaluation. Customers should be aware of this negative trend in the performance.

(37)	*Single source*	Single sourcing increases the supply risk. In case of a disruption of the supplies, the customers of the supplier compete for the supplier's resources. Therefore, they better should know as concrete as possible which volumes the supplier delivers to which customers.
(38)	*Supplier and industry changes*	Supplier and industry changes can influence the need for transparency on the supply network. Such trends include e-mobility drive technology, the signature of a contract to extend a business relationship or a change in the supplier's strategy.
(39)	*Market structure*	Does the market structure show a monopoly or an oligopoly? If the focal company is a monopolist, it does not have to bother about relationships that might potentially improve or endanger its situation. However, especially for small and medium-sized enterprises that are not market leaders, it is extremely important to capture its suppliers' relationships. The market structure requires a high transparency if there are only a few suppliers.
(40)	*Part criticality*	The part criticality signifies the percentage share of the part of the final product. Thus, an A-part like the gearbox or the engine for vehicles endangers the shipment of the final product to the customer in contrast to attachment parts.
(41)	*Preparation of a negotiation*	If a supplier asks for a price increase, a high transparency on his relationships is required. During the preparation of the corresponding negotiation, the purchaser of the focal company should figure out: How many options does the supplier have? Does he deliver other customers or industries, as well?
(42)	*Strategic suppliers*	It makes a difference, if a supplier is selected only for a single project, or if he gets a long-term or even a lifetime contract and hence becomes a strategic supplier. If the purchaser of the focal company knows that such a contract exists for A-parts between one supplier and the competitor of the focal company, this might be a reason not to assign a new project to him. Moreover, during the acquisition phase of a strategic supplier or the beginning of a joint venture with him, the purchaser should try to find out as much information about his relationships as possible.
(43)	*Part complexity*	The technical complexity of a part differentiates assemblies from standard parts. A high transparency is needed for the suppliers of complex assemblies, while a low transparency is sufficient for the suppliers of standard parts.
(44)	*Development projects*	Development projects in which both parties commonly work on high-level technologies, innovations and patents cause a high need for transparency.

(45)	*Market upswing*	If there is a boom in the market, the companies would like to know, if the supplier has enough capacity to fulfil the orders of all customers. If not: Who is the preferred customer of the supplier?
(46)	*Complementor = competitor*	The complementor of a focal company can get into a competing position if he starts to sell his complementary products directly to end-customers although the focal company sells these products to them.
(47)	*Product specification*	After the phase of product specification, the purchaser achieves his budget to source this part. In order to benchmark this target price and to get a better feeling for the supplier's manufacturing costs, he tries to find out: Which product delivered by which manufacturer at which price does the competitor use? This gives an indication if the own company is in line with the competitor's specification or if it has over- or underspecified the said part.
(48)	*Direct sourcing from manufacturer*	Parts that have been purchased from dealers, complementors or component suppliers before are relocated to their real manufacturers in order to reduce margin levels and to save purchasing costs. A high transparency is necessary regarding potential exclusivity agreements between the manufacturer and the previous supplier of the parts.
(49)	*Supplier development*	Supplier development projects are run only with a few selected first-tier suppliers of the focal company. During such a project, the company matches its purchasing statistics with the data of the developing supplier to check how he manages his commodities, selects his suppliers, etc. (which consequently are the second-tier suppliers of the focal company). Such a project requires a high degree of effort and trust. Therefore, the purchaser wants to know first who the preferred customer of the developing supplier is. If this supplier also makes a huge business with the competitor of the focal company, he might not start the project as he does not want to exchange the relevant data.

Analysing government spend behaviour - end-of-year and end-of-contract purchasing patterns

Katri Kauppi; Assistant Professor; Aalto University School of Business; P.O. Box 21210, FI-00076 AALTO, Finland; katri.kauppi@aalto.fi; mobile: +358504017112
Olli Kauppi; D.Sc. Economics, Chief Economist, Finnish Competition and Consumer Authority, P. O. Box 5, FI-00531 Helsinki, Finland; olli.kauppi@kkv.fi; tel: +358295053394

Summary
The objective of this study is to understand government agency spending behaviour through quantitative econometric analysis of several years of unique framework agreement purchasing data from the Finnish government central procurement body. The focus is on understanding purchasing behaviour at contract and budgetary 'change points', i.e. whether systematic spending spikes favouring e.g. incumbent suppliers or product categories occur at end-of-year or at the end or beginning of a new framework agreement. Agency theory will be used to formulate hypotheses on spend behaviour. The results are expected to provide an improved understanding of purchasing behaviour and policy implications.

Keywords: public procurement, spend behaviour, econometric analysis, agency theory

Submission category: working paper

Introduction

Purchasing managers are increasingly using spend analysis, i.e. aggregating, cleansing and analyzing organizational spend to gain spend visibility, identify cost trends and savings opportunities, and increase process control (Angeles and Nath, 2007; Limberakis, 2012). Secondary data use is becoming increasingly relevant and important in purchasing research as well (Ellram and Tate, 2016). Supply chain journals are also calling for the use of longitudinal data instead of surveys (Guide and Ketokivi, 2015) to improve research rigour and relevance. The Finnish Government has an objective to strengthen knowledge-based decision-making and openness (Ministry of Finance, 2017). Utilizing the vast data assets of the public sector can improve decision making, ensure transparency and step up the activities of the administration (Ministry of Finance, 2017). The Finnish Government open purchasing data initiatives thus provide an excellent opportunity to conduct highly relevant and rigorous scientific research, which can provide managerial insights into purchasing behaviour and hence assist in better management of government spend in the future. Specifically, this research is designed to analyse government spend data to better understand underlying patterns in purchasing behaviour. Two particular types of purchasing behaviour, which have received scarce attention in past research, are the focus of this research. The first behaviour is a problem frequently noted to occur in government spending, but which has received little research attention, and has not been studied in the context of framework agreements previously: the tendency of government agencies to spend their remaining budget in a hurry and potentially wastefully at the end of a (fiscal) year (Douglas and Franklin, 2006; Liebman and Mahoney, 2017). The second behaviour relates to buyer preferences for incumbent suppliers, and whether such preferences concentrate purchases towards the end or beginning of a new framework agreement period. The research goal of the project is *to understand the end-of-year, end-of-contract and start-of-contract spend behavior and how it is related to characteristics of the purchases and the buyers*. The goals will be reached by analyzing data on the purchases of Finnish Government overall and via the central purchasing body framework agreements. Agency theory is our

underlying theoretical framework. We formulate hypotheses on end-of-year and end/start-of-contract government spending behavior and test these with government spend data.

Literature review and hypotheses development

End-of-year spending

Recently, economics literature has started to focus on a government spending issue termed as 'use it or lose it' (Brimberg and Hurley, 2015; Hurley; Brimberg and Fisher, 2014;). This phenomenon is related to the fact that in most public sector organizations, government funds are allocated for a fixed annual budget, which expires at the end of the (fiscal) year (Hurley et al., 2014; Liebman and Mahoney, 2017). Any unspent funds at the end of the year must be returned, and underspending may also lead to a reduced budget the following year (Douglas and Franklin, 2006; Liebman and Mahoney, 2017).Thus, even though public organisations may at the start of the year spend cautiously to ensure a buffer stock of funds is available for any unexpected expenditures, any funds remaining will be spent in a rush at the year's end (Liebman and Mahoney, 2017). This situation presents a classic example of goal incongruence between the principal (the government allocating funds) and the agent (the agency the funds are allocated to); the loss of unspent budget at the end of the year creates misleading incentives for the agent to rush to spend down balances in a way the principal would not desire (Douglas and Franklin, 2006). Therefore we assume an end-of-year spike in spending can be detected:

H1: Government agency spending in the last month of the year will be higher than spending per month on average

There are likely to be varying levels of end-of-year spending in different types of purchases, caused by differing levels of information asymmetry surrounding them. The public sector in general has been criticized for low visibility of spend (Lempinen and Karjalainen, 2010), and low visibility of spend can particularly cause information asymmetry to arise in (public) procurement (Kauppi and van Raaij, 2015). According to Kauppi and van Raaij (2015), it is often difficult in the public sector to verify whether those with ordering rights use the pre-negotiated framework agreements or not, and in general how much is spent on what items and on which suppliers. However, the spend that does fall under the centralized framework agreements is likely to be better visible to management, as the centralized framework agreements are often associated with more control and better information systems, i.e. less information asymmetry exists between the principal (the party negotiating the agreement) and the agents (those ordering via them) and the agents would likely also be aware of the better documentation of purchases via these centralized channels. Hence it can be expected that end-of-year spend is directed outside the centralized framework agreements to keep it less visible. We thus hypothesise the following.

H2a: Government agency end-of-year spending spikes will be higher for spend outside central framework agreements

Spending at end-of and start-of framework agreement periods

We can assume both goal incongruence and information asymmetry impacting government spend behavior, the former more at the end of a framework agreement period, and the latter more at the start of a framework agreement period.

Issues of goal incongruence are likely to impact spend patterns at the end of a framework agreement period, if preferred suppliers are not chosen to future agreements. Long-term buyer-

supplier relationships are posited to have many benefits, such as increased efficiency, flexibility, better access to scarce resources and advanced technology, improved performance and competitive advantage for the buying organization (Nyaga, Whipple and Lynch, 2010; Prajogo and Olhager, 2012). On a more operative level, long-term suppliers can also provide better service and assistance (Kauppi and van Raaij, 2015). Hence, prior supplier relationship may bias buyer's choice behavior (Bendoly, Donohue and Schultz, 2006). EU directives and national legislation however prevent long-term supplier relationships in the public sector as contracts have to be re-tendered every few years. This does not mean that personnel with ordering rights would not have their preferences and habits regarding which supplier to order from; an issue sometimes leading even to contract non-compliance (Karjalainen, Kemppainen and van Raaij, 2009; Karjalainen and van Raaij, 2011). If those ordering via the framework agreements have strong preferences for existing suppliers but the supplier does not win the right to participate in the next framework agreement, they may feel the agreement is not in line with their preferences even if it fulfills the purchasing preferences of the principal. Hence, buyers may inflate their ordering behavior at the end of the framework agreement period to secure goods and/or services from their preferred supplier for as long as possible. We thus hypothesise:

H2: At the end of a framework agreement period, a supplier that has not been selected to the next framework agreement will receive a spending spike.

Both issues of information asymmetry as well as status quo preference can impact spend behavior at the beginning of a new framework agreement period.

While agency theory typically refers to information asymmetry in terms of the agent having information the principal is not privy to (Eisenhardt, 1989), agency problems may arise from information asymmetry also in terms of the principal having information the agent does not know (Hendry, 2002 & 2005; Kauppi and van Raaij, 2015). This can cause increased spending with suppliers continuing over framework agreement periods compared to new suppliers entering the agreements; buyers may not know about the new suppliers immediately if the information is not widely and timely distributed in the governmental units. If employees are not aware of the contracted suppliers and ordering procedures (Karjalainen et al., 2009), it can cause them to favor suppliers that have been involved also in previous framework agreements over new ones recently selected to the contract. This can also be connected to the goal congruence and buyer preferences discussed in relation to the previous hypotheses.

In addition to information asymmetry, the status quo bias theory can also provide an explanation for users preferring suppliers transitioning from old contracts over new ones. Most decisions made have an option of doing nothing or maintaining the current decision (Samuelson and Zeckhouser, 1988). The status quo bias or effect states that humans have a tendency to stick to their previous decisions / alternatives, and this has been proven in decision-making experiments (Samuelson and Zeckhauser, 1988). Status quo bias is based on the view that an alternative's value is raised by choosing it, and this leads to bias towards that alternative in subsequent decisions (Samuelson and Zeckhauser, 1988). Overall the bias is noted as a consequence of three factors: 1) rational decision-making in relation to transition costs and uncertainty, 2) cognitive misperceptions and 3) psychological commitment due to sunk cost and regret avoidance (Samuelson and Zeckhauser, 1988).

This tendency has been noted as an obstacle for switching suppliers due to e.g. the current suppliers' performance being better known for the buyers and because of the investments already being made in the current relationship and in becoming familiar with the incumbent's product characteristics (Samuelson and Zeckhouser, 1988; Carter, Kaufmann and Michel, 2007; Wagner and Friedl, 2007). The buyer may also perceive transition costs to arise from switching to a new supplier (Samuelson and Zeckhouser, 1988). Status quo preference has

been noted in previous organizational purchasing literature (Karjalainen and van Raaij, 2011; Puto, Patton and King, 1985) e.g. in laboratory suppliers and hotel bookings (Kulp, Randall, Brandyberry and Potts, 2006) and in overall e-procurement adoption decisions (Arbin, 2008). For both the above discussed rationales, we thus hypothesise:

H3: At the start of a new framework agreement period, 'incumbent' suppliers included also in the previous framework agreement will be favored over new 'incoming' suppliers.

Data and Methodology

We employ a unique panel data set on Finnish government agencies' purchases through centralized government framework agreements tendered and managed by the central purchasing body of the Finnish government, Hansel Ltd. The data set contains information at individual government agency level on all government spending through the central purchasing body's framework agreements from July 2007 to August 2017. One observation in the data consists of the total purchases (in euros per month) of a single government agency related to a specific supply contract belonging to a given framework agreement. In total 384 framework agreements are included in the data set. The following purchase categories are included in the data: Vehicle services, Professional services, Personnel and Health services, Professional IT-services, IT-equipment, Data center equipment and services, Transportation and logistics services, Consumer products, Accommodation and meeting services, Travel services, Software, Financial services, Telecommunications, Office services, Facilities Management services and Security technology. For example for the year 2016, this means a total of 771 million € worth of purchases representing roughly a fifth of all government purchases in that year. We use Stata 15 software for the data analysis.

Detailed monthly-level data on spending and information on the starting and ending dates of the framework agreements allows us to estimate precisely the end-of-contract and end-of-year spending patterns in the data. We employ regression analysis methods to control for seasonal variation, macroeconomic trends and other factors that may also influence spending. This part of the research is still work in progress. We also document the end-of-year spending spike using a second panel data set, which contains transaction level information on all state spending for 2016 and 2017 (i.e. not limited to framework agreements), to draw comparisons between centrally organized procurement and overall government spend. This second data set applies a somewhat different categorisation to the one mentioned above (this can be seen in Figure 2 later).

Preliminary results

Figure 1 presents the distribution of all government procurement, including purchases made via the framework agreements, in 2016-2017.[1] On average, nearly 15 percent of annual purchases are made in December, with other months much closer to the 8.3% average monthly share implied by a uniform monthly distribution.

[1] We exclude energy-related products and services from the analysis. The reason for this is twofold. Firstly, energy demand is very seasonal. Demand in December is naturally very high in Finland due to the cold weather, and including energy purchases in the analysis would thus lead us to overestimate the size of the end-of-year pattern. Secondly, for accounting reasons, the spend on energy for both December and January is reported in December invoices, further leading to overestimation of the end-of-year pattern.

In Figure 2, we present December's share of total annual purchases for different product and service categories using the same data as for Figure 1. From Figure 2, however, we can see that in all categories, the purchases for December exceed the average of 8,3%. The share is particularly high in ICT-purchases (equipment, services and software), Professional and research services and Machinery, equipment and transportation equipment. Particularly the ICT equipment is an area, where one could assume updating of equipment to take place at the end of year to ensure budgets are spent, as individual purchases are often not of very high value and thus do not go through a long approval process.

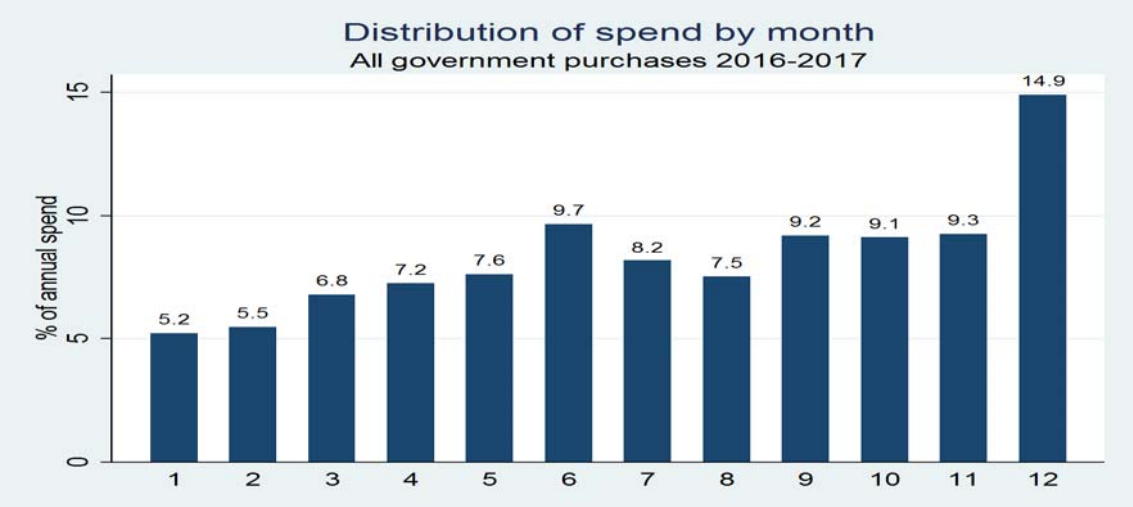

Figure 1 Distribution of spend by month for all government purchases 2016-2017

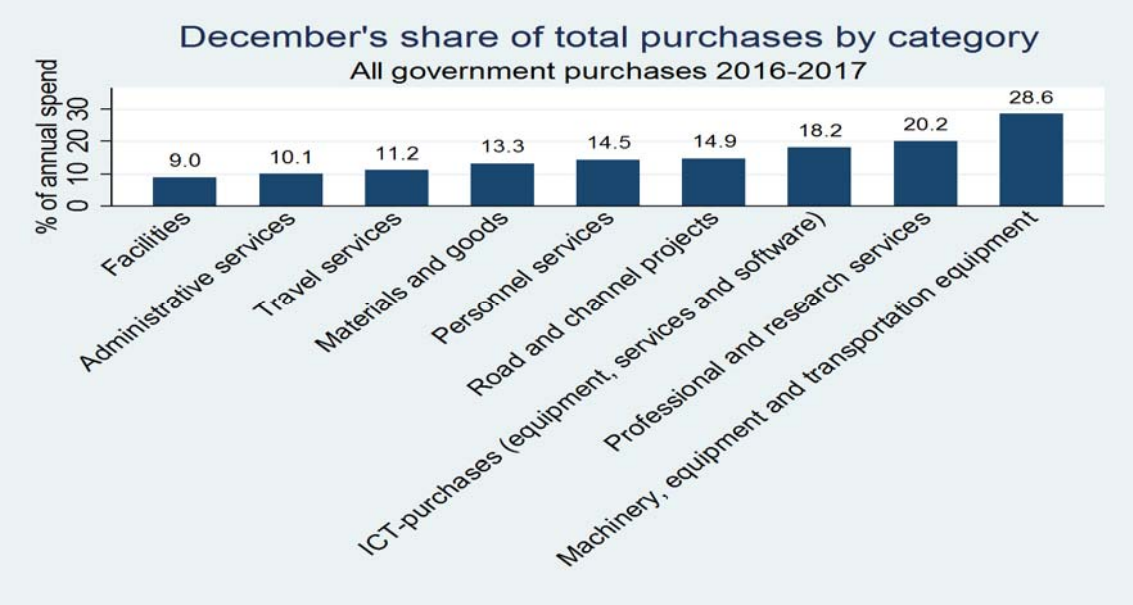

Figure 2 December's share of total purchases by category for 2016-2017

Figure 3 depicts the end-of-year pattern for different product categories using the framework agreement dataset from 2007-2016. Purchases are higher in December than on average for virtually all product categories. The highest category, accomodation and meeting services can be explained by the Christmas parties organised in each organisation typically in December (or

November), but again e.g. IT equipment is seen to have a high share of purchases in December, potentially for reasons of ensuring budgets are not cut in the following year. Overall, Figures 1-3 provide strong support for Hypothesis 1.

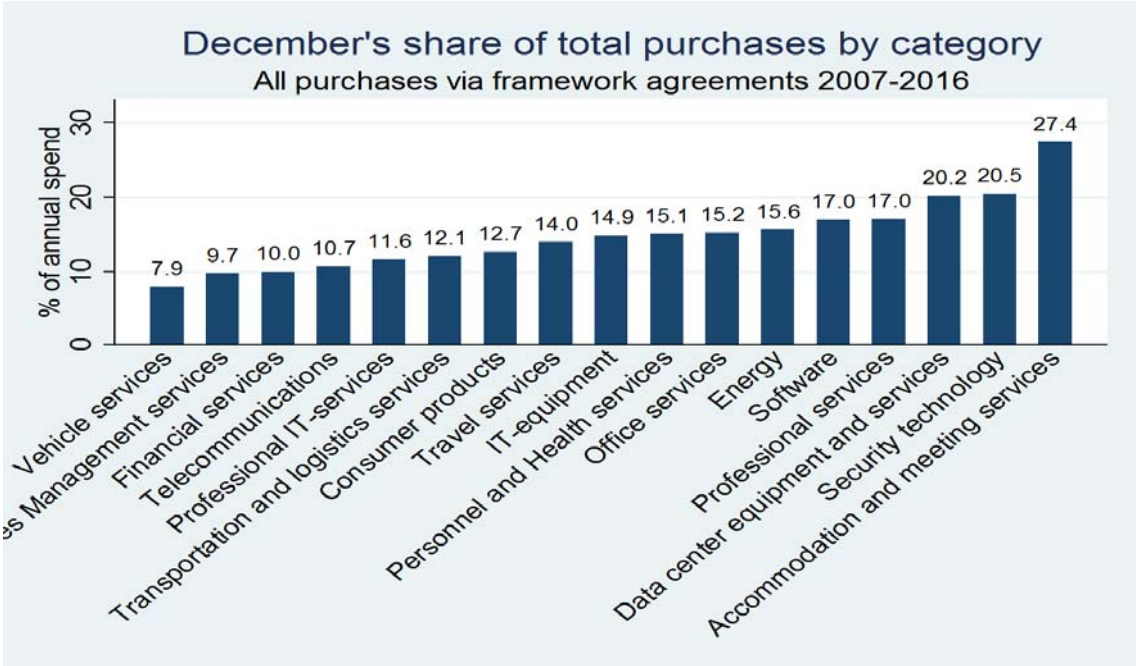

Figure 3 December's share of total purchases by category in framework agreements 2007-2016

Figure 4 compares the monthly distribution of purchases made via the framework agreements with other government procurement. To produce this graph, we combine the dataset on framework agreements with the dataset on total government procurement. The figure is based on data from 2016, the only year for which the two datasets overlap. To derive the distribution for the government purchases not made via the framework agreements, we simply deduct the purchases via the framework agreements from the figures on government total spend. As can be seen in Figure 3, the end-of-year pattern is much stronger for the government purchases not made via framework agreements. This supports Hypothesis 2. The spend via framework agreements is monitored more closely, as it is contractual spend and also reported by suppliers to the central procurement agency, thus end-of-year spend to simply spend budget would be more likely to be detected in these purchases.

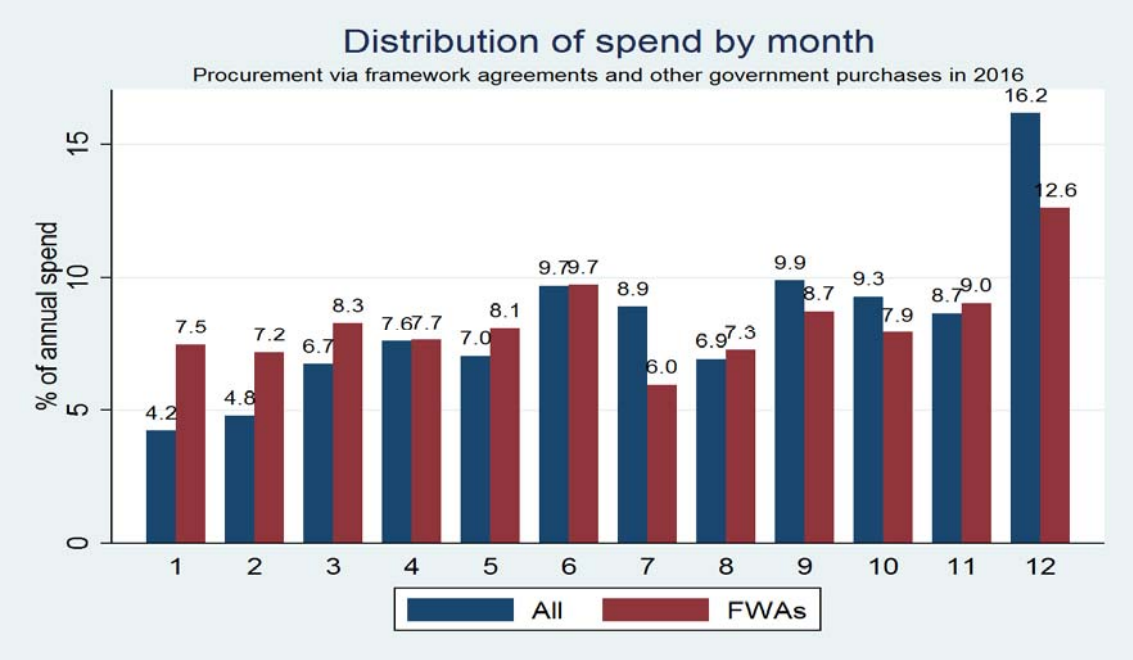

Figure 4 Distribution of spend per month comparing framework agreements with all other government purchases in 2016

Figure 5 illustrates the relationship between the end-of-year and end-of-contract patterns. We have limited the data underlying the graph to those framework agreements (2007-2016), where all purchases were made strictly within the starting and ending dates of the agreement (as within some of the framework agreements individual government agencies may have made contracts that exceed the general end-date by some months). In addition, we have limited the sample used for the graph to those framework agreements, the ending month of which was December. The monthly distribution of purchases is presented separately for the last year of the agreements and for the preceding years. As exhibited in the figure, the end-of-year spike in purchases is tempered in the final years of the framework agreements. In the final year of the agreement, December's mean share of annual purchases is 9.8 percent, whereas for earlier years it is 11.9 percent. Potentially the knowledge of a new contract with perhaps better terms serves to temper the end of year spike in spending.

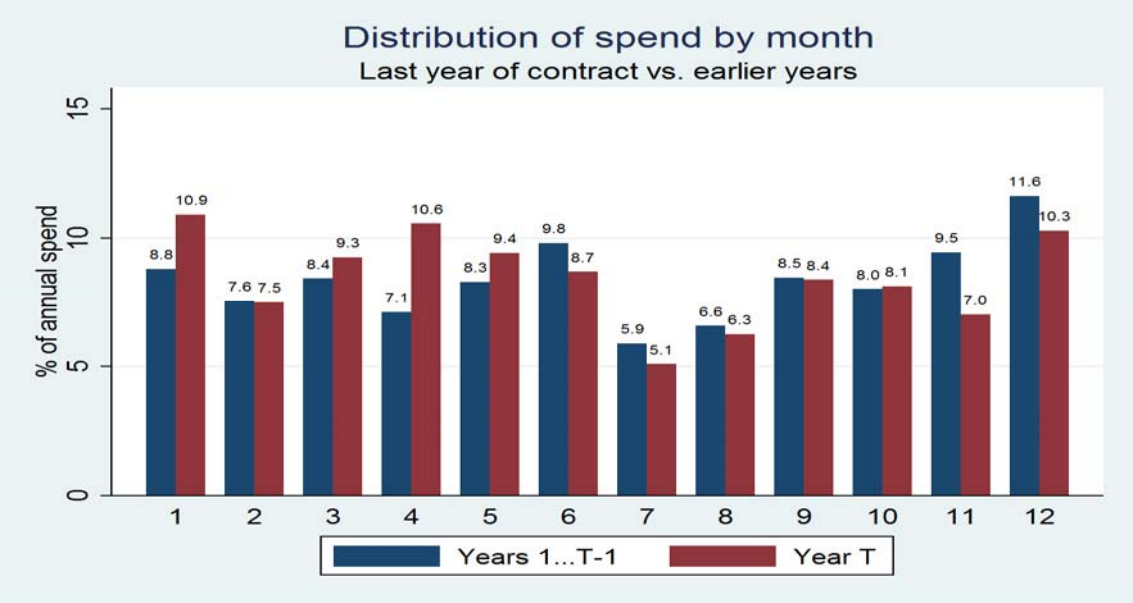

Figure 5 Distribution of spend by month to compare last year of contract spend

We are not yet able to present the results for testing Hypotheses 3. This testing requires significant manual work to match the contents of different framework agreements over the past 10 years to identify which agreement follows which one, and the work is currently ongoing. We hope to have preliminary results to present at the conference.

Discussion and expected contributions

As the research is work in progress, we only presented some preliminary results and related discussions. These results, however already provide strong support for Hypotheses 1 and 2, indicating that end-of-year spend is a significant phenomenon in government procurement, and particularly so in purchases where spend visibility is lower, i.e. supporting information asymmetry between the principal (the government) and the agent (the individual buyers) as an enabler of such spend behavior.

Overall, spend analysis is targeted at enhancing visibility, through which spend management and supplier performance can be improved (Limberakis, 2012). Data analysis with "big data" can lead to increased cost savings or improvements in procurement processes and/or overall system behaviour (Knight, Tate, Matopoulos, Meehan and Salmi, 2016). However, research on the behavioral, and potentially non-rational, aspects of purchasing has been scarce (Carter et al., 2007). Research on supplier switching is also scarce (Wagner and Friedl, 2007), as well as studies examining status quo bias in organizational purchasing. Partly these scarcities in past research have been due to lack of available data, as identifying patterns in spend behavior requires access to longitudinal purchasing data. Our unique longitudinal data on government purchases enables such identification, and later potentially improvements in government procurement based on our findings. Specifically, identifying spend patterns for end-of-year, end-of-contract and/or start-of-contract spend can provide important managerial insights in several areas. Identifying the existence (and magnitude) of potential end-of-year and end-of-contract spikes in spending (and the categories within which or the buyers by whom these appear) can 1) assist both buyers and suppliers in better forecasting spend and responding to it, 2) lead to "cost avoidance savings" in the future, if unnecessary end-of-year spend behavior can later be better controlled against. Critics of end-of year spend have noted it often results in wasteful spending on low-priority items (Douglas and Franklin, 2006), thus identifying and

eliminating it is of importance. Identifying potential supplier preferences in purchasing behavior at contract shifts and end-of-contract and start-of-contract spend can 1) assist both buyers and suppliers in better forecasting spend and responding to it, 2) provide insights to both buyers and incoming suppliers on how best to communicate and market new suppliers to ensure suppliers "transferring over from previous contract" are not over-favored over new suppliers. Overall, better understanding of spend behavior across categories can assist the buyer and the suppliers in future planning and control of government spend.

Abstract
The Video Games Industry (VGI) continues to grow dramatically. As industries mature, they rely more heavily on supply chain management (SCM) to ensure effective operations. SCM has been widely covered in many industrial areas and has more recently made forays into the service sector. Therefore, in line with other burgeoning sectors such as Tourism, there is now a heightened need to establish a structured approach to VGISCM research to meet the needs of practitioners. This paper contributes to the literature by developing existing VGISCM research by mapping, consolidating and evaluating the extant literature in order to demonstrate knowledge gaps for future investigation. Further, the work contributes to the wider literature on virtual supply chains by providing a more focused view of a specific industrial area and the drawing out of specific themes that are relevant.

Submission category: Working paper
Keywords/phrases: Supply chain; videogames; digital distribution.

Introduction

The overall aim of this paper is to start a research trajectory into the supply chains of the Video Games Industry (VGI) and establish what the extant literature area in the field of VGISCM has covered so far. The paper contributes to the literature by mapping, consolidating and evaluating this literature, to demonstrate knowledge gaps for future investigation. In addition, it serves as a "case" example of a specific industrial context for virtual supply chains in a more general sense. The work starts with a brief discussion of some key aspects of the VGI to set the context and the importance of the work. It then establishes the methodological approach to how the relevant literature was identified, selected and then analysed. The themes from this analysis are then discussed in more detail, before the elaboration of some implications for future research.

The Video Games Industry

A Brief History

Whilst some of the earliest video games originated in university laboratories earlier, it was arguably not until the late 1970s and early 1980s that typical consumers utilised home video game consoles and computers to play a variety of digital games. This preceded the 'videogame crash of 1983' (Cohen, 1984, Herz, 1997) that saw a downturn in the home videogame console market, generally believed to have been caused by poor quality titles and unsuccessful hardware launches. However, this also led to the significant development of the industry in Japan and a subsequent new generation of home videogame consoles. In tandem, home computers as videogame platforms remained commonplace and varied until the late 1990s which saw IBM PC clones become the dominant home computer platform (Farrimond, 2011a, 2011b). The late 1990s/early 2000s began to shape the industry into the form it is today, with Sony's PlayStation 2 gaining dominance prior to the launch of Microsoft's Xbox. From 2001 onwards, only Nintendo managed to continue to produce videogame console hardware to compete with Sony and Microsoft. During the subsequent 15 or so years, the continued iteration of Microsoft's, Sony's and Nintendo's products alongside the PC (and increasing home Internet availability), consumers gained greater access to content online. This content connected consumers to each other, but also to digital distribution platforms such as Steam, Xbox Live and PlayStation network – platforms that distribute products digitally, with no need for a boxed product.

The Importance of Video Games Industry Research

Whilst it is difficult to acquire precise figures, and consultancy organisations vary in their estimations, it is reasonable to assume that the value of the global videogames industry in 2017 is around US $74-$100 billion, as discussed by Kerr (2017: 32) in reviewing a variety of industry reports and consultancy sources. In addition, revenue is increasing and is greater than other entertainment industries. Mirroring a global trend, figures from the UK in 2014 demonstrated that VGI software sales alone were valued at £2.4bn, making it the biggest entertainment industry in the UK in terms of monetary value: more than film (£2.1bn) and significantly more than music (£1bn). Furthermore, and perhaps more importantly, whilst both music and film sales showed a decline year on year, digital games saw a 7.5% increase (Dring, 2015), mirroring similar findings by Kerr (2006: 49–50) comparing digital game sales to US box office revenues and recorded music sales. Whilst overall industry figures are significant, individual products compete with and often supersede revenue generation of other media. For example, 2013's highest grossing video game, Grand Theft Auto V, generated US$800 million in its first 24 hours (Goldfarb, 2013) and became the fastest entertainment property to gross US$1 billion (Pitcher, 2013).

Whilst academic interest in videogames has developed over the past 10-15 years, primarily due to the development of the field of Game Studies (Aarseth, 2001; Melcer 2015), this is not necessarily true of research concerned with the overall industry. Whilst sales have continued to increase over the past decade, academic research in this field has not paralleled this growth,

as Zackariasson & Wilson note, *"this industry has attracted surprisingly little attention from researchers of business and economics"* (2012; 1). What is clear, however, is the digital distribution and dispersed "product" development aspects of the industry mean that attention on the VGISCM is warranted. According to Sacco (2014), a significant growth in the adoption of digital distribution has been reported with 92% of PC video games sold globally via digital download. This has a direct and significant impact on the supply chain, primarily because the physical boxed product is eliminated and the reliance upon physical distribution and retail is reduced (see Figure 1 below for the traditional boxed product supply chain approach).

Supply chain management in the videogames industry

SCM overview

Definitions of SCM and its current use in different industrial fields. A rapid surge in SCM articles and books began to occur in the 1990s (Larson and Rogers, 1998). "Since its inception as a formal area of investigation in the mid-1980s, the conceptualization of the supply chain and SCM have evolved from a more narrow focus to one that today is broad and encompassing" (Stock et al., 2010: 33).

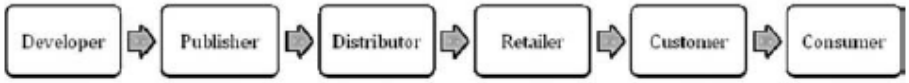
The traditional focus of SCM literature has been on manufacturing and production, where the physical flow of products can be tangibly seen as raw materials are converted into components that themselves go into larger pieces of equipment that are bought by distributors on a larger scale, before selling to a retailer who deal directly with customers. This view has been developed into service areas in which the tangible nature of supply is less clear. Similarly, largescale trends in SCM such as global outsourcing for labour and technological reasons has resulted in the development of a field of study in its own right (SCM, although this is a subfield of Operations Management). The benefits of taking a SC perspective of supply and demand are far-reaching and include, amongst others: ability to look at long term risks; consider supply chain structure and potential disintermediation.

Studies on SCM practices in different industrial sectors allow their special features to be distinguished to the applied practices, and improvement of SCM theories. These studies have been very valuable. To date, studied industrial sectors are, for example, pharmaceutical (Lurquin, 1996), automobile (Helper, 1991; Choi and Hong, 2002), apparel (Dapiran, 1992; Christopher and Peck, 1997), chemical (Vlasimsky, 2003), computer (Magretta, 1998), telecommunication (Reyes et al., 2000; Catalan and Kotzab, 2003), agriculture/food (Wilson, 1996; Cunningham, 2001) and grocery (Fernie, 1995; Zairi, 1998). Supply Chain Management has also been covered by Technovation journal, e.g. Aerospace – Berger et al., 2001; Kumer & Krob, 2005; and the special issue on Security in the Cyber Supply Chain in July 2014, but not in the Games Industry.

Concept of SCM in videogames – stages and organisations involved

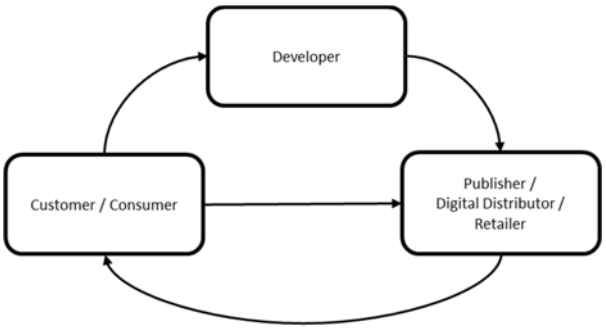
The traditional boxed product supply chain can be seen below in Figure 1. Whilst not atypical, this process makes it extremely difficult for small or independent developers to reach retail shelves without the backing of a major publisher - even if they fund their own project, they still need to find a publisher to manage distribution and retail. Although there is variation in estimates of the proportion of the sale that a developer receives from retail sales (and further study may provide a more accurate indication), many sources claim the publisher receives around 30-45% of the retail price (Yin-Poole, 2011, Good, 2015, Parfitt, 2015), which naturally means the developer receives even less, perhaps as low as 10% (Edwards, 2015).

Fig. 1 - Traditional value chain in the video game industry (Zackariasson & Wilson, 2012)



However, developments in VGI over the past 10-15 years have seen the proliferation of digital distribution. According to several sources (Yin-Poole, 2013, Francis and 2012, 2015, Parfitt, 2015), digital distribution, for example via the Internet platform *Steam*, is likely to return around 70% of the retail price to the developer - a significant difference to the traditional boxed product supply chain. Moreover, *Valve's* experiment in 2015 that allowed consumers to produce and sell their own content for developer created games (such as *Bethesda's Elder Scrolls V: Skyrim*) created a very different scenario which confers additional advantages to digital distribution for developers. Digital distribution therefore subverts the traditional supply chain and the lines between developer, publisher, retailer and consumer are blurred, often forming an iterative cycle as depicted in Figure 2.

Fig.2 - The iterative, digitally distributed supply chain (authors)



Some key aspects of the developments in the VGISCM therefore provide the practical impetus for further research in the area:

- Significant growth in the adoption of digital distribution, by developers, publishers and consumers, exemplified by 92% of PC video games sold globally are via digital download (Sacco, 2014), mean that the reliance on a physical boxed product is eliminated and the reliance upon physical distribution and retail is eliminated.
- Digital distribution platforms such as Apple's App Store and Valve's Steam (and to a lesser degree, console platforms such as Xbox Live Creators Program) enable a developer to self-publish, without the traditional need for a publishing house.
- Digital distribution offers greater market penetration, due to a changing market in terms of demographics, both from the perspective of changing attitudes towards VGI as a cultural industry but also due to the number of devices in the market that have access to digital distribution platforms for videogames by default (mobile phones, media set-top boxes ala Amazon Fire, games consoles etc).

Methodology

Scholars often question the validity and transparency of conducting literature reviews. To alleviate these concerns and conduct a rigorous and unbiased literature review, several approaches have had to be considered. A mixture of Tranfield's et al. (2003) 'systematic review' and Seuring & Gold's (2012) 'content analysis' was found to best fit with the research aims of this paper.

In detail, the first stages of the review included planning how materials would be collected and establishing the overall criteria and rules for inclusion and exclusion of studies. Specifically, the review was designed to include articles from the following six major databases: ABI/Inform Global, ScienceDirect, Scopus, Springer Link, Taylor & Francis and Web of Science. The keywords used were 'video games', 'video games industry', 'games industry', 'digital games', 'computer games' AND 'supply chain', 'Supply Chain Management', 'digital distribution', 'value chain', 'procurement' and 'purchasing' to ensure that a broad range of studies is captured. This also enables other scholars to fully appreciate the current breadth and depth of this area of VGISCM in an unfiltered manner, something which has not been previously conducted. To ensure a high quality output, only articles published in journals that are listed in the ABS 2015 Academic Journal Guide were selected.

This initial review resulted in the identification of sixteen papers and these were read by at least two of the researchers, to ensure inter-rater reliability. This resulted in the findings of Table 1 which shows the descriptive analysis as per the data extraction forms including information such as author(s); year of publication and context/keywords of study. Some of the analytic categories presented were derived from the research process model of Stuart et al. (2002), such as aim of research; method of data gathering and method of data analysis. In addition, the careful reading of the papers identified an additional three papers that were deemed relevant and these were added to the review process, totalling the number of reviewed papers to 19. This detailed analysis also provided us with a way of eliminating papers that would not contribute to a relevant thematic analysis, which is contained in Table 2. The development of themes was done inductively, allowing them to develop from the data.

Findings and Discussion

Table 1 shows the different papers that have been identified and the more descriptive aspects of them.

Table 1 – Descriptive analysis of papers reviewed

Author(s) and Year	**Keywords/Context of Study**	**Aims**	**Data capture/analysis**
Bryceson (2009)	Computer & Video Games; Agribusiness; Business Education; Supply Chain Management; Arts, Entertainment & Recreation	To introduce a prototype animated, interactive, three-dimensional virtual environment model of a supply chain in the agribusiness sector	Qualitative evaluation of model is undertaken.
Bhuiyan et al. (2015)	Computer Games; Experimental Design; Supply Chain Management Education	To explore the application of an interactive game/simulation in a supply chain context	Experimental study using Keller's ARCS model
Chiung-Lin Liu (2017)	Video Game-Based Learning; Experiential Learning; Simulation Games; Supply Chain Management; Logistics	To evaluate undergraduate students' opinions regarding supply chain and logistics management learning	Two questionnaires used to evaluate the students' perceptions
Marchand & Hennig-Thurau (2013)	Video Games; Entertainment Industry; Digital Distribution; Social Media	To pose the question as to whether flat-rate fee services are viable	The authors develop a conceptual framework of value creation

			through video games
Henfridsson & Holmström (2002)	Computer Games; Corporate Value Chain; Customer Involvement; E-Commerce; Online Entertainment; Systems Development	To explores the role of consumer participation in videogame development; how they produce knowledge, how it is exploited and how it is incorporated into packaged software	Interpretive case study of a computer game developer
Jöckel et al. (2008).	Value Chain; Computer & Video Games; Distribution ; Electronic Commerce; Experiment/Theoretical Treatment	To explore content creation and the opportunities offered by digital distribution, focusing on the prosumer – consumer created content as examined in relation to distribution, not development	Comparative case-study design
MacInnes et al (2005)	Digital Distribution; Software And Books Industries; Impediments	To explore elements that could hinder the digital distribution of books and software	Comparative case-study design
Teipen, C. (2008)	Labour Regulation; New Economy; Software Industry; Value Chain	To discuss VGI as part of 'Creative Industries' and investigate how VGIs can be more successful and expand to more markets	The empirical research is based on semi-structured interviews with industry experts and selected case studies
Wang, X., Jiang, L., & Shu, L. (2014)	Manufacturing and Logistics Industry, Fuzzy Cooperative Games, Improved Interval Shapley Value, AHP-GEM, Fuzzy Comprehensive Evaluation Method, Profit Allocation	To establish an indicator system and a new model for profit allocation in manufacturing and logistics industry alliance	Interval Shapley value method is applied and AHP-GEM method is incorporated.
Wilson, F. (2010)	Electronics Industry; Logistics; Sales Forecasting; Computer & Video Games	To generate forecast with a logistic model	N/A
Chandra, A.N. & Kurniawan, Y. (2015)	Entrepreneurs; Creative Industry; Interactive Games; ICT Strategy; Value Chain	To provide an overview to the games industry as a whole, particularly focussed on the potential of the industry in Indonesia	Qualitative analysis based on desk research and interview sources
Masur, S. (2006)	Value Chain; Technological Change; Software Industry; Payments; Games; Contracts; Advertising Campaigns; Licensed Products	To explore the development of games for mobile use, as opposed to games created for platforms like PCs or game consoles where users expect higher production values	N/A

Mai, E., Yang, J., & Chen, H. (2011)	Consumer Behaviour; Video Games; Internet; Online Video Game Industry; Complementary Products Retailing; Network Size; Customer Characteristics; Purchase Frequency	To explore the link between number of consumers who have adopted VGI products and sales of complementary products	A panel dataset was used to verify the proposed theoretical framework. Two-level hierarchical linear modelling was used to test several hypotheses
Chen, H. (2014)	Consumer Behaviour; Behavioural Psychology; Consumption Values	To empirically clarify the impact of product scarcity and uniqueness in buyers' purchase of games of limited-amount version	Data of 204 respondents were gathered using a survey method conducted and analysed with partial least square
Kim (2015)	Gamification; supply chain	Book on Gamification	N/A
Uijl, S., & De Vries, H. (2013)	Technological Change; Video Games; Consumers; Strategic Planning; Supply Chain Management; Digital Technology; Economics	A historic account of how Blu-Ray surpassed HD-DVD by building business networks, shifting allegiances and creating markets.	N/A
Sabet, E., Yazdani, N., & De Leeuw, S. (2017)	Supply Chain Management; Supply Chain Strategy; Supply Chain Integration; Agile Supply Chain; Fast Evolving Industries; Responsive Supply Chain	To define the “fast evolving industry” (FEI) and its SCM challenges	Uses a literature review to develop a conceptual model
Keskinocak, P., Xia, S., Janakiram, M., & Maku, T. (2011)	Supply Chain Management; Collaboration; Computer & Video Games; Colleges & Universities; Software Industry	To explore the application of an interactive game/simulation in a supply chain context	N/A
Broekhuizen, T.L.J., Lampel, J. and Rietveld, J. (2013)	Specialized Complementary Assets; Online Distribution Channels; Vertical Integration; Vertical Bypassing; Gatekeepers; Video Game Industry	To explore the two ‘views’ of video games distribution, i.e. that the emergence of online distribution allows content producers in the creative industries to bypass powerful publishers and distributors OR the view that this strategy cannot succeed without the complementary	Case study of the Dutch Video Game Developer (DVGD) bringing to market an identical game using two different but comparable

		assets that these intermediaries provide	distribution channels as a quasi-experiment

Table 2 shows the thematic analysis conducted, identifying key emerging themes in an inductive manner. Some papers were eliminated from the thematic analysis for the following reasons and these are useful to identify as they will provide guidance for future research in delimitating the boundaries of VGISCM and focusing their research more quickly and robustly.

- Those that looked at the application of an interactive game and/or simulation in a SCM context (e.g. Bryceson, 2009; Bhuiyan et al., 2015; Chiung-Lin Liu (2017; Keskinocak, et al., 2011) in that they are concerned with game based learning using specific contexts.
- Those that used the combination of words, but were not related to the concepts of VGI or SCM, for example Wang, X., Jiang, L., & Shu, L. (2014) which looked at the application of mathematical 'fuzzy cooperative games'.
- The search also picked up books (e.g. Kim, 2015) on topics such as gamification, which whilst of undoubted interest, did not demonstrate topical research in the area.

Table 2 – Thematic analysis of papers reviewed

Theme	**Discussion**
Change to purchasing behaviour	Influencing consumer behaviour by considering fees and publisher efforts to push from physical to digital to counter resale (e.g. Marchand & Hennig-Thurau, 2013) and ways of up-selling other products (e.g. Mai, E., Yang, J., & Chen, H. (2011), which look at initial positioning of primary products (e.g. Microsoft or Sony products) and then further sales of complementary products (e.g. purchasing Xbox360 or Wii afterwards). In addition, there is a consideration of macro-economic supply and demand factors, for example Chen (2014), which shows that product scarcity, an oft used marketing strategy, and shows that buyers bought games for perceived quality and uniqueness caused by scarcity and not assumed expensiveness.
Need for product development	Papers which provide an indication of some aspect of the product, e.g. sales of hardware (Wilson 2010) or the development of specific technologies (e.g. Uijl & De Vries, 2013).
Change of customer preferences	The key role of the prosumer in two aspects: (i) Customer influence on the development of products, specifically around how they produce knowledge, how it is exploited and how it is incorporated into packaged software (Henfridsson & Holmström, 2002) and the integration of user-made content (Jöckel et al., 2008). (ii) Customer influence on the development of distribution networks (e.g. Jöckel et al., 2008), which shows a move from the classic retail business of pre-packaged goods to a more knowledge-intensive, personalized distribution process.

Change of value creation	Value distribution and allocation in the supply chain (e.g. Chandra, & Kurniawan, 2015), which state that others will be more profitable than the "creator".
Need for localisation	A focus on specific geographical regions (e.g. Chandra, & Kurniawan, 2015), which focused on the Indonesian market.
Change to traditional supply chain structures	Supply chain structure (e.g. Masur, 2006), which shows that in certain cases, a single company might vertically integrate to act as a developer, publisher and aggregator, who acts as a retail-distributor in the sense that it provides one commercial outlet for several different publishers. In addition, there is work which identifies the role of disintermediation, in the transition from retail to Internet service provider or gaming (e.g. Jöckel et al., 2008) and those that posit benefits of different supply chain options. For example Broekhuizen (2013), identifies that the emergence of online distribution allows content producers in the creative industries to bypass powerful publishers and distributors or offering a counter view that this strategy cannot succeed without the complementary assets that these intermediaries provide. Finally, there is work, such as Teipen (2008), which sets out examples of VGISCMs (as shown in Figure 3 below).  ***Fig.3 - Graphical representation of a VGISCM (Teipen, 2008)***
Change of market size	The identification of barriers to the development and success of organisations within VGISCMs, such as being of a critical size (e.g. Teipen, 2008).
Change of market characteristics	Overall industry characteristics, specifically being categorised as a "fast evolving industry" (as per Sabet et al. 2017), which demonstrate high levels of innovation and differentiation, high-product/service variety and low-product/service life or replenishment cycles and increasingly sophisticated customers.

Although, it is not a content based theme, an area of note is the timing of research in the field is critical and that technological and consumer trends develop rapidly and more frequent research is needed. For example, the potential flat rate fees identified in Marchand & Hennig-Thurau (2013) are now a reality (e.g. as shown by Spotify) and this means that care needs to be exercised when making use of extant literature.

Conclusions & Contributions

This research has made a contribution to the games design field by offering the first systematic treatment of VGISCM. Further, it is hoped that this is the start of a research trajectory into VGISCM by the identification of specific thematic areas which gives an insight into the how digitally distributed supply chains differ from traditional models as well as the key priorities and drivers for VGI success.

Furthermore, one of the common assumptions associated with SCM is that an integrated supply chain will result in increased customer satisfaction, lower costs, and increased profitability for the supply chain as a whole (Amato-McCoy 2006; Chan et al. 2006; Harkins and Chin 1999; Yeung 2008). "This 'common sense' approach to SCM has been supported largely by anecdotal evidence provided in short case studies published in trade and professional journals. However, little empirical data beyond these case studies have been presented to substantiate those intuitive perceptions" (Stock et al. 2010: 37). This paper therefore provides additional evidence to support this debate and calls for more empirical research into the field of VGISCM to further understand the implications and opportunities provided by integrated and iterative supply chains.

It must be noted at this point that the relatively limited number of papers identified through this literature review, whilst highlighting research gaps, does suggest that a broader view of virtual supply chains is needed. This research, therefore, has provided a thematic basis and approach for this future work.

Summary

This study estimates the cost of corruption risk (CR) in the supply chain. Using an event study, we found significant market penalties for allegations of the firms' CR and its subsequent events. However, the market penalties were found to be driven mostly by initial events, but not by its subsequent events such as regulatory. Furthermore, albeit partially, this study revealed that the market reacts more negatively to CRs that occur upstream with suppliers than downstream with customers. Our regression analysis further suggested that there is no significant role as a remedy of firm accommodative response during the CR.

Keywords: Corruption, Supply chains, Event study

Submission category: Working paper

Introduction

Corruption risk (CR) has always been an issue in the global business. However, this topic is often neglected in the supply chain context. This apparent neglect is more surprising given that we are all now chronically aware of firms' corrupt behavior within a supply chain. As an example, consider the Apple's bribery issue – in 2010, a former sourcing manager was accused of receiving more than US $1 million in kickbacks from six suppliers in Asia (Kane, 2010). The then global sourcing manager pleaded guilty a few months later, agreeing to forfeit more than US $2 million. As another example, consider the Alcoa's scandal – in 2008, a Bahraini aluminum firm, known as Alba, accused Alcoa of a conspiracy involving overcharging (Simpson, 2008). According to bank records, Alcoa was found to steer payments for the material alumina more than US $2 billion over the last 15 years. Indeed, the CR should not be ignored in this field of research.

The lack of interest is more pronounced when compared to the area of general management research, where a CR seems to have been a major subject. Scholars in this field seem to pay much attention; for example, special calls by many outlets such as Academy of Management Review (Ashforth et al., 2008) can be viewed as its significant interest. This one-sided attention might be because CRs can often be regarded as a problem made by individuals and groups (i.e., "micro" view), or a problem beyond the unit level such as organization, industry and even country (i.e., "macro" view). As noted above, however, a large number of firms have been caught engaging in corrupt scandals, occurring up (i.e., toward suppliers) and down (i.e., toward customers) their supply chains. In this study, we aim to advance our understanding on this under-researched area by taking what we defined as a "chain" view of CRs (see Figure 1).

A CR is known to devastate the alleged firm's reputation (cf. Kroll, 2017). They also undermine the firm's supply chain, thus making business more costly. For example, a study by Arnold et al. (2012) argued that the damage by a CR causes the firm's financial loss of more than US $2 million in 2009. In the same year, a global survey of 729 senior executives found an average loss over the last three years associated with fraud, including corruption and bribery, of US $8.8 million (Kroll, 2017). A report by UNGC (2016) also revealed that the cost of a CR has been estimated at about US $2.6 trillion, which almost equates to over 5% of world GDP. These estimates would be good indicators for showing how detrimental a CR to the affected firm. However, their views are too micro or macro to define the true impact of a CR on the firm within a supply chain. This study attempts to overcome this limited aspect by estimating the shareholder value of target firms in the supply chain context.

In addition to the issue above, there is still a paucity of study with CR in the context of supply chain. One point is that a supply chain consists of firm activities connecting supply with demand or the opposite (Sellen and Soliman, 2002). Within a supply chain, CRs can thus occur in both directions (i.e., upstream- and downstream-facing CR). However, no supply chain studies we are aware of examine the impact of CR with this point of view. Another point of scarcity is that existing studies fail to reveal what increase the risk of corruption, and how the affected firms mitigate its consequences. This lack of research leads us to address the following research questions (RQs):

1. In the supply chain context, how does a CR affect firms' value, and how much?
2. How do upstream versus downstream CRs affect the firms' value differently?
3. What and how firm response strategy can mitigate the consequence of the CR?

This study takes a first step to examine what we term CR in the global supply chain context. Specifically, this study conducts an event study analysis to investigate how allegations of firms' CR and its subsequent events shape investors' responses. This study then examines the differential effects of a CR that occurs both upstream with suppliers (hereafter, "upstream CR") and downstream with customers (hereafter, "downstream CR"). To provide additional insights, we take a further look at firm response that might mitigate the consequences of a CR. In this study, we focus on firm's accommodative response, a strategy that could be a remedy during the CR scandal. Our results are based on a sample of 315 US publicly traded firms' CR events that were announced during 1984-2014.

By answering to the RQs, this study contributes to the literature in the following aspects. First, this study is a first effort to investigate the impact of corruption in the supply chain context. Few supply chain studies have been found examining corruption issues (e.g., Arnold et al., 2012). However, they are limited to the micro or macro view of CR, and do not provide the robust performance impact associated with CRs (for a review, see Kim et al., 2016). Second, the impact of a CR occurring up and down a supply chain is complex (Ashforth et al., 2008). In this study, we address this issue by integrating attribution (Weiner, 1985) and signaling (Spence, 1973) theories. This approach will help us to better explore the impact of complex phenomena associated with CRs within a supply chain (Wagner et al., 2011). Third, this study further extends the aforementioned framework by investigating how firm response is associated with the consequence of CR. We argue that the impact of CR can be attenuated by the affected firm's response strategy, something that has yet to be less explored in the literature.

Corruption in the supply chain

Typically, corruption involves two parties: provider (e.g., briber) and demander (e.g., bribee). Thus, a CR has a supply and demand side (i.e., wide view). Ashforth et al. (2008) noted that "the demand side focuses on corrupt institutions and officials who, for instance, demand bribes or other accommodations to conduct business transactions, whereas the supply side focuses on those who respond to the demands and, thus, perpetuate a corrupt system." Extending this view of corruption, for our purpose, this study sets a target firm as the focal point in a supply chain, and then focuses on a CR occurring upstream with suppliers (i.e., upstream CR) and downstream with customers (i.e., downstream CR), as illustrated in Figure 1. In this study, we define this view as a chain view of CR, involving the supply- and demand-side of corruption that occurs both up and down the supply chain. The chain view thus shifts a focus of analysis from the typical angles, such as micro and macro, to CRs that occur within

the supply chain context.

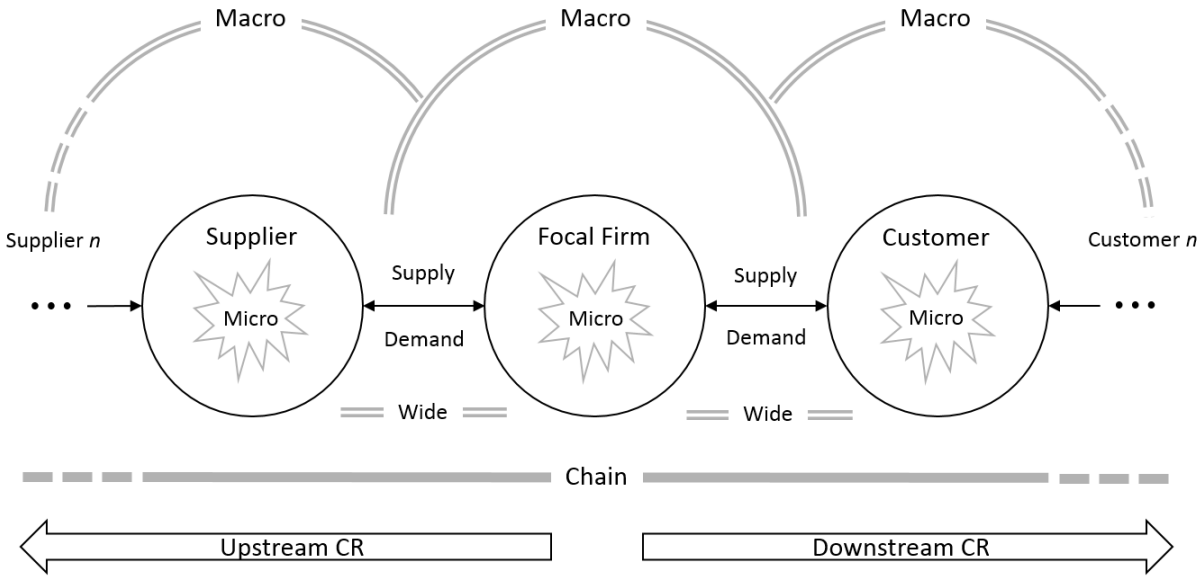

Figure 1 Chain view of CR occurring up and down a supply chain

Theory and hypotheses

In this study, multiple theories were considered to explain how a firm's misconduct regarding CR is punished by stock market. Specifically, by applying attribution (Weiner, 1985) and signaling (Spence, 2002) theories, we posit the following hypotheses: *H1. CRs will provoke a negative reaction by stock market in the target firm, H2. Upstream CRs will be penalized more by stock market then downstream CRs*, and *H3. During CRs, the market's negative reaction will be attenuated by the firm's accommodative response*.

Methodology

Data description

We compiled the data set of CR announcements via the ABI/INFORM Collection, a business database that contains the full text of the most widely read news publications. Following prior studies (e.g., Davidson et al., 1994), we chose the *Wall Street Journal* (WSJ) as our search source of CR events (1984-2014). The WSJ is the largest business newspaper in the US, which plays an influential role in shaping investors' perceptions. Our search terms consisted of combinations of the following CR-related key words such as buyer, supplier, contractor, vendor, supply, chain, bribe*, kickback, fraud, and corrupt*. We note that 1984 was chosen as the starting point because that was the first year WSJ news items regarding CR appeared.

We then read the full text of article to ensure that it was clearly about a firm's CR-related behavior. For a CR-related event to be included in our final data set, we used the following inclusion criteria: (1) alleged firms must be publicly traded on US exchanges including NYSE, AMEX and NASDAQ, (2) stock price data of the alleged firms must be available on the Center for Research in Security Prices (CRSP), and (3) the CR-related event must be

isolated from the effects of other financially relevant events such as earnings announcement. These criteria left us with a final sample of 315 CR-related events collected from 285 WSJ announcements.

In this study, building on Karpoff et al.'s (2008) typology, we categorize our sample into the following sequence of CR events: trigger, investigation, regulatory, and resolution. Here, a trigger event refers to the first disclosure of a potential CR, which include, for example, self-disclosures of misdeed and whistleblower charges. When a CR comes to the front, regulatory bodies perform informal inquiry or formal investigation. Following this investigation event, the regulators either drop the case or proceed with the investigation. We label this case as regulatory events. Finally, when the investigation is closed, a resolution event occurs. As indicated in Table 5, our sample involves 114 trigger, 29 investigation, 77 regulatory, and 30 resolution events. The other CR-related events, which are not categorized into any of the event types, were labelled in this study as "other".

Analysis of the data

This study estimates the cost of corruption (CRs) (H1) occurring up and down their supply chain (i.e., chain view) (H2). To this end, following prior studies, we apply an event study. This method is based on the principle of market efficiency, assuming that the investor's perception is immediately reflected in the stock price of a firm. It thus allows us to achieve our study aim by estimating changes in stock price associated with CR events (i.e., shareholder wealth effect of CRs). Many scholars argue that estimating stock prices or shareholder wealth is supposed to reflect the true value of firms (e.g., McWilliams and Siegel, 1997), which is what we also pursue in this study.

Shareholder wealth is typically measured by estimating an abnormal return (AR) associated with an event. Following prior studies (e.g., Brown and Warner, 1985), we estimate the AR using the market model:

$$AR_{it} = R_{it} - \left(\hat{\alpha}_i + \hat{\beta}_i R_{mt}\right),$$

where R_{it} is the return on the stock of firm *i* on day t, R_{mt} is the return of the market index, S&P 500, on day *t*, $\hat{\alpha}_i$ and $\hat{\beta}_i$, are estimated using ordinary least square regression over an estimation period of 200 trading days (i.e., –210 to –11). To capture the cumulative effect over the event window, we also calculate cumulative ARs (hereafter, CARs). For more details about its technical issues, we refer the interested readers to Brown and Warner (1985).

This study also aims to examine whether the negative market reaction to CR is attenuated by a firm's response strategy (H3). To achieve this, we estimate the following regression models in hierarchical order:

$$\mathrm{CAR}_{(-1,0)} = \beta_0 + \sum_{k=1}^{4} \beta_{1,k}\,\mathrm{Type}_{k,i} + \sum_{k=1}^{4} \beta_{2,k}\,\mathrm{Industry}_{k,i} + \beta_3 \mathrm{Size}_i + \beta_4 \mathrm{Prospect}_i + \beta_5 \mathrm{Performance}_i + \beta_6 \mathrm{Organization} + \varepsilon_i \quad (1)$$

$$\mathrm{CAR}_{(-1,0)} = \beta_0 + \sum_{k=1}^{4} \beta_{1,k}\,\mathrm{Type}_{k,i} + \sum_{k=1}^{4} \beta_{2,k}\,\mathrm{Industry}_{k,i} + \beta_3 \mathrm{Size}_i + \beta_4 \mathrm{Prospect}_i + \beta_5 \mathrm{Performance}_i + \beta_6 \mathrm{Organization} + \beta_7 \mathrm{Upstream}_i + \beta_8 \mathrm{Response}_i + \varepsilon_i \quad (2)$$

where '$\mathrm{CAR}_{(-1,\,0)}$' is the cumulative AR over the two-day event window. A number of control

variables were firstly entered as a block in Model 1, followed by main variables, the locus of CR (1 if the CR occurs in the upstream side) and firm response (1 if the event is firm response to CRs), in Model 2.

Results

As discussed earlier, we applied an event study to test H1 (negative market reaction to CRs). Consistent with prior studies, we found that, on average, a firm's CR triggers significant negative market reaction. As shown in Table 3, the mean CAR over the event window is –0.56%, which is statistically significant at the 0.1% level. The two-day median CAR is also negative (–0.29%) and highly significant. The mean and median CAR for all other intervals, which are often used in recent event studies, are small and only marginally significant. This finding confirms the assumption of what we use in this study that a firm's stock price reflects all currently available information (i.e., in this study, CR events) immediately. Taken together, this evidence provides strong support for H1.

Table 3 CAR for CRs and by its event-type

Event day [t]	Mean (%)		Median (%)		% Negative	
Day before [–1]	–0.17	(–1.62)	0.06	(–1.01)	49.52	(0.41)
Event day [0]	–0.39**	(–3.19)	–0.19**	(–2.98)	56.83*	(–2.18)
Day following [1]	0.13	(1.46)	0.14	(1.22)	47.94	(0.97)
Event window [–1, 0]	–0.56***	(–3.35)	–0.29**	(–2.83)	54.29	(–1.28)
Alternative: [–1, 1]	–0.43*	(–2.45)	–0.31*	(–2.51)	55.56^{+}	(–1.73)
Alternative: [0, 1]	–0.26^{+}	(–1.81)	–0.14^{+}	(–1.88)	54.29	(–1.28)

Notes: n = 315; t-statistics for means, Wilcoxon signed-rank Z-statistics for medians and generalized sign Z-statistics for % Negatives are shown in parentheses.
$^{+}p < 0.10$; $^{*}p < 0.05$; $^{**}p < 0.01$; $^{***}p < 0.001$.

Table 4 Robustness checks for CAR [–1, 0]

Alternative model	n	Mean (%)		Median (%)		% Negative	
Mean-adjusted	315	–0.44*	(–2.37)	–0.17	(–1.60)	52.06	(–0.81)
Market-adjusted	315	–0.51**	(–3.11)	–0.29**	(–2.86)	55.24^{+}	(–1.66)
FF three-factor	315	–0.54***	(–3.36)	–0.21**	(–2.73)	53.97	(–1.11)
FF four-factor	315	–0.53***	(–3.42)	–0.25**	(–2.81)	54.92	(–1.41)

Note: t-statistics for means, Wilcoxon signed-rank Z-statistics for medians and generalized sign Z-statistics for % Negatives are shown in parentheses.
$^{+}p < 0.10$; $^{*}p < 0.05$; $^{**}p < 0.01$; $^{***}p < 0.001$.

The above results are based on using the market model to estimate CARs, which is common practice in the literature. One may argue that our study results could be driven by the choice of the model (Brown and Warner, 1985). Scholars also argue that the results may be reflected by other factors such as size, book-to-market, and prior performance (cf. Carhart, 1997). To verify our results are robust, we thus re-estimate the CAR using mean-adjusted, market-adjusted, three-factor, and four-factor models. As shown in Table 4, our results are robust to alternative models.

To provide further insights into the market reaction associated with CRs, we estimate the CAR by categorizing the CR scandal into different types of events. Table 5 presents stock market reactions to each type of CRs. As expected, the stock market reacts most negatively to trigger (–0.90%) and investigation (–1.14%) events. However, the negative impact by investigations was found to be marginally significant ($p < 0.1$). Thus, the shareholder wealth impacts of CRs are driven by the WSJ announcement associated mostly with trigger or somewhat investigation events, but not actually by its subsequent events such as regulatory and resolution.

Table 5 CAR [–1, 0] by CR event-type

	n	Mean (%)		Median (%)		% Negative	
Trigger	114	–0.90**	(–3.04)	–0.42**	(–2.65)	61.40*	(–2.25)
Investigation	29	–1.14+	(–1.81)	–0.43+	(–1.68)	58.62	(–0.86)

This study is mainly capturing a short-run impact of CRs, which is estimated over a two-day event window. One can however argue that a CR within the supply chain may not be an "overnight issue", and thus could distort perception of the investors in a long-run way. To verify this issue, this study estimates CARs over the next 60 days (i.e., roughly a quarter) using Fama-French factor models. In our non-tabulated analysis, we only used the "trigger" events ($n = 114$), which reveal that the mean and median CARs over the post-announcement period are statistically insignificant. We also found in our sample that the average time required to end CR scandal (i.e., from trigger to resolution) is about two years. We thus re-estimated CARs over a longer period: 120, 250 and 500 trading days. As a result, no significant impacts were found for both mean and median CARs. This result provides evidence that the market is only sensitive to CRs around the event date, which is consistent with our findings shown in Table 5.

To test H2 (upstream CRs will be penalized more), we divide our sample based on its locus of CRs: upstream versus downstream. As indicated in Table 6, we estimate its differential

impacts: upstream CRs have a mean (median) CAR of –1.04% (–0.64%), while downstream CRs are associated with a mean (median) CAR of –0.42% (–0.24%). However, a t-test (Mann-Whitney Z-test) for the difference in the means (medians) of stock market reactions was found to be insignificant. To verify this result further, we re-estimate its differential impacts based on using the type of events. We found that investors' reactions to upstream versus downstream CRs are only statistically different in trigger CR events. No significant differences were found in other subsequent events of CR. This evidence provides a partial support for H2.

Table 7 Regression estimation of CAR [–1, 0]

+$p < 0.10$; *$p < 0.05$.

As a further check, we regress the two-day CAR on the locus of CR. The results are shown in Tables 7-8. As the result reveals, the impact of upstream (versus downstream) CR is only statistically significant in the trigger model (Model 1 in Table 8). For the whole sample and other types of CRs (i.e., investigation, regulatory, and resolution), its impact was found to be insignificant. This result ensures the robustness of our finding that trigger events are only significantly different in negative market reactions.

Next, we also perform a regression analysis to test H3 (the negative impact will be mitigated by firm response). Contrary to expectations, we found no statistically significant impact of firm (accommodating) response, as shown in Table 7 (largest VIF = 1.986). Earlier, we found

that there is a significant difference in market reactions between the loci of CRs, albeit only for trigger events. To make sure our regression results are not driven by this difference, we re-regress the two-day CAR on firm response using each data set. The results presented in Table 8 still show no significant impact of firm response in both upstream and downstream CRs. This evidence provides a warrant to reject H3.

Conclusion

CRs, such as bribery and kickbacks, have been a troubling issue for decades in the global business. Against this backdrop, many efforts have been made to fight corruption within and outside the firm boundary. Examples include individual firm's compliance programs, enforcement actions like the US Foreign Corrupt Practices Act, or multi-stakeholder

initiatives such as the United Nations Global Compact's 10th Principle. Despite such efforts, however, they have shown a limited success (Kroll, 2017). Although firm-, industry- and country-level initiatives are constantly being refined (cf. UNGC, 2016), CR still seems to have run rampant in the supply chain.

The aim of this study was to advance our understanding on this aspect of corruption within the supply chain context. Drawing from attribution and signaling theories, the findings of this study provide rigorous evidence on how detrimental CRs are in the supply chain (RQ1), how different the magnitude is between the loci of CR (RQ2), and how effective the firm response strategy is during the CR (RQ3). Corruption is something an important topic in the field of general management, but has been relatively neglected in that of supply chain research. As also discussed earlier, extant evidence on this aspect also seems to be too micro or macro to reveal a true impact of corruption. This study is one of the first effort to overcome this under-researched area by taking what we defined as a chain view of CR, a new perspective that has yet to be introduced in the field.

Summary

Hydroponics have been evolving rapidly during the last decade making large projects both economically and environmentally sustainable. Hydroponics are now a viable option for soilless farming nearby or even within large metropolitan areas, altering the supply chain management options on harvested goods. This paper examines the potential of major hydroponics projects within large metropolitan areas and remote areas such as islands in scope of the opportunities that arise throughout the Supply Chain.

Keywords: Logistics, Hydroponics, Green Logistics

Submission Category: Working paper

Introduction

In Hydroponics systems, production takes place in nutrient solutions (water, fertilizers etc.), inside enclosed environments, designed to control conditions such as temperature, light, water and nutrition. So every factor effecting the plants is controlled with precision, standardizing the growth and minimizing the risks (viruses, weeds, extreme temperatures or rain / hail or natural disasters).

The major advantages of hydroponics could be summarized to the following: a) high crop yield, b) indifference to ambient temperatures and seasonality, c) minimal land use, d) efficient use of water and fertilizers (controlled at drop level), e) mechanization and disease control (Jensen, 1999).

Hydroponics today

Hydroponics is gaining strength in Canada, US, Europe (western mostly) and Japan. The implementation of hydroponics projects is capital intensive and involves high level technology, most of which derives from Japan and in most cases is adjusted or even evolved in other countries applying hydroponics, as not every system is cost effective in every location. In the United States, hydroponics are used mostly for garden type vegetables, such as tomatoes, cucumbers and lettuce and lately, for marihuana, since its legalization in certain states. In Europe and Japan, the above mentioned vegetables, plus peppers, eggplants, strawberries and herbs are grown in hydroponic systems for large scale commercial exploitation.

The rapid evolution and spread of LED lights, alternative energy sources and automation processes used throughout a hydroponics project have made those technologies cheaper, thus making hydroponics economically viable, by optimizing ROI (Return On Investment) and IRR (Internal Rate of Return).

Hydroponics effects on logistics in urban areas

In terms of logistics, the current paper examines the effects of large scale food production in urban areas and the factors that need to be met for benefit optimization. In a more general definition, adopted by the United Nations, urban agriculture is an industry that produces, processes and markets food, largely in response to the daily demand of consumers within a town, city, or metropolis, on land and water dispersed throughout urban and peri-urban areas (Smit, et al., 1996).

To get a glimpse of the urbanization status, 2007 was set as a landmark for the up rise of urbanization, as the ratio of people living in urban areas to the total population exceeded 50% for the first time in history. In many countries through Europe and Asia, this ratio is well above 70% (Kourtit, et al., 2012) generating the need for more and more solutions toward sustainability in order to prevent the urban areas from collapsing in terms of economic, environmental and social discomfort.

Two major benefits of urban agriculture are: a) optimal use of resources (minimum land, water and fertilizers use), b) reduced food miles, since food is produced nearby the urban centres where it is consumed (Specht, et al., 2014). Food miles reduction, eventually leads to reducing harmful environmental emissions and cost of transportation (Bosschaert, 2008). Furthermore, less energy is used for transport, cooling, storage, and packaging, strengthening the local food system enhancing climate change adaptation and mitigation for cities (De Zeeuw, 2011).

Another major advantage is the ability to rapidly alter the products produced, according to the trends of demand. The time advantage is twofold with hydroponics near or inside urban areas reducing the time needed to adjust the production and for the goods to be distributed to meet demand in metropolitan areas.

Hydroponics, one of the most sufficient methods for urban agriculture, have also been connected to the concept of smart cities. Cities aiming towards and designed for economic, social and environmental sustainability, covering all three major factors of sustainable development. Information and communication technologies (ICT) are crucial for developing smart cities, not as an end in itself, but by enhancing the above stated economic, social and environmental sustainability of the city. So, hydroponics systems which are more often than not based on ICT could act as best practice on the concept of smart cities. According to the EU policy, smart cities should mobilize knowledge centers (universities, R & D centers, innovative private companies etc.) and motivate them to collaborate into innovation hubs. Hubs are purposed to multiply the innovation outcome above and beyond the combined knowledge, due to the multiplier effect and most importantly to disseminate the knowledge outcome beyond the hub members. As far as demand is concerned, smart cities are associated with citizens highly informed as consumers, who would prefer pesticide-free and local produce, produced and delivered to them through a highly innovative supply chain (Santos, 2016).

Agrifood Hubs could act as more specialized innovation hubs for the agricultural sector, enhancing the smart cities priorities. In particular, the Agrifood Hubs (AH) have contested over the last decades within the academic and public institutions as main enabler of the economic, social and environmental sustainability of SMEs in the dominated surrounding conventional agrifood system in developing countries.

AH provide knowledge and information for potential markets throughout the world and value adding services, promoting collaborative action/synergies and enabling market thus access particularly for SMEs through integrating agrifood supply chains, bridging small producers and the consumers-individuals and families as well as big buyers (Ploeg, et al., 2012).

Hydroponics potential in Urban Centers

The research question of this paper is to what extent hydroponics could affect food logistics in urban areas such as the Region of Attica and if the conditions for implementing large-scale hydroponics projects are met or could be met in the near future. Likewise, for isolated areas, such as the Greek remote islands, especially in Cyclades and Dodecanese. The above will be examined by reviewing literature on the effects of hydroponics on food supply chains and best practices applied and comparing the suggested conditions to the current status in Attica. Factors such as current transport infrastructure, production volume, current farming and local demand appear to be to be crucial, as suggested by current literature on the subject, along with the share of highly educated people needed to perform knowledge-intensive jobs on large-scale hydroponics projects.

In terms of transport infrastructure, the region of Attica, is supported by the port of Piraeus, Athens International Airport Eleftherios Venizelos, a vast road network leading to Southern and Northern Greece and railroad network soon to be upgraded by foreign investors. The port of Piraeus was ranked 7th in 2016 in terms of TEU (Twenty-foot equivalent unit) transport among the European ports, with a 9,4% growth compared to its 2015 performance (Notteboom, 2016). Athens International Airport (initialized as AIA), is among the newest airports in Europe and ranked 29th busiest in Europe, with 21,736,466 passengers and 7,712,580 kg of cargo (freight and mail) during 2017 (AIA Statistics).

Image 1: Greek Highways (Official Government Gazette 253/21.12.2015 - www.et.gr)

Attica is connected to major cities through national roads, with Attiki Odos as crucial infrastructure crossing throughout the Region. Indicatively:

- Athens – Thessaloniki (E 75)
- Athens – Korinthos (E 94) and Korinthos – Patra (E 65)
- Korinthos – Tripoli – Kalamata (E 65)
- Patra – Pyrgos – Olympia (E 55)
- Thessaloniki – Kavala – Alexandroupoli (E 90)

Image 2:Railroad Map (www.ose.gr)

Likewise, the railroad map connects most of the country of Greece's mainland with Attica at its center. The railroad network connects Attica with regions of high quality and volume agricultural production such as Peloponesse (Korinthos, Parta, Tripoli, Kalamata), Sterea Ellada, Thessaly, Western and Central Macedonia (Kozani, Florina, Serres).

A safe holistic approach to implement successful large-scale urban agriculture is to address all four of the following priorities (Gooch, 2005; Lee, et al., 2015; Berti, et al., 2017): a) Logistics - Supply Chain Management, b) Production Management, c) ICT Support, d) Marketing and Commercialization. More specifically:

a) closed loop short supply chains should be carefully designed and implemented, with the integration of waste management and re-use, post-harvest logistics, sourcing design and analysis, flows and inventory management, food losses and operational efficiency, transport and distribution challenges, routing problem, integration of UF into the urban logistics organism (including passenger transport, utilities transport, private and public distribution networks, safety issues etc.)

b) production types should be designed according to needs per produce, Quality Standards Systems, growing techniques, water management and irrigation technologies, soil management, Life Cycle Assessment of products, Innovative production (e.g. urban aquaculture), vertical farming, living walls, green roofs, lean optimization of production

c) ICT includes traceability systems, Customer relationship management (CRM) systems, telematics and routing optimization systems (vital for urban distribution networks), SCM and Production monitoring systems, and Warehouse Management Systems (WMS)

d) last, but not least, marketing should handle retailers' view and acceptability, potential for contractual agriculture and vertical integration (leading to investments and economies of scale), consumers' acceptability, labelling and marketing of products.

Further research is needed to examine the current load and cost of transport (inbound and outbound) for Attica in order to access the potential benefits from implementing large scale urban farming projects. Both for meeting the current internal demand in Attica and in order to export to other regions and countries. Current data implies a sufficient ratio of highly educated personnel available in Attica in comparison to the rest of Greece (on average for the period 1995-2012: 23,65% of workforce in Attica holding a higher education degree - 12,60 for the rest of Greece), but there is no previous or current experience on urban farming in Attica, especially on a large scale, let alone connected to the concept of agrifood Hubs and smart cities.

Another critical factor is the ratio of acceptance of urban farming products, since in a country with significant agricultural heritage such as Greece, consumers seem to be wary of products based on non-traditional farming methods. A factor that might ease acceptance is the fact that consumers living in urban areas are more unaware of the food sources and methods applied.

Hydroponics effects on logistics in remote areas

As far as hydroponics projects on remote areas are concerned, the most extreme example would be the one concerning Antarctica. Hydroponics has proven to be the sole source of fresh vegetables during winter in Antarctica, justifying potential to provide in other hostile environments, such as lunar bases and space missions (Sadler, 1992). On a more daily-life example, an island could become less dependent on the mainland and avoid the transportation costs. Isolated areas, such as the Greek remote islands, especially in Cyclades and Dodecanese could benefit by implementing urban farming methods, such as hydroponics, aquaponics etc. Furthermore, certain installations could also provide significant amounts of fresh water (Wahlgren, 2008), a basic good currently in scarcity for most islands.

Further research is needed to examine the current load and cost of transport (inbound and outbound) for products traded from and to specific Greek islands, ideally using individual sets of data for low and high season in order to access the potential benefits from implementing large scale urban farming projects.

Summary

Based on the thematic analysis of 432 job postings, this paper explores the desired purchasing professional skills and personality traits. We conclude that more complex skills are required with increasing buyer seniority. The desired buyer personality traits mix, on the other hand, remains stable across hierarchical levels and is dominated by the Conscientiousness characterised as independence, responsibility, compliance, and risk aversion. We argue that the observed personality traits mix suggests the prevailing transactional and support procurement role in companies.

Keywords: Purchasing skills; buyer personality traits.

Submission category: Working paper

Introduction

Industrial buyer role gains importance whilst becoming more challenging (Giunipero et al., 2006). Purchasing professionals are responsible for defining and implementing category strategy, managing supply risks, establishing long-term relationships, and leveraging innovation capabilities, while simultaneously assuring all operative tasks and striving to reduce costs (Feisel et al., 2011).

The extant literature establishes a hierarchy of buyer skills which evolve from simple procurement specific skills towards generic managerial skills (Giunipero, 2000). It suggests that purchasing managers should focus on six cumulative areas of expertise to fulfil the demanding and sometimes conflicting tasks: Technical (fundamental and basic administrative skills), Advanced procurement skills (category management, sophisticated procurement levers), Interpersonal (interaction with people in teams), Internal enterprise (market analysis and internal relationships), External enterprise (supplier relationship management), and Strategic business skills (broader strategic issues and risk management) (Tassabehji & Moorhouse, 2008). The literature also demonstrates that the skillset varies with seniority: an assistant buyer relies primarily on practical purchasing skills while a purchasing manager leverages management, information processing and communication skills (Mulder et al., 2005).

Yet, our literature review suggests that the impressive body of knowledge is based primarily on purchasing community inputs and self-reports, and may therefore potentially fall victim to the respondent bias. To gain confidence in extant literature conclusions and recommendations concerning the required buyer skills and their hierarchy, it is necessary to seek input from different informants such as top management, other functional department managers or human resources.

This paper is an attempt to provide such alternative perspective. We explore whether a different mix and more complex skills are required with increasing buyer seniority on a sample of 432 job adverts for four distinct purchasing hierarchical levels. Our empirical findings overwhelmingly corroborate previous literature conclusions. Additionally, our results suggest

that employers use the professional experience and the relevant industry experience as proxies for the required skill level.

However, the main contribution of this paper relates to the importance and mix of personality traits required from procurement professionals. Even though they were mentioned in more than 75 % of advertisements, they were not subject to extant supply chain research. We therefore adapted the widely used Big Five model of personality traits (Barrick & Mount, 1991) to shed light on what represents desirable procurement professional´s personality traits. Our results revealed a consensus concerning the required traits among employers as well as across hierarchical levels except for Conscientiousness which somewhat decreases with seniority. Consciousness represented by the autonomy, reliability, diligence, and consistency is the most valued personality trait followed by the stress resistance (Emotional stability), willingness to travel and open mindedness (Openness to experience), flexibility (Agreeableness), and proactivity (Extraversion). Such personality traits coherence and mix suggest that employers still view purchasing as a primarily transactional and operative activity.

The paper is organized as follows: we shortly review the extant literature on purchasing skills and complement it with the personality traits classification model. We then outline our methodological choices. The findings section first deals with buyer skills and competencies and then focuses on the required buyer personality traits. We conclude with opportunities for further research.

Literature review

A well-functioning purchasing department is critical for company's success (Carter, 1996). The dramatic evolution of procurement role from purchasing towards supply chain management (Kraljic, 1983) requires that the taken for granted buyer clerical and purchasing process related skills are complemented with strategic management competencies (Rodrigues, 2006). This trend was particularly pronounced in the last two decades: While buyers considered the decision making, influencing, persuasion and problem solving skills as key in 1992, the same survey highlighted the importance of 'supply chain management' and 'understanding business conditions' in 1999 (Giunipero, 2000). This section first outlines the main contributions concerning the procurement skills and competencies and then reviews the research related to buyer personality traits.

Purchasing skills and competencies

Purchasing skills and competencies can be divided into two basic groups (Kolchin & Guinipero, 1993): procurement specific and generic managerial. We apply this categorization to subsequent contributions summarized in Table I (see next page).

Scholars concur that different hierarchical levels require different skillsets (Giunipero, 2000; Mulder et al., 2005; Tassabehji & Moorhouse, 2008): Purchasing professionals first acquire the initial purchasing skills (Mulder et al., 2005) and leverage the interpersonal and negotiation skills (Giunipero, 2000; Tassabehji & Moorhouse, 2008) before moving on to the advanced procurement, decision-making, internal and external coordination skills (Giunipero, 2000; Tassabehji & Moorhouse, 2008), and finally master the management and strategic business skills (Mulder et al., 2005; Tassabehji & Moorhouse, 2008) in senior purchasing positions. Our literature review suggests that the skills evolution concept was substantiated primarily through purchasing professionals´ interviews and surveys and its validity was not tested through alternative respondents or data sources such as job descriptions, advertisements, observation or experiment.

Kolchin & Guinipero, 1993	**Procurement-specific skill groups**	**Generic (management) skill groups**
Giunipero, 2000	Strategic purchasing, Quantitative purchasing	Process management, Team, Decision-making, Behavioural, Negotiation skills
Carr & Smeltzer, 2000	Technical skills	Skills techniques, Behaviour Skills
Gammelgaard & Larson, 2001	Quantitative/ technological SCM core skills	Interpersonal/ managerial basic skills
Mulder et al., 2005	Practical purchasing Initial purchasing	Information and communication Management
Tassabehji & Moorhouse, 2008	Technical (incl. Advanced procurement process), External enterprise	Interpersonal Internal enterprise Strategic business skills

Table I: Buyer skills and competencies classifications

Purchasing professional personality traits

The extant research concerning purchasing professional personality attributes remains scattered and without theoretical anchoring. For example, Killen & Kamauff (1995) identifies four key buyer personality attributes: integrity, initiative, self-esteem and decision-making without further elaboration. Faes et al. (2001) lists 21 traits important to procurement professionals, eight of which can be considered personality attributes: integrity and honesty, self-confidence, perseverance, adaptability, extroversion, self-discipline, creativity and empathy. These traits are then clustered to one of the five buyer profiles. Other scholars mention personality traits only in passing as a prerequisite for specific buyer types such as "empathy" for the "Stimulator" buyer type (Bichon et al, 2009), or include them into a skill group such as communicativeness and persuasiveness into Interpersonal skills (Tassabehji & Moorhouse, 2008), patience and flexibility into Behaviour skills (Carr & Smeltzer, 2000), creativity into Behavioural skills (Giunipero, 2000), integrity, honesty, enthusiasm or carefulness into Personal skills (Wu et al., 2013), ambition, organizing or self-discipline into Interpersonal/Managerial skills (Gammelgaard & Larson, 2001).

Missing the guidance from the extant supply chain literature, we therefore adapt the widely cited and accepted Big Five personality dimensions model (Goldberg, 1981) which is based on the large sample factor analysis and was successfully substantiated by subsequent research. The five dimensions, also referred to as personality traits or groups, are Openness to experience, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. As Neuroticism may have negative connotations, we replace it by a neutral term Emotional stability (Barrick & Mount, 1991). Table II. outlines the continuum of each personality trait and provides typical features associated with it (e.g. Goldberg, et al., 1990; John & Srivastava, 1999; Barrick & Mount, 1991; Judge et al., 1999).

The Big five model is frequently applied to the job related research such as personnel selection, job search, training and development, or career success (e.g. Barrick & Mount, 1991; Judge et al., 1999; Kanfer et al., 2001) and suggests that high Conscientiousness scores are a good generic predictor of occupational success and superior job performance (Hurtz & Donovan, 2000), while high Extraversion and Agreeableness are particularly relevant for successful salesmen (Barrick & Mount, 1991), or that Extraversion leads to better training performance.

The Big five model was also applied in SCM research: Brauner et al. (2013) do not find any significant logistics task performance differences related to personality traits. The performance varies only based on the gender and technical self-efficacy. Periatt et al. (2007) then use the personality traits as the predictors of customer orientation and conclude, that the Openness to experience, Agreeableness and Conscientiousness should be a relevant hiring criterion for customer-oriented logistics personnel. Furthermore, they find that the relative importance of personality traits change with employee's seniority, highlighting the importance of Extraversion for managers and Openness to experience and Agreeableness for frontline employees. Conscientiousness, on the other hand, is equally important across all seniority levels.

Personality traits continuum	**Typical operationalization:**
Open to experience (different culture) Versus Closed to experience	- Associated with imagination, culture, intellectual curiosity, and artistic sensitivity, - Seeking out intense, euphoric experiences, - Preference of variety,
Conscientiousness (conscience, conformity) Versus Lack of direction	- Being careful, thorough, responsible and planful, - Organized and efficient, - Self-discipline, - Aim for achievement,
Extraversion Versus Introversion	- Optimism, spontaneity, - Energy, - Sociability, - Talkativeness, - Attention-seeking,
Agreeableness Versus Antagonism	- Compassionate, trusting, likeable, - Cooperative, - Well-tempered,
Emotional stability Versus Neuroticism	- Impulse control, - Calmness,

Table II: The big five dimensions and typical operationalizations.

Research methodology

Our research started as the test of extant literature conclusions that different buyer skills and competencies are required for different hierarchical levels. However, it became exploratory once we turned attention to the purchasing professional personality traits. This section first discusses the rationale for choosing job advertisements as a suitable data collection method for buyer skills/ competencies and personality traits analysis. We then outline the two step thematic analysis with a-priori codes.

Job advertisement analysis

Existing procurement skills and competencies research is both conceptual (e.g. Anderson & Katz, 1998; Feisel et al., 2008) and empirical. The close inspection of the supporting evidence reveals its grounding in practical experience and buyer in-depth interviews (Tassabehji & Moorhouse, 2008; Giunipero, 2000) or purchasing manager surveys (Mulder et al., 2005; Kolchim & Guinipero, 1993; Faes et al, 2001). While purchasing professionals are certainly knowledgeable informants, we cannot exclude the self-reporting bias (e.g. Jenatabadi et al., 2013) nor social desirability bias (e.g. Kovács, 2008).

To eliminate this potential weakness and gain novel insights, we opted for the job postings analysis. This approach allows us to focus on the skills and traits perceived as important not by the buyers themselves, but "by the company," as employees from different departments take part in the job advert composition (Askehave, 2010), and to collect a significant amount of data from different companies and industries. To the best of our knowledge, no paper uses job advertisements analysis to explore procurement manager competencies and personality traits.

Sodhi & Son (2010) document that the job postings analysis is a well-established research method and show that most studies use the sample sizes of 400 to 2.000 advertisements depending on the industry and geographical location, and employ geographical or economical segmentation criteria in subsequent analysis. Older studies (e.g. Todd et al., 1995) use newspaper job postings while recent papers (e. g. Chao & Shih, 2005) leverage the job posting websites. This paper closely follows the methodology employed by Schlee & Harich (2010) who evaluate the knowledge and skill requirements for marketing related jobs (e.g. Schlee & Harich, 2010).

Data collection

The job postings were collected between January and May 2017 on the three most popular job sites in the Czech Republic: Prace.cz, Jobs.cz, and Monster.cz. The former two are more generalist while latter is senior and expert jobs focused. We searched the Czech term "nákup" (roughly equivalent to "procurement") and the English term "procurement"). We made a screenshot of each posting and gave it a specific number. Each entry includes the posting title, organization name, industry (manufacturing, retail or services), date, source, hierarchical position and job advert text.

We eliminated duplicate postings (posted on multiple sites, in multiple regions by the same company or the same job advertised by different agencies). We also eliminated supply chain positions which did not concern primarily the procurement such as logistics manager or warehouse manager. In total 432 postings were collected.

Method of analysis

Thematic analysis is a qualitative research method to identify patterns within the gathered data (Boyatzis, 1998). It is an iterative process where the initial codes and analysis are often refined or completed with emerging themes. We opt for the thematic analysis approach because the sample data contain many equivalents for the same skill or personality trait and because the exact context is key.

We started our analysis with *a priori* codes of the phenomenon of interest to avoid subjective biases (Boyatzis, 1998). The main five skill groups were labelled following Tassabehji & Moorhouse (2008) taxonomy and were further broken down into subgroups following Giunipero (2000), Tassabehji & Moorhouse (2008) and Mulder et al. (2005). We coded as "Others" any skills or competencies that did not match the *a priori* codes. As the "Others" group was surprisingly large, we revisited the extant literature and added the group labelled "Personality traits" which we subdivided following the Big five personality traits model (Barrick & Mount, 1991).

While buyer skills and competences are well defined in the extant literature, we had to adopt a different strategy for buyer personality traits. Firstly, to avoid cross-cultural and cross-language differences, we confirmed that the Big Five personality traits are applicable for the Czech cultural environment (e.g. Hřebíčková & Ostendorf, 1995). Subsequently we created an initial coding protocol that we progressively refined and adapted to the procurement context through the iterative and interpretive thematic analysis.

Unlike Schlee & Harich (2010) who deduce the position from the required job experience, we use *a priori* codes adapted from Mulder et al. (2005): Junior Buyer, Buyer, Strategic Buyer and Purchasing Manager.

Data coding

We coded the data manually due to the context importance in interpreting the skills and personality traits (Sodhi & Son, 2010). To minimise the marker bias, we operationalized every

code through a coding table (Boyatzis, 1998), used three independent markers (e.g. Schlee & Harich, 2010), and developed a common and unified reference for markers (e.g. Bernardin & Buckley, 1981). We reviewed the coding criteria after approximately 10 % of the data. No major adjustments were necessary, though we added keywords for each sub-category to facilitate the coding process. We achieved 87 % interrater reliability and all differences were resolved through the subsequent group discussion.

Findings

This section first provides the basic data description in Table III. We then summarize our findings concerning the buyer skills along different hierarchical levels, and conclude with the buyer personality traits exploratory study.

Category	**#**	**Sector**	**%**	**Job posting distribution**	**%**
Job postings analysed	432	Manufacturing	60%	Junior buyer	16%
Individual codes	3 877	Retail	31%	Buyer	44%
Average codes per job posting	9.0 STDDEV 3.3	Services	9%	Senior buyer	23%
				Purchasing manager	17%

Table III: Descriptive analysis

Buyer skills and competencies

Turning attention to the number of required skills per job advertisement, the Junior buyer requires on average 7 skills and the Buyer 8.5, while the Strategic buyer 11 which is more than the Purchasing manager with 9.5. This suggests that the Senior buyer is considered a highly specialized position which employers define as precisely as possible.

The average number of required skills per posting illustrates the Technical Skills dominance with 3.4 skills per advertisement. It contains both the generic skills such as computer literacy and the procurement specific skills such as the purchasing process or product knowledge. Interpersonal skills were mentioned once per job posting on average while the remaining skills appeared only 0.4-0.6 times on average. Two other requirements not mentioned in the extant literature came out in 93% of advertisements: the foreign language proficiency (78% of adverts) and the relevant job experience (57%).

Breaking our analysis down to the four hierarchical levels allows us to shed light on the skill requirement distribution (Table IV).

Skill group	**Techn.**	**Interpers.**	**Intern.**	**Extern.**	**Strat.**	**Others**	**Pers. Traits**
Junior B.	2.4	0.8	0.3	0.1	0.2	1.0	2.1
Buyer	3.6	0.8	0.2	0.2	0.5	1.4	1.7
Strat. B.	4.4	1.3	0.5	0.7	1.0	1.6	1.6
Manager	2.5	1.4	1.0	0.9	0.7	1.7	1.4
Total	**3.4**	**1.0**	**0.4**	**0.4**	**0.6**	**1.4**	**1.7**

Table IV: Average number of skills and personality traits per hierarchical level

In summary, our analysis corroborates the extant literature predictions that different purchasing hierarchical positions require different skillsets. We document that not only the senior positions require more skills but they also demand more complex skills: Advanced technical procurement skills for Senior buyers versus the generic and rudimentary Technical skills specified for Junior buyers.

Desirable buyer personality traits

Buyer personality traits are under-researched in extant literature. Yet, at least one personality trait is mentioned in 74 % of job postings with the average of 1.7 traits per posting. Interestingly, the personality traits are distributed quite evenly across the hierarchical levels with the exception of Consciousness which significantly decreases with seniority: 1.4 mentions per Junior buyer, 0.8 for Buyers, 0,8 for Senior Buyer, and 0.6 per Purchasing managers.

Conscientiousness is by far the most desirable buyer personality trait and encompasses heterogenous traits such as independence (25 % of postings), responsibility (21%), compliance (14%), risk aversion (11%), diligence (6%), dependability (5%), consistence (5%) and task orientation (4%). It is followed by Openness to experience, also referred to as intellectence or culture (Goldberg et al., 1990), embodied by two dominant traits: the willingness to travel (16%) and willingness to learn and self-improve (7%). The Agreeableness subgroup is reduced to flexibility (20 %), the Extraversion equals buyer proactivity (13%), and finally, Emotional stability stands for the stress resistance (13%).

In summary, the personality traits appeared in 74 % of job postings. Consciousness was by far the most required personality trait followed by Openness to experience and Agreeableness. Extraversion and Emotional stability, on the other hand, seem less critical. There was no significant difference among hierarchical levels concerning the number or the required personality traits mix with the exception of Consciousness which decreased with seniority.

Discussion

Our research corroborates the extant literature claims that the required buyer skills and competencies vary for different hierarchical levels (Mulder et al., 2005; Tassabehji & Moorhouse, 2008). The difference is both quantitative and qualitative. The Junior buyer requirements are limited to a few generic Technical skills such as computer literacy or drivers licence which reflect the mostly mundane and administrative tasks such as ordering and purchasing process follow-up (Mulder et al., 2005). Buyers, on the other hand, require more advanced Technical skills and at least some Strategic business skills.

The significant qualitative leap can be observed with Senior buyers and Purchasing managers who are expected to possess the full range of skills. Interestingly, Strategic buyers require more Technical and Strategic business skills than Purchasing managers. A possible explanation is that Purchasing managers do not have to be the category experts but must possess some generic management skills (Giunipero et al., 2006) such as Internal enterprise and Interpersonal skills.

Language proficiency emerged as a widely demanded skill which has not been captured by the existing research. We believe that this is due to non-English speaking country context with a large share of foreign direct investments. Some advertisements even required an additional language (typically German or French). We expect similar results in most non-English speaking countries and argue that the language proficiency is key for modern buyers at all hierarchical levels and belongs to the basic Technical skills toolbox.

The importance, consistence and mix of required buyer personality traits suggests that employers share a very clear view of buyer personality: conscientious and able to work

independently, willing to travel, flexible, proactive and stress resistant. Previous research from other job areas suggests that Conscientiousness has the positive impact on job performance and is therefore desirable for most professional environments with the exception of Sales where the Extraversion is the key trait (Barrick & Mount, 1991; Periatt et al., 2007). From this perspective, the importance of buyer Conscientiousness is warranted, especially if we consider that it is embodied by the ability to work independently, assume responsibility and assure compliance.

On the other hand, personality traits associated with innovativeness such as intellectual curiosity, with boundary spanning such as sociability, or with the team work such as cooperation are completely missing. Similarly, the self-confidence and ambition were only almost absent. Such personality traits mix suggests that the purchasing job is still seen as a support function with mainly transactional and administrative tasks, far from the active and strategic role the extant and practitioner literature assigns to it.

Concluding remarks

This paper explores the skills and personality traits required for four purchasing hierarchy levels in 432 job postings in the Czech Republic. The selected data collection method purposefully deviates from previous studies which are based on surveys (e. g. Giunipero et al., 2006; Mulder et al, 2005) or in-depth interviews (e.g. Tassabehji & Moorhouse, 2008) and which may fall victim to self-reporting and social desirability biases.

Our original research question tested the extant literature proposition that more and qualitatively different skills are required for different buyer seniority levels. The results corroborate this claim: Junior buyers are expected to possess only generic Technical skills, while Senior buyers need to command the Advanced technical skills as well as some Strategic business skills. Finally, Purchasing managers witness the most balanced skillset requirement. We also document that the minimum work experience requirement is used as a skills proxy for Buyers and Strategic buyers. Finally, we complement the Technical skills with the foreign language proficiency which seems to be mandatory for buyers in non-English speaking countries.

Subsequently, we adapt the Big five personality traits model to shed light on the required procurement professional personality traits and conclude that there are no significant differences across hierarchical levels and that Conscientiousness is by far the most required trait, which suggests a somewhat administrative and support view of procurement.

Limitations and further research

While the adopted research method complements the existing research, it limits the generalizability of our findings due to the sample size, geographical range, and the data source which is biased towards the industrial buyer jobs. Yet, we believe that our research opens several research opportunities: Firstly, alternative personality traits frameworks may provide additional insight. Secondly, research covering a wider geographical or cultural area may reveal different key personality traits. Thirdly, different data sources and in particular the qualitative research approach may contribute to the initial theory development. Finally, a study exploring the link between the buyer personality traits and job performance similar to Martin (2011) research on salesmen would greatly contribute to our understanding of the construct relevance.

Abstract

Based on primary research, TITANS and NETWORKED – two scenarios of the future of procurement and supply management (PSM) in fifteen years – describe how the wider business landscape might change and the consequences for PSM. Whilst the business landscapes portrayed are highly contrasting, and the overarching contribution of PSM in each setting is different, several key implications are the same for both scenarios. Findings are related to past research on PSM function maturity and strategic contribution. They highlight a number of strategic 'blindspots' and discuss the need for deepening insight and improving foresight, particularly related to market concentration and dynamism.

Key Words: procurement, maturity models, scenario

Acknowledgements: This study was funded by, and conducted in partnership with, the Chartered Institute of Procurement & Supply (CIPS) (UK). We are very grateful to interviewees, workshop participants and the knowledge team at CIPS (Sheena Donaldson, Nicola Robinson, Helen Alder).

Introduction

Contemporary business environments are marked by rapid and constant transformations (Kamann, Dullaert and de Leeuw, 2016, Steiber and Alänge, 2016). Organisations' responses to these transformational forces impacts their competitiveness, effectiveness and sustainability, and include a range of challenges for procurement and supply management (PSM). Despite many studies by consultants and professional associations on the future of procurement and supply management (FPSM) and the future of supply chain management (FSCM), academic studies are limited in volume, and few explore the *combined* impact of supply-side macro-environmental challenges, or the consequences for PSM. Relevant PSM knowledge is available, but fragmented, often implicit, or focused on a specific sector or factor.

FPSM as with any other field, is a difficult, complex area of study – the future landscape is not necessarily a continuation of the past and present, and developments are not deterministic. Powers of prediction are limited to short time frames, and even then, unexpected events occur. Paradoxically, these challenges increase the importance of future-orientated research (May,

1982). Future-orientated studies can help stimulate debate on preparedness for change. The best way to predict the future is to influence the discussions on what it could, or should be (Corley and Gioia, 2011).
A common theme across these studies is repositioning PSM's contribution as strategic. In this paper, we argue that the notion of strategic PSM should include consideration of a wider influence, particularly around collective actions that cumulatively shape future supply markets. This does not imply a normative positioning of PSM practice; it is an acknowledgement that PSM actions do not purely react *to* future markets, but that current practice *shapes* them. If PSM is to be truly strategic, its preparedness to respond to macro transformations and its capability to inform, influence and shape organisational directions and the wider business context must be addressed. The study addresses three research questions: (RQ1) In 15 years+ time, how might the context for PSM have changed? (RQ2) In such circumstances, how would PSM contribute to organisational goals and performance? (RQ3) What are the implications for PSM development?

Based on literature, interviews and workshops, we developed two FPSM 'plausible futures' (Wright and Goodwin, 1999). Importantly, these scenarios are not forecasts, just possible futures, used here to frame a research agenda. We link our study to purchasing maturity research to understand what outcomes a high performing PSM function of the future would deliver and how this would be achieved through practices, structures and other attributes. Our contribution concerns 'prescience', "the process of anticipating what we need to know, and ... influencing the intellectual framing and dialogue about what we need to know to enlighten both academic and reflective practitioner domains" (Corley and Gioia, 2011: 13). It aligns with growing calls for more engaged, participatory, management research, in response to the criticisms of scholarly irrelevance to practical issues (Bennis and O'Toole, 2005), and increasing recognition of PSM-related activities' impact on societal and environmental degradation (Meehan, Touboulic and Walker, 2016). The need for future orientated research embracing 'disciplined imagination' (Weick, 1989) is appropriate for emerging phenomena or new paradigms where, by their very nature, empirical data are not available (Fawcett, Waller, Miller, Schwieterman, Hazen and Overstreet, 2014).

Literature Review: procurement and supply management maturity
FPSM studies tend to look backwards, using content analysis of prior academic literature, to draw conclusions on future trends (Giunipero, Hooker, Joseph-Matthews, Yoon and Brudvig, 2008, Mogre, Lindgreen and Hingley, 2017, Spina, Caniato, Luzzini and Ronchi, 2013, Zheng, Knight, Harland, Humby and James, 2007). Some use case studies and participatory interviews (Carter and Narasimhan, 1996, Storey, Emberson, Godsell and Harrison, 2006, Tassabehji and Moorhouse, 2008). More innovative, future-orientated methods have yet to be widely adopted. Misalignment is a common theme in prior studies whether in theory-practice gaps (Storey et al., 2006), differences between functional-organisational perceptions and expectations (Tassabehji and Moorhouse, 2008), or in problems defining boundaries between the function and its processes (Zheng et al., 2007).

The dominant message in prior studies is that purchasing and SCM have strategic potential (Carter and Narasimhan, 1996, Giunipero et al., 2008, Mogre et al., 2017, Storey et al., 2006, Tassabehji and Moorhouse, 2008). Strategic impact is variously positioned including improved supply structures and cost improvements (Carter and Narasimhan, 1996), sustainable practices (Carter and Narasimhan, 1996, Mogre et al., 2017), skills development (Tassabehji and Moorhouse, 2008), and digital and e-business (Mogre et al., 2017, Zheng et al., 2007). Despite PSM's role in supply chains and, with the exception of the sustainability agenda, PSM's

strategic influence is still focused within the organisation, rather than the wider consequences of supply-side actions. Organisations are seen as market-taking (Spulber, 1996), rather than active in shaping markets through their sourcing decisions (Grandia and Meehan, 2017, Knight, Pfeiffer and Scott, 2015). And yet it is recognised that the political power of a few corporates grows as their revenues rival those of national governments and influence impacts beyond their contractual reach shaping markets, policy and society (Zingales, 2017). The potential wider role in market shaping is recognised in public procurement (Caldwell, Walker, Harland, Knight, Zheng and Wakeley, 2005, Grandia and Meehan, 2017, Knight et al., 2015). The collective impact of supply decisions in other sectors attracts little academic attention (e.g. Grandia and Meehan, 2017, Knight et al., 2015).

Strategic procurement implies procurement maturity. Maturity models commonly establish auditable, cumulative stages, typically from a process orientation through to a sophisticated value-based contribution (Rozemeijer, Weele and Weggeman, 2003). Van Weele, Rozemeijer and Rietveld, (1998) offer the only procurement maturity model that explicitly states the importance of both internal and external integration as separate stages. The staging of the maturity models has tended to ignore the factors that influence evolution and change, though more recent research acknowledges that adaptive change is situational and context-dependent (Andreasen and Gammelgaard, 2017). Empirical research highlights the importance of enablers (employee capabilities, training, IT system support, and performance tracking) to act as catalysts to more mature procurement activities and in developing strategic alignment between resources, capabilities and competitive advantage evolution (Kerkfeld and Hartmann, 2012).

Maturity is often taken as a proxy for strategic impact, yet there are arguably some subtle differences. Maturity relates to the range and scale of activities undertaken (Rozemeijer et al., 2003) while strategic procurement relates to the demonstrable impact of these activities in a competitive context. Evidence of the links between these is still lacking (Zimmermann and Foerstl, 2014). Common assumptions are that internal stakeholders will buy in to a mature procurement function, that organisations will empower buyers to undertake strategic activities, and that PSM will follow a predictable development path. We need however to understand what a high performing PSM function of the future would deliver (outcomes) and how, without assuming incremental change is possible. We also need to be open to pathways to different plausible futures, which might be very different to past development trajectories.

Methodology

Scenario planning as a research methodology is growing in popularity (Ramirez, Mukherjee, Vezzoli and Kramer, 2015). The philosophy of this method is not about prediction per se, but an opportunity to explore critical drivers and uncertainties and consider plausible images of the future. This study is a scenario exploration (Rowland and Spaniol, 2017). Following Tapinos (2012) the process has two key aspects: i) developing scenarios ii) exploring their impact. This allows us to: debate and define potential radical shifts in supply landscapes and PSM data/systems; develop scenario narratives that are plausible, coherent and thought provoking; and elucidate potential implications for PSM's future contribution, activities and resources. The narratives are critiqued in light of broad ranging future studies (i.e. not PSM-specific), and past research on purchasing and PSM's functional maturity and strategic contribution.

The study followed the most common steps of the intuitive logic scenario process (Hussain, Tapinos and Knight, 2017). Preparation involved desk-based review of academic and professional literature on macro-environmental forces and their impact. Interviews with 20

senior executives, consultants and academics from a range of sectors allowed us to explore awareness of, and responses to, these trends, and probe the driving forces and uncertainties. We built two scenarios inductively (Ramirez et al., 2015). Insights from the interviews formed part of the introductory briefing for six workshops with PSM senior experts to verify the uncertainty dimensions, elaborate the scenarios and consider their impact on PSM. With the emphasis on disruptive change and tipping points found in literature and our fifteen-year time horizon, we focused on radical change both to PSM data and system and to the supply landscape. Workshops were recorded and transcribed, and analysed using NVivo to enable open and axial coding.

The degree of change envisioned by participants was not as extensive as expected from the literature and interview stages. Whilst the workshop discussions revealed some significant gaps in issues capturing participants' attention, the analysis provided a strong basis for writing the first scenario, TITANS. Further analysis and revisiting literature on macro-environmental trends led us to recognise a coherent set of factors presented in future studies (e.g. Dewing and Jones, 2016), which were neglected in TITANS. These factors formed the core for the second scenario, NETWORKED. Thus, whereas the TITANS scenario is tightly linked to the interview and workshop data, reflecting the voice of PSM experts, NETWORKED is strongly influenced by our reading on macro-environmental forces, and so reflects the voice of experts in PSM future studies. The logic, coherence and plausibility (Wright and Goodwin, 1999) of the two inductively derived scenarios were assessed through further analysis (see themes in Table 1) and literature review, following up on key themes such as market concentration. The full scenario descriptions are provided in the study report published by the Chartered Institute of Procurement and Supply (available via CIPS website or from the authors).

The TITANS Scenario

Named after the 'tech titans' (Apple, Google etc) but also considering firms in infrastructure sectors, the TITANS scenario describes a highly polarised business landscape in terms of firm size and power, with tight-knit business groups centred on titan firms. Paradoxically, better data will underpin collaboration and deep integration of business groups, as well as fuelling rivalry between them. Beyond and around the business groups, commercial interactions will be short-term and arms-length, even for higher value/higher risk items, many of which will have become commoditised.

Familiar structures will have disappeared with banks, contracts, and accounting methods fundamentally different. Distributed ledger technology (DLT) will be used for crypto-currencies, smart contracts, and monitoring compliance. DLT will be widely deployed by traditional businesses; private control will reduce its potential for full transparency. Algorithms take decisions on new potential suppliers, sourcing, contract management and de-listing non-performing suppliers. Decisions will be brand and sustainability 'blind' unless such criteria are explicitly written into algorithms. For many purchases, there will be reduced attention to sustainability and price-dominated decisions. Reduced cost and increased speed of transactions will reduce the relative benefits of supply base consolidation and enable rapid switching. Market dynamism will be much increased. Firms will more frequently adapt their business strategy, often diversifying and integrating with partners. Buyers will have to work with less predictable suppliers and will more often find they have to compete for supply.

Many supply chains will have been radically reconfigured, driven by widespread adoption of additive manufacturing (3D printing) and servitisation. Data-driven integration will generate supply chains that are highly efficient but very vulnerable to shocks. Attention will shift from

resilience towards agility. In the highly dynamic and unpredictable business landscape, PSM leaders will emphasise 'future-proofing', strengthening capabilities to cope with, and capitalise on, whatever future unfolds. Agile sourcing will be a key capability, enabled by advanced systems and big data. Data security will be a huge risk, with supplier breaches having the potential to destroy firms. Managing relationships with outsourced systems and data providers, and key intermediaries, will become a strategic category in its own right.

PSM leaders' principal strategic contributions will be risk management and supporting business strategy. Risk management will manage the increased uncertainty from market dynamism, dealing with volatility and unpredictability. PSM experts will manage supply-side resources to facilitate rapid adjustment of business strategies. Developing plausible futures, combined with advanced analytics skills will be essential for accessing, interpreting and acting on hard data and weak signals about critical changes in the environment.

The NETWORKED Scenario

The NETWORKED landscape will be characterised by more evenly distributed firm size and market power, and tightly embedded inter-organisational relationships. Widespread coordination between organisations will pool resources, and enable co-buying, often centred on regional networks. Reciprocal trading, with offset agreements and counter-trade will increase. Flatter organisational structures, the sharing economy and public scrutiny, will see decision-making significantly influenced by a wider range of stakeholders, and transparency and accountability will be increasingly valued over speed. Extensive use of virtual and augmented reality will facilitate business communications, enabling remote employee working across organisational boundaries. Reflecting increasing expectations and engagement in local communities, and reducing hierarchical power, the relative influence of central government will be reduced. This will provide benefits, but also lead to a rise in patronage.

Competition regulation will shift from prioritising price protection for consumers to assessing the impact of potential developments against social, environmental and economic outcomes. Informed by predictive analytics, the long-term cumulative impact of local decision-making and supply chain resilience will be critical factors in decision making. Competition regulation will also dampen rivalry and, in turn, affect innovation. The challenges experienced by big firms will reduce R&D budgets, with a consequent slowdown in innovation. Other approaches will partly close this gap, such as community-based crowdsourcing innovation. Reduced budgets will also mean innovation spreads by contagion rather than by marketing efforts. The widespread adoption of additive manufacturing will drive significant shifts to local manufacturing. With increased customisation of products at relatively low costs, the value of differentiation by brand will significantly decrease.

PSM leaders' principal strategic contributions will centre on network coordination and supporting network strategizing. A key challenge will be balancing the organisation's own interests and the collective interests of the business' wider community of stakeholders. These interdependencies will slow decision-making, and reduce market dynamism. PSM leaders' efforts to prepare for the future will centre on enhancing foresight, developing scenarios and analysing their implications, often collaboratively, with a view shaping emerging futures.

Contrasting Scenarios

The business landscapes portrayed in TITANS and NETWORKED would not co-exist, since their emergence would depend on highly divergent business behaviours, social change and government policies. The TITANS scenario speaks to powerful corporate models that promise

ever more cost reductions, technical innovations and efficiencies, but which also threaten abuse of market power. Organisational power shapes not only their supply chains and markets but also entire competitive fields and societal values. Owing to this dependence, failure of a major organisation could be catastrophic across multiple supply chains. The NETWORKED model is not developed as an idealised counterpoint to TITANS, but to highlight important factors raised by future trend experts not aligning with TITANS. NETWORKED's potential advantages include organisations giving greater attention to external stakeholders' interests, and taking account of the cumulative effects of network members' procurement decisions, for mutual long-term gain. Different risks would exist, particularly around speed of recovery from supply chain shocks and the rate of innovation. Organisations will strive for resilience to predict, adapt to, and recover from disruptive events. In the TITANS scenario, resilience will be displaced by agility, which is centred less on anticipation, and more the speed of response to changes.

SUPPLY LANDSCAPE AND THE WIDER BUSINESS CONTEXT		
Theme	TITANS	NETWORKED
Ownership of data and systems	Concentrated ownership of data and systems Company-centred initiatives on data privacy etc.	More distributed ownership of data and systems Strong regulation on data privacy, security etc.
Market configuration and dynamics	Polarising and concentrating market structures Predominantly for-profit intermediaries Highly dynamic and competitive markets	Fewer very large firms, more smaller ones, more diversity in business models Mixed economy of for-profit and NFP intermediaries. Rivalry dampened
Dominant axis of collaboration	Business groups	Regional networks, many city-based
Changing business strategy	Strategies frequently and rapidly adapted	More stable business strategies
Innovation rate and drivers	Innovation driven by titans	Innovation slowed – less investment, less marketing – slower diffusion
Interest in sustainability	Regulation driven attention on sustainability	Community-pull on sustainability
Value of brand	Price and 'hard' quality measures trump brand	Social capital is brand
Critical success factors	Success comes from rapid adaptation and agility, and collaboration in tight-knit business ecosystems	Success comes from network strength and resilience, and tight-knit regional collaboration

Table 1: Extract from CIPS report, summarising the scenarios against key themes

Despite their fundamental differences, it is noteworthy that the two scenarios have some PSM implications in common. In both, the majority of product purchasing is commoditised and/or automated, eroding margins and intensifying competition, particularly in the online space. In combination, DLT, predictive analytics, machine learning, the Internet of Things, and robotics will reconfigure supply chains and radically change the inter-organisational interfaces. Servitization and additive manufacturing will also lead to new intermediaries and the reconfiguration of many supply chains. In TITANS, brokers will be predominantly for profit, whereas in NETWORKED there will be a mixed economy.

Within TITANS, the overarching focus will be on risk management. PSM experts will be called upon to enable organisational business strategy, leveraging the supply base to support rapid reframing and repositioning in response to highly dynamic environments. Core activities will shift to managing intermediaries, (re)configuring supply chains for greater agility, dealing with the unexpected, rapid sourcing, and developing mitigation strategies for coping with very powerful suppliers, whether these are micro-suppliers with critical IP or Titan companies. By contrast, under NETWORKED, PSM experts' critical role will be in network coordination, focusing on developing network-level strategies and coordination to bridge upstream and downstream members of the network. Frequent, gradual adjustments will be needed as collective and organisational goals are revisited in light of feedback. Core activities will include consortia contracting, strengthening supply arrangements for greater resilience, forecasting the

impact of decisions, relationship development, and developing strategies for coping with powerful suppliers centred on learning and collective action.
Both scenarios present three key PSM roles. The first is strategy facing, and concerns interpreting business needs, identifying how these can be met through suppliers and defining PSM's contribution. The second is (IT) systems facing, translating PSM needs into systems and data requirements. Managing PSM systems will be a central activity, as the function shifts from directly acquiring specific goods and services, to designing acquisition systems and underpinning policies. The third role is category, relationship and supplier management in the relatively rare cases where these activities cannot be fully automated or outsourced.

Discussion

Perennial Issues and Strategic Blindspots

Future-focused thinking is not easy particularly in fast-paced, high-pressure environments. Despite decades of maturity research four perennial themes still dominate discussions about the future of PSM – strategic maturity, data revolution, (lack of) skills and capacity, and professional recognition. These issues' persistence and a natural leaning towards incremental change seem to create 'strategic blindspots', as illustrated through three insights from our study. First, discussion of future data systems tended to centre on the ability to conduct current tasks more efficiently, rather than the exponential gains and risks of transformative, or game-changing data and systems. Improved systems capability would facilitate management of more *complicated* supply systems and decisions, but were not necessarily seen as facilitating more *complex* activities such as network collaboration, competitive intelligence or modelling the impact of sourcing on market dynamics. Second, most mentions of the rise of Amazon centred on efficiency gains and assumed it was inevitable. Participants tended not to consider the implications for market concentration and value appropriation, or that Amazon's growth is driven by buyer behaviour. Third, although concerned about data security, risks to decision making quality stemming from problematic algorithms (O'Neil, 2017) that might lead to counter-productive outcomes in the longer term (especially with respect to ecological and social outcomes), were not discussed.

Developing a rich description of the scenario and debating its implications, rather than exploring the impact of a long list of future trends (e.g. Carter, Carter, Monczka, Slaight and Swan, 2000) allows gaps in attention to be considered more critically and holistically. In this study, participants were invited to 'uncouple' their thinking from immediate roles and sector contexts, relying more on their professional expertise and general knowledge. As researchers, we can relate emerging findings to future studies (e.g. Dewing and Jones, 2016) and highly contemporary discourse about challenges we face (c.f. O'Neil, 2017, Sas, 2017, The Economist, 2016). Furthermore, as Gowing and Langdon's (2016) evidence shows, many of the most senior business and public sectors leaders seem unable to 'think the unthinkable' and, when they do, the attention to supply-side aspects is very limited (Schwab, 2017).

Market Concentration and Market Dynamism

The combined influence of organisations' PSM practices and decisions affects far more than their individual commercial performance. It generates market structures and dynamism. Issues of power and lack of corporate diversity have cumulative impacts on people, organisations, markets, the natural world, and society. Even for today's best-in-class PSM functions, some reframing of supply-side priorities would be needed to reshape market concentration, in the case of TITANS, and develop the lack of market dynamism, in the case of NETWORKED.

The political implications of market concentration (Zingales, 2017), markets and innovation policy (Mazzucato, 2015), and zero-growth economics (Barrett, 2018) are all topics which relate directly to calls within our field for truly sustainable supply chains (Montabon, Pagell and Wu, 2016). And yet, as Knight et al., (2015) review found, what little attention has been paid to market shaping and innovation within the field of PSM is either just public sector focused and/or not recent. Some developments in neighbouring fields such as marketing and industrial marketing are promising. Nevertheless, we conclude that PSM scholars need to find ways to rapidly engage with on-going debates in economics and in innovation policy, and to capitalise on recent research in B2B marketing. This should be done synergistically with PSM leaders' initiatives to broaden the horizon of FPSM discourse.

Influence of PSM

Both scenarios suggest that leaders need to identify, evaluate and challenge the assumptions and norms that frame typical efforts to plan for the strategic development of PSM. Strategic blindspots limit critical reflection. PSM professionals may find their field moving into a future that does not deliver what is needed for their organisations, that they don't want, and for which they are not prepared. The future of PSM is however not the exclusive concern of PSM leaders. It invites serious consideration from a range of stakeholders, including organisational leaders. Market concentration and dynamism in B2B markets are of interest to them and others, such as regulators. Debate needs to grow in scope from how to increase the strategic influence of PSM professionals within organisations to include the wider impact of PSM choices, individually and collectively. This brings us back to the need to recognise and draw attention to strategic blindspots and questions how PSM can take a lead in addressing market concentration and/or dynamism. Recent developments in PSM maturity research which emphasise contextual factors such as political influence as part of a more nuanced understanding of maturity (Andreasen and Gammelgaard, 2017) provide an important foundation for such initiatives

Conclusion: Connecting to the Future

This study suggests an urgent need for more future-focused studies. Despite converging themes of power, intermediation and cooperation, the TITANS and NETWORKED scenarios are competing potential futures. A key question for organisations and PSM professionals is how to recognise critical developments that would signal whether we are transitioning towards one or other scenario. Further research adopting a scenario based approach could usefully address these 'flexpoints' (Hussain et al., 2017, Strauss and Radnor, 2004).

NETWORKED reflects the expectations captured in a major foresight study (Dewing and Jones, 2016). The embeddedness of actors, the importance of external stakeholders in decision-making and the slowing of innovation are all features which, for us, evoke many aspects of the public sector today. TITANS reflects participants' expectations well but, for many of them, not their values. Developing and using scenarios are highly value-laden activities. The role of values should receive direct consideration in future research. More research is needed to support the development of capability and capacity in preparing for/influencing the future in the PSM domain. As the field of PSM has matured, research has become more theoretically and methodologically sophisticated, with exploratory and inductive research becoming relatively less popular. Whilst we recognise that future focused studies will be seen by some as compromising those rising standards, we draw inspiration from the problematising approach to developing research questions (Alvesson and Sandberg, 2011), critiques of formulaic research (Alvesson and Gabriel, 2013) and the notion of making a contribution to research through prescience (Corley and Gioia, 2011).

From a practice perspective, both the study participants and we as researchers found it difficult to be future-focused and 'non-incremental' in our thinking. As the perennial issues and blindspots show, PSM experts, just like CEOs and top civil servants find it extremely difficult to assimilate information on rapid change in business environments, and think the unthinkable and the unpalatable (Gowing and Langdon, 2016). A crucial point apparent within the two scenarios is that supply managers are not passive actors. Supply-side management choices will shape the emerging landscape. Futures are organic, malleable and adaptive. The PSM community – practitioner and academic – needs to initiate debate, challenge current practices and build the capabilities and the capacity to develop new, appropriate PSM options, rather than sleepwalking into undesirable futures.

Abstract

This paper aims to analyse the personality profile of professional purchasers against the background of the "Big Five Inventory". A research model was designed based on the five dimensions of a personality as identified in the "Big Five Inventory". An online questionnaire was sent out to purchasing professionals to test this model. Data from 82 responses is collected and used to analyse the personality profile of professional purchasers. The findings of this study aims to help human resource managers to identify an appropriate personality for a position in purchasing departments.

Keywords: Big Five Inventory, personality, purchasing professionals

Introduction

The improvement of business performance is the focus of many different research fields. The performance of purchasing departments in particular contributes significantly to overall business success and needless to say this is always influenced by those individuals who are employed as professional purchasers (Caniato et al., 2012; Foerstl et al., 2013; Hüttinger et al., 2012; Nair et al., 2015; Van Weele, 1984). An interesting individual key factor of the people who work as professional purchasers is that of their personalities. Over the past few years, the interest of many personality researchers has concentrated on the structure and concepts of personality. Researchers agree that there are different robust factors of personality which can serve as meaningful parameters for classifying personality attributes (Barrick and Mount, 1991; Hurtz and Donovan, 2000). Ever more executives today rely on employee personality analysis to optimize their workforce. In the light of these developments the paper considers the research question: What are the personality characteristics of professional purchasers? Although the problem is not new because many researchers tried to profile purchasers (Knight et al., 2014; Koponen, 1960) the key concept of this issue is an economic method for the measurement of personalities of purchasers (Carlo et al., 2014; Flake et al., 2017). In a next step the inclusion of a performance construct of purchasers is useful to get a connection between personalities and performance of purchasing professionals (Caniato et al., 2012; Nair et al., 2015; Wen-li et al., 2003).\

The literature

Personality models attempt to analyse, structure and model the personalities of people (Barrick and Mount, 1991). In order to achieve this objective, the characteristics, the behaviour and also the physical dimensions of people are analysed and structured in groups. The resulting models should not be seen as dogmatic criteria, but merely as a useful means of systematically depicting and integrating personality differences. Personality models should also be easy to understand, to present and communicate and also show proper respect in dealing with people. The literature uses different models for the analysis of personality like Myers-Briggs indicator, Riemann-Thomann model or the "Big Five" dimensions of personality (Rammstedt et al., 2013; Riemann, 2013; Zeigler-Hill and Shackelford, 2018).

The Myers-Briggs indicator is based on Jung's inventory. It has a structure of 94 forced-choice items that yield scores on each of the eight factors as well as the famous four dimensions: introversion–extraversion, sensation–intuition, thinking–feeling, and judging–perceiving. Respondents are classified into one of 16 personality types based on the largest score obtained for each bipolar scale. The test provides linear scores on each dimension which are usually discussed in terms of types based on cut-off scores (Furnham, 2018).

The Riemann-Thomann model basically describes four opposing basic orientations of persons. These four basic orientations occur in everyone, but in different forms. Basic orientations of the human being can be seen in this model as a holistic state in which a feeling of well-being occurs in the person. These four basic orientations are: distance, proximity, duration, and change orientation (Riemann, 2013). These four basic orientations can be entered in a coordinate system, where the vertical axis includes the two extremes duration and change and the horizontal axis the distance and proximity. The vertical axis is the time axis and the horizontal axis is the space axis. This means that space and time are criteria in which people differ in their interaction (Geml and Lauer, 2008).

The "Big Five" dimensions of personality are applied together as an appropriate testing instrument (Seibert and DeGeest, 2017). Big Five Personality Dimensions (BFPD) were developed from multiple research efforts, which integrated more than 4,500 English adjectives that ended through research in five dimensions. With the combination of this five dimension all possibilities of describing a personality are included (Castillo, 2017; Mulyanegara et al., 2009; Rammsted et al., 2013). Such BFPD allow an average prediction of individuals' behaviours in many different situations and is mostly used in human resource management. Therefore, a personality can be defined as the way an individual's mental world is organized. Thus, based on this definition, researchers attempted to develop a framework that may come to explain individual differences. The Big Five model includes traits such as neuroticism, extraversion, openness, agreeableness and conscientiousness (Mulyanegara et al., 2009; Rammstedt and John, 2007). The ten item "Big Five Inventory" is an ultra-short test for assessing the five personality dimensions and this inventory is acceptable to use with a web survey (Rammstedt, 2007; Rammstedt and et al, 2016; Seibert and DeGeest, 2017). Furthermore, Rammstedt offers a very simple method for representing the personality structure on the basis of the mean values (Rammstedt et al., 2013) which makes the profiling of a personality profile very easy.

The methodology

In this section, we present details regarding the research instrument and measures and the sampling procedure that were used for developing our key constructs.

Research instrument and measures

Item measures for the personality construct in our study were adapted and built from existing scales and conceptual works of the Big Five Inventory-10 (BFI-10). The item pool was tested on academics by (Rammstedt and John, 2007). However, reverse coding and distributed placement of the item measures were used as a precautionary measure against potential response bias. Item scales were graded on a 1–5 likert scale basis, with 'strongly agree – strongly disagree' and anchors between. As a part of the scale refinement process, a preliminary survey was pilot tested among three academic and four professional experts. Table 1 shows the items based on (Rammstedt and John, 2007).

Table 1: Big Five Inventory-10 (BFI-10) based on (Rammstedt and John, 2007)

	Questions	**Dimensions**
	I see myself as someone who…	
(1)	…is reserved.*	extraversion
(2)	…is generally trusting.	agreeableness
(3)	…tends to be lazy.*	conscientiousness
(4)	…is relaxed, handles stress well.*	neuroticism
(5)	…has few artistic interests.*	openness
(6)	…is outgoing, sociable.	extraversion
(7)	…tends to find fault with others.*	agreeableness
(8)	…does a thorough job.	conscientiousness
(9)	…gets nervous easily.	neuroticism
(10)	…has an active imagination.	openness

*… item is reversed-scored

Sampling procedure

The sample frame was drawn of the "Federation of Materials Management, Purchasing and Logistics in Austria" (BMÖ) on a cross industry basis. The BMÖ represents a total population of about 1,600 purchasing professionals among all industries in Austria. Following (Bethlehem, 2010) and (Sax et al., 2003) guidelines, the final instrument was mailed via e-mail to all of the about 1,600 purchasing professionals of the BMÖ member list. About 950 e-mail addresses were no longer valid. The mailing package consisted of a cover letter and the link to the survey in lime-survey. A first reminder e-mail was mailed to all valid e-mail addresses of the members after two weeks and a second one after four weeks of mailing. Respondents were offered a summary report as an incentive to participate. Three mailings of the survey instrument resulted in a total of 82 responses, excluding returns, refusals and unusable responses. This results in a response rate of 12,62%. The answers concerning the business of the companies were divided by the economic activity classification ÖNACE of Austria and the distribution of the sample is shown in Table 2.

Table 2: Businesses of the sample

Businesses (ÖNACE)	
Manufacturing or manufacturing of goods (industry)	63%
Trade; maintenance and repair of motor vehicles	9%
Others	28%

The category “others” includes all businesses that have been named once. The maturity of the companies of the sample is working for industry. Respondents were from different purchasing functions like chief procurement officers, strategic and operative purchasers. Table 3 shows the distribution of the functions.

Table 3: Functions of the sample

Functions	
Operative purchasers	32%
Strategic purchasers	21%
Chief procurement officers	48%

The selected sample represent a cross-section of the purchasing functions. Table 4 shows the respondent profile of companies in the sample. It is shown that the whole profile of the companies is widely scattered.

Table 4: Respondent profile of companies in the sample

	mean	**std. dev.**	**min**	**max**
Number of employees	7,263	19,413	50	147,000
Number of employed purchasers	90	373	2	3,000
Turnover	€ 1,283 million	€ 4,191 million	€ 6 million	€ 32,000 million
Purchasing volume	€ 389 million	€ 902 million	€ 20,000	€ 4,000 million

Results

Confirmatory factor analysis (CFA) was used in order to simultaneously validate the measures of the Big Five Inventory-10 in the professional purchasing criteria construct. Also an exploratory factor analysis (EFA) preceded the CFA for the construct Big Five Inventory-10 in the professional purchasing. This step was undertaken to see whether the items underlying these constructs hold together as one construct or whether they form conceptually distinct factors. The EFA results suggested five distinct factors for Big Five Inventory-10. In the CFA, all items loaded on their hypothesised constructs. Factor loads below 0.3 are hidden. Reversed-scored items where recoded before. Table 5 shows the result of the principal component analysis of the CFA.

Table 5: CFA of the Big Five Inventory-10 in the professional purchasing criteria construct

I see myself as someone who…	**factors**				
	1	**2**	**3**	**4**	**5**
…is reserved.	0.851				
…is outgoing, sociable.	0.839				
…is generally trusting.					0.842
…tends to find fault with others.					0.786
…tends to be lazy.				0.825	
…does a thorough job.				0.784	
…is relaxed, handles stress well.		0.742			
…gets nervous easily.	-0.332	0.805			
…has few artistic interests.			0.841		
…has an active imagination.	-0.335		0.731		

(factors: 1=extraversion, 2=neuroticism, 3=openness, 4=conscientiousness, 5=agreeableness)

The overall model fit of the confirmatory factor analyses is weak in terms of the measure of sampling adequacy (MSA) because the Kaiser-Meyer-Olkin-criteria (KMO) reached only a value of 0.53 and is therefore as “miserable” to consider (Backhaus, 2008). Discriminant validity was evidenced at acceptable levels by means of an examination using the chi-square difference test (chi-square = 128,99; d.f. = 45).

Following evaluation is based on mean values, as described by (Rammstedt et al., 2013). In order to obtain measured values for the individual characteristics of the interviewed purchasers on the five personality dimensions, the answers to the two items are averaged per dimension. For this purpose, the respectively negatively poled item is first recoded and then the average of the recoded and the unrecorded item is formed per dimension. The range of values of the five dimensions is then between one (agree strongly) and five (disagree strongly) (Rammstedt et al., 2013). Figure 1 shows the result (n=82).

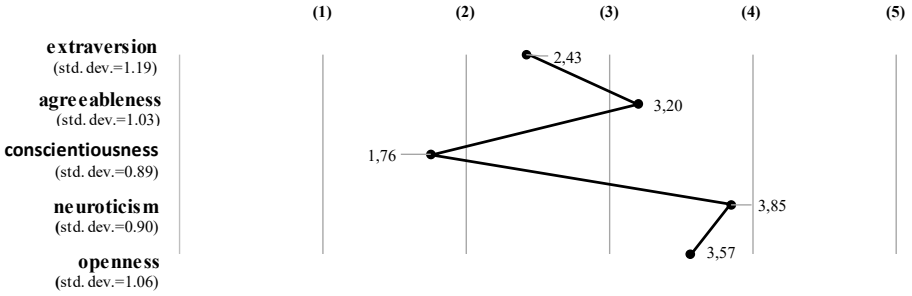

Figure 1: Personality profile of the sample of purchasing professionals

As a result of this evaluation, the personality of professional purchasers is very strong in dimension of conscientiousness and very weak in dimension of neuroticism.

Conclusion

The findings are intended to support human resources managers during staff recruitment processes to identify the “right personality” for a purchasing position in purchasing departments. It makes the appearance that the personality of purchasing professionals is very conscientiousness. The dimension of conscientiousness manifests itself through aspects such as persistence of behaviour, impulse control, success and task orientation and organization and thoroughness. Furthermore, people with a high level of conscientiousness are dutiful, orderly and purposeful (Lang, 2009). Conscientiousness is an important factor in predicting job performance among employees and workers (Hankes, 2011). The factor analyses shows that the theory of the Big Five is also found among the sample of purchasing professionals.

Limitation und future research

The study has a few limitations that present directions for future research. We consider data from Austrian companies which are mostly from the industry sector for informing our research. Furthermore, we cannot be certain whether these findings will hold in other geographical regions and businesses. Another limitation is a low number of only 82 participants which leads to the question of the quality of the factor analysis. Future research can consider a performance measurement model to link it with the personalities of professional purchasers to divide the personality profile into groups. Furthermore, future analysis of the data should consider

different personality characteristics depending on businesses and focus on the differences between the positions work experience, purchasing volume and operational or strategic purchasers. Also the prediction of purchasers' behaviours in many different situations gives room for further research.

Leapfrogging and co-evolution
—
toward a maturity model for the digital transformation to Procurement 4.0

Abstract

Procurement 4.0 promises to change fundamentally the way buying firms collaborate with their suppliers. However, do buying firms and their suppliers have the required level of "digital maturity"? This study builds on a literature review and qualitative research to develop a *Procurement 4.0 maturity model*, which is then validated in a pre-study. In contrast to traditional company-centric procurement maturity models, the newly developed model takes a dyadic perspective to highlight the crucial role of *co-evolution* between the buyer and the supplier in the digital transformation to Procurement 4.0. The research further offers *leapfrogging* as a change process that contrasts with the traditional linear and gradual processes assumed in extant maturity models.

Keywords: Procurement 4.0; digitalization; maturity model; case study research

Introduction

The fourth industrial revolution, or "Industry 4.0", refers to a new way of organizing and controlling the entire value chain across product life cycles (Lichtblau et al., 2015). As Industry 4.0 reshapes global value chains, procurement—the central interface to internal and external partners—is at an important turning point (Henke and Schulte, 2015; Pellengahr et al., 2016). In the era of Industry 4.0, academics and practitioners have coined the term "Procurement 4.0" to denote the digitalization of procurement (Batran et al., 2017; Pellengahr et al., 2016). In Procurement 4.0, the digital and autonomous links within and between companies become the focal point of supply management (Hofmann and Rüsch, 2017). Just as the fourth industrial revolution is reshaping industry, Procurement 4.0 promises to change fundamentally the way buying firms collaborate with their supply network around the globe.

Despite a growing enthusiasm around Procurement 4.0, reality suggests that procurement functions still have a long way to go on their digitalization journey. For example, a pilot study on Procurement 4.0 in Europe showed that over two-thirds of the participating companies had not yet implemented any Procurement 4.0–related applications (Pellengahr et al., 2016, p. 15). To explain and understand the level of professionalism in purchasing and supply management (PSM) organizations, extant PSM literature uses maturity models (Andreasen and Gammelgaard, 2018; Rozemeijer et al., 2003). PSM maturity models aim to describe the process of evolution through different maturity levels or stages (Adams et al., 2016; Andreasen and Gammelgaard, 2018).

However, extant literature on PSM maturity models is limited in helping to explain the digital transformation to Procurement 4.0. First, the substantive domain of traditional PSM maturity models does not account for the more recent trends of *digitalization*. Consequently, while the conceptual dimensions of extant PSM maturity models can be used as a starting point, they need to be re-evaluated to reflect key dimensions of Procurement 4.0, such as information technology (IT) systems and cybersecurity.

Second, extant PSM maturity models usually take the PSM organization as the unit of analysis (Andreasen and Gammelgaard, 2018). However, central to the concept of Procurement 4.0 are the digital and autonomous *links between companies*, which means that a certain level of digitalization maturity is required on both sides of the dyad. Therefore, in a Procurement 4.0 maturity model, the buying firm, its suppliers, and the relationships *between* the different entities must be considered. Such a dyadic perspective also draws attention to the maturity level and heterogeneity of the supply base. Given today's global supply chains, buying firms that want to consistently implement Procurement 4.0 need to establish digital links with all their suppliers, including those in emerging sourcing markets, like China or India. This point is critical because prior research found emerging market suppliers to have a lower maturity level resulting, for example from low IT investments and the use of standalone software (Saldanha et al., 2015).

Third, extant PSM maturity models address *change* as a rather linear and gradual process (Andreasen and Gammelgaard, 2018). However, recent research has started to question the assumption of linear and gradual change and suggests a more evolutionary one (Andreasen and Gammelgaard, 2018). As digitalization radically and rapidly transforms entire industries (e.g., Amazon and Uber), research needs to question how far Procurement 4.0 maturity models follow the traditional linear pattern of change. Especially in more dynamic contexts, like emerging markets or start-ups, the change processes might unfold differently than has traditionally been assumed. Accounting for potentially non-linear change processes could improve the explanatory power of maturity models and help to provide practitioners with better guidance to change.

The general purpose of this paper is therefore to conceptualize and operationalize a maturity model for the digital transformation to Procurement 4.0 by seeking answers to the following specific research questions:

1) How can Procurement 4.0 maturity be *conceptualized*? That is, what are the key dimensions, maturity stages, and change processes in a Procurement 4.0 maturity model?
2) How can Procurement 4.0 maturity be *operationalized* (i.e., empirically measured)?

Guided by Becker et al.'s (2009) procedure for developing maturity models, this paper follows a three-stage approach. In the *conceptualization* phase, we build on theory (via an extensive literature review) and on practice (via an embedded case study with one Western European buying firm and four of its key suppliers in China) to develop the conceptualizations for the Procurement 4.0 maturity model. In the *operationalization* phase, we generate a quantitative measurement instrument by following guidelines from DeVellis (2017) to derive the scale items. In the *validation* phase, we conduct a pre-study with a dyadic sample involving three Western European buying companies, eight of their European suppliers, and seven of their Chinese suppliers to corroborate and refine the model in the field.

This research aims to make three major contributions to the PSM literature. First, it advances the still-embryonic literature on *Procurement 4.0* (e.g., Richey et al., 2016) by extending the content domain of PSM maturity models to digitalization. Second, in contrast to prior PSM maturity models that take the PSM organization as the unit of analysis, this Procurement 4.0 maturity model takes a *dyadic perspective* and accounts for the maturity levels of both buyers and suppliers along several dimensions. Importantly, this perspective sheds light on the crucial role of *co-evolution* between the buyer and the supplier in the digital transformation to Procurement 4.0. Third, this study responds to a recent call by Andreasen and Gammelgaard (2018) to unravel the change processes in PSM maturity models. Instead of conceptualizing change as a rather linear and gradual process, this study finds that *leapfrogging* is a strategy for the digital transformation of procurement that contrasts with the traditional evolutionary process assumed in extant maturity models.

The paper is organized as follows: In the next sections, we review the extant literature, describe the case study methodology, conceptualize and operationalize the Procurement 4.0 maturity model, and present the empirical results from the pre-study. We conclude with a discussion, limitations, and directions for future research.

Literature review for conceptualizing Procurement 4.0 maturity

In the first part of the *conceptualization* phase, we conducted an extensive literature review as a first foundation for the conceptual development of the Procurement 4.0 maturity model (Carter et al., 2017a). First, we searched in academic publishing databases (e.g., ABI/Inform, Elsevier Science Direct, and Emerald Insight) and in Google Scholar using three keyword searches: 1) "procurement 4.0"; 2) "digital" together with "procurement" or "supply management" or "purchasing" or "sourcing"; and 3) "industry 4.0" together with "maturity" as search terms. Second, we conducted a backward and forward search by reviewing the references and "cited by" lists of the retrieved articles to identify additional potential sources. Third, because of the nascent stage of the field (Google Trends indicates that the term "procurement 4.0" first appeared in 2015), we extended our search to include practitioner publications. To identify relevant practitioner publications, we conducted a Google web search using the keywords 1) "procurement 4.0" and 2) "industry 4.0" together with "maturity" as search terms. Fourth, we reviewed the titles, abstracts, and introductory sections of each publication and eliminated the ones that were not related to our research questions. In the following paragraphs, we briefly

review the literature on PSM maturity models before synthesizing the publications on Procurement 4.0.

PSM maturity, defined as "the level of professionalism in purchasing at the business unit level" (Rozemeijer et al., 2003, p. 5), has long been recognized as an important antecedent to firm performance. A key element of PSM maturity models is the proposed process of evolution through different maturity levels or stages (Adams et al., 2016; Andreasen and Gammelgaard, 2018). Several maturity models exist in the PSM literature that assess the level of maturity in the procurement function (e.g., Paulraj et al., 2006) or in more specific areas, such as global sourcing (e.g., Trent and Monczka, 2003). Table 1 provides an overview of existing maturity models. Although these models include some dimensions relevant to Procurement 4.0 maturity (e.g., organizational structure, leadership), their applicability to the field of Procurement 4.0 remains limited because these PSM maturity models insufficiently account for the digitalization aspect (Kleemann and Glas, 2017).

More recently, academics and practitioners began to develop maturity models for Industry 4.0. Most of these models encompass a comprehensive set of dimensions (e.g., technology, organization, people) and evaluate maturity in terms of different levels of development (e.g., newcomers, learners, leaders). Although informative, many of these models are only partly applicable to the specific area of Procurement 4.0 because they do not account for procurement's critical external interface function (Kleemann and Glas, 2017).

Because the field of Procurement 4.0 is still nascent, to the best of our knowledge, no Procurement 4.0 maturity model has been provided to date in the academic, peer-reviewed literature. Starting points can be found primarily in the practitioner literature (e.g., Batran et al., 2017); noteworthy research on the topic has included a pilot study by Pellengahr et al. (2016) that describes the status quo, identifies barriers, and provides recommendations for the digitalization of procurement. Although Pellengahr et al. (2016) do not develop a maturity model, their study lays out a helpful structure of Procurement 4.0 along four dimensions: 1) technologies and systems, 2) organization and processes, 3) management and people, and 4) business models. Furthermore, Kleemann and Glas (2017) have conceptualized a digital maturity model for Procurement 4.0 that covers similar aspects with eight dimensions. Although their practitioner-oriented model accounts for the external interface function of procurement, it is limited to the buying firm's perspective only and offers few details about the conceptual development process.

These works have greatly helped to advance our understanding of Procurement 4.0, but they are still limited in that they assess only the buying-firm side. However, establishing digital links with suppliers requires a certain level of digitalization maturity on both sides of the dyad. Therefore, this paper proposes a Procurement 4.0 maturity model based on a dyadic perspective and compares the maturity levels of both buyers and suppliers along several dimensions. In the following, the maturity model is described in more detail.

Table 1: Existing PSM and Industry 4.0 maturity models

Model name	Source	Type	Methodology	Assessment approach
Purchasing and Supply Management				
Taxonomy of purchasing functions	Cousins et al., 2006	Academic	Empirical (survey)	4 purchasing function configurations based on 4 variables; derived through cluster analysis from a survey of 151 companies

Model name	Source	Type	Methodology	Assessment approach
Levels of strategic purchasing	Paulraj et al., 2006	Academic	Empirical (survey)	Assessment in 3 dimensions, with 11 items to evaluate maturity level in 3 stages; survey of 221 companies
Worldwide sourcing framework	Trent and Monczka, 2003	Academic	Empirical (survey)	Assessment of worldwide sourcing stage in 5 levels; survey of 162 companies
		Procurement 4.0		
Procurement 4.0 framework	Geissbauer et al., 2016	Practitioner	Conceptual	Conceptual development of Procurement 4.0 framework with 6 areas; no details about items and development process offered
Digital maturity model for Procurement 4.0	Kleemann and Glas, 2017	Academic	Conceptual	Conceptual development of questionnaire with 8 dimensions and 24 items to evaluate maturity in 5 stages
Pilot study on Procurement 4.0	Pellengahr et al., 2016	Practitioner	Empirical (expert interviews)	Assessment in 4 dimensions through expert interviews with 27 organizations
		Industry 4.0		
Maturity model for digitalization	Klötzer and Pflaum, 2017	Academic	Conceptual	Assessment in 2 perspectives with 9 dimensions, each to evaluate maturity in 5 levels; no empirical testing
IMPULS—Industry 4.0 readiness	Lichtblau et al., 2015	Practitioner	Empirical (survey)	Assessment in 6 basic dimensions and a total of 18 sub-dimensions with 26 items to indicate readiness in 6 levels; survey with 232 participants
Industry 4.0 / Digital operations self-assessment	PwC, 2016	Practitioner	Empirical (online self-assessment)	Online self-assessment in 6 dimensions; focus on digital maturity in 4 levels; no details about items and development process
Industry 4.0 maturity model	Schumacher et al., 2016	Academic	Empirical (case study)	Assessment in 9 dimensions with 62 items to evaluate maturity; evaluated through two case studies in industrial enterprises

Qualitative study for conceptualizing Procurement 4.0 maturity

In the second part of the *conceptualization* phase, we conducted an embedded case study to assist the conceptual development of the Procurement 4.0 maturity model from practice (Carter et al., 2017a). The embedded case study involves one Western European buying firm and four of its key suppliers in China. The unit of analysis is the buyer–supplier relationship.

Case study setting

China was selected as a particularly information-rich research context for several reasons. First, as the world's manufacturing center, the Chinese supply market has high empirical relevance (Busse et al., 2016). Second, prior studies have reported gaps in technological and managerial capabilities between Western buying firms and Chinese suppliers (e.g, Reimann et al., 2017), which potentially translate into gaps for digitalization maturity as well. Third, China is a very

dynamic market that is currently undergoing digital transformation at a very rapid pace (Woetzel et al., 2017), which makes it an interesting context in which to explore the digitalization of procurement.

Selection of cases

The investigated company, IndustryCo, represents an exemplar case (Pagell and Wu, 2009) because it is a leader in Industry 4.0 and its Chinese factory is recognized as a model factory for Industry 4.0 in China. Given IndustryCo's leading position in Industry 4.0, its top management also shows strong commitment for implementing Procurement 4.0 in its leading Chinese factory. IndustryCo's factory manager explained the overall digitalization strategy:

> With 'Made in China 2025', the Chinese government is really pushing for Industry 4.0 in order to go away from the cheap factory of the world to a more advanced factory in China. We as IndustryCo really want to be a part of this transition. We think with our digitalization that we have here in our factory, we are clearly one of the most advanced factories in China. (Factory Manager, IndustryCo)

The selection of the four key suppliers followed the theoretical sampling principle to enhance external validity and generalizability (Eisenhardt and Graebner, 2007). IndustryCo's Head of Strategic Procurement was asked to identify Chinese key suppliers with which IndustryCo had either successfully implemented digitalization projects or encountered difficulties in implementing digitalization projects (i.e., to identify polar cases). In addition, to provide a contrary replication, IndustryCo was asked to identify one non-Chinese key supplier. Our sample includes four dyadic relationships between IndustryCo and three Chinese key suppliers, as well as one Chinese subsidiary of a Western-based key supplier. Table 3 provides summary information on the case companies.

Table 2: Overview of case study companies

Company[1]	Head-quarters	Revenues (USD)	# Employees	Length of BSR in years	Informant job title(s)	# Inform-ants
IndustryCo[2]	Western Europe	120 million	500	N/A	Factory Manager, Head of Strategic Procurement, Head of Operational Purchasing, Operational Purchaser, IT Manager	10
Electronics-SPL	China	180 million	9,500	5	Key Account Manager	1
Packaging-SPL	China	1 million	45	5	General Manager	1
Plastics-SPL	China	20 million	250	2	Marketing Director	1
Semicon-SPL[3]	United States	13 billion	30,000	5	Key Account Manager	1

[1] Real names are concealed for confidentiality.

[2] Figures relate to the Chinese factory of IndustryCo.

3 Figures relate to Semicon-SPL globally, with IndustryCo sourcing from its local Chinese subsidiary.

Data collection

Data was collected in China through 14 in-depth, semi-structured interviews with both IndustryCo and the suppliers, complemented by documents and on-site visits. Triangulation of data collection methods and sources provides more accurate information from diverse perspectives, thus contributing to stronger construct validity (Eisenhardt, 1989). Our semi-structured interviews ranged from 50 to 90 minutes in duration, with an average of 65 minutes, and they were conducted face-to-face by one of the authors, except for two phone interviews. The interviews were carried out in English or Chinese, depending on the interviewee's preference. All interviews were recorded and transcribed verbatim or were translated as necessary (i.e., from Chinese to English). Table 3 provides further details on the informants.

The semi-structured interview guideline was developed from the extant literatures on Procurement 4.0 and maturity models. It included questions about the organization and digitalization strategy, digitalization initiatives, as well as barriers and enablers for digitalization. To complement the interview data and obtain a more complete understanding of the suppliers' digitalization maturity, we conducted site visits and tours of the production facilities at IndustryCo and two suppliers. In addition, we collected publicly available documents (e.g., annual reports) and company internal documents (e.g., status reports, management presentations) from IndustryCo and the suppliers for the purpose of data triangulation (Eisenhardt, 1989).

Within- and cross-case analyses

During the within-case analysis, case study reports were constructed for each buyer–supplier dyad to draw a rich picture of the digitalization maturity of the case study firms. In the case study reports, we used citations from interviews, photos, and other collected documents to stay close to the original data and to achieve high levels of accuracy (Yin, 2014). To ensure the reliability of our data, the drafts of the case study reports were reviewed by the key informants.

During the cross-case analysis, the findings from the within-case analyses were compared to identify similarities and differences among the four cases (Eisenhardt, 1989). The empirical patterns also were compared and contrasted with extant literature on maturity models to enhance internal and external validity (Gibbert et al., 2008). In the next section, we synthesize our findings from the literature review and the case study analysis to develop the dimensions, maturity stages, and change processes of the Procurement 4.0 maturity model.

Procurement 4.0 maturity model

To conceptualize the dimensions of the Procurement 4.0 maturity model, we synthesized the dimensions used in the extant maturity models (see Table 3) and integrated insights from the case study (see Table 4). Although the number and terminology of dimensions used in the extant literature varies, most maturity models take a holistic perspective that covers strategic, organizational, process-related, and technological areas.

Table 3: Dimensions of Procurement and Industry 4.0 maturity models

Reference	Field	Maturity dimensions terminology
Klötzer and Pflaum, 2017	Industry 4.0	Strategy development, offering to the customer, "smart" product/factory, complementary IT system, cooperation, structural organization, process organization, competencies, innovation culture
Lichtblau et al., 2015	Industry 4.0	Strategy and organization, smart factory, smart operations, smart products, data-driven services, employees
PwC, 2016	Industry 4.0	Digital business models and customer access; digitization of product and service offerings; digitization and integration of vertical and horizontal value chains; data and analytics as core capability; agile IT architecture; compliance, security, legal, and tax; organization, employees, and digital culture
Schumacher et al., 2016	Industry 4.0	Strategy, leadership, customers, products, operations, culture, people, governance, technology
Geissbauer et al., 2016	Procurement 4.0	New procurement value proposition, digital category and service procurement, digital supply chain and supplier management, innovative procurement data use, digital processes and tools, organization, and capabilities
Kleemann and Glas, 2017	Procurement 4.0	Integration, supplier relationships, purchasers, organization, autonomous processes, material group strategy, [digitalization] strategy, company IT

Pellengahr et al., 2016	Procurement 4.0	Technologies and systems, organization and processes, management and people, business models

For our Procurement 4.0 maturity model, we use eight dimensions: leadership, digitalization strategy, organization, skills, IT systems and security, digitalized processes, category strategy, and advanced analytics. We define and explain the rationale for each dimension in more detail in the following paragraphs, while acknowledging that the dimensions partly overlap. We do so from the buying-firm perspective.

Leadership. The leadership dimension pertains to the top managers' support for digitalization in the company overall and in procurement in particular. The PSM literature recognizes that top management support is a critical enabler for strategic procurement initiatives because top management can devote financial and personnel resources toward the procurement function (Cousins et al., 2006). Likewise, practitioners emphasize the value of leadership for driving the digitalization of procurement (Batran et al., 2017; Pellengahr et al., 2016). For example, a manager at Airbus Defence & Space emphasizes the importance of leadership for the digital transformation of procurement: "Leaders and managers should also take sponsorship of proofs of concept and digital innovation projects […] and 'speak' the language of digital" (Batran et al., 2017, p. 116).

Digitalization strategy. The strategy dimension captures the degree to which a digitalization strategy for procurement exists and the degree to which procurement's digitalization strategy is aligned with the company's digitalization strategy. Because digitalization can strongly affect procurement's value proposition and contribute to the development of new business models, the procurement strategy should set priorities for the implementation of Procurement 4.0 (Kleemann and Glas, 2017; Pellengahr et al., 2016). Kleemann and Glas (2017) further emphasize that a Procurement 4.0 strategy should be derived from and aligned with the company's overall digitalization strategy. The case study revealed IndustryCo's strong commitment to digitalization. During the case study interviews, IndustryCo frequently emphasized the strategic importance of digitalizing procurement, although no formalized digitalization strategy for procurement existed at the time of data collection:

> Today one supply chain is competing with another supply chain. So you have to integrate the partners in your supply chain—your manufacturing, your suppliers, your suppliers' suppliers—all by using digitalization to make sure to integrate these partners to produce efficiently and to respond flexibly to the customers' needs. (Head of Strategic Procurement, IndustryCo)

Organization. The organization dimension includes the roles, responsibilities, and interfaces for the coordination and integration of Procurement 4.0 within the company and with external partners. Coordination and integration can be achieved through vertical mechanisms (e.g., centralized chief digital officer) or through lateral mechanisms (e.g., decentralized cross-functional teams) (Trautmann et al., 2009). Kleemann and Glas (2017) conclude that central coordination through a function like a chief digital officer can be useful and suggest that, because of its interface function, procurement should be a driver of cross-functional coordination. Although IndustryCo employs a chief digital officer at the business unit level, at the time of data collection it did not have dedicated roles and responsibilities for digitalization in the procurement function. However, during follow-up calls, the Head of Operational Purchasing mentioned that IndustryCo recently had decided to create a dedicated position for digitalization in the procurement function.

Skills. The skills dimension describes the digital skills and competencies of procurement professionals. Most studies agree that Procurement 4.0 requires a very different skill set from procurement managers, in the dimensions of both "how to buy" and "what to buy" (Batran et al., 2017). Regarding the "how to buy" dimension, current job profiles are likely to evolve to include more strategic tasks as technologies such as robotic process automation increasingly automate routine operational processes (Pellengahr et al., 2016). This change requires that procurement professionals possess profound IT and process know-how to coordinate automated processes (Kleemann and Glas, 2017). Furthermore, new job profiles, such as data scientists or big data specialists, will be required for the digital transformation of procurement (Geissbauer et al., 2016). Regarding the "what to buy" dimension, job profiles will extend to new digital purchase items, such as virtual reality or artificial intelligence solutions (Geissbauer et al., 2016).

IT systems and security. This dimension includes the company's IT systems, as well as IT security and risk management (Kleemann and Glas, 2017). The Gartner IT Glossary defines IT as "the entire spectrum of technologies for information processing, including software, hardware, communications technologies, and related services" (Gartner, 2018). Because IT is the backbone for any digital solution (Lichtblau et al., 2015), the procurement function should have access to IT resources to implement and upgrade integrated digital tools and processes. In addition, IT security measures are critical for mitigating data and IT security risks associated with cybercrime, such as the cyberattack that hit several global companies (e.g., Beiersdorf, Merck, Reckitt Benckiser) and the Ukraine government in June 2017 *(Financial Times*, 2017). In their pilot study on Procurement 4.0, Pellengahr et al. (2016) find that sufficient data protection and IT security are among the most important requirements for the implementation of Procurement 4.0.

Digitalized processes. This dimension relates to the aspect of "how to buy" (Batran et al., 2017) and encompasses the end-to-end procurement process. This process can conceptually be broken down into a source-to-contract (S2C) phase, ranging from the start of the sourcing process to the award of the contract, and a purchase-to-pay (P2P) phase, ranging from the point of order to the payment. At present, dozens of software solutions are available on the market for the digitalization and automation of strategic and operational procurement processes, and technologies like robotic process automation (RPA) promise to automate even more tasks (McKinsey, 2018). To automate the P2P process, IndustryCo had implemented a P2P software and intended to establish classic EDI or WebEDI integration with its Chinese suppliers.

Category strategy. This dimension concerns the aspects of "what to buy" and encompasses the category strategies for digital products and services (e.g., apps and software for connected driving), as well as the search for digital innovations (e.g., from startups) (Batran et al., 2017). Kleemann and Glas (2017) illustrate how companies need to create strategies for new categories (e.g., a machine manufacturer needs to purchase a touchpad, including software, for its machines) and need to adjust existing category strategies (e.g., 3D-printing changes the category strategies for spare parts). With its internal and external interface functions, procurement increasingly becomes an important radar for identifying innovations from current and future suppliers in the supply ecosystem (BME e.V., 2018).

Advanced analytics. This dimension describes procurement's ability to analyze the data that runs between a buying company and its suppliers. Digitalization is generating Big Data—that is, "structured and unstructured relationship-based information that is unique to business because of its volume, velocity, variety, and veracity" (Richey et al., 2016, p. 720). Volume refers to the total amount of data generated, velocity to the increasing speed of data creation, variety to the multiple types of data that are created, and veracity to the changes in data that occur

during and following collection that influence the data's usefulness (Richey et al., 2016). Practitioners expect procurement to tap new sources of value by analyzing these data via advanced analytics tools (McKinsey, 2018)—for example, through pay-per-use contracting models or artificial intelligence-based forecasting procedures.

Table 4: Illustrative quotes on maturity dimensions

#	Dimension	Illustrative quotes from case study
1	Leadership	"Why is our attention toward IT not developed? This depends on where the boss puts his emphasis with regards to the company's development. For example, because labor costs might be too cheap, the boss does not want to invest a lot of money in an IT system. So this concept of EDI [electronic data interchange] first needs to get into the heart of the boss." (Key Account Manager, Electronics-SPL)
2	Digitalization Strategy	"At IndustryCo, we have high attention, on the one hand, to drive ourselves to use the digitalization tools—for example, data exchange between us and the supplier. We also, on the other hand, encourage our suppliers to invest in these digitalization solutions to make sure that the two companies can exchange information very quickly. In general, our procurement strategy for digitalization is trying to digitalize the manual work and make sure that the information is more efficient. This is the direction we want to drive by using a lot of tools, internally and externally." (Head of Strategic Procurement, IndustryCo)
3	Organization	"During a town hall meeting, we have recently discussed what we understand by digitalization.… We are now planning to have a procurement employee who dedicates part of her work time to digitalization and who can coordinate digitalization initiatives in procurement." (Head of Operational Purchasing, IndustryCo, follow-up call)
4	Skills	"The reason why we did not implement EDI [with Packaging-SPL] lies mainly at the supplier side because its employees cannot handle our data very efficiently if we send the EDI data to them. So we would have to teach them how to understand our EDI data. So they replied to us that they hoped to choose the traditional method to handle our purchase orders, by Excel and by email communication." (Operational Purchaser, IndustryCo)
5	IT systems and security	"Most local [Chinese] suppliers, maybe 90%, use some kind of ERP [enterprise resource planning] system for their internal order processing. But they might all use different systems [e.g., Kingdee, Yonyou]—not only SAP. We also have a few local suppliers who use a rather 'local' method to process the orders via Excel. Some suppliers might have the necessary system infrastructure, but they might not want to use EDI with you because the setup effort is too big." (Operational Purchaser, IndustryCo)
6	Digitalized processes	"We are a digital factory; we require suppliers to use EDI. We also consider this when we assign future orders.… Plastics-SPL is a new supplier who has a strong willingness to do business with us, so it is easier to implement EDI with this supplier than compared with other suppliers." (Operational Purchaser, IndustryCo)
7	Category strategy	As a leading producer for smart products associated with Industry 4.0, IndustryCo also purchases several IT-related material categories, such as printed circuit boards sourced from Electronics-SPL or semiconductors sourced from Semicon-SPL.
8	Advanced analytics	"We must make sure that the information from our customers goes through the whole supply chain quickly, and in real time. It must be a very efficient information transfer if we want to make sure that our whole supply chain responds very quickly. We expect suppliers to have the capability and willingness to cooperate with us—for example, on EDI solutions, the forecast, VMI. All these tools aim to make sure that all the information from our customers to our supply chain can move very fast." (Head of Strategic Procurement, IndustryCo)

Procurement 4.0 centers around the digital and autonomous links *between* companies, which means that a certain level of digitalization maturity is required on both sides of the dyad. Findings from the case study reveal that the digital transformation of procurement at IndustryCo was partly impeded by the digital maturity level of its suppliers. IndustryCo's Head of Strategic Procurement explained that the heterogeneity of the supply base in China represented a challenge for digitalization:

> Our supply base is quite varied, our suppliers are not all on the same level. We have world-class suppliers like Semicon-SPL. We do not need to teach these companies about digitalization. All you need to do with these world-class suppliers is to coordinate, discuss, find a win-win situation, and align which tools to implement and what kind of information to share. For the middle-sized and the low-end suppliers, we also need to promote digitalization, to educate them on the benefits for them. (Head of Strategic Procurement, IndustryCo)

Incorporating a dyadic perspective in the Procurement 4.0 maturity model therefore implies assessing the digitalization maturity of suppliers as well. To do so, the maturity model should cover the same eight dimensions as it does for the supplier's digitalization maturity. Appendix A shows the detailed items for the supplier perspective. Taken together, the two perspectives of the dyadic model allow us to compare the digitalization maturity of buyers and suppliers.

Maturity model stages

With each of the maturity dimensions defined, our next step was the conceptualization of different maturity *levels* or *stages* that constitute PSM maturity models (Adams et al., 2016; Andreasen and Gammelgaard, 2018). Maturity stages can either be conceptualized ex ante from theory (e.g., Kleemann and Glas, 2017) or derived ex post/empirically—for example, through cluster analysis from survey data (e.g., Adams et al., 2016; Paulraj et al., 2006). The present paper follows the former approach in that it conceptually derives maturity stages based on extant literature (see Table 1). Building on typical PSM maturity stages (Andreasen and Gammelgaard, 2018), we propose a five-stage model in which the initial stage is characterized by the absence of digital procurement and intermediary stages move toward the final stage of fully digitalized procurement. In labeling the stages, we adopt the terminology of more recent Industry 4.0 maturity models (e.g., Lichtblau et al., 2015; PricewaterhouseCoopers, 2016a):

- **Digital outsider** (Stage 1): Firms in this group are in the traditional stage of procurement. Digital outsiders have not yet started the digital transformation of procurement and do not have concrete plans for pilot initiatives.
- **Digital newcomer** (Stage 2): Firms in this group are in the nascent stage of digitalization. Digital newcomers have done either very little or are currently planning pilot initiatives in a few selected areas and with a limited number of suppliers.
- **Developing learner** (Stage 3): Firms in this group are in the developing stage, working toward the digital transformation of procurement. Developing learners are currently implementing pilot projects in some areas and with several selected suppliers.
- **Seasoned expert** (Stage 4): Firms in this group are in an advanced stage on the road to the digital transformation of procurement. Seasoned experts have already implemented digitalization initiatives in several key areas and with the majority of their supply base.
- **Digital champion** (Stage 5): Firms in this group are leading the digital transformation of procurement. Digital champions have comprehensively implemented digital initiatives in all relevant areas and across their supply base.

These five stages are detailed for each of the eight Procurement 4.0 dimensions in Appendix B. In the following section, we discuss potential change processes through the maturity stages.

Change processes through maturity stages

Linear evolution. Extant PSM maturity models address *change* through the maturity stages as a rather linear and gradual process (Andreasen and Gammelgaard, 2018). This model of a linear evolution process conjectures that reaching one maturity stage is the foundation for moving to

the next stage (Andreasen and Gammelgaard, 2018). In line with extant literature, our Procurement 4.0 maturity model views linear evolution as the standard development path. However, departing from extant PSM maturity models, the proposed Procurement 4.0 maturity model also considers co-evolution and leapfrogging as alternative development trajectories.

Co-evolution. The concept of co-evolution recognizes that the buyer's and the suppliers' digitalization maturity each develop as distinct but mutually intertwined co-evolutionary processes, where each conditions the other's evolution (Kaufmann et al., 2016). This concept is inherently dyadic in nature and suggests in our case that the digital transformation of procurement requires both the buyer and suppliers to possess and progress through specific levels of digitalization maturity. In the case study, IndustryCo's management recognized that digitalization could not stop at the factory walls; it needed to include suppliers to deliver its full benefits. The Factory Manager explained:

> I think purchasing is really important because about 70% of our product costs are purchasing spend. So if you want to be successful, if you really want to digitalize, clearly also the entire supply chain has to follow the same way. It is not working if only we are digitalized but then there is a break to our suppliers. From my point of view, the supply base also has to upgrade to the same level.… Clearly, procurement is playing one of the important roles to… really bring digitalization to the suppliers in the next years. (Factory Manager, IndustryCo)

How the buyer's development pace relates to the pace of the supplier plays a critical role in the notion of co-evolution. In the case study, the Head of Strategic Procurement suggested that the buyer would need to adjust its digitalization pace to that of the supply base:

> IndustryCo is not independent from its environment, from the city in which it is located, from China. You cannot be ten years ahead of others; then you could not integrate with suppliers. I think the best companies are three or five years ahead; then you can get the most advantages. But you cannot be successful if you are too quick. (Head of Strategic Procurement, IndustryCo)

Leapfrogging. The concept of leapfrogging recognizes that companies can skip certain intermediary stages in the digital maturity model and move directly to a higher maturity stage. This notion departs from prior PSM maturity models that conceptualize change as linear and consider the skipping of stages to be an exception (Andreasen and Gammelgaard, 2018). In the emerging market context of the case study, leapfrogging appeared to be particularly relevant for small and medium-sized suppliers, as IndustryCo's Head of Strategic Procurement explained:

> The small and medium-sized suppliers, which we now promote and educate on digitalization, might skip one step. For example, they might not build their own data centers but directly go to cloud technologies. I think this is something that they can skip, they can always learn from the newest technology. (Head of Strategic Procurement, IndustryCo)

Plastics-SPL did not even have an ERP system until 2016 and recently adopted WebEDI with IndustryCo. The case suggests that leapfrogging across stages of technological development might be a viable option for Chinese suppliers. Similar to the way China's businesses leapfrogged from using cash to using mobile payment technologies, a leapfrogging strategy could mean that Chinese suppliers upgrade from Industry 2.0 directly to Industry 4.0. IndustryCo's Head of Strategic Procurement illustrated this logic with an example from the automotive industry:

> The Chinese automotive manufacturers do not want to follow the gradual development path because if they follow this, they will always be the follower. So they want to use the chances provided by technological innovation to immediately address the opportunity to go to the next stage—for example, through robotics solutions and customization. Now this area of customization is new to everybody; it is new not only to China but also to European industrialized countries. If we follow and go to mass production, we cannot do it better than the predecessor. (Head of Strategic Procurement, IndustryCo)

For Procurement 4.0, this reasoning could imply that Chinese suppliers—without the burden of legacy ERP systems—can quickly adopt cloud-based ERP solutions or mobile applications for digital integration with their customers. In addition, leapfrogging might be practiced not only by suppliers but also by buying organizations; specifically, start-ups typically skip various maturity stages by nature.

Operationalizing the Procurement 4.0 maturity model

In developing our scale items, we followed the guidelines from DeVellis (2017). We generated multiple items to ensure item reliability and avoided lengthy items to prevent complexity and ambiguity. To increase response differentiation, we adopted a 7-point Likert-type scale as the response format (Carter et al., 2017a). We also used items from existing scales developed by Kleemann and Glas (2017) to provide a solid theoretical foundation.

In a pretest, the item pool was assessed by three supply management experts, each with more than 10 years of experience in strategic procurement and extensive knowledge about Procurement 4.0 (DeVellis, 2017). The experts were instructed to rate the item applicability to the Procurement 4.0 context and to evaluate item wording (e.g., content validity and face validity) to avoid ambiguity (Min and Mentzer, 2004). Based on the feedback, we eliminated or reworded some of the items and added others. The final item pool consists of 31 items and is shown in Appendix A.

Quantitative pre-study for validating the Procurement 4.0 maturity model

To corroborate and refine the model in the field, we conducted a pre-study and collected feedback for further improvements (Schumacher et al., 2016). In this pre-study, the Procurement 4.0 maturity measurement instrument was administered to a dyadic sample of three Western European buying companies, eight of their European suppliers, and seven of their Chinese suppliers.

Sample and data collection

The buying firm sample covered leading manufacturing companies from the automotive, industrial automation, and household appliances sectors. The selected buying firms were already engaged in Procurement 4.0 to varying degrees, thus ensuring that they had the requisite knowledge and understanding about its basic concepts (Schumacher et al., 2016). Each buying firm was asked to identify three to five key suppliers, including both medium-sized and large European suppliers, as well as Chinese suppliers.

Data collection was conducted via an online survey, with responses to the 31 items captured on a seven-point Likert-type scale. Respondents were procurement managers (for buying firms) and sales managers (for suppliers). On average, buying firm respondents rated their knowledge about Procurement 4.0 at 5.8 on the 7-point scale, whereas supplier respondents rated their knowledge about digitalization at 3.8. The number of employees ranged from 20,000 to 300,000

for buying firms and from 50 to 30,000 for suppliers. (The average size of suppliers was about 7,500 employees.)

Pre-study results

The pre-study results show that Western European buying firms rate their Procurement 4.0 maturity at an average value of 5.1 on a 7-point Likert-type scale across all dimensions. Chinese suppliers rate their maturity somewhat higher (mean of 5.5), and European suppliers somewhat lower (mean of 4.6) than the Western buying firms. A similar pattern was seen for the individual maturity dimensions, except that in the "Leadership" dimension, the buying firms showed the highest value. (Because of the low sample size thus far, we caution readers to avoid drawing concrete conclusions from the pre-study results.) Figure 1 visualizes the maturity along all eight dimensions using a radar chart.

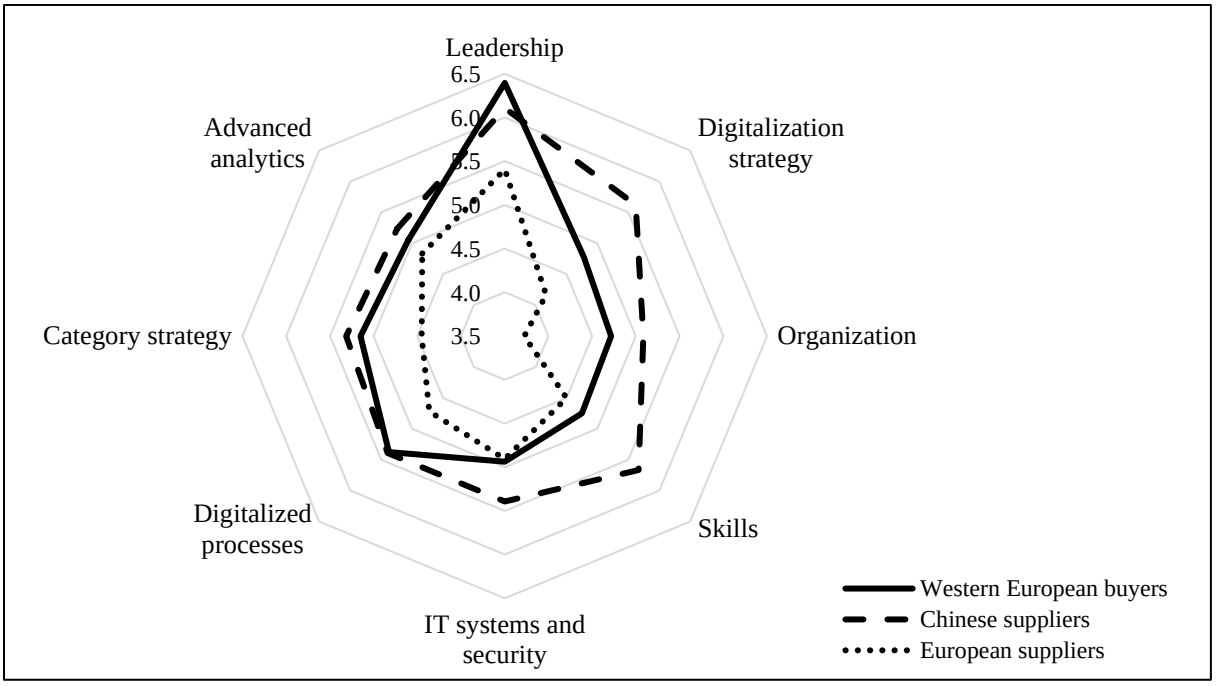

Figure 1: Radar chart visualizing Procurement 4.0 maturity in eight dimensions

To corroborate and refine the model, we presented the pre-study results to the assessed companies and collected feedback for further improvements (Schumacher et al., 2016). The clarity of the questionnaire items, the applicability and relevance of the Procurement 4.0 model, and its visual representation using radar charts received positive feedback throughout. The feedback from practitioners and further analysis of the pre-study by the research team informed the identification of potential areas for further developments, which are discussed in the next section.

Discussion and conclusion

Our research aimed to provide initial answers to two research questions. The first was to conceptualize a Procurement 4.0 maturity model. Building on a literature review and a case study, we derived eight dimensions, five maturity stages, and possible change processes. The second research question was to operationalize the Procurement 4.0 maturity model. To this end, we developed 31 items and administered a quantitative pre-study to a dyadic sample of 18 companies: 3 Western European buying firms, 8 of their European suppliers, and 7 of their Chinese suppliers.

Theoretical contributions

This research aims to make three major contributions to the PSM literature. First, it advances the still-embryonic literature on *Procurement 4.0* (e.g., Richey et al., 2016) by extending the content domain of PSM maturity models to digitalization. Although researchers and practitioners are still discussing the specific delineation of Procurement 4.0, that the digitalization of procurement offers the potential to fundamentally change the way buying firms collaborate with their supply network around the globe is undisputed (Hofmann and Rüsch, 2017). By conceptualizing eight dimensions of Procurement 4.0 maturity, our research offers an initial step toward better grasping the concept of Procurement 4.0 as it unfolds in practice.

Second, in contrast to prior PSM maturity models that take the PSM organization as the unit of analysis, this Procurement 4.0 maturity model takes a *dyadic perspective* and accounts for the maturity levels of both buyers and suppliers along several dimensions. A dyadic perspective is particularly relevant in the PSM context because critical technologies and processes for the digitalization of procurement span organizational boundaries (Liu et al., 2016; Saldanha et al., 2015). To maximize relational performance in supply chains (Carter et al., 2017b), research and practice should therefore consider both the buying firm's and the supplier's perspective. Importantly, this dyadic perspective sheds light on the crucial role of *co-evolution* between the buyer and the supplier in the digital transformation to Procurement 4.0.

Third, this study responds to a recent call by Andreasen and Gammelgaard (2018) to unravel the change processes in PSM maturity models. Instead of conceptualizing change as a rather linear and gradual process, this paper offers *leapfrogging* as a strategy particularly suitable for the digital transformation of procurement—one that contrasts with the traditional evolutionary process assumed in extant maturity models. Accounting for non-linear change processes can improve the explanatory power of maturity models and helps to provide practitioners with better guidance for change.

Managerial implications

Interest in the topic of Procurement 4.0 is growing among practitioners, and many remain confused about what the digitalization of procurement means for their business. However, extant PSM research to date offers very little guidance for managers concerning the digital transformation to Procurement 4.0. Our Procurement 4.0 maturity model aims to provide managers with initial guidance for analyzing their own and their supply base's status on the road toward Procurement 4.0—guidance that is grounded in theory and based on empirical findings. The maturity model suggests that managers should take a holistic approach, considering several maturity dimensions that range from leadership to skills to advanced analytics. Importantly, managers should develop their Procurement 4.0 roadmaps with an eye toward the digitalization maturity of their supply base so that they co-evolve together with their supply network. Companies in an early digital maturity stage might devise ways to skip or leapfrog over intermediary stages to reach a desired maturity level.

Limitations and future research

We acknowledge three limitations inherent in the exploratory nature of our study, which provide many opportunities for future research. First, the Procurement 4.0 maturity model so far takes a one-size-fits-all approach and does not differentiate among the different strategic priorities of companies. However, the digitalization profile of a company needs to fit its strategic priorities (e.g., savings, innovation, speed, agility, or risk mitigation). Future research could adopt a neo-configurational perspective (Kosmol et al., 2018) and analyze which configurations of digitalization maturity support the achievement of different strategic priorities.

Second, the somewhat surprising finding that emerging market suppliers show a higher digitalization maturity than suppliers from developed markets could be attributed to problems associated with the self-assessment method used. Although administering online surveys is less time-consuming and can reach a larger sample size than case studies, self-assessments might not accurately reflect the actual maturity level of respondents. Therefore, a methodological implication from our quantitative pre-study might be that researchers should administer their maturity assessment using on-site personal interviews or conduct on-site audits to achieve higher validity.

Third, our focus on manufacturing companies and the small sample size limit the generalizability of our results. Thus, we call for future research to replicate this study with a larger sample covering different kinds of industries.

Finally, our study provides only an initial starting point for further research in this exciting area. Because of the nascent stage of the field and the ongoing development of digitalization, many unanswered questions remain. In Table 5 we therefore suggest a comprehensive agenda for future research on Procurement 4.0 using the "5Ws and H" approach (Cao and Lumineau, 2015).

Table 5: Proposed research agenda

	What? **Area to Investigate**	**Who?** **Actors**	**Where?** **Contextual Variables**	**When?** **Temporal Variables**	**Why?** **Relevance**	**How?** **Managerial Interventions**
Key concepts	**Topic area:** psychological, social, behavioral, and structural factors **Situational factors:** barriers and enablers; type of supply chain technology	**Individual-level:** personality traits **Organization-level:** company type, power **Network-level:** associations, network effects	**Contextual factors:** institutional environment, national culture, environmental dynamism, supply network structure, industry sector	**Temporal factors:** maturity stage, technology adoption process, timing of technology implementation (early vs. late), leapfrogging	Why is it important to investigate this area? What are the outcomes and consequences of Procurement 4.0?	Measures to influence the digitalization of procurement
Possible research questions	• What key performance indicators exist to measure the dimensions of Procurement 4.0 maturity? • What barriers and enablers exist in the digitalization of procurement? • Which factors determine why some companies show higher digitalization maturity than others? • Do different types of information technologies lead to differences in supply chain integration?	• How do personality traits of company owners and top managers influence whether suppliers adopt digital technologies or not? • How do Internet companies and start-ups in the ecosystem influence the digitalization of procurement? • Which skill profiles are required from procurement managers for the digital transformation of procurement?	• How do companies mitigate institutional voids (e.g., unstable Internet connectivity) in the IT ecosystem of emerging markets? • How do government interventions (e.g., Great Firewall of China) moderate cross-border data flows in supply chains? • How do cultural and institutional factors moderate digital supplier integration? • How does network structure influence the digitalization in supply networks?	• How do companies evolve through the Procurement 4.0 maturity stages over time? • Which patterns of co-evolution exist in buyer–supplier dyads? • How do the digitalization strategies of early adopters and latecomers in Procurement 4.0 differ? • How does the adoption of IT spread across different tiers in supply chains over time?	• What are the operational, financial, and strategic performance outcomes of Procurement 4.0? • Which configurations of digitalization maturity are associated with the achievement of different strategic priorities? • Does the "IT productivity paradox" also occur for Procurement 4.0? • What are the short-term and long-term effects of the digital transformation of procurement?	• How can CPOs increase their company's Procurement 4.0 maturity? • Which mitigation strategies reduce barriers to the digitalization of procurement? • How can buying firms incentivize suppliers to invest in digital integration capabilities? • How can industry associations promote the standardization and interoperability of IT systems?
Promising theories	Socio-structural view, organizational inertia	Dynamic capabilities, network effect theory	Technology-organization-environment framework	Complex adaptive systems theory, event system theory	IT productivity paradox, supply chain practice view	Supply chain practice view, game theory

Suggested methodologies	Survey research, multiple case studies	Experiments, case studies, network analyses	Survey research, case studies	Process studies, simulations	Survey research, big data analytics, data envelopment analysis	Field experiments, action research

Appendix

Appendix A: Dimensions and items of Procurement 4.0 maturity model

#	Dimension	Abbreviated description[1]	Items (Buying companies)[2]	Items (Suppliers)[2]
1	Leadership	Top management support	Industry 4.0 and digitalization are highly valued in our company as a whole.	Industry 4.0 and digitalization are highly valued in our company as a whole.
2	Leadership	Digitalization strategy	A comprehensive digitalization strategy exists for our company as a whole.	A comprehensive digitalization strategy exists for our company as a whole.
3	Leadership	Top management knowledge and awareness	Our senior management is fully knowledgeable and aware of the importance, workings, and implications of Procurement 4.0.	Our senior management is fully knowledgeable and aware of the importance, workings, and implications of digitalization.
4	Leadership	Digitalization support	Our senior management fully supports Procurement 4.0 projects.	Our senior management fully supports digitalization projects.
5	Digitalization strategy	Digitalization guidelines	There are clear guidelines and priorities indicating how digital Procurement 4.0 should contribute to our company.	There are clear guidelines and priorities indicating how digitalization should contribute to our company.
6	Digitalization strategy	Digitalization concept	A comprehensive, up-to-date concept for digital integration with suppliers guides our strategic supplier management activities.	A comprehensive, up-to-date concept for digital integration with customers guides our strategic customer management activities.
7	Digitalization strategy	Functional influence	The procurement function regularly uses its market and supplier know-how to actively influence our company's digitalization strategy (e.g., procurement of innovations and Industry 4.0 technologies).	The sales function regularly uses its market and customer know-how to actively influence our company's digitalization strategy (e.g., data-driven services and Industry 4.0 technologies).
8	Organization	Central coordination	Digitalization projects in our company are centrally coordinated (e.g., through a "Chief Digital Officer").	Digitalization projects in our company are centrally coordinated (e.g., through a "Chief Digital Officer").
9	Organization	Roles and responsibilities	Clear and dedicated roles and responsibilities for the management of digitalization in the procurement function exist, such as a "Digital Procurement Manager."	Clear and dedicated roles and responsibilities for the management of digitalization exist in our company, such as a "Digital Sales Manager."
10	Organization	Cross-functional teams	Digitalization projects in the procurement function are often realized in cross-functional teams.	Digitalization projects are often realized in cross-functional teams.
11	Organization	External partners	Digitalization projects in the procurement function are often realized with external partners (e.g., consultants, start-ups, academia).	Digitalization projects are often realized with external partners (e.g., consultants, start-ups, academia).

#	Dimension	Abbreviated description[1]	Items (Buying companies)[2]	Items (Suppliers)[2]
12	Organization	Resources	The procurement function has sufficient resources dedicated to working on digitalization topics in the ordinary course of business.	Our company has sufficient resources dedicated to working on digitalization topics in the ordinary course of business.
13	Skills	Digital expertise	Building up functional digital expertise quickly is a core element of employee development in the procurement function.	Building up functional digital expertise quickly is a core element of employee development in our company.
14	Skills	Digital tool skills	Our procurement staff are very skilled in the use of our digital tools and processes.	Our staff are very skilled in the use of our digital tools and processes.
15	Skills	Recruitment criterion	Functional digital competencies are an important selection criterion in the recruitment of new procurement employees.	Functional digital competencies are an important selection criterion in the recruitment of new employees.
16	IT systems and security	IT updates	Our enterprise IT is updated regularly and promptly to meet new challenges.	Our enterprise IT is updated regularly and promptly to meet new challenges.
17	IT systems and security	IT resources	We have sufficient access to IT resources (e.g., software developers, IT specialists) for digitalization projects in procurement.	We have sufficient access to IT resources (e.g., software developers, IT specialists) for digitalization projects.
18	IT systems and security	Data & IT security	Data and IT security are strictly ensured through risk analyses and risk mitigation measures.	Data and IT security are strictly ensured through risk analyses and risk mitigation measures.
19	IT systems and security	Procurement/ order data	Our company has an IT system that gathers procurement data seamlessly and enables quick interpretation of that data.	Our company has an IT system that gathers order data seamlessly and enables quick interpretation of that data.
20	Digitalized processes	Internal collaboration	The procurement function frequently uses digital collaboration and knowledge exchange platforms internally.	Our company frequently uses digital collaboration and knowledge exchange platforms internally.
21	Digitalized processes	External collaboration	We regularly use digital collaboration platforms with suppliers.	We regularly use digital collaboration platforms with customers.
22	Digitalized processes	Automatic purchase orders	The workflow for regular purchase orders runs automatically within defined parameters – without human intervention (e.g., order release, control).	The workflow for regular sales orders runs automatically within defined parameters – without human intervention (e.g., order confirmation, shipment notification).
23	Digitalized processes	End-to-end supply chain	We enthusiastically drive digitalization projects with our suppliers (e.g., real-time sharing of production data, seamless drawings exchange) to move toward an integrated, end-to-end supply chain.	We enthusiastically drive digitalization projects with our customers (e.g., real-time availability of production data, seamless drawings exchange) to move toward an integrated, end-to-end supply chain.
24	Category strategy	Supplier/ customer segmentation	We regularly segment and evaluate supplier relationships in terms of their digitalization potential (e.g., EDI links).	We regularly segment and evaluate customer relationships in terms of their digitalization potential (e.g., EDI linkages).

#	Dimension	Abbreviated description[1]	Items (Buying companies)[2]	Items (Suppliers)[2]
25	Category strategy	Strategic alignment	We frequently discuss digital modes of collaboration with our suppliers (e.g., digitalization roadmaps) to achieve strategic alignment in the area of digitalization.	We frequently discuss digital modes of collaboration with our customers (e.g., digitalization roadmaps) to achieve strategic alignment in the area of digitalization.
26	Category strategy	Digital categories	We use material categories and up-to-date category strategies for the procurement of a wide range of digital goods and services (e.g., intelligent sensors, software, CAD drawings).	We use product categories and up-to-date product management strategies for a wide range of digital solutions and services (e.g., customized products, predictive maintenance, online customer support).
27	Category strategy	Technology impact	Our procurement function regularly analyzes the effects of new technologies (e.g., 3D-printing, blockchain technology) on the make-or-buy decision.	We regularly analyze the effects of new technologies (e.g., 3D-printing, customer analytics) on our strategy.
28	Category strategy	Innovation radar	Our procurement function proactively looks for suppliers and products in the area of new, innovative technologies to anticipate changing requirements.	We proactively look for solutions and products in the area of new, innovative technologies to anticipate changing demands.
29	Advanced analytics	Big data analytics	We widely use software to automatically analyze critical parameters, like inventory range, procurement spend, order frequency, and raw material prices (i.e., Big Data Analytics).	We widely use software to automatically analyze critical parameters, like inventory range, sales volume, order frequency, and customer satisfaction (i.e., Big Data Analytics)
30	Advanced analytics	Predictive analytics	We widely use automated, real-time analyses to trigger forecast-based orders (predictive analytics).	We widely use automated, real-time analyses to trigger forecast-based production (predictive analytics).
31	Advanced analytics	Innovative contracting	Our procurement function proactively analyzes the viability of innovative contracting models for digital services (e.g., pay-per-use, performance-based contracting).	We proactively analyze the viability of innovative contracting models for digital services (e.g., pay-per-use, performance-based contracting).

[1] P4.0 = Procurement 4.0
[2] All items are measured on a seven-point Likert-type scale ranging from 1 = strongly disagree to 7 = strongly agree.

Appendix B: Overview of maturity stages

Dimension	**Digital outsider** (Stage 1)	**Digital newcomer** (Stage 2)	**Developing learner** (Stage 3)	**Seasoned expert** (Stage 4)	**Digital champion** (Stage 5)
Leadership	Digitalization is not incorporated in the company's strategy. Top management shows no or very limited knowledge or support for digitalization in the company and in the procurement function.	Digitalization is only starting to be incorporated in the company's strategy. Top management shows limited knowledge and support for digitalization in the company and in the procurement function.	Digitalization is largely being incorporated in the company's strategy. Top management shows basic knowledge and support for digitalization in the company and in the procurement function.	Digitalization is incorporated in the company's strategy. Top management shows extensive knowledge and support for digitalization in the company and in the procurement function.	Digitalization is firmly incorporated in the company's strategy. Top management shows very strong knowledge and support for digitalization in the company and in the procurement function.
Digitalization strategy	No digitalization strategy exists for the company. No Procurement 4.0 concept exists.	Procurement has no or only very limited influence on the company's digitalization strategy. Selective elements of a Procurement 4.0 concept are starting to be developed.	Procurement has limited influence on the company's digitalization strategy. A comprehensive Procurement 4.0 concept is being developed.	Procurement has considerable influence on the company's digitalization strategy. A comprehensive Procurement 4.0 concept exists and is selectively used.	Procurement has major influence on the company's digitalization strategy. A comprehensive Procurement 4.0 concept exists and is being implemented throughout the company
Organization	No roles and responsibilities for the coordination of Procurement 4.0 within the company or with external partners have been assigned.	Roles and responsibilities for the coordination of Procurement 4.0 within the company and with external partners are starting to be designated.	Roles and responsibilities for the coordination of Procurement 4.0 within the company and with external partners are selectively being implemented.	Clear roles and responsibilities for the coordination of Procurement 4.0 within the company and with external partners exist (e.g., Digital Procurement Officer).	Clear roles and responsibilities for the coordination of Procurement 4.0 within the company and with external partners are established throughout the company.
Skills	Procurement employees have no digital skills or competencies.	Procurement employees have only very limited digital skills and competencies.	Procurement employees have basic digital skills and competencies (e.g., basic IT tool skills).	Procurement employees have advanced digital skills and competencies (e.g., IT know-how, data analytics skills).	Procurement employees have excellent digital skills and competencies (e.g., profound IT know-how, data analytics skills).
IT systems & security	The company has inadequate IT systems and security in place (e.g., disintegrated, outdated legacy	The company has only very basic IT systems and security in place (e.g., heterogeneous IT landscape).	The company has basic IT systems and security in place (e.g., centralized databases, basic firewalls).	The company has advanced IT systems and security in place (e.g., integrated IT architecture, strong firewalls).	The company has excellent IT systems and security in place (e.g., agile, cloud-based IT architecture, fast

Dimension	Digital outsider (Stage 1)	Digital newcomer (Stage 2)	Developing learner (Stage 3)	Seasoned expert (Stage 4)	Digital champion (Stage 5)
	systems, serious IT security gaps).				response to cyber-security incidents).
Digital tools & processes	No digital tools or processes are in place.	Basic digital tools and processes are selectively being implemented (e.g., digital contract database).	Basic digital tools and processes are implemented throughout the company (e.g., supplier portal, WebEDI).	Advanced digital tools and processes are selectively being implemented (e.g., integrated e-procurement suite).	State-of-the-art digital tools and processes are implemented throughout the company (e.g., robotic process automation for P2P).
Category strategy	No category strategies exist for digital products and services. Procurement is not actively searching for digital innovations.	Basic category strategies exist for selected digital products and services. Procurement searches for digital innovations (e.g., touchpads) in a few areas.	Basic category strategies exist for a wide range of digital products and services. Procurement actively searches for digital innovations (e.g., sensors for preventive maintenance) in selected areas.	Advanced category strategies exist for selected digital products and services. Procurement actively searches for digital innovations (e.g., 3D-printing, blockchain) in several areas	Advanced category strategies exist for a wide range of digital products and services. Procurement actively searches for digital innovations (e.g., 3D-printing, blockchain, artificial intelligence) in many areas.
Advanced analytics	No advanced analytics tools are in place.	Implementation of selected advanced analytics tools (e.g., spend cleansing) is being evaluated.	Selected advanced analytics tools (e.g., spend cleansing) are being implemented.	Several advanced analytics tools (e.g., predictive analytics for purchase prices) have been implemented.	State-of-the-art advanced analytics tools (e.g., predictive analytics for purchase prices) have been implemented throughout the company.

CREATION OF COMPETITIVE ADVANTAGE THROUGH SUPPLY MANAGEMENT CAPABILITIES: A RESOURCE ORCHESTRATION PERSPECTIVE

Summary: This study tackles the debate regarding how suppliers can become a resource that helps buying firms achieve competitive advantage. Extant literature is still dissonant in using terms such as resources, capabilities and practices. We use resource-based theory (RBT) and resource orchestration theory (ROT) to investigate how companies utilize their supply management capabilities to manage relationships with their key suppliers, as external resources, to compete on two strategic paradigms: cost and differentiation. We elaborate and test hypotheses through survey data collected in the USA after the downturn, which reshuffled the priorities of many previously existing buyer-supplier dyads.

Keywords: Resource Orchestration; Supplier Management; Survey; Structural Equation Modeling

Category: Competitive Paper

CREATION OF COMPETITIVE ADVANTAGE THROUGH SUPPLY MANAGEMENT CAPABILITIES: A RESOURCE ORCHESTRATION PERSPECTIVE

Introduction

If we accept that our current time is an "age of secular stagnation," we should acknowledge that global GDP may remain close to zero for quite some time (Summers, 2016; Eggertsson, Mehrotra & Summers, 2016). This situation poses interesting questions to management scholars regarding the capabilities that determine firms' success in the absence of significant growth. If the unusually deep recession initiated by the 2008 economic downturn will not be followed – as it seems – by an unusually rapid recovery, what should companies do? This is a multidisciplinary question, but we believe that a major area that should be revisited is the management of business-to-business relationships across the supply chain.

Recent research on companies' most important buyer-supplier relationships (BSRs), or dyads, has shown that the 2008 economic downturn significantly affected many of these relationships. Krause & Ellram (2014) reported that key BSRs, characterized by significant levels of interdependence, differ on various dimensions, including the degree of convergence of the parties' competitive priorities and performance goals. They suggested that the downturn represented a quasi-stress test of these relationships; some emerged from the downturn ready to compete, while others regressed to a relationship characterized by lower levels of cooperation and trust than prior to the downturn. Some dyads came close to dissolution. The authors observed that when cost was a strong focus of a key BSR prior to the downturn, the discussions and activities that took place within the relationship during the downturn were characteristically different than relationships that had previously emphasized performance imperatives other than cost.

The data in the present study was collected several years after many or most firms had recovered significantly from the negative effects of the downturn. These negative effects had included decreased sales, lost or diminished capabilities, reduced capacity through plant closings, and lost market share. Further, there were supply situations where financially vulnerable suppliers had either gone out of business or had laid off many employees and closed some plants, leaving their customers to decide whether to look for new suppliers or to work with these suppliers to rebuild their capabilities and capacity. As a result, many BSRs have been rebooted in order to fit with the new macroeconomic reality that the downturn delineated, and some companies appear to have changed the way they leverage their supplier management capabilities (Krause & Ellram, 2014).

In addition to the observation of a new reality for BSRs, the field needs to bring clarity to the literature applying resource-based theory (RBT) to study BSRs. As indicated by a recent debate in the Journal of Operations Management (Hitt, Xu, & Carnes, 2016; Bromiley & Rau, 2016; Hitt, Carnes, & Xu, 2016), RBT contributes to our understanding of how resources and capabilities are integrated across the supply chain for competitive advantage. However we believe that extant studies have not yet provided clarity regarding how competitive advantage is generated. Since RBT can be complemented with other theories for investigating how firms achieve competitive advantage (Hitt et al., 2016a), we incorporate resource orchestration theory (ROT) based on Sirmon, Hitt, & Ireland (2007), which seems particularly well suited to interpret the BSR phenomenon, and offers an opportunity for theory advancement. Since only a handful of studies have adopted ROT (e.g., Liu et al. 2016; Koufteros, Verghese, & Lucianetti, 2014) we believe it is an important emergent theoretical stream that needs further refinement, especially a clear contextualization into supply chain management.

Resource-based theory and management of key BSRs

The primary research questions in this paper are as follows: *Do companies utilize their BSR management capabilities to manage a BSR focused on cost differently than they manage a BSR focused on differentiation? If so, how?* To approach these questions we adopt the resource-based theory (RBT) of the firm (Wernerfelt, 1984). RBT proposes that companies are able to develop, and perhaps even sustain, a competitive advantage via management of resources that are valuable, rare, inimitable, and non-substitutable.

A resource is defined as those tangible and intangible assets that are semi-permanently tied to the firm (Wernerfelt, 1984), including physical, human, and organizational capital (Barney, 1991). Firms need resources that are valuable and rare to gain competitive advantage, but these resources must also be difficult to imitate and difficult to substitute (Hitt et al., 2016a, p. 78). Intangible resources may be more difficult to imitate because of ambiguity associated with their formation (Hitt et al., 2001). However, Barney (1991) cautions that not all of a company's resources are strategically relevant, and that some companies are better than others at managing their resources for competitive advantage. Thus, recent scholarly efforts within the RBT literature have introduced the sub-theory of resource orchestration (ROT) (Sirmon et al., 2007; Sirmon et al., 2011), which focuses on *how* firms manage their resources.

Sirmon et al. (2011) use ROT to explain how managers transform a collection of resources into capabilities. As noted by Hitt et al. (2016a), this notion of resource orchestration overlaps with the notion of asset orchestration typical of the dynamic capabilities perspective. Dynamic capabilities are considered complementary to RBT; they help explain how resources are developed into capabilities, over time, and in response to changing competitive environments (Teece, Pisano & Shuen, 1997). Barney (2012) notes that purchasing management can be a capability, and when developed within the firm (i.e., not purchased in strategic factor markets) can yield competitive advantage. He also notes that purchasing managers focus on acquiring resources from outside the firm's boundaries, that is, from suppliers. Similarly, Quintens, Pauwels, & Matthyssens (2006, p. 882) define purchasing-related capabilities as "combinations of purchasing routines that are organizational processes by which available resources are combined, transformed and deployed to create valuable purchase-related outcomes."

Unfortunately, the operations and supply chain literatures display some dissonance regarding the distinction between resources and capabilities (Hitt et al., 2016a), which raises the need for clarity in the use of these terms. Our review of the literature about BSR management reveals several sources of dissonance including: (i) different terms that – within the same study – are used interchangeably; (ii) different terms that – across studies – indicate the same concept (e.g., resources and capabilities, skills and capabilities, practices and capabilities); and (iii) same terms that – across studies – indicate different concepts (e.g., capabilities). This dissonance appears to not be limited to the supply chain literature (Wang & Ahmed, 2007).

Referencing the definitions provided above and applying them to purchasing and purchasing managers, we view purchasing managers' knowledge and skills as internal resources of the firm. Suppliers are resources that are external to the firm, that have their own internal resources and capabilities. Purchasing's capabilities are developed through the integration of managers' knowledge and other employees' skillsets to manage BSRs with the strategic goal of aligning supplier-resources and capabilities with those of the firm.

For the present study, we propose that purchasing managers can build BSR management capabilities within the firm that may be relatively unique to the firm and be, from an external observer, causally ambiguous. We argue that as a company accumulates human capital, specifically in the form of purchasing managers and related personnel, over

time it can manage these resources for competitive advantage. Thus, a firm may build purchasing capabilities focused on management of BSRs, which in turn are able to access suppliers as external bundles of resources and capabilities. The firm's internal purchasing capabilities may become, over time, valuable, rare, inimitable and non-substitutable (VRIN) (Barney, 1991). These internal capabilities may be applied to manage key BSRs in unique ways, yielding further capabilities within the BSR that become VRIN. Due to space constraints, we are not further expanding on this argument, which finds support in the purchasing literature.

Resource orchestration theory: transforming purchasing resources into BSR management capabilities

Once we acknowledge that BSRs can be VRIN and are worth the time and effort to develop, the next question becomes: how can firms build BSRs that will become VRIN and therefore generate a competitive advantage in terms of either cost or differentiation? This question might be answered by considering the managerial routines that purchasing managers put in place to integrate external resources residing within suppliers with resources internal to the firm. Despite extant studies offering some suggestions regarding complementary theories that would serve this purpose (including transaction cost theory, dynamic capabilities, knowledge based view, and agency theory – Hitt et al., 2016a, p. 81) we did not find a sufficiently comprehensive explanation that is rooted in the core principles of supply chain management. Therefore we advance resource orchestration as a possible solution to this gap.

ROT is focused on managers' efforts to effectively manage resources. Sirmon et al. (2007, p. 273) define resource management as "the comprehensive process of structuring the firm's resource portfolio, bundling the resources to build capabilities, and leveraging those capabilities with the purpose of creating and maintaining value for customers." The authors further propose that *structuring* resources involves "acquiring, accumulating and divesting" resources to bundle and leverage them. *Bundling* is the dynamic process of "stabilizing, enriching, and pioneering" resources to build capabilities (Hitt et al., 2016a). *Leveraging* is "mobilizing, coordinating and deploying" capabilities with an external focus on accessing market opportunities.

Structuring the Supply Base via Acquiring, Accumulating, and Divesting

We propose that the unit of analysis changes as the firm seeks to manage its supply base through the structuring, bundling and leveraging processes, as shown in Figure 1. A supply base is defined as constituting "only those suppliers that are actively [and directly] managed through contracts and the purchase of parts, materials and services" (Choi & Krause, 2006, p. 639). During structuring, the focal firm analyzes its supply base in relation to the supply network, which includes "all inter-connected companies that exist upstream to any one company in [a] value system," (p. 638) regardless of whether the focal company is knowledgeable of their existence. In structuring, the focal firm seeks to raise the caliber of its supply base through establishing contractual relationships with new suppliers (*acquiring*), and seeking to bolster its store of external resources and capabilities that reside within its

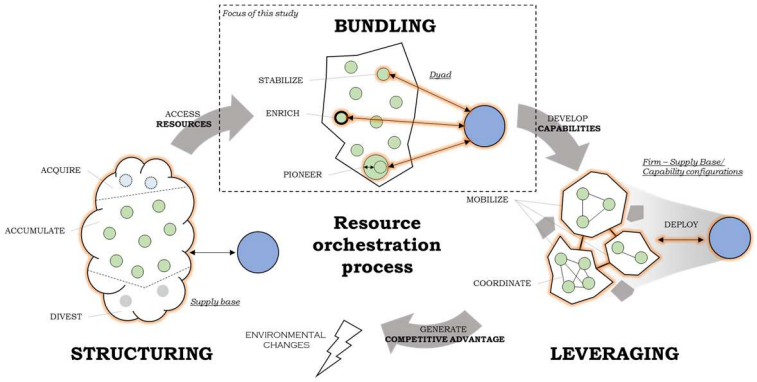

Figure 1 – Resource Orchestration Process

suppliers by *accumulating* and *divesting*, that is, adding additional suppliers where needed and eliminating those suppliers that are not performing well or are not needed from a resource-based perspective (Treleven & Schweikhart, 1988). The unit of analysis in this effort is the supply base. This process is known in the supply chain literature as supply base optimization or supply base rationalization (Choi & Krause, 2006), and may be a continual, ongoing effort. Goals of this process include minimization of risk, lower transaction costs, and ultimately maximizing value for the focal firm's customers.

Bundling Key Dyads via Stabilizing, Enriching, and Pioneering

Although supply base rationalization may be an ongoing process, especially in the context of significant environmental uncertainty, the effort to orchestrate resources also includes a focus on the focal firm's most important BSRs. Sirmon et al. (2007) note that bundling "is the process by which capabilities are formed" (p. 281). Here, the unit of analysis shifts to focus on each of the many key dyads managed by the focal firm, that is, on a specific supplier relationship, its performance and capabilities. Specifically, the unit of analysis for bundling is the dyad. From a purchasing perspective, *stabilizing* may be a remedial process, and thus focused on a particular supplier's perceived weaknesses. Stabilizing capabilities may include rearranging or reallocating resources, and this may take place across organizational boundaries as the companies within the dyad seek to build capabilities, uniquely combining their resources (Sirmon et al., 2007). The expectations are, at minimum, for incremental improvements in one or two areas of a supplier's performance. Next, *enriching* may involve strengthening a supplier's capabilities that are related to already existing capabilities. The effort here is focused on building or extending capabilities. Finally, *pioneering* involves efforts to build new capabilities (Sirmon et al., 2007). These efforts may be the result of attempts to innovate new products, or to further differentiate existing products.

Leveraging the Joint Capabilities of the Firm and its Supply Base via Mobilizing, Coordinating and Deploying

We propose that the unit of analysis again shifts to now include the entities of the focal firm *and* the suppliers in the firm's supply base. The leveraging process involves the focal firm now using its enhanced supply base, including and its key BSRs to mobilize, coordinate and deploy these newly enhanced resources and capabilities (Sirmon et al., 2007). *Mobilizing* refers to the buyer picking the right supplier for the right task within the pool that has been created during the bundling phase. Rather than independently selecting each single supplier, the buying firm must consider the complex set of possible interactions between suppliers and *coordinate* them for the creation of capability configurations that are consistent with the firm's strategy. This task may become increasingly difficult as the complexity of the supply base and the pattern of interactions increase (Choi & Krause, 2006; Wu, Choi, & Rungtusanatham, 2010). Finally, *deploying* refers to the activation of the required sets of supplier capability configurations at the right time, for example in a given moment of the new product development process (to ensure the efficient and effective integration of supplied components ahead of the engineering phase), or during the normal production planning cycle (to ultimately ensure the final customer service level).

Hypotheses

In the present study, our primary focus is on the firm's use of its existing supply management resources and capabilities to align key supplier resources with its competitive strategy. After the economic downturn that started in fall 2008, companies began to emphasize cost as a supplier performance criterion to a greater extent than prior to the downturn (Krause & Ellram, 2014). From an RBT/ROT perspective, we propose that the supply base has largely been structured, through a continual process of selecting and accumulating suppliers, and divesting

of suppliers that either do not align with the firm's competitive strategy or do not exhibit a willingness or ability to align. In the present study, we focus on bundling the firm's internal resources and capabilities with the external resources and capabilities represented in the supplier. Therefore, our unit of analysis for this study is key buyer-supplier dyads.

In bundling the BSR, the firm may seek to *stabilize* a supplier's capabilities, *enrich* or enhance the supplier's capabilities where needed, and to *pioneer* or develop new capabilities with the supplier. If successful, these bundling activities will produce a BSR that combines and aligns the internal resources and capabilities of the buying firm with those of the supplier's. Ultimately this relationship will be leveraged to enable the two companies to reach their competitive goals through leveraging, via mobilizing, coordinating and deploying, these resources and capabilities in the marketplace.

BSR Management Capabilities vis-à-vis Differentiation and Cost Leadership Strategies

Following Sirmon et al. (2011), the present research focuses on cost leadership and differentiation as two fundamental business strategies companies use to gain competitive advantage. Firms competing through differentiation attempt to differentiate their products and/or services from those of their competitors. Sirmon et al. (2011) note that "the capabilities through which the firm provides superior value must be dynamic in that they have to be constantly updated in order to remain ahead of competitors. As such, dynamic managerial capabilities are needed" (p. 1398) in environments that are characterized by significant levels of competitive rivalry and its resulting levels of environmental and technological uncertainty and change.

In contrast, a cost leadership strategy "requires investments in specific resources to build capabilities that produce efficiency while simultaneously minimizing investments in other resources that do not help them meet efficiency goals" (p. 1398). Therefore, we propose the following *overarching or foundational* propositions as an underlying assumptive framework for our hypotheses. We provide specific hypotheses further below.

> ***Proposition 1a****: Companies whose purchasing personnel focus their resources and capabilities on aligning a cost-focused BSR, will engage in a different collection of supplier management, or resource orchestration activities than those companies working to align a differentiation-focused BSR.*
>
> ***Proposition 1b****: Respondents that claim to be competing on a differentiation strategy will report greater levels of technological uncertainty than respondents competing on the basis of cost leadership.*

Overall, it is the buying firm's human capital resources, in the form of purchasing managers, that decide what combination of capabilities and resources should be used to maximize the value the firm attempts to derive from any particular BSR.

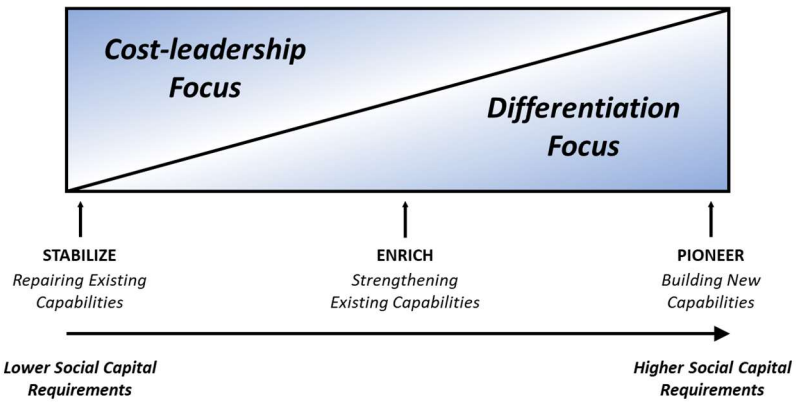

Figure 2 – Bundling stage of BSR management

Six independent constructs were used in this study to represent a range of activities that supply managers may use to influence the performance of key suppliers and ultimately result in capabilities that may be characterized as VRIN. The first three variables are *supplier competition*, *black box monitoring*, and *operational communication*. Overall,

these constructs represent relatively low levels of resource expenditure by the buying firm and relatively little social capital investment by purchasing managers. As such, they are more likely to be utilized by cost leaders who are focused on efficiency, while minimizing investments in alternative, more resource-intensive, supply management resources that do not help meet efficiency goals (Sirmon & Hitt, 2009), as shown in Figure 2.

The last three constructs are *close monitoring*, *know-how exchange*, and *supplier collaboration*. Each of these constructs involves significantly higher levels of resource commitment, including social capital building, than the three discussed above. Dynamic managerial capabilities are comprised of managerial cognition, managerial social capital, and managerial human capital (Helfat & Martin, 2015). Choosing to engage in close monitoring of suppliers, know-how exchange with suppliers, and supplier collaboration requires that managers understand the implications of their choices (managerial cognition), are willing to expend resources in developing goodwill with suppliers (managerial social capital), and have knowledge regarding how to combine a supplier's resources and capabilities with those of their own firm's (managerial human capital) (Helfat & Martin, 2015, pp. 1285-1286). These underpinnings of dynamic managerial capabilities are especially important for managers who work in highly competitive, quickly changing environments that experience rapid technological change (Teece, 2007).

Although these six independent constructs may be used by firms that are competing as cost leaders as well as those competing on a differentiation strategy, we propose that *supplier competition*, *black-box monitoring* and *operational communication* are more likely to be emphasized by cost leaders, in that they represent relatively low levels of resource commitment, and are more likely to be used to stabilize a supplier's weaknesses and result in incremental improvements in the capabilities that become embedded in the BSR.

BSR Management Resources and Capabilities for Low Levels of Resource Commitment

The following three independent constructs in this study, supplier competition, black box monitoring and operational communication represent relatively low levels of resource commitment to the BSR and relatively low levels of managerial cognition, managerial social capital, and managerial human capital. The scale items used to measure each construct are shown in Table 3.

1. ***Supplier competition***: Competition in a supply management context involves the use of more than one supplier for the purchase of a particular item or service. Purchasing an item from multiple suppliers decreases the buying firm's dependence on any one supplier. Putting an item out for bid to alternate suppliers may keep suppliers price-competitive. Essentially, the firm is deliberately using market factors to achieve this goal, minimizing the use of its internal resources and capabilities. Clearly, any firm may use competition to incentivize supplier performance, but we expect that firms focused on competing as a cost leader would use competition to a greater extent than firms focused on a differentiation strategy. The two scale items used to measure this construct have been used in previous studies (Krause, 1999; Krause, Handfield, & Tyler, 2007).

2. ***Black-box monitoring***: Similar to competition, black-box monitoring represents a relatively low level of resource use, where the supplier is assumed to be able to perform with relatively little supervision or intervention by the buying firm. Evaluation systems are put in place, but only the product shipped by the supplier is evaluated, for example, evaluation of incoming quality at the buying firm. The focus is on the product, not the supplier's processes that make the product. Three scale items, adapted from Oliver & Anderson (1994), were used to measure this construct. Black box monitoring suggests that the buyer assumes, perhaps based on experience, that the supplier has the capabilities to perform.

3. ***Operational communication****:* Here, the buyer makes an effort to provide the supplier with long-range forecasts, production plans, and design changes. These informational inputs could be shared via communication systems, but also person to person. These survey items (Noordewier et al., 1990) suggest that the buyer is communicating its plans so as to allow the supplier to schedule efficiently.

These three approaches make use of market forces and represent low-cost, efficient efforts to manage BSRs. They also require low levels of social capital, thus consuming fewer resources. Overall, we expect cost-oriented buying firms will prefer the adoption of these three relatively low-cost BSR management resources, relative to firms oriented towards differentiation:

> ***Hypotheses 1a, b, c****: Less affected by high levels of technological uncertainty, companies whose purchasing personnel focus their resources and capabilities to align a cost-focused BSR will engage in a) supplier competition, b) black-box monitoring, and c) operational communication to a greater extent than a BSR focused on differentiation.*

BSR Management Capabilities for High Levels of Resource Commitment

We propose that close monitoring of a supplier, know-how exchange with a key supplier, and supplier collaboration are more likely to be emphasized by firms pursuing a differentiation strategy, in that they represent relatively high levels of resource investments and require greater investments in BSR management capabilities. As such, they are more likely to be used to enrich existing capabilities, and/or pioneer new capabilities, that become uniquely embedded in a key BSR. These activities also require greater levels of managerial cognition, social capital and human capital (Helfat & Martin, 2015) and may be required for firms competing in markets with relatively high levels of technological change. As above, all scale items used to measure these constructs are shown in Table 3.

4. ***Close monitoring***: Here, the buying firm has moved well beyond the black box approach, and is concerned that the supplier knows *how* to do its work. The focus is on the supplier's processes. The scale items for this construct (Oliver & Anderson, 1994; Verbeke, Ouwerkerk, & Peelen, 1996) suggest a more proactive approach by the buyer, keeping in close contact and staying well informed of the supplier's activities. Empirical evidence suggests that better results can be obtained when the supplier is involved in the design of a monitoring system and when such system is used to mutually develop the buyer-supplier relationship rather than as a punishment tool (Luzzini, Caniato, & Spina, 2014).

5. ***Know-how exchange****:* The scale items for this construct are adapted from Doney & Cannon (1997) and indicate a willingness to share confidential information in order to help the supplier perform. The sharing of confidential information represents a relationship-specific investment and implies at least minimal levels of social capital, as shown in Figure 2, and trust within the relationship.

6. ***Supplier collaboration****:* These items based on Krause et al. (2007) manifest a significant effort by the buying firm to use its personnel to help the supplier improve. Regular visits and a supplier development team manifest a significant allocation of resources to work with the supplier face-to-face to effectively manage the capabilities that the supplier represents. As shown in Figure 2, these efforts involve greater levels of social capital and may be focused on building new capabilities within the BSR.

Building on these premises we can introduce our third set of hypotheses:

> ***Hypotheses 2a, b, c****: Affected by relatively higher levels of technological uncertainty, companies whose purchasing personnel focus their resources and capabilities to align a differentiation-focused BSR will engage in a) close monitoring, b) know-how exchange, and c) supplier collaboration to a greater extent than a BSR focused on cost leadership.*

Method

To test our hypotheses we administered a mail survey to Supply Chain professionals in the USA using contact information provided by the Institute of Supply Management (ISM). The data were primarily collected in 2015, i.e., after the downturn had shown its effects. The survey questionnaire contained specific questions about purchasing priorities, capabilities and results obtained using scales derived from the literature. Before distribution, the questionnaire was pre-tested by several supply chain executives and academics to check the clarity of the questions. Before and during the pre-testing phase, special emphasis was placed on the quality of the question formulation in order to reduce potential bias resulting from respondents' misleading cognition (Poggie, 1972; Schwarz & Oyserman, 2001). In particular we concentrated our questions on observable data and excluded possible scope of interpretation.

The survey targeted supply chain professionals and the instructions asked respondents to "please focus your answers on *one* supplier that provides your firm with a *critical* item (material, component, or service). The supplier should also be one that your firm has made an effort to improve. This improvement effort could be relatively limited and include activities such as supplier evaluation, or be more extensive and include such activities as training of the supplier's personnel. We are interested in your responses regardless of the extent of the effort." Thus, this primary section of the survey focused on our unit of analysis: a key BSR dyad.

ISM provided a random sample of 2,538 of its members' mailing addresses, limiting the names to members working in manufacturing industries. One of the authors was in charge of the data collection process in the USA, which focused primarily on postal mailings. Following similar key-informant-based research studies, the goal was to find the right person within the organisation who was able to respond to questions about their firm's purchasing strategy, a key buyer–supplier relationship, and performance. For this reason, mostly senior supply managers were targeted. In the end, 1,349 names were randomly chosen from the original set of names provided by ISM for the first mailing. A subset was chosen because of budgetary constraints, and because the goal was to achieve as high a response rate as possible from a smaller number of prospective respondents. Reminder postcards and additional surveys were mailed to non-respondents. To further increase the response rate, we attempted to identify phone numbers for all non-respondents by searching LinkedIn.com and Google.com. When successful in this search attempt, a graduate student phoned the non-respondents, asking for their participation. In these cases, the surveys were typically emailed to respondents who had agreed, via phone, to participate. Some surveys were returned via email attachment, others via fax, while the majority were returned via postal service. A small number of returned surveys were incomplete, and they were deleted from consideration for analysis. Approximately 60 surveys were returned because the respondent was no longer at the address provided by ISM or the company had a policy of not providing survey responses. After digitalizing and cleaning the data, 203 usable surveys were retained, representing a response rate of approximately 15.7 percent.

Non-respondent bias was examined by using the oft-used approach of testing for differences in terms of size and sector distributions between respondents and non-respondents (Armstrong & Overton, 1997). No differences were found. In addition, given that we relied on a single respondent design (with the exception of collecting a very small number of surveys from suppliers for validation), we controlled for common method bias in two ways: through the design of the study and through statistical control (Podsakoff et al., 2003). Regarding the survey, the research project was labelled as a broad overview of purchasing and supply chain management: no explicit reference to the intention to test antecedents of cost and differentiation outcomes was evident. Thus, the respondents' attention was not drawn to the relationships being targeted in this study. Questions including items and constructs related

to each other in the general model were also separated in the questionnaire in order to prevent respondents from developing their own theories about BSR management capabilities and possible cause–effect relationships. Further, the questionnaire was carefully pre-tested and respondents were assured of strict confidentiality. Finally, we used different scales and formats for the independent and criterion measures (Podsakoff et al., 2003). As a second means to ensure against common method bias, we examined the unrotated factor solution for the constructs included in our model (Podsakoff & Organ, 1986), checking that neither a single nor a general factor was likely to account for the majority of the covariance among the measures.

We asked the buyer respondents if they would be willing to share information on a contact at the "key supplier" they had reported on in the buyer survey. We assured confidentiality in this effort; however, only 31 buyers provided supplier contact names. Subsequently, we distributed a symmetric questionnaire to those 31 suppliers to check their responses against buying firm's answers. Unfortunately, only seven supplier surveys were received. While this result represents a twenty-two percent response rate, the absolute number of surveys is too small to perform any valid analysis.

Description of Sample

The survey respondents were upper level purchasing managers and executives with an average of 12.4 years with their respective companies. Titles of the respondents included Directors, Purchasing/Supply Managers, Senior Buyers, Category/Commodity Managers, and other similar miscellaneous titles. These titles, combined with the respondents' average years of experience with their respective companies, suggest that these respondents were highly qualified key respondents, and as such were capable of answering the survey questions. Respondents were employed in a variety of manufacturing industries, including aerospace, electronic equipment, construction equipment, testing equipment, industrial tools and medical devices. These respondents worked primarily for medium to large companies, in terms of gross annual sales dollars. These companies had an average of 16,400 employees (median: 1,700). The respondents estimated their firm's percentage of total purchase dollars to total sales dollars on average to be 42 percent (median: 40 percent).

Results

Hypotheses were tested using structural equation modelling (SEM) with the maximum likelihood (ML) estimation method. Most SEM applications described in the literature are analyzed with this methodology. The hypothesized model was tested statistically in a simultaneous analysis of the entire system of variables to determine the extent to which it was consistent with the data. Where goodness-of-fit is adequate, the model can be seen as a plausible explanation of postulated interactions between constructs. The research model is analyzed and interpreted sequentially: first the assessment of the reliability and validity of the measurement model, and secondly the assessment of the structural model (Hulland, Chow, & Lam, 1996). The R software (https://cran.r-project.org) was used to estimate both the measurement model and the structural model. The ML algorithm was used to obtain the paths, the loadings, the weights, and the quality criteria.

Measurement model

Since we aimed to test supply management capabilities that ultimately affect the supplier's contribution to cost reduction and differentiation we designed two sets of single-item scales aimed at measuring these two concepts as latent variables. Respondents rated each item on a Likert scale where 1 = strongly agree, 4 = neutral and 7 = strongly disagree. We based our

measures on existing scales (Krause et al., 2007) and subsequently conducted an exploratory factor analysis (EFA) with Varimax rotation for validation.

In order to include the most important concepts in terms of BSR management capabilities we conducted a thorough review of the literature and leveraged on the authors' experience of supply management within firms as well. As a result we designed a list of items measuring BSR management capabilities and subsequently conducted an EFA, dropping a small number of items with cross-loadings and low loadings.

Finally, in addition to the dependent variables and independent variables measuring BSR management capabilities we included in the model a latent variable measuring technological uncertainty as part of our hypotheses. The scale items were adapted from Ross et al. (1997), Jap (1999 and 2001), Scannell (2002), McEvily & Marcus (2005), Krause et al. (2007).

The resulting measurement model consists of nine multi-item constructs with a total of 25 indicators. We used several tests to determine the convergent and discriminant validity of the six reflective constructs. As anticipated, we controlled through an EFA that all item loadings between an indicator and its posited underlying latent variable was acceptable with no relevant cross-loadings. Next, Table 3 shows the measurement scales of the reflective constructs investigated by our research model through confirmatory factor analysis (CFA). We verified the measures by assessing reliability and unidimensionality of each of the nine constructs, i.e. item-to-total correlations within each construct were examined (Churchill, 1979). Our measurement model is able to provide to a great extent discriminant validity as well as convergent validity (Bagozzi & Yi, 1988; Anderson & Gerbing, 1988; Fornell & Larcker, 1981): both composite reliability (CR) and average variance extracted (AVE) were above the recommended threshold of 0.7 and 0.5, respectively (Fornell & Larcker, 1981; Nunnally and Burstein, 1994). Only the *close monitoring* and *know-how exchange* show AVE slightly below the threshold. To further test for discriminant validity, we compared the squared correlation between two latent constructs and their AVE estimates (Fornell & Larcker, 1981). These constructs meet the validity condition of the AVE estimates exceeding the squared correlation between each pair of constructs.

Finally, we evaluated the overall model fit in two ways (Hu & Bentler, 1998): with the chi-square goodness-of-fit statistic and with other absolute or relative fit indices. It is quite common in management literature to avoid using the chi-square p-value as this measure is particularly sensitive to sample size and assumptions of normality (Hu & Bentler, 1998). As a consequence, other fit indices are preferred to the p-value. Some authors suggest checking for the ratio between chi-square value and degrees of freedom in the model, where cut-off values range from <2.0 to <5.0 depending on the investigator (e.g., Kelloway, 1998). Another way to evaluate the fit of a model is to use fit indices that have been offered to supplement the chi-square. Fit indices range from 0 to 1, with values closer to 1 indicating good fit. Hu & Bentler (1999) recommend MLE-based fit indices and also suggest a two-index presentation strategy with, among others, the comparative fit index (CFI), and Gamma hat or root mean square error of approximation (RMSEA). The CFA revealed a sufficient model fit attested through such fit indices for the measurement model (Shah & Goldstein, 2006): χ^2=326.4; χ^2/d.f.=1.38; RMSEA=.045; CFI=.954.

TABLE 3 – Confirmatory factor analysis of latent variables

First-order construct	Indicator	Loading	CR	AVE
Technological uncertainty	Our industry is characterized by rapidly changing technology	0.903	0.780	0.613
	If we don't keep up with changes in technology, it will be difficult for us to remain competitive	0.865		
	The rate of product obsolescence is slow *(reverse coded)*	0.470		
Supplier competition	Use of multiple suppliers for this purchased item to create competition among suppliers	0.764	0.759	0.613
	Occasionally put the item we buy from this supplier, out for bid to keep this supplier competitive	0.801		
Black-box monitoring	This supplier is only judged based on its performance in areas that matter to us	0.609	0.754	0.561
	With this supplier, only tangible results matter to us	0.937		
	We don't care what this supplier does, as long as they produce	0.642		
Operational communication	We keep this supplier informed of our production plans	0.926	0.817	0.672
	We provide this supplier with long-range forecasts of supply requirements	0.741		
	We inform this supplier well in advance of impending design changes	0.831		
Close monitoring	We make sure this supplier knows what to do and how to do it	0.573	0.684	0.428
	We stay in close contact with this supplier	0.822		
	We stay well informed of this supplier's activities	0.611		
Know-how exchange	Any information that might help this supplier will be provided to them	0.788	0.792	0.413
	Exchange of information in this relationship takes place frequently	0.794		
	It is expected that the parties will provide proprietary information if it can help the other party	0.612

Structural model

The postulated path model produced a sufficient fit to the data (χ^2 = 1020.6; χ^2/d.f. = 1.64; RMSEA = .053; CFI =.943). Figure 3 shows the results of the hypotheses testing.

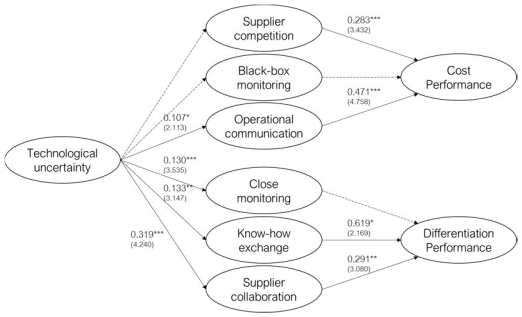

Figure 3 – SEM results

Most of our hypotheses were confirmed. We found clear evidence that companies competing as differentiators engage in a different set of resources orchestration activities to manage key BSRs than cost-focused companies. This result provides support for our overarching proposition, P1a. Further, Technological Uncertainty was significant to a greater extent for Differentiators than Low-Cost competitors, providing support for P1b.

Two of the three constructs that we expected to relate to cost reduction performance (i.e., *supplier competition (H1a)* and *operational communication (H1c)*) were significant, while *black-box monitoring (H1b)* was not. At the same time, these factors were not significantly linked to differentiation performance. Similarly, two of the relatively more resource intensive and social capital intensive constructs (i.e., *know-how exchange (H2b)* and *supplier collaboration (H2c)*) were significantly related to differentiation performance but not to cost performance.

Overall, we found that technological uncertainty significantly affects the adoption of relational-intensive capabilities that are typical of differentiators whereas less relational-intensive capabilities are not affected, with the exception of operational communication.

Discussion

The focus of this study was to investigate how buying firms can work with their suppliers, as external resources, to develop their capabilities with a goal of improving the buying firm's ability to compete on the basis of cost or differentiation through capabilities built across key buyer-supplier dyads. Our unit of analysis is key buyer-supplier dyads, or BSRs. We proposed that BSRs can be VRIN resources for the buying firm, perhaps ultimately contributing towards achieving a competitive advantage. We think the results of the analysis support this conclusion, and support our theoretical model in Figure 2.

We used RBT and ROT to explicate and test how purchasing and supply managers can manage their supply bases through structuring, bundling and leveraging activities. *Structuring* is focused on the supply base, that is those suppliers that are actively [and directly] managed through contracts and the purchase of parts, materials and services" (Choi and Krause, 2006, p. 639), and involves establishing relationships with new suppliers, and divesting of suppliers that are not needed from a resource-based perspective, a process often referred to as supply base rationalization. *Bundling* is focused on specific BSR dyads, through stabilizing, enriching and pioneering processes, where the emphasis is on strengthening existing suppliers' capabilities and building new ones where needed. Bundling may also result in synergistically building capabilities across the buyer-supplier interface, such that neither party is capable of building these capabilities alone. *Leveraging* is focused on the buying firm *and* its supply base,

collectively, a combination of the internal resources and capabilities of the buying firm and the resources and capabilities of key suppliers.

The primary focus of our hypotheses and analysis was on the *bundling* stage, as depicted in Figure 2. We proposed that companies competing as differentiators, and as such dealing with technological uncertainty to a greater extent than low-cost producers, would focus their activities more toward strengthening existing capabilities and building new capabilities within key BSRs. Low-cost competitors, in contrast, are focused on efficiency, and will refrain from spending resources unless absolutely necessary. As such, they are primarily concerned with repairing suppliers' existing capabilities, as opposed to building new ones, and doing so as efficiently as possible. These efforts tend to minimize the time and resource consuming processes of building and maintaining BSRs.

Our findings suggest that low-cost competitors do manage their key BSRs differently than companies that compete as differentiators. Differentiators engaged in activities that required higher social capital investments, focusing to a significantly greater extent than low-cost competitors on *know-how exchange* with key suppliers and *supplier collaboration*. Low-cost competitors engaged in activities with lower social capital requirements, focusing on *supplier competition* and *operational communication*.

Only the two monitoring constructs (i.e. *black-box* and *close monitoring*) did not significantly affect cost and differentiation performance respectively. We can interpret this result as an indication that monitoring systems per se are not sufficient to ensure the creation of a competitive advantage. Considering the BSR capabilities with lower social capital requirements, black-box monitoring was not significant compared to putting competitive pressure on suppliers and sharing operational information. Similarly, between the more resource-intensive BSR capabilities, collaborating with suppliers and sharing sensitive information were more effective than close monitoring. On the one hand, we might conclude that supplier evaluation systems are now widely adopted, up to the point of becoming necessary but are insufficient for significantly improving a supplier's capabilities. On the other hand, we think that the complex dynamics characterizing the agency problem would require inclusion of other classical agency theory constructs that are outside the scope of this study (such as incentives, goal congruence, and supplier opportunism).

Our study also illustrates the usefulness of resource-based theory and resource orchestration theory to the understanding of supply chain relationships. RBT suggests that suppliers and purchasing departments can be a source of competitive advantage even though some extension is needed to clearly apply RBT in the context of BSRs. Specifically, ROT is a valuable and complementary theory in explaining how competitive advantage is created through structuring, bundling and leveraging stages.

Limitations of our study include the lack of significant numbers of supplier responses that might have further validated our results. Only a few buyer respondents provided contact information for the suppliers on which they had reported. Although more than twenty-percent of the suppliers we contacted did respond to a mirror-version of our buyer survey, the absolute number of returned supplier surveys was insufficient to perform statistical analysis. We think that this result is partly due to the sensitive nature of these key BSRs, and the resulting reluctance to share information about them, and also because of time constraints that prospective respondents often claim when declining to participate in survey research. Additionally, we based our results on a single respondent

survey. Even though this is appropriate considering the scope of our study (i.e. the buyer's management of the supplier relationship), future studies might provide additional validation through objective data and/or multiple respondents. Further, we chose only to investigate the bundling stage of the resource orchestration process. In order to extend the analysis to the other stages (i.e. structuring and leverage) a different research design is needed, with attention paid to the shifting units of analysis we have proposed. For example, a study encompassing all three stages would necessarily require a longitudinal perspective. Moreover, since this is one of the first studies to adopt ROT in the context of BSRs, we were limited to testing the direct relationship between capabilities and performance. Future studies might provide a more nuanced view by exploring boundary conditions and contingent factors starting from our base model. Finally, we already commented the unexpected results related to the monitoring constructs: it might be worth exploring this issue more in depth, allowing a compelling evaluation of the effectiveness of monitoring activities.

However, we recognize that some of our limitations might open an avenue for further research. Firstly, we base our result on a single respondent survey. Even though this is appropriate considering the scope of our study (i.e. the buyer's management of the supplier relationship), future studies might provide additional validation through objective data and/or multiple respondents. Future studies might also provide a more nuanced view by exploring boundary conditions and contingent factors starting from our base model.

Conclusion

In this study we advanced the theory of BSRs management by adopting an RBT perspective in connection with ROT. In particular we contribute to clarifying why – in line with RBT – purchasing and supply management capabilities can be considered VRIN resources and how – in line with ROT – such resources can be transformed into capabilities that are expected to generate a competitive advantage. Resources and capabilities residing within the buying firm can be brought to focus on key supplier relationships, and working with suppliers can build additional capabilities across the BSR. Success through these efforts may bring competitive advantage for buying firms, whether they are competing on the basis of low-cost or differentiation.

We reviewed the foundational principles of ROT (Sirmon et al., 2007, 2011) and demonstrated unique opportunities the BSR domain offers in term of theory development. Despite previous studies essentially applied ROT within the firm boundaries, BSRs and the supply chain at large seem an ideal lab to extend and test the theory as they inherently require the orchestration of an increasingly complex set of resources and capabilities. Out of the three main stages of the resource orchestration process (i.e. structuring, bundling, and leveraging) our focus is on the bundling stage, which is concerned with the development of BSR management capabilities at the dyad level. Through cross-sectional survey data collected in 2015 we show that firms aiming at cost-reduction focus on a fundamentally different set of capabilities as compared to firms oriented towards differentiation. We also show that differentiation-building capabilities are adopted in the presence of higher technological uncertainty, which is consistent with the ROT predictions.

Abstract

The paper reports on the findings of a multiple case study, focusing on orchestration of external resources in a manufacturing context. The empirical research focuses on six case companies and their 17 strategic buyer-supplier relationship, with a purpose to empirically identify how orchestration is manifested in their activities, and whether it is context-dependent. The key findings are first, that the concept of orchestration can be identified empirically. Second, based on governance model and relationship focus, four managerial situations are established. Third, a viable orchestration profile for each of the situations is developed. The paper contributes to the discussion of management of interconnected firms and external resources.

Keywords: External resources, orchestration, governance

Introduction

Effective utilization of external resources has become a source of competitiveness of companies and has also received substantial attention at major academic journals (see Tanskanen et al 2017) during the last decades, when purchasing has evolved from transactional function to the current more strategic position (van Weele, 2005, van Weele and Raaij, 2014, Tanskanen et al., 2017). Parallel to the evolution of purchasing, also the concept of orchestration emerged late 1990´s, as companies and academics started to look for strategic alternatives for vertically integrated companies, emphasizing the focus on accessing and leveraging external resources, in contrast of owning and operating the resources. In the following chapter the extant literature around orchestration is reviewed, but as a summary the concept can be initially defined as an *intentional act where a company is creating and capturing value by building, directing and leading networks of external resources*. This definition, however, fails to take into account at least on two critical aspects. First, what practices actually relate to the generic concept of orchestration? Second, do the definition or related practices depend on situation, context, or capabilities of the orchestrator? The earlier contributions identify lists of activities that orchestrators may do or may need to do in general, but specific research findings identifying activities that make orchestration possible and happen, especially in specific situations and in a manufacturing environment, are still scarce. Objective of this paper is to *clarify the concept of orchestration* in context of external resource management, and to identify *how orchestration is manifested in different managerial situations* that the case companies face. The literature review begins with perspectives on governance, in order to ground the managerial situations to a

theoretical background, and continues with review of the extant literature on orchestration itself as well as on integration, coordination and procurement discources, to provide the basis for analysis of the managerial practices. The main emphasis is to report the findings from a serie of case studies from six case companies, identifying the orchestration situations as well as the related managerial practices, respectively. At the end the contribution of the findings is discussed.

Literature background

Governance forms in external resource management

The external resource management (ERM) discourse has been dominated by two theoretical backgrounds, namely transaction cost economics (TCE) and resource-based view (RBV) (van Weele and van Raaij, 2014; Tanskanen et al., 2017). In the TCE the firm is seen as a governance structure, where markets and companies are seen as alternative means for organizing similar kinds of transactions. Some scholars (e.g. Williamson, 2000; 2008) have argued that an economical exchange can be arrayed in a continuum-like fashion with discrete market transactions on one end and the highly centralized and integrated firm at the other. Later this discourse has advanced to recognize a variety of hybrid modes of governance and related practices (Williamson, 2008). However, many scholars have observed that governance of inter-organizational exchanges involve more than formal contracts. The relational view and social network theories have provided important insights (Gulati, 1998; Dyer & Singh, 1998; Lavie, 2006). The main observation is that inter-organizational exchanges are embedded in social relationships (Poppo and Zenger, 2002) and often governed through different types of contracting that can be for instance recurrent or relational (Ring & van der Ven, 2002). Additionally, network forms of governance and their relationship to the markets – hierarchies –continuum have received increasing attention (Jarillo, 1988; Powell, 1990; Choi and Krause, 2006; Gulati et al., 2011). An interesting view to governance is provided by Heide (1994) who analyzes the governance of partnerships and other inter-firm alliances. By analyzing relationship initiation, features related to relationship maintenance and relationship termination, he divides the governance approaches to three categories - one of market governance and two types of nonmarket governance: unilateral/hierarchical and bilateral (Heide, 1994) where bilateral governance includes many relational governance aspects. The governance theories, in this research primarily the TCE –rooted perspectives, provide a solid grounding for an ERM – focused research. The empirical findings related to the managerial situation and the intended managerial approach in the dyads are later analysed using the different forms of governance as the basis. The governance perspective, however, does not provide a very pragmatic foundation for the second part of the research question i.e. how the orchestration is manifested in the different situation. In order to identify the potential managerial practices for orchestration *a priori*, the orchestration –focused contributions as well as the more applied purchasing and supplier management literature are reviewed shortly next.

The concept of orchestration

The concept of orchestration is still vaguely defined, but some contributions exist. Hinterhuber (2002) defines orchestration as a way of creating and capturing value by structuring, coordinating and integrating activities. With the definition he captures a broad range of activities both from the perspectives of network configuration, i.e. selection of partner companies, and network management i.e. optimal resource utilization, and connecting the

orchestration concept to new value creation and new markets (Hinterhuber, 2002). Focusing on loosely coupled systems, Dhanaraj and Parkhe (2006) define orchestration in the context of an innovation network as a set of deliberate, purposeful actions undertaken by the hub firm as it seeks to create and extract value from the network. The orchestration activity is connected to loosely coupled innovation networks in a sense that no hierarchical controls exist in the relationship and the parties also preseve certain degree of independence. In the same way focusing on the innovation networks Ritala et al. (2009) follow mainly the perspective of Dhanaraj and Parkhe adding however the network design and recruitment perspective. They define orchestration as the capability to purposefully build and manage inter-firm innovation networks. From the supply chain management perspective, Vollmann et al. (2005) approach the orchestration concept by putting emphasis on facilitation and coordination aspects of the concept, and Choi & Krause (2006) connect the concept with increasing levels of outsourcing.

Management practices

Many of the management practices are associated with supplier integration, a discource motivated by realization of interdependence between the buyer and the supplier. Supplier integration is realized through practices that involve a combination of internal purchasing-manufacturing and external supplier related initiatives (Das et al., 2006) and also may involve a number of secondary activities that are concerned with value stream cohesion (Hines, 2008). A perspective closely related to the integration view is the perspective of coordination. Some authors, in fact, consider terms like *integration*, *collaboration*, *cooperation* and *coordination* complementary to each other (Arshinder et al., 2008). The discourses focusing on power and dependency, and later also the discourse around the concept of attractiveness, are addressing the management practices from capability point of view. The power/dependency theory (c.f. Cox, 2001) argues that the focal company power/dependency situation with its suppliers determines the ability of the focal company to manage its supplier relationships. The attractiveness discourse (Hald et al., 2009) in turn argues that this depends on the perceived attractiveness of the buyer.

The importance of practices related to strategic supplier base management and the strategic supplier base design is broadly acknowledged. Supply base design has been discussed mainly in relation to segmentation of supplier base and related use of purchasing portfolio-mapping techniques, which have been considered as the major breakthrough in the development of professional purchasing, simplifying a complex purchasing situation and helping companies to understand how to differentiate purchasing strategies (Gelderman and Semeijn, 2006; van Weele, 2005). However, the question of design between a buyer and a supplier is not limited to purchasing strategies and supplier selection only, but it includes also a question of interface specification between the buyer and then supplier (Araujo et al., 1999; 2016). Interfaces should be seen as resource contact points, where the design decisions can have implications to e.g. interaction and collaboration possibilities, productivity, innovation and mutual dependency in a buyer-supplier relationship (Araujo et al., 2016).

When moving on from strategy and design questions to existing buyer-supplier relationships, a related topic to supplier management and supplier integration is supplier development. Supplier development in general is a long-term cooperative effort between a buying firm and its suppliers to upgrade the suppliers´ capabilities and foster ongoing improvements (Watts and Hahn, 1993; Krause and Ellram, 1997; Sako, 2004). Supplier development discource involves a broad range of tangible managerial practices, that may be used by the focal company to influence and direct

the supplier. Furthermore, also operational dimensions like management of logistics and order fulfillment (Mentzer et al., 2001; Lee and Billington, 1992) form a part of management practices between a buyer and a supplier.

The Table 1 below summarizes managerial practices based on the extant literature. The identified practices are used in the empirical study as a priori constructs.

Research design

Research approach

The purpose of the research reported here is to provide empirical insight into a relatively new concept, orchestration, which is investigated in context of external resource management. By nature this research is qualitative, and also inductive in nature, intending to provide novel contributions to external resource management discourse. To study the phenomenon the case study approach was selected, as case study research with its central notion to use cases as the basis from which to develop theory inductively (Eisenhardt and Graebner, 2007), is suitable for the objectives of the research. Selection of cases follows the theoretical sampling approach. In-depth access to the empirical data, which is critical for qualitative case studies, was the first

selection criterion. Access to data, as well as the necessary pre-understanding, was ensured through close interaction with the potential case companies during a preceeding research project and was futher confirmed through close interaction with the companies. The second level selection also followed the theoretical sampling, selecting from the longer list of potential companies those that were actively developing their supplier relationships, and which also were providing perspectives to different industries. Focus was all the time on manufacturing environment, but in order to mitigate a possible industry-specific bias, the case companies represent four different industry segments: Electronics, pharma, mechanical industry, and textile industry. The third level of selection comprises the selection of the buyer-supplier dyads. Together with each of the case companies, 2-3 buyer-supplier relationships were selected to closer investigation in addition to company-level data collection, summing up to 17 relationships in total. The selection criteria was similar to the case company selection: Access to relationship-specific data, development of the relationship, and diversity across industry segments were emphasized. All relationships, however, were considered to be strategically important by the case company, which may affect the generalization of the findings.

Case company details are reported in Table 1 below.

	Business	Revenue (MEUR)	Personnel	Reach
TelTech Inc.	Large globally operating electronics manufacturer having manufacturing plants in Europe, Asia and the US	>10000	60 000	Global operations and sourcing
Pharma Inc.	Develops, manufactures and markets pharmaceuticals, active pharmaceutical ingredients and diagnostic tests for global markets. An innovative European R&D-based company	770	3000	European based operations, global sourcing
CommTech Inc.	European-centric international electronics manufacturing, installation and service company	120	1200	Three manuf. locations (EU, China), global sourcing
HeavyMetal Inc.	Offers a range of machinery solutions in B2B market. Operations based on the combination of service network, leading technology and a focus on efficient supply chains	1700	10 000	Production facilities in 12 countries, global sourcing
Design Inc.	Design & brand consumer goods company with both own manufactured and subcontracted and traded goods portfolio (branded)	<100	400	European-centric operations, global sourcing

Table 1: The case companies (key figures by the time of research)

Situational factors

The governance view, as well as the network strategy and power/dependency perspectives, are forming the first category of a priori constructs in the research. They are used as constructs for empirical observation and analysis. Relationship management objectives are considered when analyzing the situational factors, motivated by realization that companies set targets not only for themselves but in many cases also for suppliers and for relationships they have or want to

have with their suppliers and other external resources. These objectives are in various ways guiding the efforts, resource usage and activities in that context.

	A PRIORI CONSTRUCTS	INDICATORS	REFERENCES
SITUATIONAL FACTORS	Focal company position in the value network	Stated position	Kraljic,1983; Bates and Slack, 1998; Gelderman, 2003
	Strategic focus areas	Focal company interest areas	Edelman and Heuskel, 1999; Hagel et al., 2002; Hinterhuber, 2002
	Approach to governance	Type of uncertainty	Williamson, 2000; 2008; Barney, 1999
		Asset specificity	Williamson, 2000; 2008; Barney, 1999

Table 1: A priori constructs used to observe and analyze the situational factors

Performance objectives

The performance objective constructs relate to performance focus on experienced or perceived performance of the external resources i.e. suppliers in the particular relationship. Depending on the maturity of the focal company in terms of performance management and supplier relationship management, the performance impact is assessed qualitatively, quantitatively, or both. However, a direct measurable relationship between management activities and business or operational performance is not provided, due to the complex nature of the phenomenon.

The performance constructs and their measurement are specified in the Table 3 below.

	A PRIORI CONSTRUCTS	INDICATORS
PERFORMANCE OBJECTIVES	Measurable key performance indicators	KPI's set for the relationships
		Actual performance
	Competitive factors	Defined objectives for the relationships
		Identified competitive factors

Table 2: A priori constructs used to observe and analyze performance objectives

Data collection

Collection of the empirical data took place through interviews and by participating as subject matter expert in the development projects in close collaboration with the companies. The first phase was conducted as an extensive in-depth case study in collaboration with the company in

multiple areas. It focused on the three supplier relationships and included 38 interviews, each with a duration of 2-3 hours, half- or full day workshops with the case companies, as well as more targeted meetings and reviews of the company internal material. Based on the case research, including comparison with literature, the first constructs were developed. For the second data collection phase, interviews were the main data collection methods. Like in the phase 1, the data collection was focused on the supplier relationships and on the overall company perspective. Data collection was more focused, and the interview structure was revised based on the interim observations at phase 1 and their comparison with literature. From the perspective of initial theorizing this research design including a two-part process, the revision of the research constructs based on empirical observations, and constant comparison between data and the constructs, is likely to enhance validity and generalizability (Eisenhardt, 1989). The phase three was based on the learnings from the two previous phases and was particularly focused on studying innovation sourcing. Also in Phase 3 the main data sources comprised interviews of selected key informants similar to the two previous phases. The data sources include company strategy documents, participation in workshops and meetings and internal documentation of the companies. To improve validity, the informants reviewed both the documentation from the intoerviews, as well as the company-level reports summarizing all the findings related to the case company and the investigated buyer-supplier relationships.

Data analysis

The data analysis began with case descriptions, introducing the focal companies and the embedded relationships with the suppliers. Based on the empirical case data supported by related literature review the buyer-supplier dyads were categorized according to their dominant governance approach and main focus and objectives. Following this categorization, the supplier base management practices in different business situations were identified. The practices of the focal companies were grouped under three broad categories and subcategories. The case descriptions were consolidated through cross-case analysis in order to identify cross-case patterns (Eisenhardt, 1989). A priori constructs, which were developed based on the literature review, were used as the dimensions of analysis and all case results were tabulated accordingly. A close fit and multiple iteration rounds between literature, a priori constructs, and empirical data, provided additional validity to theorizing.

The cross-case analysis focused on the perspectives of:

1. Situational factors, i.e. understanding potential similarities and differences in the managerial situations that the focal company is in.
2. Managerial practices that the focal company uses to orchestrate its external resources. Purpose of the cross-case analysis is to identify potential common patterns from the empirical data and connect the patterns to the respective managerial situation
3. Outcomes, i.e. objectives and performance that the focal company can achieve with its managerial practices in the particular situation

Results

The concept of orchestration is the starting point for this research. The key question is whether it exists in the first place, what it includes, what is the definition of orchestration, and whether orchestration is dependent on situation. First, the cross-case analysis reveals a clear pattern of intentional activities that the investigated focal companies are conducting with a purpose to

orchestrate the external resources. They are 1) positioning themselves in an influental position in a network 2) making efforts to architect the network, including supplier selections and design of the interfaces between them and the suppliers, 3) steering the buyer-supplier relationships, and 4) facilitating the performance through indicators and regular assessment and follow-up practices. The cross-case analysis table is included in Appendix 1. Developing the initial definition based on the empirical findings orchestration is defined as *an intentional act where a company is creating and capturing value by building, directing and leading networks of external resources.* Based on the empirical results, it can be further specified that orchestration is done through *orchestration practices, which relate to focal company positioning in a value network, to product and network architecture, to relationship management practices, and to facilitation of operative processes and performance.*

Second, the cross-case analysis reveals common patterns from the objective and performance indicator point of view. The case dyads can be divided to two categories pertaining to *cost efficiency focus*, and *focus on innovation*. The category *Cost efficiency focus* is related to overall cost efficiency orientation by the focal company, and emphasizes the aspects also towards the external resources. It may also include aspects of learning and knowledge transfer related to operational efficiency. From the target setting and performance management point of view indicators like cost, delivery accuracy, quality and asset efficiency are dominating. In turn, the category *Innovation focus* arises from the empirical data focusing on developing or capturing new innovations and added value for the focal company. Product/technology/service itself and related innovations, new business development aspects, competencies and capabilities for R&D, and new product development are emphasized in the innovation –oriented managerial situation. Product competitiveness, qualitative targets focusing on the relationship, and success in collaboration are clearly emphasized in target setting and performance indicators.

Third, comparison of the empirical observations with different forms of governance reveals a clear pattern with distinct differences related to questions of e.g. approach to contracting, and to design of the interface between the companies in a dyad. Summarizing the findings, either the approach is focused on *tight integration* between the companies, or alternatively it is intentionally respecting a clear-cut interface – *independence* - between the two companies. The *tight integration* approach includes characteristics such as long-term frame contracting, investments into relations-specific assets and resources, high level of adaptation and alignment by one or both of the parties, and clear focus on process and system integration cutting across the interface between the companies. The more clear-cut approach, where *independence* of the companies is either respected or even intentionally promoted for different reasons, has in turn characteristics of recurrent contacting, which may be even close to a market approach; it may include no investments into specific assets or resources and little adaptation, and focus is on low dependency and standardized interface between the companies with competition-dominant logic involved. The empirical observations could be connected to governance forms in slightly different ways; the best match the findings have with the classification introduced by Heide (1994), where he uses a division to bilateral and unilateral governance models to make a difference between governance approaches.

From the managerial situation –point of view the dyads can be arranged according to the dimensions of *relationship focus* – between cost and innovation, and *governance approach* – between bilateral and unilateral governance.

The situations and the position of each of the dyad is illustrated in the figure 1 below.

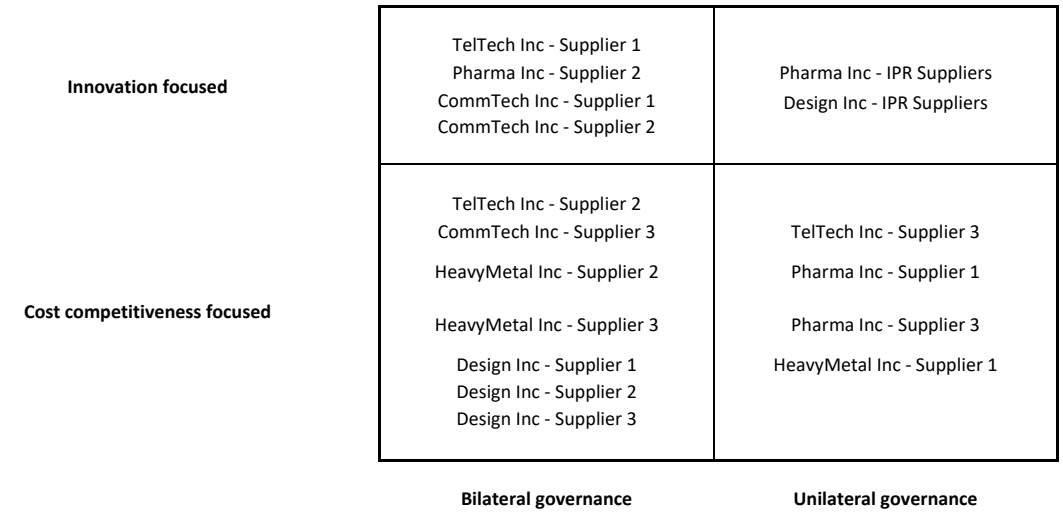

Figure 1: Identified managerial situations and the related case company / supplier relationships

The second part of the research question asks *how orchestration is manifested* in the identified managerial situations. In general, orchestration is manifested through managerial practices that can bne divided to four broader clusters: value positioning, product and network architecture, relationship management, and operative management. These clusters of practices form the basis for orchestration: the case companies are conducting activities in the four areas when they intend to orchestrate their external resources. The identified managerial practices not only provide insight into both how orchestration is manifesting itself in managerial work, but also provide insight into situational dependency of the practices i.e. into contigency view of orchestration.

The case company Pharma Inc provides an example of the managerial situations and the related profiles. The company has explicitly stated that they are owning the position at the consumer interface, and is integrating the product offering based on both own and contracted products. Sourcing strategy is directly derived from the business strategy, combining intentionally high value partner suppliers (like Supplier 2), innovation (IPR) suppliers, and lower value but high volume complementary product suppliers (Suppliers 1 and 3). The daily managerial approach differs sharply between the relationships, from a true innovation-focused, several decades long collaborative partnership with deep personal relationships to a market-based approach with clear-cut interface, cost and performance focus, location in low-cost country, and alternative suppliers continuously under evaluation. Similar patterns can be identified with other case companies as well. Following the earlier developed categorization of managerial situations, a management profile for each of the category is developed. The table 5 summarizes the profiles.

	Cost efficiency / Bilateral governance	Cost efficiency / Unilateral governance	Innovation / Bilateral governance	Innovation / Unilateral governance
Value positioning	Important	Important	Important	Important
Product and network architecture	Architecture enabling Supply Chain performance	Product architecture maintaining independence and competition	Product architecture integrating supplier innovation	Product architecture enabling absorbtion of supplier innovation
Relationship management	Institutionalized, formal relationships between organizations. Information sharing central	Relationships of independent actors. Formal and price/performance focused	Personal relationships. Shared values, trust and reciprocity central	Relationships formal and product performance focused. Parties see themselves independent
Operative management	High importance. Strong process integration	High importance. Independent operations, coordination focus	Done, relatively less important	Done, relatively less important

Table 5: Managerial situations and the related managerial profiles

From the performance point of view, the case companies having emphasis on cost efficiency as main focus, and respective managerial practices, perceive themselves being competitive in terms of operational efficiency. This competitiveness is visible e.g. through KPI:s like cost saving %, asset efficiency etc. which have been considered as being on good level. Those cases, in turn, where the focus has been on innovation and capturing of new value, the case companies perceive themselves generally being leaders in product and technology –related aspects, and less in light of cost efficiency -focused aspects. As a summary, the main practices are plotted to the managerial situation –matrix.

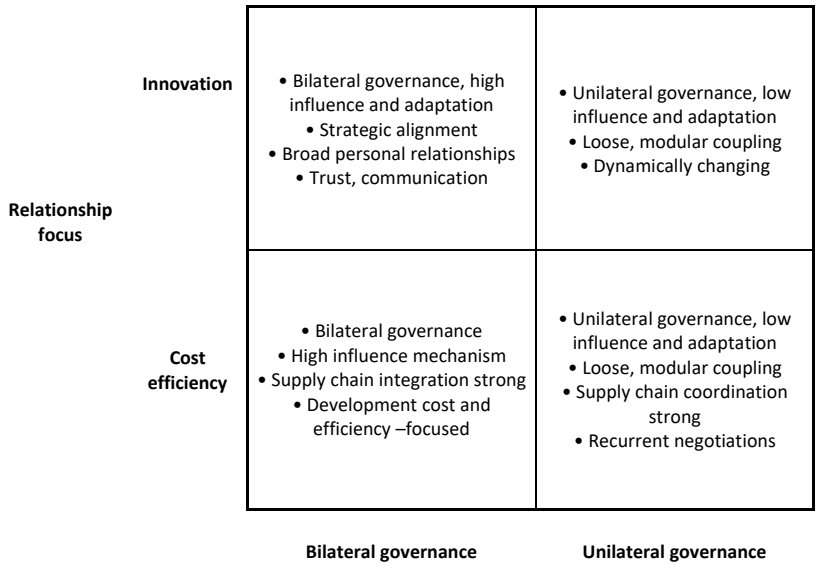

Figure 2: Identified managerial situations and the managerial profiles

Discussion and conclusions

The objective of this paper is to clarify the concept of orchestration, and to identify how orchestration is manifested in different managerial situations. The main contribution relates to the empirical findings, which are providing further insight into the orchestration concept itself, into the managerial approaches that are a part of orchestration, and also into the context-

dependency of orchestration. Furthermore, the results provide an empirical view into how the design of a buyer-supplier interface relates to the managerial situation at hand.

Focusing on the concept of orchestration, the results demonstrate that orchestration concept is relevant from the external resource management point of view and can be identified empirically. The research highlights structuring, coordinating and integrating activities, as identified e.g. by Hinterhuber (2002), by e.g. Choi et al. (2001), and which are also the main focus in e.g. coordination theory and in supply chain management, but proposes that the aspects of value creation strategy, recruitment of network members, and the architectural aspects should be included into the orchestration concept. This research also proposes that the activities focusing on the overall value creation system relate to positioning of the focal company in the value system, and to the architecture of the product and supplier network as a whole.

The classification of external resource management situations according to focus i.e. *innovation vs. cost efficiency*, which as such is not new, combined with the *governance approach* is a key contribution, in particular the feasibility of bilateral and unilateral governance approaches (Heide, 1994), and utilization of them to structure the managerial approach towards external resources. Both of the governance types were observed in the cases and were explaining many of the differences in the management approaches in the case relationships. By classifying the managerial situations in the proposed way, it is possible to gain a view on the requirements and success criteria for effective management of external resources in the identified situations, incorporate the target orientation of the focal company to the situations, and to create differentiated managerial approaches with a good fit to the managerial situation at hand.

The supplier management situations have been extensively discussed and analyzed in the purchasing literature in the context of different portfolio models, which are particularly relevant for the design of the overall external resource base. Affecting the focal company orchestration capability, major issues that appear are strategic positioning of buyer and supplier, highlighted through the dependency discussion and through different portfolio models (see e.g. Kraljic, 1983; Gelderman, 2003) as well as the perspective of buyer-supplier relationships, which has an extensive management literature stream of its own (e.g. Dyer et al., 1998; Bensaou, 1999). The portfolio models focused on the supplier relationships (e.g. Bensaou, 1999; Cox, 2004) appear as a useful framework in this research. The managerial situation –matrix introduced in this paper contributes to the discourse by bridging the managerial situation with the activities; this connection cannot be done with the existing portfolio models, which focus on more strategic or relationship perspectives.

It can also be argued that the intended governance model affects the approach that the focal company can and should have towards a supplier in terms of interface definition, relationship management approach and integration and coordination methods. Based on this study it is possible, for instance, to identify a group of key suppliers where tight integration may be desirable: the strategic supplier relationships where a stable, long-lasting relationship is expected, and where at the same time the primary objective of the relationship is joint operative efficiency in the supply chain. The research is aligning well with the typology of interfaces introduced by Araujo et al. (2009; 2016), suggesting also that the interface design is critical for successful orchestration. In this respect, there is also an analogy with the classical approach of distinguishing between arms-length and partnership approaches (Dyer and Singh 1998), with the same intention to promote balanced utilization of both strategies. The findings also provide managerial guidance for determining an appropriate management style, actions and resources for supplier base management. The managerial practices differ, however, for example from the

supply management practices identified by Lawson et al (2009), who name socialization activities, process integration, and supply base responsiveness as practices facilitating effective buyer-supplier relationship performance. Their findings indicate support for performance in a way that has similarities to cost efficiency/bilateral governance -related managerial profile.

The concept of innovation sourcing is not completely new, but is not yet extensively discussed in purchasing and supply management discourse. There are several perspectives in the process of capturing external innovation and integrating it into a company offering. The first perspective is the discussion on open vs. proprietary innovation (Chesbrough 2006). Also Phillips et al. (2006) address the need for supply relationships to generate and support discontinuous innovation. They are suggesting that for discontinuous innovation, it may in a firm´s best interest to develop a broad range of non-committal supply relationships, in concurrence with longer-term strategic partnerships. Findings from this research identify the related orchestration situation and propose a feasible managerial profile. The results also suggest that in addition to the involvement of suppliers in innovation processes, there is room for further actions from the point of view of external sourcing of radically new, even discontinuous innovations.

The last notable contribution is the insight regarding the architectural processes in supplier selection and in designing an effective supply network. It can be argued that product architecture and technology selections may affect strongly the ability to develop a desired buyer-supplier relationship. In a similar way, several of the case companies were using the product and technology architecture closely related to sourcing strategy. The focal company must determine whether it wants to proceed in close collaboration with the selected supplier in a rather permanent relationship, or whether it wants to use suppliers in more dynamic and competitive way. In both cases, the technology strategy and sourcing strategy are closely intertwined. These findings are consistent with the extant literature (e.g. Fine 2000; Fixson 2005; Araujo et al. 2016), highlighting the interplay between technology strategy and the buyer-supplier interfaces, as well as the importance of concurrent design of product, process and the supply chain also for successful supplier base management.

Abstract

The paper addresses the challenge of managing first-tier as well as lower-tier suppliers with respect to sustainability in order to prevent reputational damage for focal companies. We contribute to this field by examining assessment sharing strategic alliances (ASSAs) as a means of increasing suppliers' compliance with corporate sustainability standards (CSSs). More specifically, we present findings of an embedded multiple case study conducted in the railway, telecommunication and pharmaceutical industry. Our results confirm that ASSAs generally improve suppliers' compliance with focal companies' CSSs. However, the degree of improvement substantially depends on the configuration of the respective ASSA.

Keywords: Strategic Alliance Multi-Tier Supplier

Introduction

"Apple, Samsung and Sony face child labor claims" – Headlines like this often cause high reputational damage for the accused companies and should therefore be avoided by any means. In this specific case, the human rights organization Amnesty accused the citied companies of failing to carry out investigations to ensure that minerals used in their products are not mined by children. As became apparent, the appealed violations could not be directly linked to those companies and did not take place directly with the companies' assigned first-tier suppliers. Nevertheless, they were held responsible for these violations committed far upstream of their

supply chain by their suppliers' suppliers. This phenomenon is referred to as *chain liability effect* by Hartmann and Moeller (2014), meaning that consumers hold the focal company responsible for everything that occurs in its supply chain. This observation and the fact that many serious sustainability violations are committed further upstream of the supply chain (Tachizawa and Yew Wong, 2014) highlight the importance of extending the management of first-tier suppliers to sub-suppliers in order to effectively manage sustainability-related risks in multi-tier supply chains (MSCs) (Wilhelm, Blome, Wieck and Xiao, 2016). Thus, we equally consider the management of first-tier suppliers and sub-suppliers when discussing multi-tier supply chain management (MSCM) in the following.

Triggered by the high complexity of managing an increasing number of suppliers with respect to sustainability to meet stakeholders' growing sustainability expectations (Fayezi, O'Loughlin and Zutshi, 2012), assessment sharing strategic alliances (ASSAs) between competitors of the same industry are formed in the real-world context. The aim of these alliances is the exchange of sustainability audit reports of common suppliers in order to collaboratively safeguard suppliers' compliance in MSCs. Strategic alliances are generally defined "as voluntary arrangements of at least two companies involving the exchange, sharing and co-development of [resources or capabilities]" (Gulati, 1998, p. 293). These predominantly emerge in uncertain and complex business settings (Lin and Darnall, 2015) in order to create values that cannot be achieved isolated and independently by one single company (Dyer and Singh, 1998). Even though strategic alliances are a long-existing object of investigation in the scientific world (Beamish and Lupton, 2016), in the context of sustainable supplier management, recent research has mainly investigated vertical alliances between a focal company and its first-tier suppliers. Thus far, little attention has been put on horizontal strategic alliances in the context of sustainable supplier management. This may be explained by the fact that the formation of strategic alliances between competitors of the same industry is a recent phenomenon in the real-world context (Canzaniello, Hartmann and Fifka, 2017), which is additionally triggered by the increasing complexity of involving lower-tier suppliers in sustainable supplier management practices.

Although an embedded single case study in the chemical industry has already been conducted to observe the motivations of companies to form or join an ASSA and to reveal outcomes of ASSAs on sustainability-related supplier risks (Canzaniello et al., 2017), ASSAs as a means of implementing sustainability to MSCs have thus far not been studied. In this context, questions arise as to how supplier management practices are performed collaboratively among the alliances' members within ASSAs and which effects result from these collaborative activities on the MSCM for sustainability. In order to address this research gap, we formulate the following two research questions:

- **RQ1:** How do companies collaborate within ASSAs to manage suppliers within MSCs with respect to sustainability?
- **RQ2:** Which effects do ASSAs have on the management of suppliers within MSCs with respect to sustainability?

As there is no research yet that has investigated ASSAs in the context of MSCM, our research is explorative, aiming at elaborating existing theory, more precisely agency theory (AT). This is realized through the conduction of an embedded multiple case study (Ketokivi and Choi, 2014). For this purpose, we study the collaboratively utilized supplier management practices of three ASSAs from three different industries (railway, telecommunication and pharmaceutical) and explore the effects of their settings on the management of MSCM for sustainability by consideration of typical principal-agency constructs.

The remainder of this paper is structured as follows: first, we outline the theoretical background relating to our posed research questions. Next, our research methodology is discussed, which is

followed by the analysis and discussion section, where the results of our comprehensive cross-case analysis are represented and discussed. Finally, we close with a summarizing conclusion, where study limitations and future research avenues are highlighted.

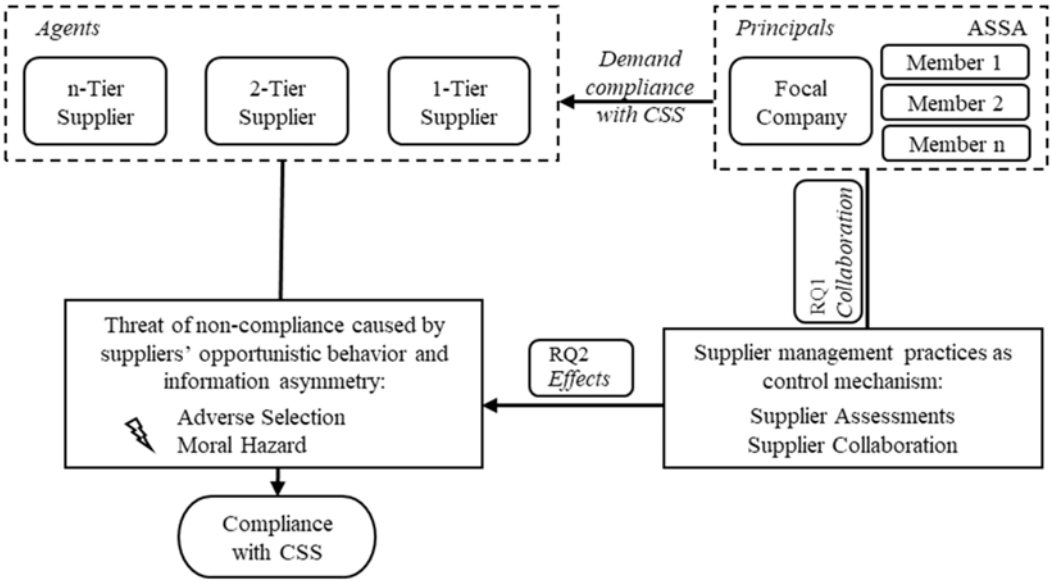
Theoretical background

The ongoing cost-oriented outsourcing trend from so-called low-wage countries, which frequently goes hand-in-hand with unacceptable environmental protection and inappropriate working conditions on the respective supplier sites (Mueller, dos Santos and Seuring, 2009), has continuously increased the public attentiveness to corporate environmental and social engagement (Martin, 2002; Schmidt, Foerstl and Schaltenbrand, 2017). Consequently, the management of suppliers with respect to sustainability is gaining increasing importance to prevent negative publicity and the reputational damage associated therewith (Carter and Jennings, 2004). However, most sustainability violations are not committed by first-tier suppliers but further upstream of the supply chain by lower-tier suppliers (Tachizawa and Yew Wong, 2014). Therefore, both direct suppliers and sub-suppliers have to be managed with respect to sustainability in order to effectively manage sustainability-related risks (Wilhelm et al., 2016).

Grimm, Hofstetter and Sarkis (2014) observed that practices that are used to manage sub-supplier are similar to those applied to first-tier suppliers, which were previously classified by Vachon and Klassen (2008, 2006) into *assessment* and *collaboration practices*. Thereby, assessment practices (e.g. sustainability standards, social and environmental audits) are executed to gather information and evaluate suppliers' sustainability performance, while collaboration practices (e.g. supplier development through training, workshops and resource transfer) are applied to improve suppliers' sustainability performance (Klassen and Vachon, 2003; Vachon and Klassen, 2006, 2008). Moreover, Grimm, Hofstetter and Sarkis (2016) revealed that the active management of both assessment and collaboration practices can improve sub-suppliers' compliance with corporate sustainability standards. However, approaching lower-tier suppliers is more defiant than approaching first-tier suppliers due to sub-supplier specific characteristics (Grimm et al., 2014; Tachizawa and Yew Wong, 2014). This is, among other things, due to the fact that focal companies do not have contractual relationships with their lower-tier suppliers and consequently possess less information about their sub-suppliers (Choi and Hong, 2002). Moreover, their influence over sub-suppliers is lower since dominant buyers often only represent a small percentage of the lower-tier supplier's business (Plambeck, Lee and Yatsko, 2012; Tachizawa and Yew Wong, 2014).

According to Tachizawa and Yew Wong (2014) there are three strategies that can be applied to approach sub-suppliers. The first one is the *direct approach*, where sub-suppliers are managed by the focal company itself, the *indirect approach*, where focal companies rely on their first-tier suppliers to manage their lower-tier suppliers and the *work with others approach* on which we focus in our research paper. The *work with others approach* can be realized in two ways. First, responsibilities of managing lower-tier suppliers can be delegated to other organizations, such as NGOs, competitors or firms from the same industry (Tachizawa and Yew Wong, 2014). Second, strategic alliances can be built with competitors or firms from the same or other industries in order to improve negotiation power over lower-tier suppliers and to manage sub-suppliers collectively (Tachizawa and Yew Wong, 2014). Through the examination of ASSAs from a sustainability perspective, the *work with others approach* will be investigated in more detail by revealing how this strategy is implemented in practice. Moreover, to better understand how ASSAs affect suppliers' compliance with CSS, agency theory is applied as our theoretical anchor. This theory was chosen as it is suitable for analyzing how to cope with risks that arise when one party (principal) delegates work to another party with conflicting goals (agent) (Eisenhardt, 1989a; Jensen and Meckling, 1976). In this context, the misrepresentation of the agent's capabilities (adverse selection) and the lacking effort of the agent to meet the principal's

requirements (moral hazard) (Eisenhardt, 1989a) are the most significant problems that occur in agency relationships (Ciliberti, Haan, Groot and Pontrandolfo, 2011). Both constructs can be related to agents' opportunistic behaviour and to information asymmetry between the agent and the principal, which makes it difficult for the principal to evaluate if the agent is behaving in accordance with the principal's requirements (Eisenhardt, 1989a). To prevent these problems, the principal can either implement information systems to reveal the agents' behaviour or reward outcomes which aligns the agent's preferences with those of the principal (Eisenhardt, 1989a). In the context of sustainable supplier management, the buyer (representing the principal) delegates work to suppliers (representing the agents) and is thus exposed to sustainability related-risks due to agents' opportunistic behaviour (Hajmohammad and Vachon, 2016). Consequently, adverse selection occurs when suppliers' sustainability-related capabilities are misinterpreted in the supplier selection process, whereas moral hazard refers to suppliers' lacking efforts to meet the required CSS of the focal company. In order to prevent the accompanying sustainability related risk, supplier management practices can function as control mechanisms (Hajmohammad and Vachon, 2016). Thereby, assessment practices can be regarded as a focal company's information system, which is utilized to gather sustainability-related information and to evaluate suppliers' sustainability performance (Klassen and Vachon, 2003; Vachon and



Klassen, 2006, 2008). Thus, richer information on the agents' behavior can be gathered, which increases the likelihood that the agents' behavior is consistent with the principal's interests (Eisenhardt, 1989a). Furthermore, collaboration practices are applied to encourage a sustainable culture and to improve suppliers' sustainability capabilities (Hajmohammad and Vachon, 2016; Klassen and Vachon, 2003; Vachon and Klassen, 2006, 2008). However, the detection of agents' behavior gets even more challenging when a multi-tier perspective is considered, as an increased number of heterogeneous agents has to be considered (Fayezi et al., 2012). Thus, our study extends existing agency theory by applying it in a strategic alliance context in order to investigate how control mechanisms can be applied collaboratively by members of ASSAs (RQ1) and to reveal how the collaborative execution of these control mechanism affects the management of suppliers in MSCs (RQ2). Figure 1 illustrates the theoretical framing of our research questions grounded in AT.

Figure 1. Underlying research framework

Research methodology

In order to address our two research questions, an embedded multiple case design was applied to collect empirical data. This method is suitable for our research endeavor as research on ASSAs for sustainability is still in an exploratory stage and existing knowledge of the effects of strategic alliances on the MSCM is scarce, as described previously (Benbasat, Goldstein and Mead, 1987; Yin, 2014). Moreover, in contrast to broad empirical research, this approach allows a closer investigation of theoretical constructs and the exposure of the underlying causal relationships (Siggelkow, 2007). Thus, a comparative comprehensive understanding of the nature and complexity of the studied phenomenon can be achieved (Benbasat et al., 1987).

Case selection

Because the number of ASSAs within sustainable supply chain management is still low, the potentially selectable amount of cases was limited. Thus, our research focused on three ASSAs from three different industries. Three alliances were chosen, as it seemed more reasonable to consider several ASSAs in order to demonstrate how companies collaborate within ASSAs to manage suppliers within MSCs with respect to sustainability. Moreover, through the consideration of three different ASSAs, differences between their configurations could be derived and the effects of those varying configuration options on the management of suppliers in MSCs could be determined. Therefore, we ensured that the chosen ASSAs were not too similar in terms of their design of supplier management practices. Moreover, we only considered ASSAs which were founded fewer than ten years ago, as interviews with employees who were directly involved in the formation of or accession in the ASSA could be interviewed. Thus, we selected ASSAs from the railway, telecommunication and pharmaceutical industries as the cases for our research endeavor. Three members companies from every alliance agreed to participate in our study, which are presented in Table 1. Additionally, publicly available secondary data, such as press releases and corporate sustainability reports of those member companies that did not participate in our study, were taken into consideration in order to test whether additional information would provide further insights which could not be revealed by data generated through the interviews of the participating companies. Since no additional relevant data were revealed, the non-existence of a potential non-response bias could be confirmed.

# informants	3	2	2	2	2	2	2	2	2

Table 1. Overview of cases and interviewed companies

Data collection

Multiple sources of evidence were taken into account in order to ensure high construct validity in the data collection process (Eisenhardt, 1989b; Gibbert, Ruigrok and Wicki, 2008; Yin, 2014). Data gathered from semi-structured interviews with key informants from the different member companies were used as a primary data source. In this context, an extensive review of relevant literature was conducted in order to develop the interview guideline. The interviews were executed with informants from the sustainability management or procurement departments of the participating companies, as employees of these departments have the most points

of contact with the respective alliance, since they actively shape its configuration and work processes. For reason of triangulation, at least two informants per company were interviewed (Eisenhardt and Graebner, 2007) and additional interviews were requested until further interviews did not reveal further insights (Yin, 2014). In total, 21 interviews were conducted in the period between June 2016 and May 2017. In addition, secondary data were used for triangulation purposes in order to increase internal validity. Therefore, corporate material of the interviewed companies (e.g. supplier codes of conducts, annual reports, corporate sustainability reports) and material from the ASSAs (e.g. process guidelines, self-assessment questionnaires, audit templates) were triangulated with the insights gained from the interviews. In conclusion, we set up a case study database in order to increase reliability (Gibbert et al., 2008; Yin, 2014).

Data analysis

The analysis of the collected data comprised two key steps. First, a within-case analysis was conducted to understand the individual ASSA approaches. Second, common patterns across and differences between the three cases regarding supplier management practices and their effects on supplier management were revealed through a cross-case analysis. To begin with, a within-case description of each of the three cases was drawn up in order to capture all relevant information about the supplier management practices of the three ASSAs with respect to sustainability. Next, a coding process was applied to identify structures and patterns in the unstructured qualitative data gathered through the conducted interviews (Strauss and Corbin, 1990; Yin, 2014). After the individual coding procedures of the two researchers were completed, the coding results were then discussed and compared with all members of the research team. This discussion was conducted until all inconsistencies were eliminated and final agreement among the researchers was achieved. Thus, a potentially inherent investigator bias could be reduced and inter-rater reliability could be ensured. Finally, following our theoretical framework, a cross-case analysis was conducted in order to identify common characteristics of and differences between the investigated ASSAs regarding their collaborative supplier management practices and to derive the effects of different ASSA configurations on supplier management within MSCs (da Mota Pedrosa, Naeslund and Jasmand, 2012; Eisenhardt and Graebner, 2007).

Results

Although the sharing of assessment results is an integral part of all three investigated ASSAs, differences between the investigated ASSAs regarding the execution of their assessment and collaboration practices could be observed (see Table 2). Moreover, due to the varying design and execution of those control mechanisms among the three alliances, different effects on the management of suppliers within MSCs with respect to sustainability could be identified.

The assessment of the sustainability performance of suppliers within MSCs is a very time-consuming and cost-intensive process (Foerstl, Reuter, Hartmann and Blome, 2010; Grimm et al., 2014), especially for companies which are not organized in ASSAs. Consequently, only a small number of suppliers and an even lower number of sub-suppliers were assessed by companies prior to their accession to an ASSA. With this complex setting in mind, companies within an industry decided to found or join an ASSA in order to be more effective in assessing the sustainability performance of their suppliers. Within all investigated ASSA, a standardized assessment process based on collectively accepted requirements is used to measure the sustainability performance of suppliers within MSCs. Moreover, a supplier is assessed by only one member company and the assessment results are shared between the members of the strategic alliance, as can be seen in Figure 2.

As a result, assessment costs as well as workload for the alliance's members are reduced through all three investigated alliances' settings. However, the setting of all three ASSAs does not only lead to efficiency gains for the members of the alliances, but also for their suppliers. Due to the fact that the results of sustainability assessments are shared among the members of an alliance, suppliers only receive one single assessment request from one of the member companies. Thereby, suppliers have to perform a reduced number of assessments. The efficiency enhancement on the suppliers' side not only raises the willingness of suppliers to accept and perform assessments, as $Alpha_A$'s head of international procurement and $Alpha_A$'s corporate sustainability expert confirmed, but also to share sustainability-related information with an increased number of their customers through the alliances' shared audit pool, as the head of sustainability of $Gamma_G$ stated.

Case	Alpha	Beta	Gamma
Industry	Railway	Telecommunication	Pharmaceutical
Year of foundation	2015	2010	2006
# of founding members	6	3	7
# of members	8	13	24
Membership open to	Railway operators and companies across the railway industry	Telecommunication operators	Pharmaceutical or healthcare companies
Membership requirements regarding SSM	Subscription to third party assessment platform Initiation of 100 supplier assessments or 60% of relevant procurement spend	Execution of five on-site audits on behalf of the alliance through a third party auditing company	Active participation in the alliance including the shared audit program and working committees Execution of five on-site audits per years
Control mechanisms			
Supplier assessment	Assessment of the suppliers' sustainability performance through a common assessment tool provided by a third party provider	Assessment of the suppliers' sustainability performance through on-site audits based on standardized audit guidelines	Assessment of the suppliers' sustainability performance through common self-assessment questionnaires and on-site audits based on standardized audit guidelines
Assessment performed by	Third party provider	Third party auditing firm	Third party auditing firm or members' internal auditors
Nomination for assessments	At discretion of members	Only those supplier which are engaged with a predefined minimum number of the initiative's members are nominated for a common audit	At discretion of members
Result sharing	Assessment results are not automatically visible to all member companies Suppliers can decided with whom they share their audit results	Before an audit is performed, suppliers have to agree to share the audit report to all members of the alliance Audit reports are automatically shared among all members	Supplier and audit leading member company have to agree to share the audit report Suppliers can decided with whom they share their audit results
Costs	Costs are paid by the supplier	Costs are paid by the audit leading member of the initiative	Costs are paid by the audit leading member of the initiative or by supplier themselves, in the case that they nominated themselves for the audit
Supplier collaboration	Members' individual business	Follow-up process to resolve audit findings is part of the alliance's joint auditing process Supplier development exceeding the follow-up process is not part of the initiative's processes	Follow-up process to resolve audit findings is part of the alliance's joint auditing process Capability building program to build supplier knowledge and expertise regarding sustainability issues is part of the initiative's activities

Table 2. Collaborative supplier management practices of investigated ASSAs

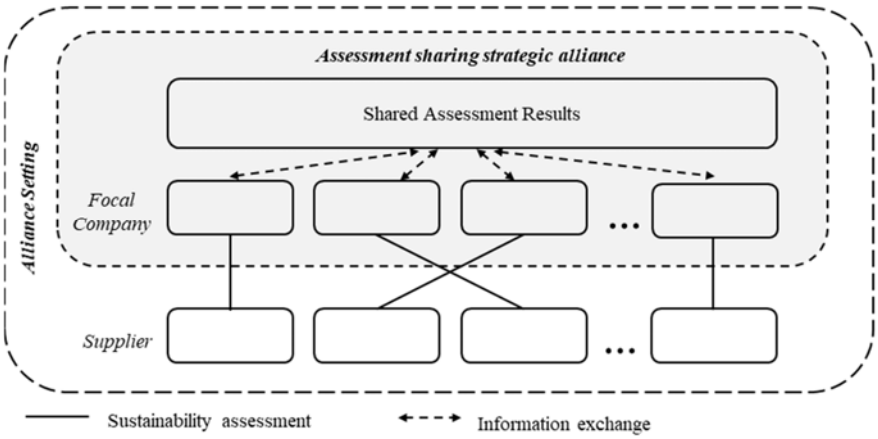

Figure 2. Schematic representation of an alliance setting

In addition, suppliers use the respective ASSA as a platform to promote their good sustainability performances to their customers, as Alpha$_A$'s corporate sustainability expert stated. Thus, the incentives for suppliers with a good sustainability performance to perform sustainability assessments increase. Moreover, the willingness of poorly performing suppliers to improve their performance and to share updated sustainability-related information through re-assessments is fostered. The execution of voluntary sustainability assessments and re-assessments requested by suppliers themselves, which were reported by Alpha$_A$'s corporate sustainability expert, Alpha$_C$'s sustainable procurement expert and Gamma$_I$'s supplier performance expert, confirm those statements.

If a sustainability assessment reveals any sustainability violation, Beta's and Gamma's assessment leading companies have to execute subsequent follow up-processes on behalf of the alliance to address suppliers' shortcomings. Thus, suppliers no longer see assessments as surveillance actions. This is due to the fact that these follow-up processes do not solely include a re-assessment after a predefined period of time, but a collaborative development of corrective action plans together with the audit leading company. Moreover, in comparison to follow-up processes organized by non-member companies, the quality of the member companies' proposed corrective actions is monitored within the alliance, which allows the exchange of good and bad solution approaches to resolve sustainability-related issues, as the head of supplier performance of Beta$_E$ stated. Therefore, suppliers consider the proposed corrective actions of alliances' members as very valuable to improve their sustainability performance, leading to additional business in the future, as Gamma$_I$'s sustainability expert confirmed.

Moreover, the execution of follow up-processes on behalf of the alliance also enables sharing of expenses and effort involved in follow-up processes among the member companies of Bata and Gamma, since the improvement of suppliers' sustainability performance is not at each company's discretion like it is for Alpha's members. Moreover, Gamma even deploys a joint supplier development program, which is an integral part of the alliance's activities. Thus, supplier workshops and webinars are organized and performed with the involvement of several member companies, and therefore allowing cost savings, as Gamma$_G$'s head of sustainability management stated. Moreover, it is more effective to work together with other member companies to address certain issues, as the sustainability procurement expert of Gamma$_G$ confirmed. Consequently, supplier collaboration activities can be performed more efficiently from a single companies perspective, as process inputs (collaboration costs and workload) are reduced while collaboration outputs (number of approached suppliers) increase.

Since serious sustainability violations are mainly committed by sub-suppliers, the focus of at least some of the interviewed companies has already shifted further upstream of the supply chain, as Alpha$_C$'s sustainable procurement director, Beta$_E$'s head of supplier performance and

the sustainable supply chain expert and the head of procurement strategy and corporate responsibility of Beta$_D$ confirmed. Particularly in the telecommunication industry, first-tier suppliers are now rarely producing directly, and so the consideration of lower-tier suppliers is essential, as the head of supplier performance of Beta$_E$ stated. Therefore, by 2015, 84% of the performed audits of Beta pertained to subcontractors. However, the hurdles of managing sub-suppliers usually make it necessary to work closely with the first-tier supplier in order to manage upstream suppliers with respect to sustainability, as Beta$_D$'s sustainable supply chain expert stated. However, due to the membership structure of Alpha and Gamma, it is not absolutely necessary for focal companies to contact lower-tier supplier in order to ensure their compliance with CSS. Since membership of these two alliances is open to suppliers as well, reports of assessments of lower-tier suppliers, which were conducted by participating first-tier suppliers, are available for the focal company without any direct contact with their sub-suppliers, as Alpha$_A$'s procurement strategy expert explained. Thus, the transparency of MSCs on various tiers can be increased, as Figure 3 demonstrates. Moreover, according to the sustainability procurement expert of Gamma$_G$, the alliance is also a good platform for suppliers, which are members of the respective ASSA, to exchange best practices with other member companies in order to improve their own sustainability knowledge. Thus, those suppliers can pass on the sustainability principles of the respective alliance to their suppliers, whereby second-tier or even third-tier suppliers can be reached, as Gamma$_I$'s sustainability expert stated.

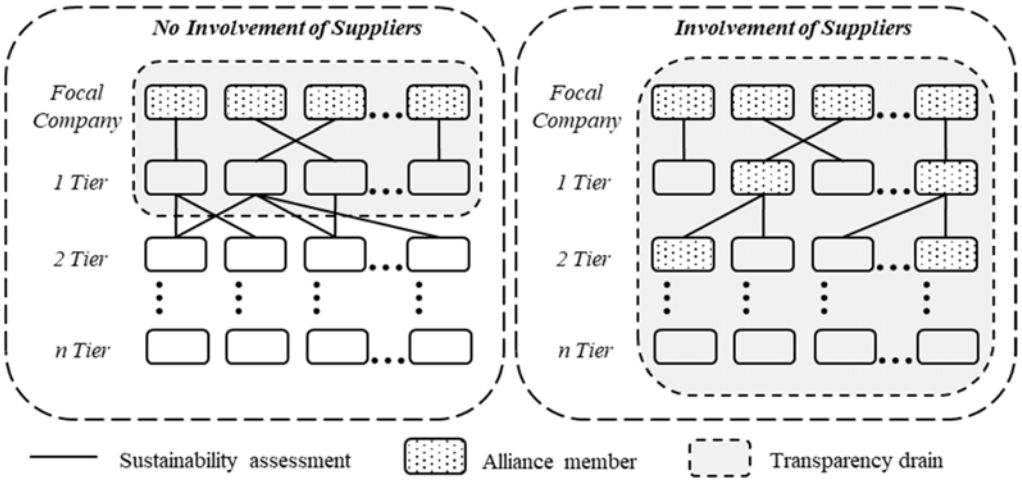

Figure 3. Schematic presentation of increased transparency through the active involvement of suppliers in ASSAs

Discussion

In order to derive propositions on the effects of ASSAs on the management of suppliers within MSCs, we connect our case study observations which were presented in the previous section with the rationales of AT.

Relating to AT, the more information a principal possesses about its agents' behavior, the more likely agents are engaged in behaviors that are consistent with the principals interests (Eisenhardt, 1989a). As observations show, the setting of ASSAs facilitates information gathering from suppliers as it increases suppliers' willingness to share sustainability-related information and thereby enriches focal firms' information on their MSC. However, the setting of Beta and Gamma provides additional incentives for suppliers to perform sustainability assessments due to their subsequent compulsory centrally controlled follow-up activities, which support suppliers in improving their sustainability performance. This is especially helpful for poorly performing suppliers. Thus, we posit the following two propositions:

Proposition 1a. The exchange of assessment results between the members of an ASSA increases suppliers' incentives to share sustainability-related information, fostering information-gathering mechanisms within MSCs.
Proposition 1b. The execution of compulsory centrally-controlled follow-up activities positively influences the willingness of non-compliant suppliers within MSCs to share sustainability-related information.

Deviations from the CSS of a focal firm, which are expressed as audit findings, can be traced back to the agency constructs adverse selection and moral hazard. To encounter these issues, collaboration activities with respective suppliers have to be executed, which cause additional agency costs and expenditures for the focal company. However, as observations reveal, the setting of Beta and Gamma fosters a more efficient collaboration between the focal company and their suppliers, as collaboration practices are organized and executed collaboratively among the members of the ASSAs. Moreover, Gamma's setting leads to additional efficiency gains, as its degree of collaborative actions among the members of the alliances regarding supplier collaboration is higher than Beta's. This observation is consistent with previous research by Oum, Park, Kim and Yu (2004), who found supporting evidence that the higher the level of cooperation in horizontal alliances, the greater the impact of alliances on a focal company's efficiency. This is why we postulate the following two propositions:

Proposition 2a. Collaboratively organized and executed supplier collaboration practices lead to efficiency gains for focal companies by reducing collaboration expenses while increasing the number of approached suppliers within MSCs.
Proposition 2b. The more supplier collaboration activities are managed jointly by the members of an ASSA, the higher the efficiency gains regarding supplier collaboration within MSCs for the focal company.

While the first two propositions relate to suppliers in MSCs in general, including first-tier suppliers and sub-suppliers, the following propositions solely focus on the management of the latter. Considering previous research and the rationales of the AT, the observation of the agent's behavior is hampered through the inclusion of sub-suppliers in supplier management practices (Fayezi et al., 2012), which exposes the principal to a heightened risk of opportunism by its agent. However, as observations revealed, the setting of ASSAs helps to mitigate barriers that prevent the detection of sub-suppliers' actions with respect to sustainability and thereby increases transparency in MSCs. More precisely, an ASSA is a useful tool to increase the leverage power on sub-suppliers, as purchasing volumes of single alliance members can be pooled, whereby negotiation power increases. This finding is consistent with previous research that illustrates that firms can improve their bargaining power by entering an alliance (Porter, 1980). Therefore, the barrier of a limited influence on sub-suppliers can be mitigated through the cooperation of firms within ASSAs. Moreover, through the membership structure of Alpha and Gamma, sustainability assessments of and collaboration with sub-suppliers can be executed through focal companies' suppliers which are also members of the ASSA and which have a contractual relationship with those suppliers. Consequently, the barrier of a lacking contractual relationship between the focal company and their lower-tier suppliers becomes also less predominant within ASSAs and, as a consequence, transparency in MSCs increases. Thus, we postulate:
Proposition 3a. The cooperation of firms within ASSAs positively affects the management of sub-suppliers within MSCs by improving focal companies' negotiation power over sub-suppliers.
Proposition 3b. Involving suppliers in ASSAs fosters the passing of CSS along MSCs and increases the transparency in MSCs on various tiers from a sustainability perspective.

Since the jointly executed supplier management practices of ASSAs facilitate the management of suppliers, improved suppliers' compliance with CSS could be observed through follow-up assessments by member companies of all three investigated ASSAs. This observation can be explained by considering the rationales of the AT. According to that, ASSAs, on the one hand, increase the amount of available information on the sustainability performance of suppliers within MSCs (see Proposition 1a, 1b, 3a, 3b). Therefore, the sustainability performance of a higher number of suppliers along various tiers of MSCs can be identified. Thus, the likelihood that those suppliers engage in behavior that is consistent with the focal firms' interests increases (Eisenhardt, 1989a). Moreover, collaborative supplier activities represent a further control mechanism to mitigate suppliers opportunistic behavior (Hajmohammad and Vachon, 2016), which can be executed more effectively through ASSAs (see Proposition 2a, 2b). Thus, suppliers sustainability capabilities, which were previously insufficient due to adverse selection, can be effectively improved, which fosters suppliers' compliance with CSS.

On the other hand, the setting of ASSAs aligns agent's preferences with those of the principal, which is another possibility for reducing risks in agency relationships (Eisenhardt, 1989a). This can be achieved through the provision of appropriate incentives for the agent, since the agent usually works towards maximizing rewards (Fleisher, 1991). As case study observations show, the setting of ASSAs improves the incentives for suppliers to comply with CSS of the buying companies. This is because the results of the sustainability assessments are potentially visible to all member companies of the ASSA and therefore a non-compliance has potentially higher negative effect on supplier's business. Thus, it can be concluded that cooperation of firms within ASSAs improves suppliers' compliance with CSS.

However, the configuration of Gamma's supplier management practices could be observed as the most effective at improving suppliers' compliance with CSS. This assumption is based on the fact that Gamma comprises all configuration options, which we refer to as having a positive effect on supplier management in our proposed propositions. Thus the conclusion can be drawn that Gamma's ASSA setting allows the most active management of suppliers within MSCs and therewith facilitates the greatest improvement of suppliers' compliance with CSS (Grimm et al., 2016). Thus, we posit:

Proposition 4a. The cooperation of firms within ASSAs improves suppliers' compliance with the focal company's CSS through the reduction of information asymmetry within MSCs and the alignment of suppliers' interests to those of the focal company.

Proposition 4b. An ASSA setting which simultaneously comprises compulsory centrally controlled follow-up activities, a high degree of jointly executed supplier collaboration practices and the active involvement of suppliers in ASSAs additionally promotes suppliers' compliance with CSS in MSCs.

Conclusion and implications

Triggered by the high complexity of managing an increasing number of suppliers with respect to sustainability, strategic alliances between competitors of the same industry are formed in the real-world context to meet stakeholders' growing sustainability expectations (Fayezi et al., 2012). The focus of our study lays specifically on ASSAs, which are primarily formed to shared audit reports of common suppliers to collaboratively manage shared suppliers. More precisely, three ASSAs from the railway, telecommunication and pharmaceutical industries were analyzed to gain insight on how companies collaborate within ASSAs to manage suppliers with respect to sustainability and to reveal the effects ASSAs have on the management of suppliers within MSCs. As no research thus far has investigated strategic alliances in the context of sustainable MSCM, our study findings are beneficial for both scholars and practitioners. In line with extant literature, by considering the rationales of AT, our study's findings confirm

that strategic alliances are an appropriate option for managing suppliers within MSCs with respect to sustainability (Tachizawa and Yew Wong, 2014). Moreover, our study not only confirms but complements extent literature by revealing how the sub-supplier approaching strategy *work with others* is implemented in practice and by providing insight on how sub-supplier specific barriers, such as missing contractual relationships (Choi and Hong, 2002) and limited negotiation power (Plambeck et al., 2012; Tachizawa and Yew Wong, 2014), are mitigated in a real-world context in order to improve suppliers' compliance with CSS. In this context, our study shows that members of ASSAs collaboratively execute supplier assessment and optionally supplier collaboration practices in order to prevent sustainability violations in MSCs.

Additionally, our study regards sustainable MSCM from an AT perspectives and thus applies AT to a new context. More precisely, it states that information asymmetry, which is caused by the typical agency constructs, adverse selection and moral hazard, poses a threat to suppliers' compliance with CSS. However, observations revealed that those agency problems can be controlled more efficiently within ASSAs since control mechanisms such as supplier assessment and supplier collaboration practices are executed collaboratively among the members of the respective alliances. Thus, suppliers' compliance with CSS is fostered through collaboration in ASSAs.

Even though ASSAs do in general improve suppliers' compliance with the focal company's corporate sustainability standards, the configuration of jointly executed supplier management activities as well as membership conditions vary between ASSAs and consequently influence the effects ASSAs have on the management of suppliers in MSCs. In this context, it was found that configurations such as compulsory centrally controlled follow-up activities, a high degree of jointly executed supplier collaboration practices and the involvement of suppliers in ASSAs have an additional positive effect on suppliers' compliance with CSS, as a more active management of suppliers within MSCs is fostered (Grimm et al., 2016).

From a managerial perspective, our research confirms that companies can benefit from a membership in an ASSA, as suppliers' compliance with CSS can be increased through collaborative supplier management. In addition, our research provides a guideline for practitioners on how to design ASSAs in order to most effectively manage suppliers in MSCs with respect to sustainability.

Although the application of a multiple case study design allowed an in-depth analysis of ASSAs in the context of MSCM for sustainability, it inherently possesses the difficulty of generalization. Thus, a large-scale study could be conducted to test the generalizability of our derived propositions. Additionally, other ASSAs could be investigated to reveal further configuration options and to study their effects on MSCM in order to provide further arrangement options to practitioners. Moreover, since our study exclusively explored effects of ASSAs on the focal companies MSCM, further studies could explore those effects from a suppliers' perspective. Although many positive effects of ASSAs on the management of suppliers within MSCs could be revealed, reasons why firms choose not to enter an ASSA are still unknown as our research focused exclusively on alliance members. Thus, the investigation of entry barriers for ASSAs could be a further interesting future research avenue. Furthermore, future studies could focus more specifically on the moral behavior of individuals, as moral decisions that influence a firm's compliance with CSS are not taken by a supplier as an entity, but they are taken by one or more individuals working for the supplying company. In the context of ASSAs, moral disengagement theory, which was introduced to supply chain management by Eriksson (2016), could be applied to investigate whether moral behavior of supplying companies' employees is influenced by a focal company's membership in an ASSA. Thus, another dimension could be added to this research topic.

In summary, our multiple embedded case study on ASSAs brings the present body of sustainable MSCM forward by identifying strategic alliances as a suitable means to manage both first-

tier and lower-tier suppliers with respect to sustainability. Thus, our present article functions as a starting point for further investigations exploring strategic alliances in the context of sustainable MSCM. Moreover, it provides helpful guidelines for supply chain professionals on how to design ASSAs to improve suppliers' compliance with CSS the most effectively. Thus, our research will undoubtedly support scholars and practitioners to solve MSCM problems, thereby not only reducing sustainability-related risks for focal companies but also fostering fair labor conditions as well as ecological sound practices in supply chains to ensure livable living conditions for present and future generations.

Building an IoT vision

Report on the creation of a learning journey for Executive MBA students

Legenvre Hervé, PhD

European Institute of Purchasing Management

hlegenvre@eipm.org

Abstract:

The present article explores how at EIPM, we developed a learning experience for our Executive MBA students on how to create an IoT (Internet of Things) vision for a company. We present why we believe this was an important development in the current business context. We illustrate this thanks to an industry example on autonomous ships. We also describe the business ecosystem mapping methodology we used to create this learning experience. We then define how the learning experience was implemented and what we have learned from its implementation with two different MBA classes. We conclude with some reflection on the topic itself, on how we could approach education and research to reduce the time it takes between the emergence of new business challenges, to the development of valuable learning experiences that can help executives and professionals to address them.

Arthur C Clarke, the famous science fiction writer, believed that advanced technologies cannot be distinguished from magic. Today, you only need to watch the recent keynotes from leading high-tech firms to understand the relevance of his disconcerting observation. Gartner, the business intelligence company has taken this hindsight seriously and therefore issues every year a series of hype curves that map new technologies along a curve that includes a "peak of inflated expectations", a "disillusionment phase" and finally a "productivity plateau".

Today with the rise of the Internet of Things (IoT) together with the emerging technical and business systems (Robots, AI, Clouds, etc.) large scale disruptions, amazing societal benefits, fear of job losses and massive productivity gains are announced and debated every day. It will take a few years to understand the speed of diffusion and the true impacts of this transformation on industries. In this context of uncertainty, defining the right business strategies is an intricate task.

Connecting trillions of smart things, ranging from implants to industrial equipment; the Internet of Things merges the physical and online worlds. As machines are increasingly connected together, companies, governments, and consumers face opportunities and threats. The survival of some companies will be at risk, while others will be able to rethink their business models and to generate growth.

Today it is essential for Executives to build an IoT, or a digital vision where they identify opportunities and potential external collaboration they could benefit from. Looking at every single idea one by one, or discussing opportunities with all start-ups that have developed an interesting prototype cannot be the way forward. A vision for the future needs to be established so that promising directions can be further investigated, while others can be abandoned.

The present article outlines how, at EIPM, we have decided to address this challenge within our Executive MBA Programme. As part of the Innovation and Entrepreneurship module we have created a learning experience that focuses on this issue. We will look at how the Internet of Things (IoT) impacts business dynamics and we will see that it is essential to map the business ecosystem in a forward-looking mode to build an IoT vision. From this, we will briefly present The Ecosystem Mapping methodology we have developed over the past years. Hence, we will see how it is integrated within a learning experience where our Executive MBA students reinvent the Champagne value chain. We will conclude on the challenges associated with implementing such an approach within companies.

The IoT; Product-Service hybrid and the relevance of business ecosystems

The IoT has been defined by the International Telecommunication Union as "*the global infrastructure for the information society, enabling advanced services by interconnecting (physical and virtual) things based on existing and evolving interoperable information and communication technologies*." The IoT changes products into product/service hybrids. As "Things" get connected, data is generated. The IoT can therefore be used to deliver digital services and to power new business models. A company like Michelin is well known for selling tyres. Today, sensors inside the tyre help its client reduce their fuel consumption and their operating costs. Michelin's innovation business model also enables its clients to pay for tyres on a per-kilometre basis.

Combining the physical with the virtual world requires assembling diverse capabilities. This calls for establishing collaborations that bring together companies and organisations with a different knowledge base. We often perceive the business world as a battle between old and new industries, as a race amid the east and the west, or as a competition between big corporations and start-ups. In reality, this world of competition is also a world of collaboration. This is a business ecosystem, where a diversity of

players "*coevolve their capabilities and roles and tend to align themselves with the directions set by one or more central companies*."(Moore, 1996)

This can be easily illustrated by recent announcements on autonomous ships at the marine division of Rolls Royce

Since 2014, Rolls-Royce Marine business performance has been negatively impacted by the consequence of the oil price collapse. The workforce has been cut by 25% over two years. However since 2015 new strategic initiatives have been communicated. Mikael Makinen, the head of Rolls-Royce Marine has announced: "Digitalisation will transform the shipping industry in the years ahead, and the time is now right to set out how we are going to make this happen," Rolls Royce focuses on autonomous ships. With limited investment capacity and a need to develop and access new skills and technology, the company has decided to look for partners. The following slide was presented at a conference in May 2016 by Oskar Levander, the Innovation VP of Rolls-Royce Marine. It clearly illustrates this last point.

Fig 1: Rolls-Royce Marine on Digital alliances

Indeed some alliances, partnerships and collaborations have been announced. In 2015, the Advanced Autonomous Waterborne Applications (AWAA) Initiative was launched. It is funded by Tekes, the Finnish Technology and Innovation Agency. It brings within a consortium different academic partners and existing maritime industry players such as DNV, Brighthouse, NAPA, Deltamarin, and Inmarsat. Most of this consortium work streams focus on technology, but some of them look beyond and address business and legal implications of autonomous ships. In 2016 and 2017 new partnerships on the client side were announced. Then in 2017, two new partnerships were announced including one with the European Space Agency (ESA) aimed at pursuing space activities to support autonomous shipping, and another with Google on AI to enhance the intelligent awareness systems. As we can notice collaboration is at the centre of the Rolls-Royce strategy to spearhead development for autonomous ships. Such partnerships include both academic and industry players. Furthermore, industry players go beyond the existing industry boundaries to include ESA and Google. The case of the Rolls-Royce autonomous ship strategy raises some interesting questions: How do you develop a vision and a strategic roadmap for such a transformation? How do you identify partners? How to effectively implement a strategy in such a context?

Thinking in ecosystems: A methodology

We see that with the rise of IoT and the ongoing series of digital transformations, Executives need to address some important questions. Consequently, their answers will have a fundamental impact on the future of their company. These questions include: *"Who will be our most important external innovation partners in the next X years?" and "How will we work effectively with them?"* Answering the first question requires looking well beyond what they see as their existing strengths and weaknesses to spot forthcoming opportunities and threats. It can only be achieved by scanning what is taking place within and beyond the industry boundaries; by finding out where are the outposts of future transformation of the industry architecture (startups, new suppliers, new clients, and new players from other industries that could help change how value is created and captured). A classic Porter five forces analysis will take you in the right direction, but you will need to look at the peripheral forces and to consider future developments. You need to understand what changes happening today could, in the future, generate new business models and bring substitutes to their existing offers.

Thinking in ecosystems does not need comprehensive and lengthy analysis. It requires people to change their perspectives, to spot opportunities, to experiment rapidly so new hypotheses can be tested and new knowledge can be gained before business model innovations can be achieved

At EIPM we have developed a methodology that can contribute to this. It is based on Six steps, they are as follows:

1-***Define the scope of application***: this can be a business unit, a product group, a value chain or some key business activities. Within that scope, current business goals, value drivers and main challenges should be identified.

2- ***Identify the trends that will bring changes in the future***. This should help participants extract themselves from their day to day environment, so they can to develop their sensitivity to weak signals and emerging forces.

3- ***Identify future Ecosystem players***. Finding out who you work with today is relatively easy. It is more difficult to identify who could be important to work with tomorrow. Building on the analysis of the trends, you can identify some companies or organizations that can be future ecosystem players.

4- ***Map the ecosystem***. We will show some examples later in the text. Here, you can position next to each other four types of players: (1) the customers, (2) current value chain players, (3) potential or rising members of the value chain, (4) influencers (mainly governmental bodies and Non-Governmental Organizations). This is a visual representation that will help everyone have some key discussions.

5-***Understand the dynamics within the Ecosystem***. No one can predict the future but a few simple questions can help. They include: Today who competes with whom… on what? Who collaborates with whom… on what? Tomorrow who could compete with whom… on what? Who could collaborate with whom on what? These are simple questions but they help to lift today's blinders and explore what might happen tomorrow.

6-***Define your ecosystem strategy***. Here you can simply agree on the following three priorities: What you should monitor in the future? Who you should start to talk with in the near future? And who you should try to partner with in the near future? This is a plan that could evolve over time but it will give a sense of direction to the transformation you will undertake

To learn more about this methodology, you can use an article published in the European Business Review (Legenvre; 2016)

Building an IoT vision: Creating a learning experience For EIPM Exec MBA Participants.

Over the past years The Executive MBA has been strengthened to reflect the business environment

- The Business strategy course has integrated a specific module on platforms
- The Strategic Information System Module has evolved to reflect the challenge associated with a digital transformation
- Special additions have been made to some specific courses such as Blockchain and Smart Contract that are now covered in the supply chain module and discussed more in depth in our 2017 master Class
- Integration of Design thinking / Lean Startup and Business Ecosystem analysis in the course on Innovation and Entrepreneurship since 2015

In 2017, we created a more integrated learning experience that would help our Executive MBA students to build a compelling IoT vision for a business. Following our research activities on the impact of IoT we had realized the importance of providing our participants with something practical and concrete they could use in their business environment.

We established the following objectives for this learning experience

- Help participants understand the challenges and opportunities associated with the IoT
- Equip participants with tools to build a Digital / IoT vision for their business
- Help participants see the big picture so they can avoid a sub optimisation trap
- Think in Ecosystems / Develop a portfolio of innovation collaborations

As we developed the learning experience, we added the following learning goals

- Discover the power of Minimum Viable Products
- Explore challenges associated to innovation with external players

For this learning experience we decided to focus on the Champagne industry. This is an appealing and interesting industry for participants. They can rapidly discover it as there are limited technical complexities that need to be understood. But most importantly, it offers a wide diversity of contexts as it touches on farming activities, production activities, distribution and supply chain, retail and customer experience. So instead of focusing on what IOT means for agriculture or retail, we have here a broad value chain that can combine diverse perspectives.

Prior to the learning experience, we had two other sessions that provided some useful inputs to it:

- A session on trends where we described what the Internet of things is. We provided an overview of the IoT, some examples of application and some analyses of how it changes industry architectures. This provided a chance to discuss what opportunities Buyers could seize in this context.
- A session on Design thinking, where participants were introduced to two concepts that are important for the learning experience: Pain point as a source of innovation ideas and Minimum Viable Products as a way of designing and presenting an innovation.

The learning experience started right after lunch on the third day of the course and participants were required to present the outcomes of their work at 12.00 the day after. They therefore had about 24 hours to work on it. The groups were provided with the following inputs:

- ***The Goal of the workshop***: help a Company active in the Champagne business to make the most of the Internet of things by creating a compelling vision
- ***The Champagne value chain*** was presented to the participants. It was structured around the following six steps:

Fig 2: The champagne value chain

We used videos to introduce the industry context:

- https://www.youtube.com/watch?v=HRxPWRZgicM
- https://www.youtube.com/watch?v=wGffdxnM0_U

Participants were split into small groups. Each group had to focus on two steps of the value chain. They were free to choose. Some clearly had more interest on specific steps of the value chain.

Each group was briefed orally on the business goals and pain point challenges associated with the steps of the value chain they had chosen. The briefs were developed using industry reports found in the ProQuest database and thanks to an interview conducted with the CPO of an existing industry player. We decided that readings would not be provided and that presenting it orally was the best way forward. We wanted them to focus on the IoT related reading, and not on the industry information

Each group had to go through the following steps.

1. Define the scope of their work. Here they had to summarise the business goals and the pain points encountered during the stages they were working on.
2. Perform a full Ecosystem analysis. For this they were provided with an Ecosystem toolbox so they could go through each step of the Ecosystem's methodology swiftly.
3. Propose one Minimum Viable Product using one picture or one slide. The key idea here, was to confront them with the challenge to pitch one idea in a compelling way
4. Define the IoT solutions you intend to implement and the expected benefits associated with these.
5. Prepare a Four slide presentation. We will see an example underneath

The overall process was summarised using the following diagram

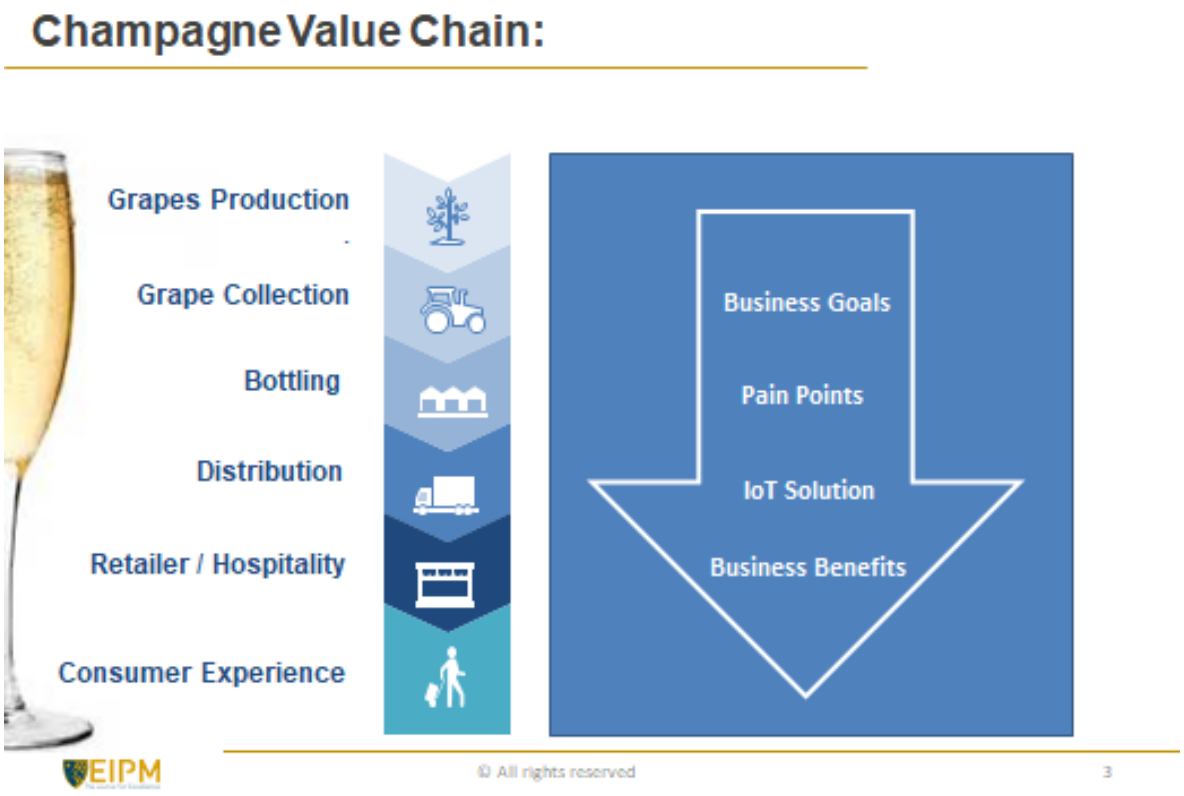

Fig 3: Summary of work to be completed

Each group was provided with a wealth of information on start-ups and innovation that could impact the steps of the value chain they were looking at. The idea was to create an information overload, and to confront them with the reality of being overwhelmed with opportunities.

We had discussed the opportunity of creating a more condensed pack of information with a pre-selection of ideas and innovation. However, we wanted to be closer to the real world and we decided to provide extensive data.

To do this we used different types of resources. Some aimed at providing an overview of many solutions with limited depth. Participants were free to find more information on the concept they could be interested in.

Here we used resources from CB insights including:

- The Ag Tech Market Map: 100+ Startups Powering The Future Of Farming And Agribusiness https://www.cbinsights.com/research/agriculture-tech-market-map-company-list/
- Stocked Up: 150+ Companies Attacking The Supply Chain & Logistics Space https://www.cbinsights.com/research/supply-chain-logistics-tech-infographic/
- The Store Of The Future: 150+ Startups Transforming Brick-And-Mortar Retail In One Infographic https://www.cbinsights.com/research/retail-store-tech-startups-2016/

These are excellent because they are quite synthetic and provide a wealth of ideas.

More specific and detailed articles were also provided. They were meant to provide examples of innovation with more depth, but also to question the value of these innovations, this included for instance:

- IoT now helping make smart wine? https://readwrite.com/2016/04/04/iot-makes-smart-wine-agriculture-if4/
- Kuvée: The internet-enabled smart wine bottle no-one asked for http://www.independent.co.uk/life-style/gadgets-and-tech/news/kuvee-smart-wine-bottle-screen-internet-indiegogo-a6958751.html

These helped to provide descriptions of more tangible applications.

All groups worked extensively on their topic. Some worked late at night, others started very early in the morning. They received support throughout, especially on the use of the Ecosystem methodology.

They all presented their outcomes and an overall presentation was aggregated and redistributed to all of them. One copy was also sent to the CPO of the Champagne Company. His feedback was the following:

"Thank you for the document. This outcome is interesting and I would welcome the opportunity to hear more about that investigation work."

It was circulated back to the participants who appreciated it.

Building an IoT vision for the Champagne Industry: The outcome of this learning journey

The quality of the results from each group was very consistent. All of them developed a well-documented ecosystem and described a four or five slide IoT vision. The best way to describe these outcomes is to show what one of groups came up with:

They summarised for each step the business goals and the pain-points. For the distribution step, they presented a few bullet points that were explained more in depth orally.

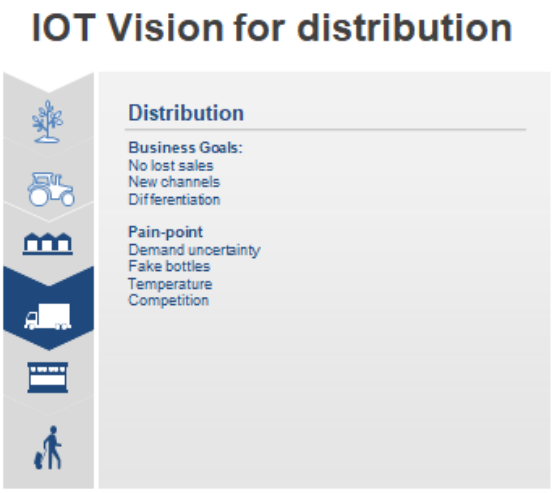

Fig 4: Example of outcome:

All Groups performed an in-depth ecosystem analysis and created a map of the ecosystem for the steps they covered. This was shared in their final presentation. All groups had identified six to twelve rising and new players. This was a good outcome. The next figure presents the outcome of the group that addressed distribution.

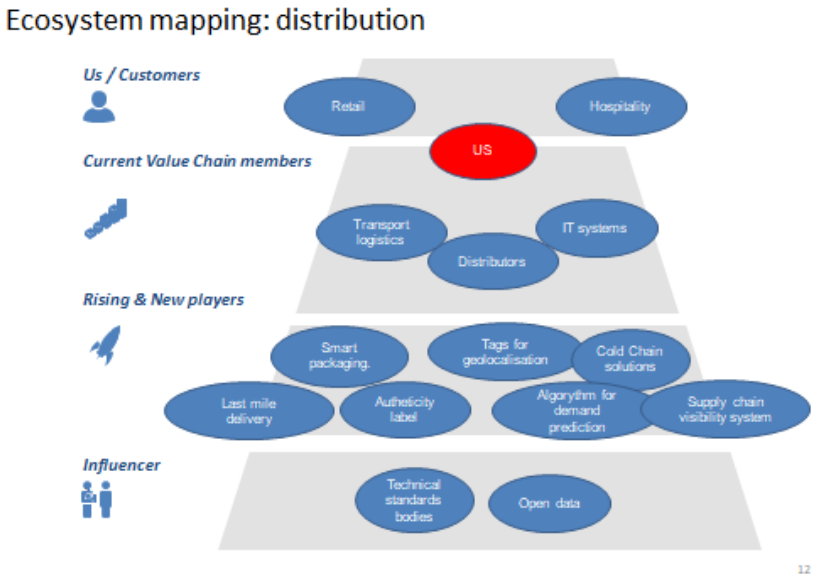

Fig 5: Ecosystem map for Champagne distribution

The third expectation for the final presentation was to present one Minimum Viable Product. The idea was to encourage them to pick one idea from the few proposed and to pitch it to the group. The next figure presents the creative outcome of the group that addressed distribution.

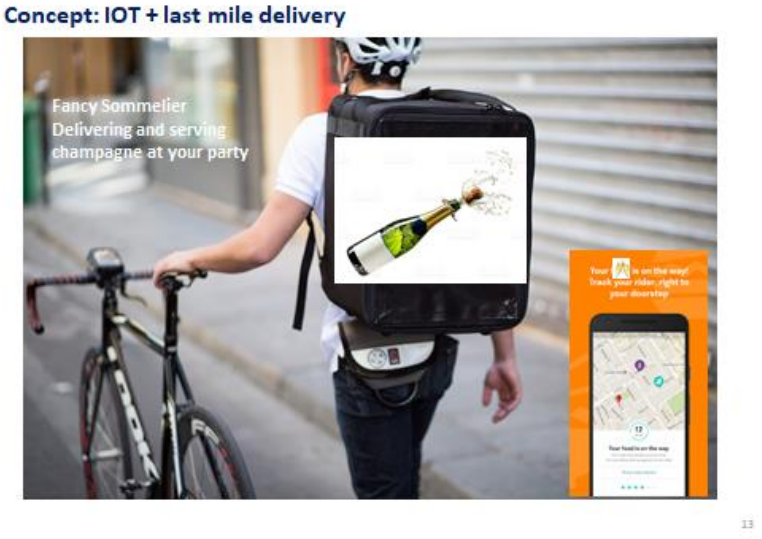

Fig 6: MVP for Champagne distribution

Finally, each group had to conclude the exercise with a helicopter view of the IoT solutions and the expected benefits. The next figure presents the outcome of the group that addressed distribution.

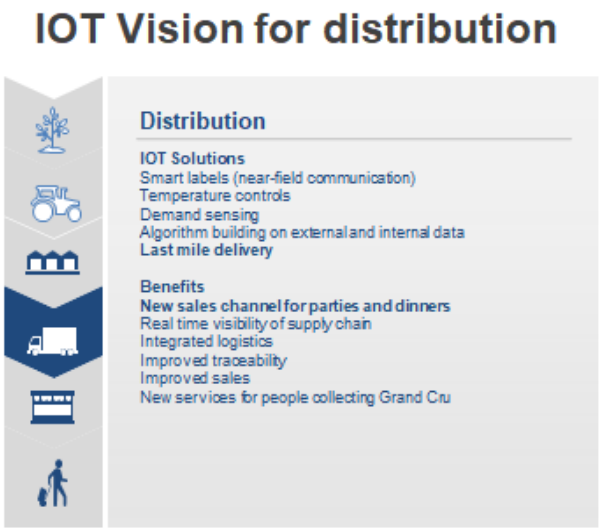

Fig 7: final slide on IoT vision for Champagne distribution

Education outcomes and lessons learned

This module was delivered in Europe during the summer of 2017 and in China in November 2017. Feedback was gathered from the participants both as a group and individually. The main learnings were the following:

- This significantly raised the participants' awareness of the impacts of the Internet of Things on their industry. We had overestimated their awareness. They associated IoT with an idea or two, but they did not suspect that it could impact an industry throughout its entire scope. This did not hamper the learning. It was an additional benefit
- Participants enjoyed the case. In Europe, participants liked a lot the choice of the Champagne industry that offered a diversity of perspectives. In China, we had a little surprise. Chinese tend to prefer warm drinks to cold drinks. This made it hard for them to start the exercise, especially on the distribution and retail side. They found it challenging to find ideas on how to promote Champagne within China. Nonetheless, they ended up with some interesting ideas to connect this promotion with wedding banquets
- Some participants expressed the view that there was a lot of documentation to read. However, they also said if the group was well organized, it was not a problem to handle this. In fact they enjoyed having access to so many startup examples and many of them subscribed to the CbInsights newsletter afterward.
- Relative to mapping ecosystem. They had no difficulties in applying the methodology thanks to the toolbox they had received. They suggested to have a more structured individual debrief and feedback of their use of the toolbox, instead of having a generic feedback with the full group.

All Participants found the exercise interesting and of value. They said they would like to have the opportunity to do something like this within their company. Nevertheless, some of them found it difficult and challenging to implement. Some comments included:

- "We don't have the necessary maturity in my company to do something like this"
- "It would be difficult to involve all departments in doing this"
- "We are still expected to reduce the number of suppliers and here we go in the opposite direction".
- "It forces us to look at what we don't usually look at. It is good but this is hard"
- "Who has time for this?"

These were not questioning the methodology and the tools used. This was all about questioning the ability of their company to be ambidextrous enough to go in this direction.

This overall experience was very positive, and we will continue to pursue it. We intend to fine tune and enrich it. The main improvement ideas relate to the documentation provided. We will keep the same logic, but we will limit the number of articles that have more depth. Also we intend to associate for the session in Europe someone from this industry to the workshop. For China, We are considering taking a more local case, using for instance a drink based on herbal medicine. This would be very much welcomed by the Chinese participants.

Conclusions

Recently the former CPO of an FMCG company said in a CPO forum "*The question is not if the IoT will impact our business. It is about how the IoT will Impact us and how it will change the supply base and market dynamics within our segments. We need some frameworks to help us with this."* The present paper outlines a learning experience we created to address this expectation. In a fast-changing world, we cannot adopt a linear approach: starting from research, developing case studies and then creating teaching cases on a specific topic. We need to work closer with companies that are at the forefront of the merging changes, we need to understand their expectations and how we can adapt our frameworks to help them progress. We need to experiment, so we can provide an engaging learning experience to our students and participants. Such learning experiences might also provide opportunities to develop and apply new research methodology, so we can reduce the time gap between what takes place in supply chains, and the development of research outcomes.

We have reported in the present paper on the development of a learning journey that can help our students and course attendees develop IoT or digital vision. What have we learned from this?

On the topic itself, thinking and working in ecosystems requires executives to question their current practices:

- They need to challenge their way of thinking by looking at the trends that will define success tomorrow. This is not about being creative, but this requires combining lateral and long-term thinking. It can be nice and easy to do this once… but the challenge is to persevere and to become more ambidextrous as an organization.
- We need to prepare executives and professionals to welcome the idea that external collaborations become more essential to their company's success. This can be a challenge for

many people. It is also a challenge for buyers. When they see innovation, they see risks not opportunities. We need a cultural transformation here.

Also In terms of education and to some extend research, we should consider some new ways of thinking:

- We need to anticipate changes in the business world, so we can better equip our students with the right frameworks and ways of thinking
- We need to experiment and develop progressively new learning experiences in a structured and systematic way
- Beyond using teaching cases or well-established simulations, we need to think about the advantage and inconvenience of using real materials and creating life like situations. This needs to be fulfilled without sacrificing on simplicity and the quality of learning. This is an interesting challenge
- Creating new learning experiences can help generate knowledge and help us answer some emerging research questions. This is indeed an opportunity we could explore.

Abstract
This paper defines what we mean by combining distant capabilities. We combine different stream of literature to show that innovation result from the combination of an assortment of capabilities characterized by certain degrees of geographic, knowledge, social, institutional and organizational distance amongst them. We focus on knowledge and organizational distance as the main characteristics of our research framework on how to combine distant capabilities. We then develop a model where cognitive fluidity and cognitive rigidity impact on how inter-organizational and inter-personal linkages evolve over time. This offers practical advantages to understand how capabilities are combined, integrated and transformed into innovation and economic value.
Keyword: distance innovation, network

This article develops a research framework on how distant capabilities are combined to generate innovation and economic value. We first provide some definitions and suggest that the micro-foundations of how distant capabilities are combined together still need to be developed. We describe our understanding of how inter-organizational and inter-personal networks combine distant capabilities over time. While new organizations and individuals come in, others disappear; some become more central to the innovation effort while others take a more peripheral role. In such a process, individuals are connected together through inter-organizational and inter-personal linkages. Their assumptions and belief evolve as ill-defined problems are framed and solved. Their actions and decisions modify existing linkages, eliminate some of the previous ones and create new ones. Innovation occurs as distant capabilities get combined thanks to cognitive process that frame inter-organizational and inter-personal linkages. After developing our research framework we acknowledge that combining distant capabilities could be studied through a diversity of theoretical lenses. We therefore develop some complementary hypothesis outlining influences that could impact on the evolution of the inter-organizational and inter-personal linkages that combine distant capabilities.

Introduction: distant capabilities

In October 2017, Rolls Royce and Google announced a partnership aimed at using machine learning to create autonomous ships. Cameras, sensors and scanners located on Rolls Royce

vessels will provide data that will be analyzed thanks to Google's Cloud Machine Learning Engine. This will allow tracking objects encountered by ships so hazards can be anticipated. In the aerospace industry, Airbus looked into existing options for geo-localization and asset tracking services and they selected early 2017 a Belgium start-up named SENSOLUS as partner. Their solution offers Airbus the ability to track in real time recyclable packaging that contain plane parts and spare parts across the company and its suppliers. The solution is energy-efficient, easy to install, reliable and scalable. It builds on another start-up, SIGFOX that offers connectivity through low-power wide-area network. Such collaborations amongst unfamiliar players are not solely the result of the existing digital transformations; other concerns such as sustainability can motivate their developent. For instance, since 2010, in Great Britain, Network Rail has partnered with an NGO to reduce suicide on the railways.

As firms realize their organization do not control all capabilities required to excel, strategic collaborations amongst players with heterogeneous sets of resources and capabilities are becoming more common and visible. Firms need to innovate by exploring external resources and capabilities they lack (Chesbrough & Crowther, 2006; Pisano & Verganti, 2008; Gualandris, Legenvre & Kalchschmidt, 2017). This takes us back the insight of Adam Smith (1776), who looked beyond the division of labor within factories and associated innovation with the combination of distant capabilities: "*All the improvements in machinery, however, have by no means been the inventions of those who had occasion to use the machines. Many improvements have been made by the ingenuity of the makers of the machines, when to make them became the business of a peculiar trade; and some by that of those who are called philosophers or men of speculation, whose trade it is not to do anything, but to observe everything; and who, upon that account, are often capable of combining together the powers of the most distant and dissimilar objects*". This division of labor in innovation activities reflects for instance how the British textile industry during the late 18th century harnessed the power of the steam engine and other technical and social changes that were diffusing across Europe. Today as many value chains are highly fragmented; as firms compete against new entries or enter new strategic arenas, as a new technologies and business models are changing the rules of competition, firms need to combine distant capabilities to deliver superior performance and innovate in this rapidly changing world.

This motivated us to identify important gaps in our theoretical and empirical understanding of how innovation occurs through the combination of distant capabilities and to suggest future research avenues. The relevance of this approach has been outlined by different school of thoughts; however we realized that the micro-foundations of how distant capabilities are combined together still need to be developed. We therefore propose in the present paper a research framework to study how innovation networks combine distant capabilities. We see this attempt as a contribution to the better understand how ecologies of diverse organizations, institutions and agents produce product and service innovation (Dougherty & Dunne, 2011). We look beyond single firm perspective to investigate how two, three or more organizations combine different capabilities in order to innovate. In our approach, organizations own specific capabilities that are combined thanks to inter-organizational and inter-personal networks. The actions and decisions of interdependent individuals change the structure of innovations networks at individual and organizational level. This allows to combine distant capabilities and to generate new streams of innovation.

This paper is structured as follows. It first frames the concept of distant capabilities by building on three research streams: the resource based view of the firm, the proximity school and the study of local vs distant innovation search process. This will allow us to better define

what we mean by distant capabilities and to highlight existing research gaps. From this, in a second part we further explore the micro-foundation of how distant capabilities are combined by looking at how inter-organizational and interpersonal linkages evolve over time. As linkages evolve problems that are due to the distance between the capabilities are identified framed and solved. This impacts the beliefs of individuals who through their actions and decisions change existing linkages, eliminate some and create new ones. As we propose a composite concept that combines different disciplines and multiple levels of analysis, our research framework will benefit from the contribution of different theoretical viewpoints. Without trying to be exhaustive, we then suggest how different theoretical lenses offer hypothesis on some of the critical influences that could affect the evolution of inter-organizational and interpersonal linkages. This will lead us to reflect on our work and on describing future research avenues.

Combining distant capabilities: theoretical foundations

Defining what we mean by distant capabilities starts with looking at the meaning of capabilities. In the 1990's, management scholars increasingly described firms as a bundle of "resources and capabilities" (Barney et al. 2001). Capabilities have been defined as a firm's capacity to deploy resources thanks to information-based, tangible or intangible processes (Amit & Schoemaker, 1993). Capabilities span a continuum from general purpose capabilities that can be applied to a broad range of use used to application specific capabilities with limited range of use (Pisano, 2015). A subset of capabilities with specific characteristics could provide the firm that owned or controlled them a sustainable competitive advantage. The extended resource-based view (Eisenhardt & Schoonhover, 1996; Lavie, 2006) and the more recent literature on dynamic capabilities (Teece, 2007) shows that firms innovate through collaborations with a variety of actors in the firm's ecosystem – i.e. "the community of organizations, institutions, and individuals that impact the enterprise and the enterprise's customers and suppliers" (Teece 2007, p. 1325). Concepts such as absorptive capacity (Diana Van Aduard De Macedo Soares, T et al.) or ambidexterity (Lucena & Roper, 2016) have been refined over time to describe how firms come in contact with distant actors, markets, and technologies compared to their knowledge domain. The theoretical foundations of dynamic capabilities specify the stages of sensing, seizing and reconfiguring the firm's ecosystem as a key passage to generate competitive advantage. However, extant studies only partially tap into the challenges of combining distant resources and capabilities. The strategic management literature on complementary assets (Helfat 1997), mostly focuses on the outcomes of complementarities rather than addressing how such complementarities are merged to build value.

Another group of scholars have shown that different forms of proximity matter for innovation (Balland & al., 2014). The proximity school allows us to better define what we mean by "distant" when looking at distant capabilities. Beyond geographical proximity four other forms of proximity: cognitive, social, institutional and organizational proximity have been studied over 20 years. Cognitive distance refers to the extent to which actors hold different knowledge base. In our framework presented underneath we will prefer using the word knowledge as we reserve the word cognition for another purpose. Organizational distance refers to the membership of actors to different organizational entity. Social distance refers to a lack of prior personal relationships amongst actors. Institutional distance refers to the heterogeneity in terms of norm and incentives that characterized the actors involved in joint innovation activities. As proximity reduces cost and facilitates communication it facilitates collaborative innovation activities. In a study of automotive and pharmaceutical firms a U-

shaped relationship between cognitive distance and innovation performance has been identified. This led to the idea that an optimal distance could exist (Noteboom, 2007). Recent research findings have highlighted the existence of the proximity paradox. Proximity enables the formation of knowledge networks but does not necessarily lead to superior innovation performance (Boschma & Frenken, 2010; Broekel and Boschma, 2013; Cassi & Plunket, 2013). Future studies are expected to investigate how knowledge networks and proximity co-evolve over time (Balland et al., 2014). If on one hand proximity facilitates the formation of ties in networks; on the other hand as innovation networks evolve they create proximity. The proximity school helps us define the meaning of "distant" and suggest us to consider diverse distance factors. It also points us in the direction of studying the factors that influence the evolution of innovation networks to develop our approach.

We will now look at the literature that investigated the relevance of local and distant innovation search. This will provide us with the foundation to define "distant capabilities". As we will see that the impact of local and distant search on innovation outcomes has been extensively studied we will also realize that we still need to explore the micro-foundation of how distant capabilities are combined. Innovation results from the combination of different bodies of knowledge (Nelson and Winter, 1984; Kogut & Zander, 1992). Consequently the search for new source of knowledge has been regarded as an essential dimension of innovation. The distinction between local vs distant search has existed since the seminal work of March and Simon (1958) Local search is defined as a search for solution in the neighborhood of the firm current knowledge base (Rosenkopf & Nektar; 2001). These searches can be characterized by different level of depth and breadth. It was repeatedly emphasized that organizations tend to focus on local search (Dosi 1982, Rosenkopf & Nektar; 2001). New search are constrained by past ones and firms display myopic behaviors. An over-focus on local search can be harmful for a firm (March 1991; Rosenkopf & Nektar; 2001). Recently, the complementarity between local and distant search has been emphasized. Kaplan and Vakili (2014) demonstrated that combining distant and local search allows the transformation of novel ideas into economically valuable ones. They suggested that further research needs to be undertaken in order to understand how conflicting practices can lead to effective outcomes by that an inter-organizational perspective. What they describe as a "conflicting creative process" needs still need to be investigated.

The meaning of distant capabilities

The three research streams presented above show that the major research gap we need to address lies in the absence of micro-foundations on how distant capabilities are combined to generate innovation. They nevertheless help us define what we mean by distant capabilities. In our framework, innovation occurs through the combination of diverse general purpose and application specific capabilities. The distance between the capabilities mobilized can be characterized by the geographic knowledge, social, institutional and organizational proximity they have together.

For the sake of clarity, in the present article, our definition of distant capabilities focuses on two specific factors: Knowledge: to what extent the capabilities combined together rely on heterogeneous knowledge base and Organization: to what extent intra or inter-organizational linkages with familiar or unfamiliar organizations occur. This is consistent with Rosenkopf & Nektar (2001) who have developed a typology of exploration behaviors where organizations span both organizational and technological boundaries when performing distant search. The remaining proximity factors will be integrated within our research framework.

The following graph illustrates our definition of distant capabilities. It can be applied to the combination of two or more capabilities with one of them acting as the reference in the bottom left quadrant.

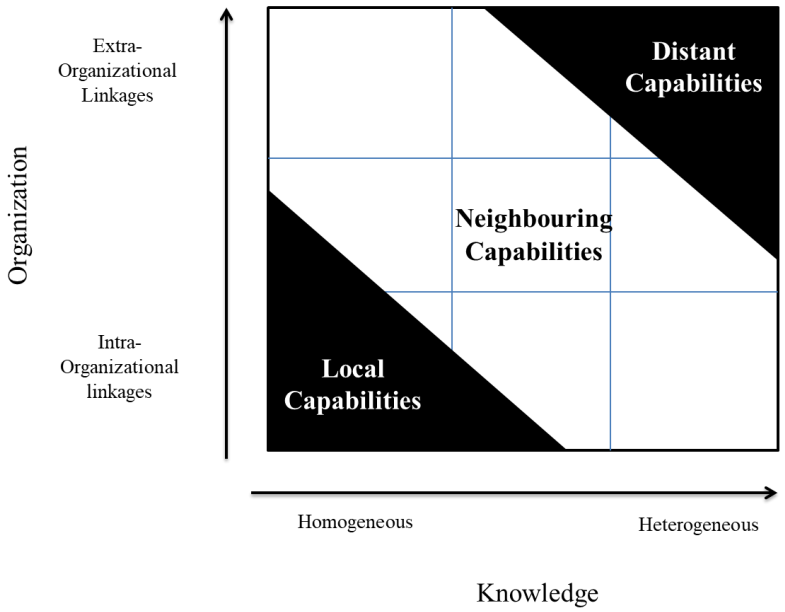

Fig 1: Combining distant capabilities

If an organization intends to deepen an existing capability, it can use intra-organizational linkages. This can be done thanks to a cross functional team that brings different department together or by a collaboration across different units across the business. Rolls-Royce who wanted to build on its experience in data-led services acquired for instance with aircraft engines has launched a Data Labs to bring together expertise from across the business and support further data innovation. If the aircraft engine business of Rolls-Royce was working with this lab we would typically be on the bottom left corner of the matrix

Deepening an existing capability can also rely on extra-organizational linkages. A firm can work with an unfamiliar electronic design house to expand its electronic design capabilities. In such a case we would be in the top left quadrant of the matrix where the knowledge is homogeneous but where inter-organizational linkages with unfamiliar organization are established.

Broadening a portfolio of capabilities can be achieved through intra organizational linkages. Continuing with the example of The Rolls-Royce data lab, A Rolls-Royce Business Unit with no experience with data-led services can leverage the Central Data lab to access new capabilities. From this it can combine its own capabilities with the central Data lab know how in order to develop innovative business models for its own market. Here we are in the Bottom right quadrant of the matrix.

In 2017 Rolls-Royce and Tata Consultancy Services (TCS) decided to expand their long-standing partnership in order to exploit future data innovation opportunities. The focus of this collaboration is to leverage the TCS IoT platform within Rolls-Royce activities. We are here in the central quadrant of the matrix we describe this as combining neighboring capabilities.

Indeed, this initiative focuses a neighboring knowledge field: the IoT platform thanks to extra-organizational linkages an industry neighbor: TCS.

Finally, we can look at the collaborations between Rolls-Royce Marine Business with Google on machine learning. This was presented as a first of its kind agreement in the marine business and the aim was to develop intelligent awareness systems for future autonomous ships. This can be positioned on the top right corner of the quadrant, as an attempt to combine distant capabilities.

We have now defined our approach. We have described the concept of distant capabilities by focusing on two proximity factors: knowledge and organization. Other factors will be addressed in our research framework that can be now established

The distant capability research framework

We can now move to the development of our research framework. According to Taylor and Hefat (2009) "*innovating firms need to go beyond simple access to complementary assets to successfully navigate technological transitions. Companies must create and manage organizational linkages involving the new core technology, new complementary assets, and potentially valuable pre-existing complementary assets. Otherwise, without the organizational ambidexterity required to link the new with the old, the end result may be a technological advance that fails to meet market needs."* These authors outline the importance of linkages to manage technological transitions. If they acknowledge the need for external linkages, they decided to focus on linkages within an organization. In our approach, we will adopt two different levels of analysis. The first one is at organizational level and it will allow us to consider inter-organizational linkages. The second one is at the individual level and it will allow us to look at interpersonal linkages that take place within and across organizations. Furthermore Taylor and Hefat (2009) identify four critical influences: economic, structural, social, and cognitive on managerial linking activities; in our framework, we will initially focus on how cognitive processes influence linking activities, We will consider how the evolution of the assumptions and belief held by the individuals involved in combining distant capabilities impact on the evolution of the inter-organizational and inter-personal linkages.

Initially, some individuals decide to tie together different and sometime distant sources of knowledge and expertise with the aim to create innovation and generate economic value. Individuals are then connected together to frame and solve ill-defined problems. Such problems can be exacerbated by the distance between the capabilities (or eased by their proximity). When experts from a tennis racket manufacturer meet with specialists of artificial intelligence with the aim to create a connected tennis racket that will give feedback to the user, they might not have a common language that will help them to make progress. As problems are framed and solved the beliefs of individuals involved throughout the linkages evolve and through their through their actions and decisions they change the boundaries of the network. New inter-organizational and inter-personal linkages are created while others are eliminated. This leads to another set of problem framing and problem solving activities that impact on the belief of individuals and ultimately on the linkages. Individual involved in this process learn how to manage and sometime how to abolish the distance between the

capabilities. This is achieved through the communication and coordination activities that underpin the problem-solving ones. The following diagram describes our research framework.

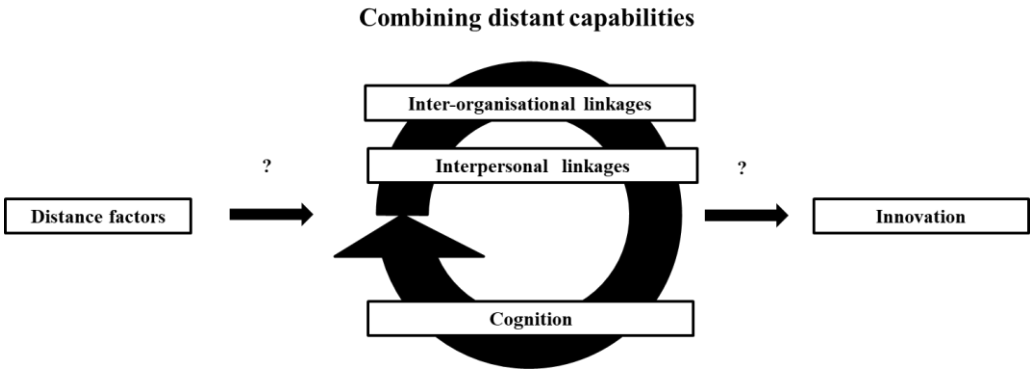

Fig 2 Research framework: Combining Distant Capabilities

The distance factors taken into account within our research framework are described in the table below. This builds on Boschma (2005) and on Balland & al (2014)

Knowledge Proximity	Knowledge proximity means that individuals share the same knowledge base and expertise Knowledge proximity allows individuals to absorb and use new information rapidly. Knowledge distance hinders effective communication and learning. Excessive knowledge proximity can prevent individuals from seeing opportunities while knowledge distance can favor creativity and novelty As distant capabilities are combined knowledge overlaps increase amongst the individuals involved.
Organizational Proximity	Organizational proximity is characterized by pre-existing linkages within and across organizations. This can be described as strong ties such as hierarchies, as loosely coupled networks or weak ties such as buyer-supplier relationships or networks or simply as no ties. While organizational proximity allows controlling intellectual Property rights and to reduce the risks of opportunistic behavior; organizational distance prevents myopia and offers more flexibility to access a diversity of resources. As distant capabilities are combined, organizational distance diminishes at least temporarily. Weak ties emerge between organizations that had no common experience before and some firms might acquire a partner and create stronger ties.
Social proximity	Social proximity is characterized by the the existence of trust due to friendship, kinship and experience.

	While social proximity is expected to favor the exchange of tacit knowledge and the commitment of individuals over time; social Distance can prevent actors from being locked in long term relationships and commitments so they can seize new opportunities more effectively. As distant capabilities are combined, social distance reduces; individuals go through common experiences and build personal relationships.
Geographic Proximity	Geographic proximity is defined by the spatial or physical distance between individuals. Geographic proximity allows to access knowledge externalities. It reduces the costs associated with face to faces interactions and the time required for taking decisions. Geographic Distance can however prevent some of the individuals from being overwhelmed by interactions. A startup with limited resources can benefit from geographic proximity in order to create enduring linkages. It can also be protected by the distance from being involved in an overwhelming number of interactions. As distant capabilities are combined, Geographic distance can be temporarily or permanently reduced as individuals can be temporarily co-located or as some organizations can re-locate activities
Institutional proximity	Institutional proximity consist of common habits, routines, established practices, rules, or laws that regulate relationships and interactions between individuals and groups

We now need to further describe the managerial influence we have selected: managerial cognition. As described above search are constrained by past ones and myopic behaviors are common in exploration (March 1991; Rosenkopf & Nektar; 2001). This outlines some inability to recognize opportunities or difficulties and to act upon them. This lead us to focus on one of the critical managerial influence on linking activities identified by Taylor and Hefat (2009): Managerial Cognition. This choice is in line with Gavetti (2005) who has suggested that we need to rethink the micro-foundation of capabilities development and more specifically that we need to study how cognition affects the early stages of capabilities development. Managerial Cognition relies on some simplification of the world called frames of reference. They help screen and filter the environment. Frames validate perceptions and perception validate the frame of reference (Cornelissen and Werner, 2014). While frames have been presented as rigid knowledge structures that have difficulties to make sense of unexpected events, it has also be shown that they can evolve (Kaplan, 2008) and that they can be reconstructed to overcome rigidities. This dichotomy has been suggested by a diversity of authors including Smith and Tushman (2005) to describe the handling of strategic contradictions and more recently by Garima and Bansal (2017) to describe effective and

ineffective collaboration between Business and NGOs. We have structured the following table to outline what can be described on one hand as cognitive rigidity versus cognitive fluidity.

Cognitive rigidity	**Cognitive fluidity**
Contradiction are rejected by privileging consistency over inconsistency (Smith & Tushman, 2005)	Contradiction is embraced by handling inconsistencies despite forces that push for consistency (Smith & Tushman, 2005)
When two options, conflict one of them has to be true and to prevail (Smith & Tushman, 2005)	Recognizing and accepting contradictory forces (Smith & Tushman, 2005)
Actors use enduring and fixed frames that select specific signals from the environment (Garima and Bansal 2017)	Actors 'align, or blend, cognitive frames, or elements of such frames, to derive new inferences (Garima and Bansal 2017)
Actors apply categorical labels that automatically triggers an interpretation and specific actions (Garima and Bansal 2017)	Actors start with a frame, but update the frame through experimentation and interaction with others (Garima and Bansal 2017)

We assume that cognitive fluidity will to a certain extent help build relevant inter-organizational and inter-personal linkages while cognitive rigidity will prevent from building them. Cognitive fluidity is expected to help reframe problems so distant capabilities can be gradually combined in order to deliver innovation.

Finally combining distant capabilities can be described as a composite concept that blends different perspectives including networks, cognition, proximity factors, capabilities, innovation, and entrepreneurship. It favors the study of phenomenon at multiple levels of analysis: the invention or product-service level, inter-organizational networks, interpersonal networks and cognitive frames. This has epistemological implications for our research framework. We would suggest that the core model presented above could be complemented by a diversity of theoretical viewpoints that should be considered in empirical work. Without trying to be exhaustive, we suggest underneath how different theoretical lenses offer insights that could help understand the evolution of inter-organizational and interpersonal linkages and contribute to combining distant capabilities. They are summarized in the following table

Theoretical view point	Complementary perspectives for our research framework
Clock-speed and timing (Fine, 2009)	Difference in terms of clock-speed across organizations impacts on their ability to synchronize their decision and execution cycles and therefore on how linkages functions effectively. This could be framed as a proximity factor. Very different clock-speed could be associated with distance and similar clock-speed with proximity
Customer Attractiveness (Huttinger, Schiele & Veldman 2012)	PSM literature has studies what makes a customer attractive and why and how they get preferential treatment. This stream of literature could help us understand why and how some

	organizations could decide to develop and strengthen some inter-organizational linkages at the expense of others
Architecture, modularity and Orchestration models (Brusoni & Prencipe 2013) (Nambisan & Sawhney 2011)	The architecture of an emerging innovation and the structure of the innovation network that delivers it influence each other (Chesbrough and Teece, 1996; Brusoni & Prencipe 2013). When standard product interfaces exist, the different organizations involved in the network tend to work on their components independently of each other, innovation can be coordinated across different organisations through information and knowledge sharing activities. However, when an innovation requires to redefine the architecture and the interfaces for an emerging innovation, this requires bringing diverse capabilities and source of knowledge together to explore; test and validate different options in terms of architectures Also Architecture and modularity also call for different orchestration models for innovation networks (Nambisan & Sawhney 2011) These affect Inter-organisational and inter-personal networks.

Conclusion

In the present paper, we have defined what we mean by combining distant capabilities. This was done by building on three research streams: the resource based view of the firm, the proximity school and the study of local vs distant innovation search process. We have shown that innovation result from the combination of an assortment of capabilities characterized by certain degrees of geographic, knowledge, social, institutional and organizational distance amongst them. More specifically, we have decided to focus on knowledge and organizational distance as the main characteristics of our research framework on how to combine distant capabilities. To do this, we have suggested a model where cognitive fluidity and cognitive rigidity impact on how inter-organizational and inter-personal linkages evolve over time. As linkages and managerial cognition co-evolve, distance is lessened and capabilities are progressively combined to deliver innovation. This framework offers some practical foundations to study how innovation occurs across organizations. Distance, managerial cognition, linkages together with their interrelations can be described and studied along a timeline. This offers practical advantages to understand how capabilities are combined, integrated and transformed into innovation and economic value over time. Indeed, aggregating exploration and exploitation within a single concept is essential to measure their combined impact on business outcomes, however to make sense of how innovation takes place, studying over time how managerial cognition, distances, interpersonal and inter-organizational linkages will offer us promising developments for our empirical and theoretical understanding of the micro-foundations of innovation. This can also be the base for a more normative theory that can guide practice. We should aim at understanding how firms can map the distant capabilities that could play a key role in their competitive and collaborative arena

and we should provide guidance on how to effectively combine distant capabilities. Further research should build on longitudinal case study that investgate how some distant capabilities have been combined to deliver innovation. We will need to map the evolution of linkages over time and to document the rigidity and fluidity of the cognitive process over time. This will call to record quantitative and qualitative data to understand the interplay between cognition, network and innovation with the aim to progress our academic understanding of how the economic and technological future is unfolding in front of us.

Public procurement and innovation: A conceptual framework for analysing project-based procurement strategies for innovation

Abstract: This paper discusses a conceptual framework for analysing the use of public procurement strategies to stimulate innovation in projects. This framework is developed as part of an explorative study, which uses a multiple case study approach to gain a deeper understanding on *how* and *for what reasons* innovation is stimulated in projects. The framework allows for a systematic analysis of the decisions in project and procurement strategies, and how these decisions interact and influence the tender offers with respect to innovation. The framework can also be used by researchers and practitioners for evaluating the use of procurement of innovation strategies in projects.

Keywords: public procurement; innovation; project-based procurement;

Submission category: Working paper

1. Introduction

The interest in public procurement as an innovation policy instrument has increased considerably over the last fifteen years (Lember et al., 2011; OECD, 2011). A common policy rationale for stimulating innovation through public procurement is that innovation is widely accepted to lead to technological development, competitiveness and economic growth of nations, regions and private organisations. Moreover, the stimulation of innovation through public procurement is considered to play an important role in addressing the societal challenges we will face in the years to come.

Although the concept of stimulating innovation through public procurement, and its effectiveness with respect to other innovation policy instruments has perceived much attention in recent years, there is a lack of knowledge on how and for what reasons innovation is stimulated through public procurement by public organisations on the level of individual projects. Furthermore, there is a specific lack of knowledge on how decisions in project and procurement strategies interact and influence tender offers with respect to innovation. Many individual factors influencing innovation through public procurement can be found in literature. However, how goals in the project and decisions in the project and procurement strategy interact and influence tender offers with respect to innovation remains to a large extent a black box.

This paper presents a conceptual framework which can be used as a tool to: (1) investigate *how* and *for what reasons* public procurement strategies are used to stimulate innovation in projects, and (2) to analyse and explain how decisions in project and procurement strategies interact and influence tender offers with respect to innovation. In addition, the framework can be used by practitioners as a tool for evaluating the use of procurement strategies to stimulate innovation in projects. The paper first discusses the research methods used for developing the framework. After this, the theoretical background of the framework is discussed, followed by the conceptual framework itself. In the last part of the paper, the framework is applied on an example case to show its relevance and practical use as a tool for analysing projects in which innovation is consciously stimulated through public procurement. The paper ends with conclusions and a short discussion.

2. Research methods

An inductive approach is used for the development of the conceptual framework, which is based on a literature review and preliminary research. The literature review focused on public procurement, the use of procurement as an innovation policy instrument, and methods for stimulating innovation through public procurement. Preliminary research focussed on the use of public procurement to stimulate innovation in projects and was performed in close collaboration with two large municipalities. It included a document analysis of various procurement projects and procurement policy documents with respect to stimulating innovation, several interviews with four project managers of project in which innovation is stimulated, two policy makers, five procurement experts, and numerous informal discussions with civil servants working at various places within the municipalities.

The conceptual framework was tested and further developed in an explorative study focusing on *how* and *for what reasons* public procurement strategies are used to trigger, adopt and/or organize innovation in projects related to civil engineering and construction. The construction industry was selected as this sector presents a significant share of the procurement budgets, has a large influence on the economy, employment and the wellbeing of citizens, and the critical role it plays in addressing societal challenges such as the effects of climate change. To address these research questions an inductive multiple case study approach was selected (Eisenhardt, 1989; Eisenhardt and Graebner, 2007). One of the cases in the multiple case study is used in this paper to illustrate how the conceptual framework can be used as a tool in the analysis of the case.

3. Theoretical background

3.1. Project-based procurement

Procurement in projects is highly influenced by project logic, in which activities are performed and resources allocated to obtain a specific set of aims and objectives, within a clearly defined scope, timeframe and budget (Munns and Bjeirmi, 1996). To initiate a project two essential steps have to be taken. The first is the development of the *aims* of, *objectives* in, and scope of the project. The aims of the project are the higher goals to which the project should contribute, whereas the objectives in the project are specific goals within the project. The second step is the negotiation and allocation of budgets and resources to the project. Both steps are largely influenced by stakeholders who have different stakes and interests in the project, vary in their power to influence decision making in the project, and may or may not have budgets and resources to allocate to the project (Turner and Müller, 2003). For these reasons, the initiation of a project can be regarded as a political process in which decisions are taken with far-reaching implications for the rest of project, including the project and procurement strategy. Moreover, it acknowledges the importance of the interaction between projects and the *environment* in which they take place, including the historical and organizational context (Engwall, 2003).

Differences in stakes and interests of stakeholders also influence their perspective on what they regard as a successful project. As Shenhar et al. (2001) put it: “Project success means different things to different people”. Therefore, it is impossible to determine the success of a project without stating the criteria where it should be assessed against first. Traditionally, project success is often assessed in terms of its ability to meet time, budget and quality requirements

(Atkinson, 1999). Alternatively, the success of a project can be assessed against its ability to accomplish the pre-defined aims and objectives of the project (Artto et al., 2008). Assessing project success this way allows for a systematic analysis of decisions in the project and procurement strategy, and their influence on innovation in tender offers, with respect to the aims of and objectives in the project.

This is relevant with respect to the rationale for stimulating innovation through public procurement. From an innovation policy perspective, innovation is stimulated to foster the competitiveness and economic growth of nations, regions and firms (Edler and Georghiou, 2007; Lember et al., 2014). Yet, from the perspective of public organisations, innovation is mostly stimulated to: (a) respond to specific human needs and societal challenges (Edquist and Zabala-Iturriagagoitia, 2012), (b) serve the needs of the public organisation (Dalpé, 1994; Edler and Yeow, 2016), or (c) increase the quality of the products and services procured (OECD, 2011; Yeow and Edler, 2012). It is also possible to procure innovative products and services for other public organisations or private end users, which is called catalytic procurement (Hommen et al., 2005). The stimulation of innovation through public procurement are often part of a broader set of aims of and objectives in a project. However, in some cases the procurement or development of one or more innovations is a project in its own right (Yeow and Edler, 2012).

In conclusion, the stimulation of innovation through public procurement can play different roles in a project, which is linked to the rationale for stimulating innovation. From stimulating innovation in the private sector as a horizontal/secondary policy objective (Arrowsmith, 2010; European Commission, 2010), to the procurement of an innovative product and/or service as the main objective of the project (Yeow and Edler, 2012). As a result, the importance of stimulating innovation through public procurement for obtaining the aims of and objectives in the project can vary substantially.

3.2. Stimulating innovation through public procurement

The use of public procurement strategies to stimulate innovation in the private sector has been discussed under many terms, which are based on different concepts and rationales for stimulating innovation. Some examples are: public procurement for innovation or innovation procurement, previously known as public technology procurement (Edquist and Hommen, 2000; Edquist and Zabala-Iturriagagoitia, 2012); public procurement of innovation (Rolfstam, 2013); public procurement of innovative solutions (European Commission, 2014); innovation-friendly procurement (Uyarra and Flanagan, 2010), and pre-commercial procurement (Edquist and Zabala-Iturriagagoitia, 2015; European Commission, 2008). Despite some profound differences between these concepts, they all should be differentiated from innovative procurement, which refers to innovation in procurement processes, such as e-procurement (Moon, 2005). Although the use of novel procurement processes in order to stimulate innovation in the private sector is not uncommon, they should not be mixed up.

The OECD (2011) presents three different types of procurement strategies for stimulating innovation. The first type of procurement strategy, innovation-friendly procurement, focusses on making regular procurement practices more conducive to innovation (Uyarra and Flanagan, 2010). The second type is strategic procurement, in which public organisations demand new

technologies, products and services for addressing specific organisational needs and societal challenges (Edler and Yeow, 2016; Edquist and Zabala-Iturriagagoitia, 2012). The third type is the procurement of R&D services, in which public organisations use highly targeted subsidies to stimulate the development of new solutions for organisational needs or societal challenges (Edquist and Zabala-Iturriagagoitia, 2015; Georghiou et al., 2014). Usually with the aim to have several new solutions available for subsequent procured to fulfil organisational need or address societal challenges (European Commission, 2008).

Differentiating these types of procurement strategies is relevant as each procurement strategy type uses different methods to stimulate innovation and targets innovations in different stages of development (Hommen and Rolfstam, 2009). From adopting innovations which are directly applicable and procuring innovations which require more R&D before implementation, to triggering the development of new innovations. Further, the procurement strategy types vary in terms of the expected time, expertise and resources needed from the public and private organizations to be performed.

3.3. Methods for stimulating innovation through public procurement

Regular public procurement can affect innovation by influencing the *demand* for certain products and services or by specifying *requirements* and *standards* for procured products and services (Caerteling et al., 2008; Dalpé et al., 1992). In addition, there are several methods to make regular public procurement more conducive to innovation. Most of the methods discussed in literature are either related to (a) providing *incentives* to candidates to innovate and/or offer additional quality and innovative solutions in their tender offer, or (b) to increase the *solution space* within the tender assignment to include alternative and innovative solutions.

Several papers discuss demand for new products and processes as an important factor for stimulating innovation in the private sector (Edler and Georghiou, 2007; Geroski, 1990; Mowery and Rosenberg, 1979). Increasing the demand provides *incentives* for potential suppliers to innovate as it decreases the uncertainty of future sales (van Meerveld et al., 2015). Other well-known methods for stimulating innovation by providing incentives to innovate are: (a) performance-based tendering instead of awarding based on lowest price (Dreschler, 2009), (b) placing an order for the fulfilment of needs which cannot be met through conventional solutions (Edquist and Zabala-Iturriagagoitia, 2012), (c) including high quality standards in tender specifications (Dalpé, 1994), and (d) favourable arrangements on intellectual property rights (Butler, 2014).

On the other hand, there are several methods which work by increasing the *solution space* of offers which are accepted by the procurement organisation. The most common method is the use of functional specifications instead of technical specifications, to specify the needs and requirements of the tender assignment, (Dalpé, 1994; Uyarra et al., 2014). Another method is to explicitly accept alternative solutions when using technical specifications (Butler, 2014). Somewhat less obvious from the literature is the impact of external requirements on the solution space. Some examples are: requirements from policy documents, stakeholders and legislation, or requirements for obtaining permits and approval of the fire department.

Methods for increasing the solution space, as well as methods for providing potential candidates incentives to innovate primarily focus on the tender phase of the procurement

process. Methods for stimulating innovation through *market approach*, on the other hand, are more inclined to the pre-procurement phase and when applicable, the pre-selection of potential suppliers. A first method is to perform a market sounding and consultation. They can be used to communicate the needs and requirements of the public organisations to potential candidates, to obtain feedback on the feasibility of the assignment and interest from potential candidates, and foster collaboration and the development of consortia between candidates (Lenferink et al., 2012; van Meerveld et al., 2015). Innovation can also be indirectly influenced through the requirements and selection criteria used for the pre-selection of eligible candidates. These requirements and selection criteria determine to a large extend what type of potential candidates, with different innovation capabilities, will be invited to put in an offer for tender. A third method associated with the market approach is the use of procurement procedures which allow for more communication between the public organisation and candidates during the procurement process. Two examples of these are the competitive dialogue and the competitive procedure with negotiation (Telles and Butler, 2014).

Lastly, several studies state the importance of articulating the needs of the procurement organisation in relation to simulating innovation (Dalpé, 1994; Edquist and Zabala-Iturriagagoitia, 2012). The underlying idea is that the *focus* on innovation, and to what it should contribute, can steer the direction of innovation efforts and the inclusion of innovations in tender offers. The focus on innovation, and to what it should contribute, is highly related to the rationale for stimulating innovation through public procurement.

4. Conceptual framework

The conceptual framework, presented in figure 1, describes the interaction between the contracting authority and the candidates and tenderers leading to the development and submission of tender offers by tenderers. More specifically, the framework can be used to: (a) analyse and evaluate the use of public procurement strategies for stimulating innovation in projects with respect to the scope and aims of, and objectives in the project, and (b) help explain how decisions in the project and procurement strategy interact and influence the offers submitted by the tenderers with respect to innovation.

The scope and aims of, and objectives in the project are regarded as input for the development of the project and procurement strategy of the contracting authority. The aims of the project indicate the goals to which the project should contribute, whereas the objectives in the project indicate the goals within the project. Note that in some cases, decisions in the project and procurement strategy can also influence the scope and aims of, and objectives in the project.

The project and procurement strategy is conceptualised as a list of decisions which are: (a) of importance with respect to stimulating innovation, (b) of importance to obtain the aims of and objectives in the project, or (c) of importance to both. Each of these decisions are categorised in one or more of the four identified categories of ways through which innovation can be influenced by the decisions in the project and procurement strategy. These categories were identified based on a literature review and preliminary empirical research. Decisions in these categories are related to:

- provided *incentives*/disincentives for tenderers to provide innovative solutions, including financial incentives, distribution of risks related to innovation, expected future demand and arrangements on intellectual property rights;
- provided *solution space* for eligible tender offers, including the specification of the assignment and requirements, externally imposed requirements, and optionally the acceptance of alternative solutions;
- selected breath and degree of *focus on innovation* within the project and to what it should contribute; and
- selected *market approach*, including market analysis and communication of the tender assignment to potential candidates, selection of eligible candidates, and the interaction with candidates and tenderers before and during the tender procedure.

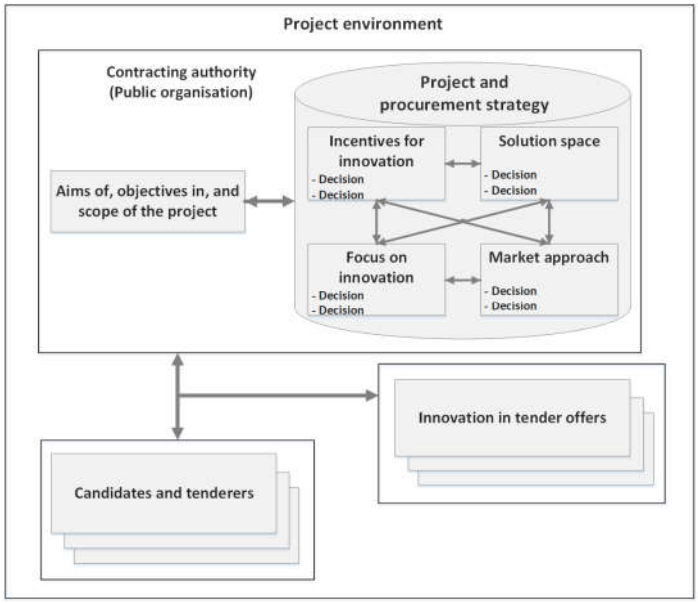

Fig. 1. Conceptual framework for analysing public procurement strategies for stimulating innovation in projects.

It is possible that one decision influences innovation through different ways and therefore belongs to multiple categories. An example is the decision to limit the breath of the *focus on innovation* in the award criteria to a specific part of the project (Decision J in the case below). This provides *incentives* for tenderers to include innovations with respect to that part of the project, whereas is provides disincentives to include innovations with respect to other parts of the project. The degree of focus on innovation in the award criteria in the case is expressed through the fictional reduction in tender price, which tenderers are likely to be able to obtain for including their innovations in the tender offer, with respect to the other award criteria.

The project environment is added to the conceptual framework to acknowledge that decisions in projects are not made in isolation, but are influenced by the environment in which the project takes place. This includes the interests and power position of relevant stakeholders with respect to the project. As a result, the project environment should be included in the analysis of projects with respect to the use of procurement strategies to stimulate innovation in tender offers, and their role in obtaining the aims of, and objectives in the project.

5. Applying the conceptual framework to the case "The Boekelosebrug"

To show the relevance and practical use of the conceptual framework in the analysis of projects in which procurement strategies are used to stimulate innovation, the framework is applied on the case "The Boekelosebrug" as an example. Due to page limitations the analysis is very concise, a bit clinical and includes: a short case description with the scope, aims of and objectives in the project; key decisions in the project and procurement strategy, and how they influenced tender offers with respect to innovation. The purpose of this analysis is to show in how the conceptual framework can be used as a tool for analysis, not to provide an exhaustive analysis of the project.

5.1. Short case description

The tender assignment of the Boekelosebrug consisted of the design and realisation of new bridge across the channel on the south-side of city of Hengelo, to replace the old bridge. Further, it included the realisation of a part of the avenue providing access to the city centre from the south side of Hengelo. The bridge is part of this avenue, and the project the Boekelosebrug as a whole, is part of a large area redevelopment project called "Hart van Zuid", on the south side of the inner-city.

The *aim* of the project was "to improve the accessibility, traffic flow and traffic safety of Hengelo within time and budget restrictions of the project". In addition, the project aimed to: (a) realise added value through the application of product- and process innovations, (b) realising of an architectural appealing bridge of high aesthetical quality fitting within the pre-established spatial guidelines for the design of the bridge ("ruimtelijke kaders" in Dutch), and (c) minimalizing inconvenience and nuisance to citizens due to the realisation of the project. The *objectives* in the project were: (a) to replace the old bridge by a new bridge, which allows for more and heavier traffic and is designed and realised within the predefined requirements for the bridge, and (b) the realisation of the southern part of the avenue "Laan van Zuid" according to design specifications.

5.2. Key decisions in the project and procurement strategy

Due to the focus on architectural and aesthetical quality of the bridge was decided to combine the design and realisation of the bridge in one assignment (Decision A). Within the assignment there was a lot of design freedom with respect to the bridge, with possibilities to design a plate-, arch or cable-stayed bridge (D B). However, with respect to the realisation of the avenue the solution space was limited due to elaborate design specifications (D C). The European restricted tender procedure was used for this assignment (D D). In the selection stage, the number of eligible candidates for tender was reduced based on their ability to perform the five pre-defined core competences integrally, the extent to which innovation is a part of their corporate strategy, and their relevant achievements with the development and application of innovations in projects comparable to this assignment (D E). In the tender stage, tenderers could obtain a max. fictive reduction on their tender price of € 4,25 M for providing additional quality on top of the base requirements. The maximum allowed tender price was € 8,2 M (D F). The criteria for assessing the additional offered quality were: (a) architectonical and aesthetical quality of the design of the bridge max. € 3 M (D G), (b) extent of and scale of innovation in the innovations offered max. € 1 M (D H), and (c) reduction in time needed for the realisation of the work max. € 0,25 M (D I). Other key decisions were: defining definitions

of product and process innovation in relation to the project, the three categories on the extent of innovation, and the three categories on the scale of innovation (D J); specific request to include three product and/or process innovations in the offer for the design and realisation of the bridge (D K); the use of a traditional market approach with written communication (D L) and the decision to not perform a market consultation as part of the market analysis (D M).

Table 1
Key decisions in the project and procurement strategy.

Incentives	Solution space	Focus	Market approach
Decision E	Decision A	Decision E	Decision E
Decision F	Decision B	Decision H	Decision L
Decision G	Decision C	Decision I	Decision M
Decision H	Decision K	Decision J	
Decision I		Decision K	
Decision J			

5.3. Influence of decisions in the project and procurement strategy on tender offers

The adoption of innovative solutions in the project was one of the aims of the project, partly motivated by the requirement of the Province of Overijssel to stimulate innovation in the project for getting funding from them for this project. Within the project was decided that the innovative solutions should provide an added value to the bridge design/performance and/or the realisation process of the project, without prescribing what type added value this should be to provide a broad solution space with respect to eligible innovations. This combined with: (a) a selection of candidates partly based on innovation criteria, (b) sufficient financial incentives to provide innovative solutions as part of the tender offer, and (c) sufficient solution space to include product and process innovations, resulted in a broad range of bridge designs, product and process innovations in the tender offers. Hence, it is the combination of decisions which resulted in the inclusion of innovations in the tender offers.

The large range of ways in which innovations were allowed to provide additional value was used by tenderers to offer a large variation of product and process innovations. Each with their own benefits. Though some more relevant than others with respect to the design/performance of the bridge and/or realisation process of the project. The winning tenderer provided (1) a process innovation using augmented reality for the positioning of the bridge, (2) a product innovation to make the bridge energy neutral by means of solar panels in the road, and (3) the use of a low baked powder coating in an outside environment (product innovation).

This in a nutshell, provides some insight in *how* public procurement strategies were used to adopt innovations in the project, to what these innovations should contribute, and *for what reasons* innovation was stimulated in the project. Nevertheless, one should note that this is a highly stylised and simplified version of the analysis due to page limitations. As such, this analysis cannot explain the full complexity of, and the considerations behind, the decisions made in the project and procurement strategy and how they influence tender offers with respect to innovation.

6. Conclusions and discussion

This paper presents a conceptual framework for analysing the use of public procurement strategies to stimulate innovation in projects. More specifically, the framework can be used as a tool to: (a) analyse and evaluate the use of public procurement strategies for stimulating innovation in projects with respect to the aims of, objectives in and scope of the project, and (b) help explain how decisions in the project and procurement strategy interact and influence the offers submitted by the tenderers with respect to innovation. As such, the framework provides a structure for the analysis and comparison of different projects. This in turn can be used to facilitate learning and knowledge exchange, on the use of public procurement strategies for stimulating innovation, across projects and organizations.

Based on a literature review and preliminary empirical research four categories of ways through which innovation can be influenced by decisions in the project and procurement strategy were identified. Decisions in these categories are related to:

- provided *incentives*/disincentives for tenderers to provide innovative solutions;
- provided *solution space* for eligible tender offers;
- selected breath and degree of *focus on innovation* within the project and to what it should contribute; and
- selected *market approach*, including market analysis and communication of the tender assignment to potential candidates, selection of eligible candidates, and the interaction with candidates and tenderers before and during the tender procedure.

The framework is contributes to the analysis of projects by unravelling the project and procurement strategy in a list of decisions, which are taken to obtain the aims of and objectives in the project and/or to stimulate innovation. Subsequently, categorising these decisions based on the way they are expected to influence innovation helps to analyse and explain how the project and procurement strategy as a whole influences innovation in the tender offers.

Despite the logical mechanisms behind the ways through which innovation is stimulated/hindered in each of the identified categories, it could be that a fifth category, or different way of categorising decisions in the project and procurement strategy, will provide different insights and/or bias. Further, it is important to realise that: (a) aims of, objectives in and scope of the project, (b) decisions in the project and procurement strategy, and (c) the project context, may change over time. If this occurs it is important to investigate when and why they have changed as part of the analysis.

Sustainability assessment in the fresh fruit and vegetables supply chain

Abstract

Despite the growing attention to sustainability, in sensitive industries as food, limited attention has been devoted to sustainability assessment at the different stages of the supply chain. The aims of this study are to investigate how different stages in the food supply chain address sustainability assessment, and to identify the elements that could motivate companies to assess sustainability. Twelve cases operating in four stages of the fresh fruit and vegetables supply chain in Italy were studied. The analysis shows that the sustainability assessment is highly heterogeneous for the practices implemented, and that such assessment is not dependent on the supply chain stage but on the type of practice. The factors that foster sustainability assessment are company size, complexity of the measurements and the level of vertical integration.

Keywords: Sustainable supply chain, sustainability assessment, food industry

Submission category: Competitive Paper 17

Introduction

Sustainable supply chain management responds to increasing pressures from stakeholders, policymakers, and consumers for companies to devote efforts to environmental and social sustainability (Seuring and Müller, 2008; Gualandris et al., 2015; FAO, 2014; European Commission, 2014). Accordingly, literature has grown as well with studies about sustainable practices, drivers and performance indicators, in different industries and with different supply chain scopes.

Specifically, this study focuses on the performance measurement in the supply chain that concerns the application of groups of measures in different stages of the chain (Beamon, 1999). Furthermore, this study addresses sustainability performance measurement involving the application of different measures in environmental, social and economic areas. Authors claim that the use of indicators and-or measures for assessing sustainability in different stages in the chain, increases the complexity to develop an effective assessment system (Gualandris et al. 2015; Trienekens et al. 2012). Along with that, given the diversity of sustainability indicators in literature, the assessment risks to be ineffective when companies do not know how practices should be evaluated and for what reasons (Bourne et al. 2002). Therefore, the need of understanding how companies in the supply chain assess sustainability arises together with the aim of identifying the company's features that foster sustainability assessment.

The food industry is characterized by unique sustainability challenges. Scarce natural resources that need to be preserved, attention to consumer's health and safety, communities' economic development around the world, are only some of them (Pullman et al. 2009; Maloni and Brown, 2006; Beske et al. 2014). Unsurprisingly, this industry that deals with increasing stakeholder's demands for better sustainability performance in the triple bottom line (i.e, environmental, social and economic) has started developing assessment policies, standards and reporting (Bloemhof et. al, 2015; Trienekens et al., 2012; Bourlakis et al. 2014) in the attempt of fulfilling such expectations.

In Italy, the food industry is the second most important economic sector in terms of production volumes, import and export (Foodweb, 2015), representing one of the main income sources for the country. Many different products are cultivated and exported around the world. In the EU, Italy is the second main fruit and vegetables processor and third main exporter, thanks to the various microclimates that characterize the food variety in the country (Eurostat, 2016). From the variety of Italian products available in the market, this study is concentrated in the fresh fruit and vegetables (FF&V) supply chain, analyzing four stages: growers,

processors, wholesalers and retailers. Twelve companies with operations in one or more of the four stages were studied with two objectives. First, to understand how different stages in the food supply chain address sustainability assessment. Second, to identify the elements that motivate sustainability assessment in this food supply chain. The study is grounded on the stakeholder theory as it helps to analyze and interpret the findings based on the argument that companies implement sustainability to gain competitive advantage and to respond to stakeholder pressures (Sarkis et al. 2011). Besides, given the pressures exerted by stakeholders are important for companies, it becomes crucial to measure the firm´s ability to respond effectively (Freeman et al. 2010). Findings in the study characterize the variety of sustainability practices implemented in different stages of the FF&V supply chain, as well as the diverse assessment methods used to evaluate or monitor such practices.

In the following, the paper presents a comprehensive literature review about sustainability in the food supply chain management and about assessment food supply chain; next, the research questions and methodology are described; and finally, the data analysis, findings and discussion are explained.

Conceptual Background

Sustainability in the food supply chain

The food industry needs to deal with increasingly demanding expectations of product quality and availability for the growing population, and also with an accelerating environmental and social impact assessment policies and standards to respect (Bloemhof et. al, 2015; Fritz and Matopoulos, 2008; Banterle et al. 2013). Consumers are becoming more concerned with the products they consume, including their origin, the inputs used during production, the labor standards implemented and the environmental impact of production (Trienekens et al., 2012; Maloni and Brown, 2006; Pullman et al. 2009). Hence, as Schmitt et al. (2017) mentioned, the sustainability of food production is implicitly multidimensional, involving environmental care, social wellbeing, and economic performance.

Accordingly, the significance of sustainability in the food industry is revealed by the vast number of practices, projects and/or initiatives deployed, and the increasing contributions in literature regarding the study of environmental and social sustainability practices. For instance, Maloni and Brown (2006), Banterle et al. (2013), Beske et al. (2014), Pullman et al. (2009), Trienekens et al. (2012) have identified different sets of sustainability practices to be applied in the food supply chain, and together with guidelines provided by international organizations (UN Global Compact, 2012; FAO, 2014; European Commission, 2014; IFOAM, 2005; ISEAL, 2014) can be summarized in the following seven categories:

- *Emissions reduction and resource preservation*: this category refers to all the practices involving actions and techniques in food production, processing, packaging and transportation that aim to reduce emissions and the use of pollutant chemical substances, e.g. responsible farming methods (reducing fertilizer and pesticides), elimination of contaminant and pollutant agents, reducing CO2 emissions and GHGs, reduce pollution.
- *Resource efficiency*: this category includes the practices that improve sustainability by increasing resources and processes' efficiency. For instance, reducing water consumption, efficient water use, waste water re-use and recovery. Other practices include reducing energy use, energy conservation, reducing the use of other input materials, reducing fuel consumption, and optimization of transportation and logistics processes.
- *Waste reduction and packaging*: this category includes the practices and initiatives to reduce waste that could be food or packaging material. For example: to reduce waste throughout the production, packing, transportation and storing processes, to decrease

and/or eliminate hazardous materials, to compost organic waste, to produce renewable energy or animal feed with food waste, food and material recycling. In particular, regarding packaging: reuse and recycling, reducing packaging, using reusable/ recyclable packaging, sustainable packaging design (e.g., an appropriate packaging can allow longer food preservation and also to reduce food waste).

- *Health and Safety*: refers to the practices that help ensuring and increasing consumer's health and safety, i.e., product quality and control, reducing contamination risk (food safety and security), traceability, promotion of healthier products and diets, communication and education to consumers.
- *Labor and Human Rights*: are all the practices to improve the working conditions and enhance workers' wellbeing, for example: regular employment, training, education, respect of worker rights, safe working environment, fair compensation. These practices can be either regulated or voluntarily applied by the companies in the supply chain.
- *Community*: this category refers to the practices aimed at supporting local communities, philanthropic initiatives, contributions to improve quality of life in the community, educational projects, health campaigns, promote gender equality and diversity, respect local biodiversity.
- *Ethical trade:* This dimension is even more resonated for food industry given the relationship of food and social and economic development in many geographies. Several certifications schemes promote ethical practices and transparency between buyers and suppliers, to improve the quality of life thanks to a premium price for sustainable-grown products, respect and fairness.

However, the identification of practices implemented in different supply chain stages has not been yet individualized per stage neither the performance assessment understood per stage. As Gualandris et al. (2015), mentioned, the range of issues or dimensions that a company considers in its sustainability efforts will determine the scope of the sustainability evaluation. Hence, it is important to identify the sustainability practices implemented per supply chain stage prior determining an assessment system.

Sustainability assessment in the supply chain

The increasing stakeholders' demands for better sustainability performance have triggered the interest on sustainability performance measurement. However, measuring sustainability is highly complex given that it involves social and environmental issues that cannot easily be translated into economic indicators.

Some authors have proposed frameworks to deal with sustainability measurement in the supply chain for different industries and for food in particular. Mostly they have concentrated on determining the areas to be evaluated and defining the measures or indicators, e.g., Aramyan et al. (2007), Fritz and Motopulos (2008), Varsei et al., (2014), Yakovleva (2007), Bloemhof et al. (2015), Ilbery and Maye (2005), Arena and Azzone (2012). However, the vast number of indicators in literature risks to make the assessment ineffective, especially when companies do not know how and why practices should be evaluated (Bourne et al. 2002). In this line, Genovese et al. (2017) pointed out that the main challenge for companies is to identify which indicators to apply for the environmental assessment without overloading users with too many measures and avoiding information redundancies, thus evidencing the need for simpler assessment with core indicators.

In addition, regarding sustainability assessment in the supply chain, Gualandris et al. (2015) define sustainable evaluation and verification in the extended supply chain, as all the activities related to measures' identification, data collection and processing, data verification and disclosure. The authors discuss how focal companies in a supply chain could deploy a

sustainability evaluation strategy, considering different stakeholders' requirements, firm capabilities and the degree of supply chain integration. Consequently, the sustainability assessment system (methods/ techniques applied for measuring, monitoring and controlling sustainability) will vary between firms in the supply chain according to the scope or range of issues to be measured and how are they measured, if they are.

In order to better understand how companies in the supply chain are assessing their sustainability efforts, we identified the main sustainability assessment methods mentioned in literature and summarized in the following groups:

- *Absent*: when there is no sustainability assessment even if one or more sustainability practices are implemented.
- *Non- Structured*: refers to the case when sustainability practices are assessed in some way, but the assessment is limited to an economic or operative perspective. For example, as in the dimensions proposed by Aramyan et al. (2007): efficiency, flexibility, responsiveness; or as Varsei et al. (2014) proposed for economic performance: cost and service level; or productivity as proposed by Fritz and Matopoulos (2008). In these cases, data collected for evaluations is not used to assess sustainability per se.
- *Structured*: when there is a structured performance measurement system that is formalized and integrated with other systems in the company. For instance, systems that are integrated with the accounting, planning and/or manufacturing areas; and are used for control, evaluation, coordination and benchmarking of activities (De Toni and Tonchia, 2001). In the case of sustainability performance measurement systems, some schemes are proposed in literature and industry such as the GRI (Global Reporting Initiative) that provides a set of indicators in the sustainability triple bottom line; the LCA (life cycle assessment) that provides a method to determine a product environmental impact; and other in-house developed reporting systems, codes of conduct, own sustainability reports, fall into this category.
- *Certification*: is the most formal performance measurement system. Certifications are structured, provide standardized guidelines that are shared with all the actors adopting them, and are assessed by specialized third-parties (i.e. certification bodies). Sustainability certification schemes are usually complex and demanding in terms of time and resources investment requirements, because they imply interactions with external actors or organizations (Gualandris et al. 2015), but they are internationally recognized and help companies to ensure compliance, to gain competitive advantage, to optimize processes and reduce risks (Trienekens et al. 2012, Gualandris et al. 2015). Specifically, for the food supply chain, some of the most renowned sustainability certifications are: the BRC (British Retail Consortium), IFS Food (International Featured Standards), FTI (Fair Trade international), RFA (Rain Forest Alliance), IFOAM (organic food consortium), UTZ. (Trienekens et al., 2012; Gualandris et al. 2015).

The four abovementioned groups refer to the different levels of assessment that a company could apply for all or some practices implemented. All of them, however, focus mainly on single companies, sometimes including the relationships with supply chain partners, but to our knowledge, none of these frameworks explains the way different supply chain stages assess different sustainability practices. This issue becomes relevant as it is necessary to consider that each stage has its own objectives, capabilities and strategies, and may face different pressures or challenges for performance measurement (Genovese et al. 2017). Furthermore, as Gualandris et al. (2015) and Trienekens et al. (2012) posit, sustainability assessment and transparency varies between firms and between supply chains, according to intrinsic and extrinsic food product attributes, firm capabilities, stakeholder's importance, and supply chain integration.

Hence, in this study we address the need to identify how sustainability practices are assessed in different supply chain stages and the company's features that foster sustainability evaluation.

Research questions and context of study

Food industry in Europe is one of the main economic sectors in terms of number of companies, revenues, and employment. In Italy, this industry represents132 billion € turnover, 58,000 companies and employs more than 1,2 million people (Foodweb, 2015). In the EU, Italy is the second main fruit and vegetables processor and third main exporter, thanks to the various microclimates that characterize the food variety in this country (Eurostat, 2016). The characteristics of this supply chain provide an interesting scenario where the complexity for sustainability implementation and assessment exists: high perishability, high product variety and packaging sizes, long production times, long set-up times, high set-up costs. (Kaipia et al., 2013).

Recalling the gaps identified in the previous sections, this study intends to focus its attention on the sustainability assessment that companies in different stages of the FF&V supply chain apply, and if there are specific elements that motivate such assessment. We considered stakeholder theory as the most appropriate lens for this study as it suggests companies implement sustainability practices with the expectation of gaining competitive advantage, besides, such implementation is considered essential because of the various stakeholder´s pressures (Sarkis et al. 2011). In this line, companies should take into account how well a specific practice help them to achieve their objectives and to deal with stakeholder influences (Freeman et al. 2010). Therefore, the sustainability assessment is necessary to understand if the company is attaining its performance objectives and improving relationships with stakeholders as well (Freeman et al. 2010; Clarkson, 1995).

Accordingly, the first objective in this study is to understand how different stages in the fresh fruit and vegetables (FF&V) supply chain address sustainability assessment, with the perspective of different stakeholders involved. Therefore, we first need to describe the type of sustainability practices implemented, and then to identify if they are evaluated or monitored in any way. Hence, the first research question in this study is:

Research question 1:

How are sustainability practices assessed in the FF&V supply chain?

On the other hand, not all companies develop a sustainability assessment strategy nor even apply indicators because as (Bourne et al. 2002) explain, they do not know what to measure and how. Moreover, bearing in mind Gualandris et al. (2015) arguments regarding how different stakeholder´s pressures and companies 'capabilities shape a firm´s sustainability performance assessment strategy, the second objective in the study is to further characterize if there are any elements that motivate sustainability assessment in the FF&V supply chain. Thus, the second research question in this study is:

Research question 2:

How stakeholder characteristics contribute to the application of sustainability assessment in the FF&V supply chain?

Methodology

A case-based methodology was selected. The study involves multiple cases with the objective of collecting evidence that offers the possibility to compare behaviors (Eisenhardt and Graebner, 2007) regarding the sustainability approach in different firms of the Italian FF&V supply chain. In a first screening, we selected companies in the FF&V food industry, registered in a national database, associations and cooperatives databases. Following, companies were selected because they have set up a sustainability strategy in their operations within different

axes of action: specific sustainability strategy, development of organic product lines, higher attention to product quality and traceability, sustainability reporting, etc. Lastly, cases were selected according to their availability and willingness to participate in the research. The final sample is composed by 12 companies of different sizes, geographical locations and levels of vertical integration, that is, different business units are integrated in one legal entity (Trienekens et al. 2012) and thus, operate in more than one stage of the chain (Gualandris et al. 2015; Arena and Azzone, 2012). The supply chain stages considered in this study are: *Growers*, *Processors*, *Wholesalers*, and *Retailers* (see Table 1 and Figure 1).

Table 1 –Cases under study

Case	Product	Sales [mln €/year]	Supply chain Stage
A	Fresh fruit	1	Grower
B	Fresh fruit and vegetables	2.100	Grower, Processor, Wholesaler
C	Fresh vegetables	32	Grower, Processor, Wholesaler
D	Fresh fruit and vegetables	230	Grower, Processor, Wholesaler
E	Fresh fruit	34	Grower, Processor, Wholesaler
F	Juices and canned vegetables	400	Processor
G	Dried fruit and juices	110	Processor
H	Frozen vegetables	N/A	Processor
I	Fresh fruit	14	Wholesaler 2
J	All	12.400	Retailer
K	All	200	Wholesaler, Retailer
L	All	1.000	Retailer

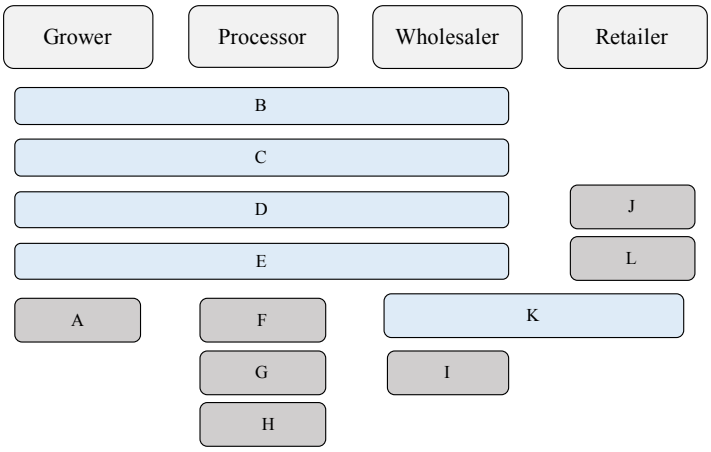

Fig. 1: Cases of study- Distribution across FF&V supply chain stages

Growers are the companies cultivating and harvesting the fruit and-or vegetables. Usually, they clean and sell the product in bulk without particular packaging. *Processors* are the companies in charge of some kind of product processing or transformation, e.g., portioning, boiling, grinding, squeezing. They also classify, weigh and pack the product before selling. *Wholesalers* are in charge of collecting and warehousing the fruit and-or vegetables prior distributing to the retail. Quality control and reconditioning are some additional activities that these companies could perform. Lastly, the *Retailers* are the companies that sell the products directly to consumers. Before displaying the product in the shelves, one or more points of quality control could be performed, as well as reconditioning the product in different packaging presentations (e.g., carton boxes, plastic or Styrofoam trays, plastic or paper bags). In addition, these companies commonly handle product waste recovery that can be destined to processing, re-processing, re-selling or for donating. Thus, the companies selected provide a pertinent scenario

to study the diverse sustainability practice implementation and assessment, across the FF&V supply chain, that is, in multiple stages, with companies of various characteristics.

Data collection and analysis

Data were collected from several sources as semi-structured interviews, companies' websites, online publications, and when available, the company's annual sustainability report. In addition, some of the companies provided internal documentation reporting sustainability projects and results. The use of multiple sources for data triangulation was helpful to ensure construct validity as well (Eisenhardt and Graebner, 2007; Yin, 2009).

In particular, the interviews followed a semi-structured approach that is, researchers followed a pre-defined protocol (See Appendix A) while allowing the interviewee to develop his/her ideas, and this way the researchers were able to take advantage of emergent themes and unique case features (Eisenhardt, 1989). Three researchers developed the interview protocol based on the literature review, then it was validated and updated as interviews went on. Two or three researchers conducted the interviews and transcribed the data. Data analyses were revised and updated as new data was collected for each case. Researchers worked on variables identification, as well as patterns recognition, first individually for avoiding bias, then in group for validation and agreement.

Data analysis was performed in three steps: within case, cross-case and cross-stage. Accordingly, first, variables of the study were analyzed within each case for identifying the sustainability practices implemented in each company and assessment applied, if existing. Second, a cross-case analysis involved the comparison of company's behavior in terms of practice' implementation as well as assessment, for pattern identification in cases in the same supply chain stage. Finally, a cross-stage analysis involved the comparison of sustainability practices and assessment applied across the different supply chain stages studied.

Findings

In the following, findings for each research question are described, firstly, for analyzing the sustainability practice ´assessment it is necessary to characterize the sustainability practices implemented in different stages of the supply chain with the perspective of different stakeholders. Secondly, the elements identified as motivators for sustainability assessment are described.

Sustainability practices in the FF&V supply chain

With the aim of answering the first research question, a within case and a cross-case analysis were performed. The sustainability practices implemented in the FF&V supply chain were identified in the cases analyzed and then aggregated per supply chain stage.

A total of 92 different practices were found, with 279 observations. We noticed that attention to sustainability is not equally distributed among the sustainability areas: approximately 65% of the practices falls in: "Emissions reduction and resource preservation", "Waste reduction and packaging" and "Health and safety" areas (See Figure 2).

Following, the cross-case analysis implied the aggregation of observations per stage in order to understand the commonalities and the differences between practices adopted. In the *Processor* and *Retail* stages, practices are mostly in three main areas mentioned before: "Emissions reduction and resource preservation", "Waste reduction and packaging" and "Health and safety". On the other hand, the *Grower*'s sustainability behavior is almost entirely to the practices for crop protection and reduction in the use of pesticides. Companies recognize that even if the cost of production could be higher, they intend to develop products that are safer and healthier for consumers who are willing to pay a premium price. All companies in this stage are committed to this practice. Lastly, *Wholesalers* were found as the stage that implement the

lowest number of sustainability practices. Two common factors causing this effect were identified. First, company size (smaller companies are unable to run long-term investments for sustainability), and second, vertical integration (most companies in this stage are integrated with processors and growers and thus sustainability practices are concentrated in those business units).

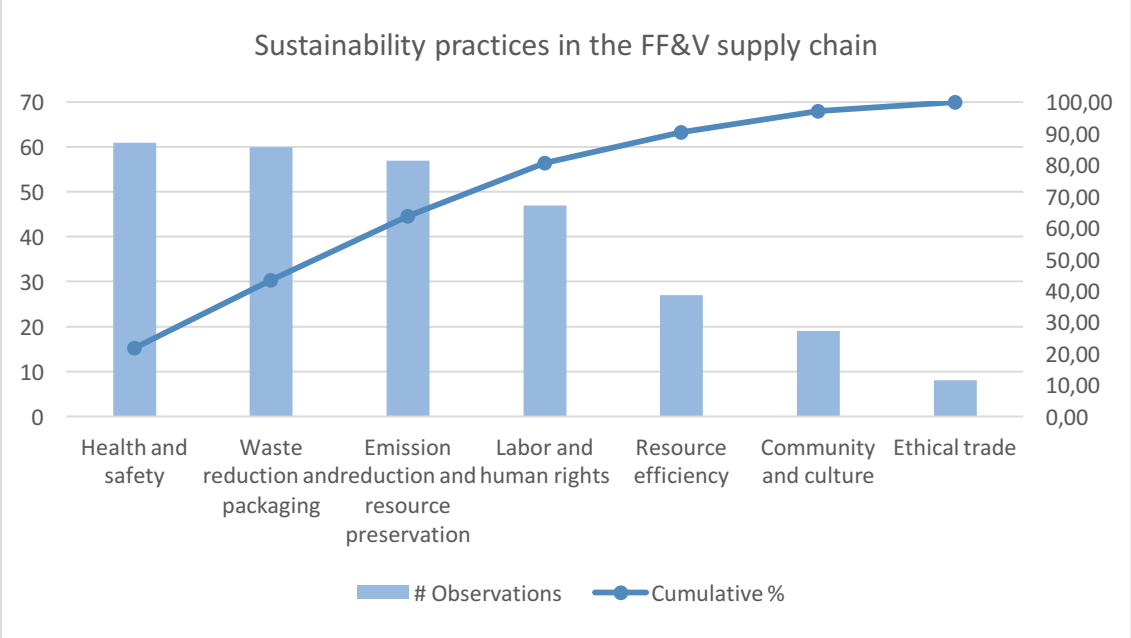

Fig. 2: Sustainability practices implementation in the FF&V supply chain

Sustainability assessment in the FF&V supply chain

In order to complete the answer to Research Question 1 we needed to identify which practices are assessed, if any, and how. Figure 3 summarizes the findings, showing that approximately half of the practices are either not assessed or assessed in a non-structured way, which means that even if companies are in fact assessing their sustainability practices, there is not a standard or unique way of doing such assessment in this supply chain.

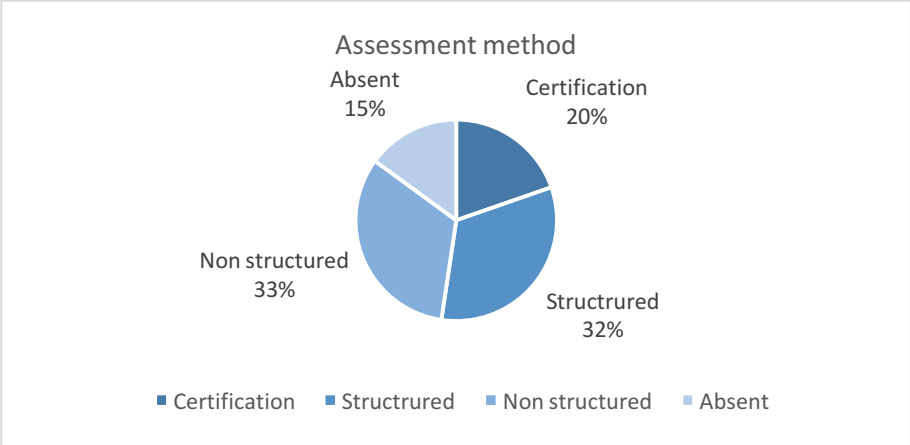

Fig. 3: Assessment methods used in the cases studied

On the other hand, looking at the type of practices implemented, a higher variety in the distribution of the assessment methods applied was observed. In Figure 4 we can observe for example that "Health and Safety" practices are mostly assessed with a certification or in a

structured way, allegedly because these practices are essentially regulated. Whereas, in the "Emissions reduction and Resource preservation" and "Labor and Human Rights" areas, all kind of assessment methods are present. Thus, it is observed that highly heterogeneous assessment mechanisms are applied in the companies under study.

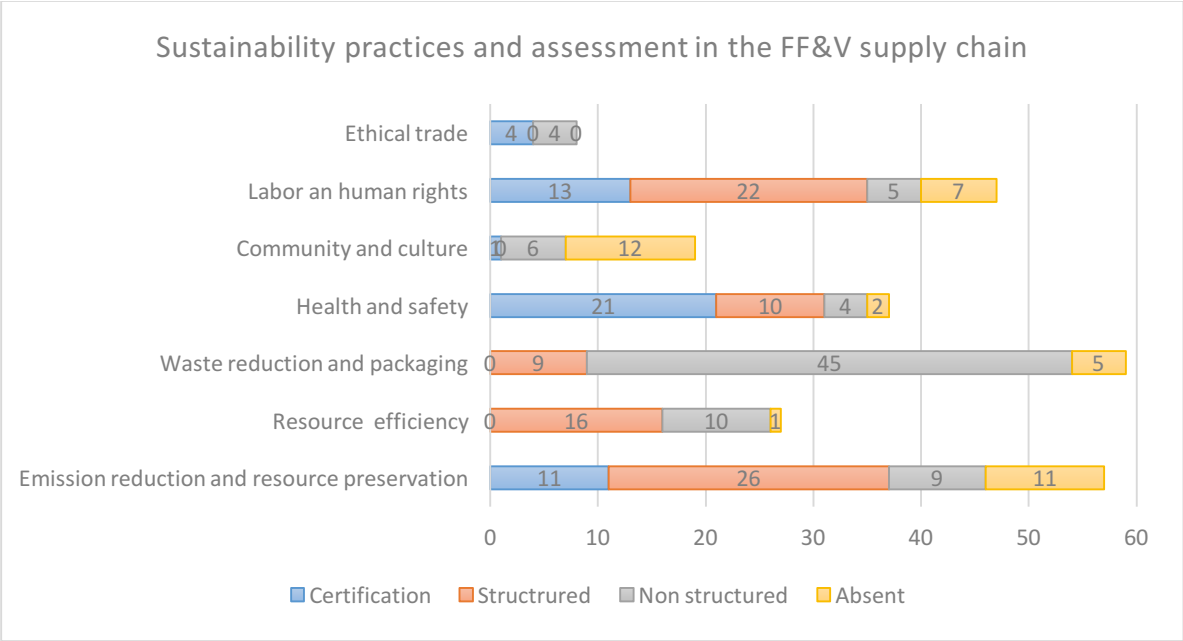

Fig. 4: Sustainability practices and assessment mechanisms in the FF&V supply chain

Characteristics motivating sustainability assessment

Aiming at answering Research Question 2, three company characteristics fostering the adoption of such varied assessment methods were identified during the analysis: company size, assessment complexity and level of vertical integration.

Regarding company size, interviewees explained how smaller companies tend to evaluate less and usually in a non-structured way; e.g., Case C and Case I implement several environmental practices but focus on counting the amount the material consumption for inventory refill, that is, a non-structured assessment. Whereas for larger companies evaluating or monitoring sustainability practices is not different than evaluating other activities, especially since they already have structured assessment systems or certification schemes implemented. For instance, Case J assesses almost all its practices with a structured method via its own yearly sustainability report or by adhering to certifications for animal welfare, traceability and transparency.

Second, companies explained that different assessment is applied depending on the complexity of the measures or mechanisms. Several interviewees explained that when they evaluate or monitor their sustainability practices is usually because this assessment does not interfere with daily operations or when the practice is already assessed for any other purpose like reporting to customers. Contrarily, if the assessment requires larger investments in terms of people, IT systems, or any additional cost, then the practice is usually not assessed. For example, Case D monitors packaging waste for optimizing its processes and that information is useful to evaluate waste generation. However, company D does not assess the use of a low emission truck as it requires specific IT systems to monitor the emissions.

Third, the sustainability assessment also depends on the level of vertical integration. Assessment (structured or certification) was observed more frequently in the companies with a higher level of vertical integration as they expand the data collection and processing for different practices more efficiently along their operations. For instance, Case E evaluates its

"Resource Efficiency" practices through its own measurement system in a structured manner, and adhered to the BRC and IFS certifications for their "Health and Safety" practices. Similarly, Case B certified its "Labor and Human Rights" practices, and has its own structured performance measurement system for most of the practices implemented.

Discussion

Sustainability assessment in the FF&V supply chain

Figure 2 showed a high variety of sustainability practices implemented in the FF&V supply chain. According to the stakeholder theory and as summarized by Freeman et al. (2010), such variety or actions taken, explains how companies respond to varied stakeholder pressures. Moreover, as Sarkis et al. (2011) also argued on the base of stakeholder theory, companies implement sustainability practices that do not necessarily bring benefits or competitive advantages but are required because of stakeholder pressures.

Accordingly, this study identified several elements shaping this varied behavior in companies of the FF&V supply chain such as industry characteristics, benefits or competitive advantages expected, company culture, consumer attention. First, the intrinsic characteristics of the fresh food supply chain (e.g., freshness, perishability, quality variation) (Trienekens et al. 2012) make companies particularly devoted to reduce the contamination in the fields, to optimize the use of resources and decrease waste generation, and to prioritize safe food production. Moreover, companies consider these practices to be easier to implement than others, and they could perceive the benefits sooner, for instance reducing emissions in transportation and production, or reducing waste. On the other hand, some practices were case-specific, in cases where the company culture drove sustainability actions like community involvement or reinsertion of displaced or disadvantaged people, as in Case J and Case K. This type of strategy has been identified in literature and in international organizations that increasingly propose social sustainability practices as part of the overall sustainability strategy (Maloni and Brown, 2006; Pullman et al. 2009; ISEAL, 2014; FAO, 2015).

Furthermore, it was observed that practices in particular stages respond to specific objectives, not necessarily related to sustainability performance but in order to achieve competitiveness, increasing revenues as suggested in Pullman et al. (2009) and Varsei et al. (2014), or for responding to stakeholder pressures (Sarkis et al. 2011). An example was the *Grower* stage that is committed to reduction of emissions and resource contamination practices for developing safer and healthier products that consecutively also aim at increasing sales with premium prices. Companies recognized the importance of reducing the contamination for the environment, and it was even more relevant if these practices enable the company to increase market share and revenues. Findings in our study support the expansive implementation of environmental and social sustainability practices in the food supply chain as companies intend to catch the attention of new consumers that value a wider range of sustainability initiatives, from philanthropic to the ones oriented to safer and healthier food as well.

Regarding sustainability assessment, the level of formalization, i.e., definition of measurement criteria, frequency, cost of the measurement, obligations/ responsibilities for each measurement; and integration, i.e., if it is isolated or inputs are shared with other organizations (De Toni and Tonchia, 2001), is varied among the practices implemented and among type of companies. In addition, the assessment method applied in this supply chain is highly heterogeneous and this behavior is rather uniform across stages, that is, there is not a direct dependence between stages and type of assessment applied.

Still in the sustainability assessment topic, the intention in this study was to outline if there is any kind of assessment used in different kinds of companies and in different stages in the FF&V supply chain, and what kind. Given the high complexity in the Italian fruit and vegetables supply chain (i.e. different sizes, locations, products, strategies), the assessment

cannot be taken for granted. Findings supported the argument that companies in this food supply chain apply a more structured (or certification) kind of assessment when the practices are regulated or when a particular product is to be promoted (Marshall et al. 2015; Schmitt et al. 2017, Varsei et al. 2014). In line with Clarkson (1995), it is seen that companies in the FF&V supply chain generating assessment data demonstrate more attention to issues considered more important, e.g., regulations. Hence, this kind of stakeholder pressure justifies to be managed and therefore, evaluated. Otherwise, the assessment is highly varied. Such heterogeneity in the sustainability assessment is consistent with previous literature as well. Authors have mentioned that when the number of sustainability issues covered increases, the complexity of evaluation and verification tends to increase too (Gualandris et al. 2015). Moreover, findings in this study suggest that the sustainability assessment benefits depend on how the practices are evaluated and also depend on certain firm characteristics that need to be identified as well.

Company´s features influencing the application of sustainability assessment

There are three main company´s features that allegedly foster the sustainability assessment in the food supply chain. These characteristics are: company size, assessment complexity and level of vertical integration. In line with Arena and Azzone (2012), this study illustrates that smaller companies face more challenges implementing sustainability reporting or a more structured assessment due to lack of capabilities, resources and/or instruments to support them. On the other hand, consistently with previous studies, in the FF&V supply chain the identification and selection of measures demands efforts that could be overloading the people involved with overly sophisticated or redundant information (Bourne et al. 2002; Genovese et al. 2017). Therefore, companies prefer to focus the evaluation on already existing systems that do not alter daily operations, and thus, sustainability assessment remains unstructured or even absent. Besides, when the issue is not considered crucial to be managed, i.e., the stakeholder pressure is not as important as others, as Clarkson (1995) argued, the company would not generate evaluation data as well. The third feature identified in our case studies, vertical integration, is also in line with Trienekens et al. (2012) and Gualandris et al. (2015), who explained that in vertical organizations the use of standards could be spread, traceability facilitated and the scope of the sustainability evaluation could be increased.

Nonetheless, these factors alone might not be the only ones fostering sustainability assessment and might not influence companies simultaneously. Sustainability assessment expectations from customers (wholesalers, retailers), regulators and other stakeholders have triggered the search for support in order to better manage those pressures considered more important than others, or that could be in conflict with others (Sarkis et al. 2011, Freeman et al. 2010, Clarkson 1995). The way companies deal with different stakeholder pressures for sustainability and sustainability assessment could be also promoted by external actors. For instance, the role of cooperatives in the FF&V supply chain is determinant for sustainability assessment purposes, especially for *Growers*. Cooperatives usually group a high number of members and product volumes, and facilitates collective investments to implement and assess sustainability. *Growers* in our cases are associated in cooperatives and have been able to implement European food safety sustainability certifications like BRC (British Retail Consortium) Global Standards and IFS Food (previously known as International Food Standard). These international certifications have become mandatory for *Growers* in order to be able to work with the major retailers. Therefore, in order to access the mainstream market, *Growers* are compelled to get the certifications, and cooperatives play a key role for these companies to comply with the expectations and- or regulations Actually, horizontal integration through cooperatives has allowed these *Growers* to obtain the production scale to meet the main customer´s requirements. Contrarily, Case A that is not a member of any cooperative, doesn't have these certifications since it doesn't have the financial means to invest on them.

For better dealing with stakeholder pressures firms should generate evaluation data (Clarkson, 1995) that help them to attain benefits expected from their sustainability efforts. Accordingly, companies in the FF&V supply chain need to set up sustainability practices and assessment mechanisms that are in line with their size, capabilities and with their own complexity determined by the level of vertical integration. External actors as cooperatives could assist to develop capabilities and improve such sustainability assessment objectives.

Conclusions

The aims of this study were to understand how companies in the FF&V supply chain assess their sustainability practices if they do, and to identify the factors contributing to the application of sustainability assessment. Firstly, we identify the type of sustainability practices implemented in different stages of the FF&V supply chain, and then describe if they were assessed and how. Finally, the main elements influencing the use of sustainability assessment are identified. The study is grounded on stakeholder theory that helps the findings description and interpretation considering how companies deal with pressures to act and evaluate sustainability. We analyzed 12 companies with operations in four different supply chain stages: *Growers*, *Processors*, *Wholesalers*, and *Retailers*.

The companies studied mostly implement practices related to "Emissions reduction and resource preservation", "Waste reduction and packaging" and "Health and safety". From the total of practices implemented, approximately half of them were either not assessed or assessed in a non-structured way, therefore, this highlights a major issue to be addressed, since a non-assessed practice implies either a missed opportunity, or even a mislead effort. Regarding assessment, a variety of methods is applied depending on the type of practices implemented, e.g., the "Emissions reduction and Resource preservation" practices, are assessed with all methods; "Health and Safety" are mostly certified or evaluated with structured mechanisms; "Waste reduction and Packaging" are either not assessed or assessed in a non-structured way. Finally, we identified three main factors that motivate companies to assess their sustainability practices: company size, complexity of measurement, and level of vertical integration.

In terms of theoretical implications, studies that consider sustainability performance evaluation and management beyond the metrics definition are lacking. As Bourne et al. (2000), Genovese et al. (2017) and Gualandris et al. (2015) argued, companies struggle with metrics implementation and information use, especially when multiple objectives are considered and multiple stakeholders are involved. Trade-offs would need to be managed when conflicting stakeholder pressures exist (Freeman et al. 2010) and thus, companies would require to find the appropriate way to deal with those pressures while getting benefits form their sustainability efforts (Sarkis et al. 2011). In this regard, and in line with Clarkson (1995) and Freeman et al. (2010), sustainability assessment would provide the data reflecting the management of stakeholder´s pressures. If such data is collected and analyzed, then, companies would be able to determine if their sustainability efforts are worth. However, not all firms are capable to deploy such assessment for different reasons, or are partially doing it in response to what they consider to be most *important* pressures. This study analyzes the use of sustainability assessment in different types of companies in different stages of the FF&V supply chain, and identifies the characteristics influencing the use of sustainability assessment. Sustainability assessment is found to be varied, thus confirming that no standard or unique system is applied in this supply chain, and our findings support the idea of the assessment being dependent on the type of practices implemented, the type of company and supply chain; the complexity of the assessment mechanisms; and, different levels of vertical integration.

This study could be also of practitioners´ interest by identifying the assessment mechanisms implemented for different kind of sustainability practices, and the factors that foster sustainability assessment. These could be useful for setting up better sustainability assessments

along the FF&V supply chain, according to companies' individual capabilities and objectives, supporting a more effective sustainability strategy and stakeholder management along the chain.

Future research opportunities could emerge from the findings in this study. The analysis here was concentrated in a specific type of food supply chain in a particular geography, thus, it could be interesting to validate the results in a supply chain dealing with products with longer shelf-life or with products that are exported/imported to/from other countries. In addition, studies could address the feasibility of designing an ad-hoc sustainability assessment system that covers multiple dimensions simultaneously, and is also easy to use and interpret.

Appendix A: Interview Protocol

Company profile

- Company history, business sector, main operations, main products.
- Supply chain description: suppliers, customers.
- Sustainability related strategy: role, responsible, activities (if there are)

Sustainability implementation

- Please detail the type of practices implemented in every operation: category, individual practice, how is it implemented, collaboration, third party involved (if it is the case)

a) Emission reduction and resource preservation
Practices in every operation to reduce emissions and the use of pollutant chemical substances, e.g. responsible farming methods (reducing fertilizer and pesticides), elimination of contaminant and pollutant agents, reducing CO2 emissions and GHGs.

b) Resource efficiency
Reducing water consumption, efficient water use, waste water re-use and recovery. Reducing energy use, energy conservation, reducing the use of other input materials, reducing fuel consumption, and optimization of transportation and logistics processes.

c) Waste reduction and packaging
Reducing food or packaging material waste in the production, packing, transportation and storing processes. Decreasing and/or eliminating hazardous materials, composting organic waste, producing renewable energy or animal feed with food waste, food and material recycling. Packaging reuse and recycling, reducing packaging, using reusable/ recyclable packaging, sustainable packaging design (e.g., for longer food preservation).

d) Health and Safety
Ensuring and increasing consumer's health and safety through product quality and control, reducing contamination risk (food safety and security), traceability, promotion of healthier products and diets, communication and education to consumers.

e) Labor and Human Rights
Improving and guaranteeing good working conditions and enhance workers' wellbeing: regular employment, training, education, respect of worker rights, safe working environment, fair compensation. These practices can be either regulated or voluntary.

f) Community
Supporting local communities, philanthropic initiatives, contributions to improve quality of life in the community, educational projects, health campaigns, promote gender equality and diversity, respect local biodiversity.

g) Ethical trade
Promoting and applying ethical practices and transparency between buyers and suppliers, to improve the quality of life thanks to a premium price for sustainable-grown products, respect and fairness. Certification schemes related.

Sustainability assessment

- Are the practices (refer to every practice implemented) assessed in any way? If yes, How? If not, why not?
- Is it possible to determine the benefits or advantages of implementing the sustainability practices? How? (Certification, method, measure, indicator)
- Is there a performance measurement system regarding sustainability? Does the company create a report to communicate the sustainability results?

Working capital models in manufacturing value chains: Towards a generic framework

Summary
This paper concerns the working capital models of companies in manufacturing value chains. The objective is to identify working capital models and working capital positions in the value chains. The empirical financial data from 100 companies were analyzed systematically with the financial value chain analysis method. The findings indicate that similar working capital models are applied in the value chains of the automotive and pulp and paper industries but with different emphases. Based on the empirical findings, a framework for working capital models is proposed, and it introduces six different working capital models applied in the manufacturing value chains.
Key words: working capital, financial supply chain
Submission category: competitive paper

Introduction

Working capital is an asset keeping the operations of the firm running. Rapid changes in business and challenging financial conditions have increased the interest towards efficient asset management (Mullins, 2009). In the value chain context, working capital links the material and financial flows: it is an investment in inventories, and balancing between financial flows upstream and downstream. Farris and Hutchison (2003) note that instead of focusing on individually managing each working capital component, companies should define their unique combinations of all components of operational working capital: inventories, accounts receivable, and accounts payable. It has also been shown that the most efficient way to improve the profitability of the value chain by working capital management in the value chain of the automotive industry is to manage all components simultaneously (Viskari et al., 2012), but this kind of a comprehensive view to working capital management has not been applied by companies (Brandenburg, 2016). Thus, research on working capital models is highly relevant and needed.

While studies on finance have traditionally concentrated on trade credit issues, operations management has focused more on the management of inventories. The emergence of the research stream of financial supply chain management (FSCM) has brought the value chain perspective and collaborative working capital management into discussion (e.g. Randall and Farris, 2009; Hofmann and Kotzab, 2010; Protopappa-Sieke and Seifert 2017), and hence, combined the financial issues with the management of supply chains. Still, only a few studies on working capital management take into account the holistic view on working capital consisting of both the material (inventories) and financial (trade credit) flows. The concept of working capital models calls together the fragmented academic literature of working capital management from two research streams. However, prior research on working capital models is scarce. The studies have mainly concentrated on different working capital practices and used survey data (e.g. Belt and Smith, 1991; Ricci and

Morrison, 1996; Howorth and Westhead, 2003). The literature lacks studies based on numerical financial data, which reveal the realized working capital models companies have applied.

Today, companies operate in a networked environment and competition occurs between inter-organizational value chains. The perspective of a single company, and praising the superiority of the strategy aiming at minimizing working capital by using power at the expense of value chain partners are perspectives too narrow in the current business environment. For example, the studies have shown that payment term adjustments towards suppliers provide short-term benefits by improving immediate liquidity, but on the long-term may have a negative impact on the firm (Kroes and Manikas, 2014; Huff and Rogers, 2015; Grosse-Ruyken, Wagner, and Jönke, 2011; Wandfluch, Hofmann and Schoensleben, 2016). Several researchers have highlighted the need for collaborative working capital management (e.g. Hutchison, Farris and Fleischman, 2009; Gomm, 2010; Vázquez, Sartal and Lozano-Lozano, 2016). FSCM aims at the optimization of working capital at the value chain level. Companies in the value chain should have different kinds of working capital strategies depending on their position in the chain, as all companies do not benefit from similar working capital actions (Viskari et al., 2012). However, all firms should ensure that their working capital decisions are in line with the structure of the value chain (Grosse-Ruyken, Wagner and Jönke, 2011), and Wuttke, Blume and Henke (2013) also highlight the importance of understanding the positions in the value chain.

The objective of this paper is to explore different working capital models applied by companies and the companies' working capital positions against each other in two manufacturing value chains representing the automotive and pulp and paper (P&P) industries. The study aims at adding to the understanding of realized working capital models in the value chains, as well as at providing a framework for positioning and categorizing the value chain actors on the basis of their working capital models. This will enhance the awareness of the working capital environment of the value chain. The answers to the following research questions are sought after: *Which working capital models can be identified in the manufacturing value chains? Can we find patterns in working capital management between the value chains in different industries?*

Literature review

FSCM has been one of the most interesting research streams in supply management and as well as in management accounting, but the robust theoretical background has been missing. This study applies the theories of transaction cost theory (TCE), the finance, and inventory management to FSCM phenomenon. Taking care of the allocational efficiency of capital markets, and ensuring that the resources are allocated to where they are most productive, is essential due to the limited amount of resources (Arnold 1998). This serves as the theoretical foundation of this paper. In recent years, the concept of FSCM has gained more attention in academia, and brought the flow of money and financial aspects into the discussion on supply chains (Protopappa-Sieke and Seifert 2010). Wuttke et al. (2013) defined the purpose of FSCM as "optimized planning, managing, and controlling supply chain cash flows to facilitate efficient supply chain material flows". In other words, as a combination of these two perspectives, financial resources should be allocated for more productive objectives in the supply chains. This calls for the reduction of working capital

to a reasonable minimum in the supply chains, but also for the optimization of working capital within the supply chains.

The management of operational working capital consists of the management of inventories, accounts receivable and accounts payable. In this paper, we take a holistic perspective on working capital by focusing on the unique combinations of all working capital components (Farris and Hutchison, 2003), i.e. working capital models. Traditionally, research on working capital management was separated into two fields: the literature of finance studied trade credit, and supply chain management literature focused on inventory management. The concept of a working capital model brings these streams together. Trade credit is a common practice between companies. It is created when a buyer delays a payment for purchased goods according to the agreed payment terms between the companies. The motives for the use of trade credit vary: suppliers may offer trade credit due to competitive pressure, and buyers demand it in order to pool payments, reduce cash balances, and to replace bank loans (Seifert and Seifert, 2008). Studies on trade credit have concerned e.g. credit risk models, trade credit motives and credit term decisions (Seifert, Seifert, and Protopappa-Sieke 2013). The reduction of accounts receivable has been found to be positively associated with firm performance, but the accounts payable were not linked with performance (Kroes and Manikas, 2014). The study highlighted that the increase of accounts payable only improves immediate liquidity, but on the long-term may have a negative impact on the firm. Similar statements were presented by Grosse-Ruyken et al. (2011) and Wandfluch et al. (2016), as well as by Huff and Rogers (2015), but they noted that advantages gained by improving inventory management are longer-lasting. This is in line with the conclusion that the sustainable reduction of working capital should be done via effective management of inventories as payment term adjustments offset each other in the supply chain context (Lind et al., 2012).

Inventory management research has concentrated on efficient operations and the correct sizing of inventory in relation to economic order quantity (EOQ), management philosophies like just-in-time (JIT) and lean, and issues in demand characteristics and marketing environment (Koumanakos 2008). Inventory management involves the control of assets produced to be sold in the normal course of a firm's operations. The general categories of inventory include the inventories of raw materials, work-in-process, and finished-goods. The importance of inventory management to the firm depends on the extent of its inventory investment. Inventories can be seen as tied up capital, as a more or less intended investment, which should be aimed at achieving solutions as economical as possible. Managing inventories involve a lack of funds and inventory holding costs. The maintenance of inventory is expensive, so why should firms hold inventories? Keynes (1936) differentiated three motives for holding money/cash: 1) the transaction motive, 2) the precautionary motive, and 3) the speculative motive. These can also be applied to inventory problems, and they are motives to be distinguished in most used classifications (e.g Arrow et al., 1958):

1. *The transaction motive* propels a business to maintain inventories so that there are no bottlenecks in production and sales. It is natural for a business to plan inventory investments commensurate with the level of transactions in the business.

2. *The precautionary inventory management motive* necessitates the holding of inventories for unexpected changes in demand and supply factors.
3. *The speculative inventory management motive* compels to hold some inventories to take advantage of changes in prices and getting quantity discounts.

The purpose of carrying inventories is to uncouple the operations of the firm – that is, to make each function of the business independent of other functions – so that delays or shutdowns in one area do not affect the production and sale of the final product. Decision-making about inventory levels involves a basic trade-off between risk and return. The risk is that if the level of inventory is too low, the various functions of business do not operate independently, and delays in product and customer delivery can ensue. But a lower level of inventory can also save the firm money and increase returns. Moreover, as the size of inventory increases, storage and handling costs as well as the required return on capital invested in the inventory rise. In short, as the inventory a firm holds is increased, the risk of running out of inventory is lessened, but inventory expenses rise.

It is also worthwhile to mention cash (i.e. cash and cash equivalents consisting of excess cash and cash needed for daily operations) in the light of inventory management. This is because the stock of cash carried by a firm is simply a special type of inventory. In terms of uncoupling the various operations of the firm, the purpose of holding a stock of cash is to make the payment of bills independent of the collection of accounts due. When cash is kept on hand, bills can be paid without prior collection of accounts. Bianco and Gamba (2017) show that inventory and cash holdings are synergic tools: while the first is a valuable operational hedge against the commodity price risk, the second enhances the hedge offered by inventory in the face of costly external finance.

In today's networked environment and competition between inter-organizational value chains, the perspective of a single company on working capital is rather narrow. FSCM emphasizes efficient working capital management throughout the value chain, and researchers suggest companies to take a supply chain approach to working capital to ensure the supply chain profits as a whole (Hutchison et al., 2009; Hofmann and Kotzab, 2010). However, studies have found that in practice, instead of collaboration, companies move harms in terms of inventories and/or trade credit along the value chains (Vázquez et al., 2016; Lorentz et al., 2016). In the value chain context, it should be considered how working capital should be managed in the different parts of the chain as all companies cannot reduce their working capital close to zero without affecting other companies. Each firm should ensure that their cycle time of working capital is in line with the structure of the value chain (Grosse-Ruyken et al., 2011), and firms should understand their position in the supply chain before making decisions related to FSCM (Wuttke et al., 2013). It has been found that the relation between working capital management and profitability differs in different parts of the value chain, which suggests that companies have and should have different strategies in working capital management depending on their position in the chain (Viskari et al., 2012). Previous literature on working capital management lacks the research on these different patterns of managing working capital. This study aims at narrowing down this gap by identifying working capital models existing at the value chain level.

Research process and design

Description of the value chains

Two industries were selected to demonstrate the current state of working capital management in manufacturing value chains. The automotive and P&P industries were chosen as capital-intensive representatives of traditional manufacturing industries, where certain amounts of working capital are needed to ensure the fluent flow of production. They represent different types of production: the automotive industry is an example of batch and serial production, and the P&P industry represents process industry. As a forerunner of lean management, the automotive industry has a strong orientation towards efficient working capital management, and the importance of working capital has been highlighted by companies such as BMW (2010) and Valeo (2014). Working capital management in the automotive industry has also been studied by other researchers (e.g. Brandenburg 2016; Vázquez et al., 2016). In the P&P industry, the return on capital employed is very sensitive to the amount of capital tied in the inventories of raw materials and finished products, which has made companies focus more and more on reducing working capital (Carlsson and Rönnqvist, 2005). The structures of the value chains and the total samples can be seen in Appendix 1, and they follow the approach by Lind et al. (2012) and Pirttilä et al. (2014).

Data and measures

The empirical data of this study consists of financial figures gathered from the official consolidated financial statements of the years 2006–2010. Moers (2007) has criticized the archival data approach due to the uncritical usage of databases. In this study, we tackled the problem by collecting the financial statements only from public sources, which were mainly company websites, and collected and calculated the financial figures manually. This ensures the correctness and traceability of the used figures.

In this study, working capital models are measured with cycle times. The cycle time approach has been used in several studies regarding working capital management (e.g. Farris and Hutchison, 2003; Hofmann and Kotzab, 2010; Grosse-Ruyken et al., 2011; Pirttilä et al., 2014). Table 1 introduces the used measures and the determinants of the working capital model.

Table 1. The definitions of used determinants and measures.

Variable	*Component*	*Definition*
DIO	Cycle time of inventories	DIO = (Inventories/Sales)*365
DSO	Cycle time of accounts receivable	DSO = (Accounts receivable/Sales)*365
DPO	Cycle time of accounts payable	DPO = (Accounts payable/Sales)*365
DSO-DPO	Net trade credit	
CCC	Cycle time of working capital	CCC = DIO + DSO - DPO
ROC%	Return of capital employed	ROC% = EBIT/((Equity$_t$+Equity$_{t-1}$)+ (Long term liabilities$_t$+Long term liabilities$_{t-1}$))/2

The values for inventories (including raw material, work-in-progress, and finished goods), accounts receivable and accounts payable were collected from balance sheets. The cycle times are calculated as a proportion of sales (Shin and Soenen, 1998; Lind et al., 2012), and the value of sales was picked from income statements. In this study, the working capital models have been determined by the DIO and DSO-DPO, which is considered as the balance between trade credit components. Together the components constitute the cycle time of working capital, i.e. cash conversion cycle (CCC). The variable DSO-DPO (also

called net trade credit), combines the components of financial flow and describes the balance between them. The variable has been used as a measure in previous research as well (Nadiri, 1969; Lorentz et al., 2016).

The results of the study show the companies' average figures from 2006–2010. This approach was chosen in order to analyze a company's long term working capital management and eliminate the yearly fluctuation in performance. Due to the unavailability of data, some firm-year observations are missing (see Appendix 1). In these cases, the company averages were calculated with the figures of the available years. Table 2 provides descriptive data on the sample.

Table 2. Descriptive data on the research sample.

	Number of		CCC (days)			DIO (days)			DSO (days)			DPO (days)			DSO-DPO (days)		
Industry	Companies	Stages	Avg.	Min.	Max.	Avg.	Min.	Max.	Avg.	Min.	Max.	Avg.	Min.	Max.	Avg.	Min.	Max.
Automotive	55	6	70	8	146	49	11	98	55	13	141	34	7	71	20	-21	97
Pulp and paper	45	8	59	8	110	41	3	85	53	21	100	35	9	78	18	-26	65

Methods

The financial value chain analysis (FVCA) is used as a research method in this study to identify different working capital models applied by companies in the value chains of the automotive and P&P industries. The method was chosen as it provides a systematic process to analyze the financial figures in the value chain and its different stages (Lind et al., 2012). The method has been used previously to analyze the cycle times of working capital at the value chain level in several studies (e.g. Lind et al. 2012; Pirttilä et al. 2014). This empirical study employs an archival research approach (Moers, 2007). The results of the FVCA are analyzed in the WCM matrix (Lind, Monto and Kärri, 2017) described in Figure 1.

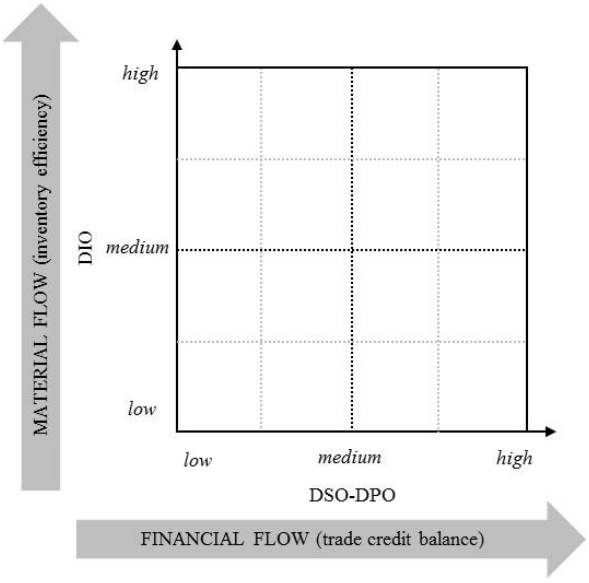

Figure 1. WCM matrix (adapted from Lind et al., 2017).

The WCM matrix approach was chosen as the it enables the analysis of different working capital models, combining the two flows of working capital, in the same figure. This kind

of a holistic view to the working capital of companies is emphasized by several researchers (e.g. Farris and Hutchison, 2003; Viskari et al., 2012; Brandenburg, 2016). In addition, the WCM matrix enables the analysis of the working capital positions of the companies against each other in the value chain, the definition of the working capital models applied, and a comparison of working capital models in the different value chains. The vertical axis of the matrix describes the efficiency of inventory management (DIO), whereas the horizontal axis presents the net trade credit (DSO-DPO). In this paper, we have divided the WCM matrix into 16 working capital models. This was done by dividing both axes equally into four parts between the minimum and maximum values of the samples. Hence, the border values for the working capital models are different in the automotive and P&P industries.

Limitations

The data from financial statements represent the situation on one day of the fiscal year. During the year, seasonal factors may cause remarkable changes in working capital and make it differ from the year-end figures. The use of monthly data instead of annual figures would enable the observation of differences in working capital during the year. However, obtaining monthly data reliably or from public sources at this scale is difficult. Therefore we rely on the annual figures from official sources. The figures from annual reports are suggestive enough for the purposes of our analysis, but the authors advise to keep this feature of the used data in mind.

Empirical results

The analysis of the results is conducted by positioning the companies on the basis of their DIO and DSO-DPO in a WCM matrix. The WCM matrix scatter charts (Appendix 2) show the average value of the years 2006–2010 for each company, and the companies are grouped by the stages. Additionally, the average working capital models of the stages are presented in the charts. The sample has been organized into 16 different working capital models.

The shortest cycle times of working capital can be achieved by applying a working capital model in which both the DIO and DSO-DPO are low, or in which slightly higher inventory levels are compensated with particularly efficient management of financial flows, and vice versa. In the WCM matrix, these models are located in the bottom left corner. The results showed that the most companies in the extreme stages of the value chain of the automotive industry, i.e. raw material suppliers and car dealers, were applying this type of working capital model. In the P&P value chain less companies were located in this part of the matrix. The companies applying the most efficient working capital model were mainly brand owners and publishers representing the downstream part of the value chain.

The scatter chart (Appendix 2) shows the peculiarity of the business model applied by car manufacturers. The long DSO caused by the financing and leasing services car manufacturers offer to their customers (Lind et al., 2012) has led to the great difference between the DSO and DPO in all companies within the stage. Thus, they can be seen operating as financiers in the value chain. However, car manufacturers differ from each other in the management of inventories. In the P&P industry, the stages differ from each other in inventory management. The stages of market pulp, chemicals, and machinery act as inventory holders in the value chain, whereas publishers, printers and brand owners have low inventory levels. This follows the structure of the value chain: the upstream part of the

chain ties up more working capital in the inventories than the downstream part. However, the companies within the stages of the P&P value chain have different practices related to trade credit management.

In both value chains, the companies within the several stages seem to be located close to each other in the WCM matrix. In other words, many companies seem to follow the same or similar working capital models with their competitors. For example in the automotive industry, car dealers and raw material suppliers focus on minimizing their working capital, and refined raw material suppliers operate as inventory holders, whereas the working capital model by printers in the P&P industry is characterized by low inventories and higher net trade credit. However, opposite behavior was identified as well. For example, component suppliers in the automotive industry and chemical and machinery suppliers in the P&P industry applied several very different working capital models.

Figure 2 shows the division of the sample companies into different categories of the WCM matrix. In this figure, the value chain of the automotive industry (referred to as "A" in Figure 3) and P&P industry ("P") are shown together, but it should be noted that the border values of the categories were different in the value chains due to the different minimum and maximum values of these two separate samples.

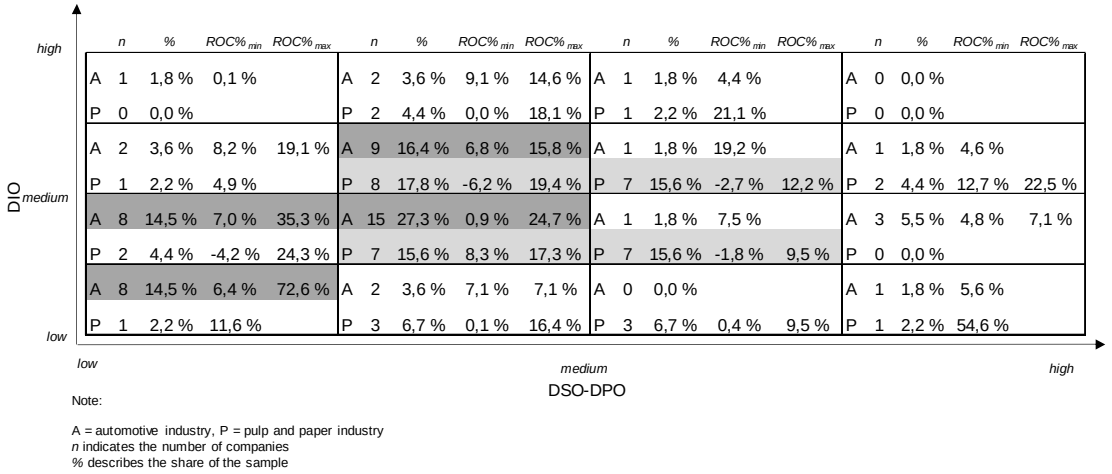

Figure 2. The division of the working capital models in the value chains.

As shown by Figure 2, the four most popular working capital models can be explicitly identified in both value chains (colored with grey in the figure). Other models were only applied by 1–3 companies. However, the value chains differ in their emphasis of working capital models. The automotive industry seems to aim more strongly at minimum working capital, whereas the most popular working capital models in the pulp and paper industry are formed around the medium values. Figure 3 also shows the range of the ROC% of the companies within the working capital models. Due to the relatively small sample size, the results are mainly descriptive and explicit conclusions cannot be drawn.

In the value chain of the automotive industry, the most popular working capital model with fifteen companies is the model directly below the medium borders of the matrix. This indicates that the companies may aim at minimum working capital, but for one reason or

another, room for improvement in the management of material as well as financial flows still remain. Three other popular working capital models are applied by 8–9 companies. One of these working capital models is directly above the previous one, and hence differs by having higher inventory levels. The other two most applied working capital models are the one with minimum working capital, and the one that focuses on low net trade credit, but keeps slightly higher inventory levels than the minimizers. In the P&P industry, the working capital models in the middle of the matrix are the most popular. Companies are equally divided into these four models, which can be described as inventory focused working capital model (8 companies), financing focused working capital model with lower inventory levels (7 companies), financing focused working capital model with higher inventory levels (7 companies), and working capital model aiming at short cycle times (7 companies).

Framework for working capital models in a manufacturing value chain

The analysis shows that companies within the value chains have different mixes of inventory and trade credit management, i.e. working capital models. Some similar patterns are found in the studied value chains, but with different focuses. On the basis of this analysis, general working capital models in the manufacturing value chain can be identified. Figure 3 concludes the findings in a preliminary framework for working capital models.

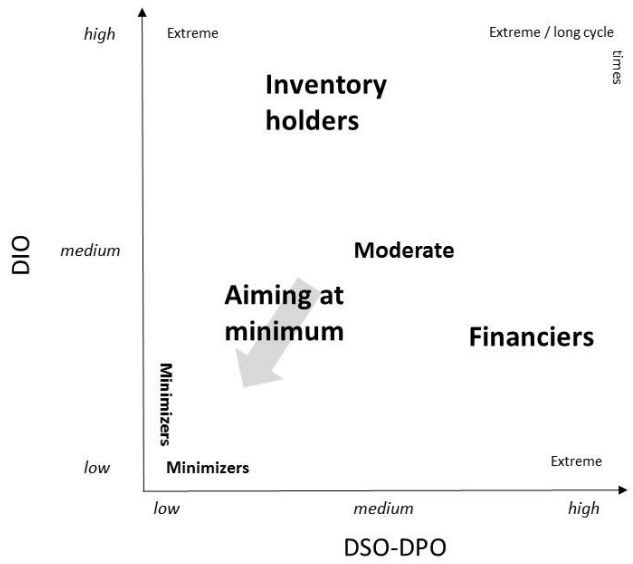

Figure 3. Preliminary framework for working capital models.

Both value chains emphasized the working capital model that *holds inventories*, as well as the model that seems to *aim at minimizing* working capital, but still has potential to improve it. In the automotive value chain, *minimizers* were identified, whereas in the P&P industry, companies focused on the medium levels of working capital by applying the *moderate* working capital model. *Financiers* were found in both value chains, but it characterized the value chain of the automotive industry even more. The *extreme* working capital models, containing the working capital models with the *longest cycle times*, were applied only

occasionally. The size of the text illustrates the incidence of working capital models in the studied value chains.

Discussion and conclusions

The analysis of working capital models in the WCM matrix revealed that, in the value chain of the automotive industry, working capital is managed in a relatively efficient manner, as the majority of the companies had minimized, or they aimed at minimizing, their working capital. The extreme working capital models were applied only occasionally. This indicates that the working capital efficiency of the total value chain could be improved by supporting the companies with weaker working capital management. This could be done e.g. by payment term adjustments as a compensation for holding inventories, or by providing opportunities for reverse factoring. On the other hand, it could be discussed what kind of collaborative actions could be done in order to reduce the inventory levels of these companies. The analysis of the value chain of the P&P industry, in turn, showed that companies were positioned in the middle of the WCM matrix. This indicates that not all potential to release working capital from the value chain has been utilized. Actions to improve working capital management throughout the value chain could benefit all actors and make the value chain more effective.

Theoretical and Managerial Implications

The financial value chain analysis applied in this study enables the identification of different working capital models. A generic framework for working capital models in the manufacturing value chain context, based on our empirical findings, offers a holistic view on working capital management, and introduces six working capital models: Inventory holders, Aiming at minimum, Financiers, Moderate, Extreme (including the longest cycle times) and Minimizers. The framework enables the analysis of working capital models at the company and value chain level, but it can also be used to analyze different value chains. As a relatively new research area, FSCM has lacked general frameworks and systematic theory development studies (Gelsomino et al., 2016; Singh and Kumar 2014). This paper is an initiative towards theory development of working capital models targeted at strengthening the basis of FSCM literature with a holistic view on working capital. The study provides new perspectives on the working capital models used by companies by being based on financial data, and considering the value chain perspective.

The paper provides empirical analysis of working capital management in the value chain context. The introduced framework supports collaborative working capital management and the optimization of working capital at the value chain level. The framework can be used as a managerial tool in managing working capital in three ways. *First*, the framework complements the financial value chain analysis (Lind et al., 2012), and helps companies understand the working capital positions in the value chain. *Second*, the framework enables the analysis of working capital models as a combination of all working capital components, which is required when aiming at improvements in working capital management (Farris and Hutchison, 2003). *Third*, the framework supports companies and value chains in defining their targets for working capital management.

Another managerial implication is that firms should recognize their inventories as tied up capital, as an intended investment, which should be aimed at achieving economical

solutions. Managing inventories involve the lack of funds and inventory holding costs but also provide some gains. Inventory and cash holdings are typically considered substitutes in operations and in generating liquidity. In earlier studies it has been implied that inventory and cash holdings can be complementary assets, but the authors would like to highlight the importance of taking into account the broad definition of cash, including not only cash and cash equivalents, but the components of trade credit as well.

Limitations and future research

The presented framework provides a preliminary perspective on working capital models in the value chains. In this study, the value chains only represented manufacturing industries. Further research should attempt to complement and validate the framework with data from different types of value chains, e.g. including service companies. This could raise different issues and working capital models to be considered in the framework. The financial wealth of companies is based on several aspects: growth, profitability, liquidity, and solvency. The concept of a working capital model and the presented framework take a stand on the liquidity positions of the company, but do not reveal the well-being of the company in terms of growth, profitability and solvency. Future studies should find ways to implement these dimensions in the framework as well in order to evaluate the holistic financial positions in the value chain. This information could be further elaborated to determine the most optimal working capital management strategy for the value chain.

Summary

This paper studies working capital management in paper and board companies. The paper combines the financial analysis of working capital components and case study approach. The case company, Stora Enso, has been able to reduce its working capital by systematical strategic management through the organization, but working capital issues are still considered case by case. The financial figures show that the most effective action in reducing working capital in the past years has been factoring. The reduction of working capital has also been related to the structural changes and savings programs in the forest industry. Trust and transparency are the biggest challenges in moving towards collaborative working capital management at the value chain level.

Keywords: Working capital management, Forest industry, Financial supply chain management
Submission category: Working paper

Introduction

The forest industry has faced challenges during the current millennium. The financial crisis in 2008 hit the industry and caused difficulties for the companies, and digitalization and decreased paper demand has led to remarkable structural changes in the industry. Cutting down paper production and the introduction of new products related to construction, furnishing, bio energy and renewable materials have given an upturn for the field. This paper concerns operational working capital management in the forest industry. The forest industry is characterized by its capital-intensive nature, and thus, broad interest is directed to the management of long-term assets. However, previous studies have shown that the industry also ties up short-term assets and has potential to release working capital from the operations of the value chain (Pirttilä et al., 2014), which would have a positive effect on relative profitability (Viskari, Pirttilä and Kärri, 2011).

Recently, many studies regarding working capital management have highlighted the need for collaborative working capital management in the value chain (e.g. Hofmann and Kotzab, 2010; Grosse-Ruyken, Wagner and Jönke, 2011; Huff and Rogers, 2015) and proposed tools and models to support this target (e.g. Protopapppa-Sieke and Seifert, 2010; Viskari and Kärri, 2012; Wuttke et al., 2016). However, the practical challenges of working capital management inside a company have not been discussed widely – let alone the value chain and the collaborative perspective. The objective of the study is to analyze working capital management in the paper and board companies, and to gain understanding of the current state and challenges regarding intra- and inter-organizational working capital management in the focal stage of the forest industry value chain. The research questions of the paper are: How have the paper and board companies managed their working capital in the years 2013–2016? How does an

individual company see their working capital management and possibilities for collaboration in the value chain?

Literature Review

Working capital management concerns several functions within a company. Consisting of the management of inventories, accounts receivable and accounts payable, working capital management bridges inbound material activities with suppliers, production operations within a company, and outbound sales activities with customers (Farris and Hutchison 2003). Thus, within a company it is affected by the decisions made by several functions, such as production, finance, purchasing and sales. Traditionally, companies have aimed at reducing their working capital to a minimum, as it has been found to increase profitability (e.g. Deloof 2003; Enqvist, Graham and Nikkinen, 2014; Singh, Kumar and Colombage, 2017) and decrease financing costs (de Almeida and Eid Jr., 2014). However, recent studies have suggested that instead of aiming at minimum working capital, companies should find their optimal level of working capital, which maximizes their profitability. The results of the studies have shown that moving away from the optimal level by releasing or tying up more working capital deteriorates profitability. (Baños-Caballero, García-Teruel and Martínez-Solano, 2012; Aktas, Croci and Petmezar, 2015; Pais and Gama 2015)

During the last decade, research on working capital management has increased. Several studies have taken the supply chain perspective to working capital in order to ensure fluent financial flows through the chain (e.g. Hofmann and Kotzab 2010; Wuttke et al., 2013; Huff and Rogers 2015). In this emerging research field of financial supply chain management, studies have separated into two, slightly different areas, i.e. finance and supply chain oriented views (Gelsomino et al. 2016). Whereas the latter one focuses on collaboration in working capital management among the supply chain actors, the finance oriented view focuses on the financial solutions provided by external financial institutions. These solutions include e.g. dynamic discounting, factoring, and reverse factoring (Polak, Sirpal and Hamdan, 2012), of which the latter has gained the most interest among the supply chain finance researchers, and is even used as a synonym for supply chain finance (Grüter and Wuttke 2017). While traditional factoring is based on a firm independently selling their accounts receivable to a factor for immediate cash reception (Klapper 2006) and reducing the tied-up working capital of a firm by shortening the cycle time of accounts receivable, reverse factoring is initiated by the buying company to provide the supplier access to cash on buyers' credit rating while the buyer is able to extend its cycle time of accounts payable (Grüter and Wuttke 2017). The benefit of reverse factoring is the ability to reduce the cost of trade credit, and it is typically considered a win-win situation (Iacono, Reindorp and Dellaert 2015). In both arrangements, the financial institution benefits in terms of the interest of the loan as well as the service fee.

Some earlier studies have studied working capital management from the perspective of the forest industry. Pirttilä, Viskari and Kärri (2010) analyzed the cycle times of working capital in the value chain of 44 companies in the years 2004–2008. The results showed that the value chain ties up working capital: the cycle time of working capital (CCC) was positive in each stage of the value chain. In their study, the value chain was divided into three parts: the focal stage in the middle of the value chain was pulp and paper, while the upstream part of the chain was formed by three stages and the downstream by four stages. The results showed that the CCC was longest in the upstream, while it shortened on the way towards downstream. According to Pirttilä et al. (2014), the average CCC of the years 2006–2010 in the pulp and paper industry was roughly 60 days, which is longer than in the ICT industry (40 days) but shorter than in the automotive industry (70 days), and the differences are due to the cycle time

of inventories (DIO). In the value chain of the pulp and paper industry, the DIO was on average around 40 days. In the pulp and paper industry, the inventories and accounts receivable form approximately 20% of the total assets, which is equivalent to the share in the ICT industry (Pirttilä et al., 2014). The findings by Viskari, Pirttilä and Kärri (2011) indicate that companies in the value chain of the pulp and paper industry can improve their profitability by managing the components of working capital together.

As discussed above, working capital management has gained interest among academic researchers. The scholars have widely emphasized the collaborative perspective to working capital management in the supply chains and introduced innovative solutions to enhance the financial flows along the chain. However, working capital management is a complex issue and thus a challenging task even within a company, not to mention the even larger construct of a supply chain. Studies on the practical challenges of working capital management in companies and supply chains have been limited. In addition, previous studies on working capital management in the context of the pulp and paper industry concerned a time period when the industry was facing challenges for example due to the financial crisis. No studies have considered working capital management in the forest industry in recent years, when the impact of the structural change of the industry might have affected working capital management as well.

Research design

Research methods

This study contains aspects of both quantitative and qualitative research. First, financial value chain analysis (Lind et al., 2012) is conducted in one value chain stage with quantitative data collected from the financial statements of six paper and board producers for the period 2013–2016. The method is a seven-step process for analyzing the financial data in the value chain context, and it can be used to analyze financial phenomena in the value chain or in a certain value chain stage. In this study, we have applied the method in the paper and board stage of the value chain of the forest industry. The purpose of the analysis is to observe the competitive environment in terms of working capital by analyzing the current state of the working capital management of the companies. Also, the development of the cycle times of working capital during the observation period and in comparison to previous studies is analyzed. In addition to cycle times, we observe the working capital models of the companies and their working capital positions against each other in the WCM matrix (Lind, Monto and Kärri, 2017). In the second part of the study, a case study approach is applied. The case study is based on a semi-structured interview conducted in a case company, which was selected on the basis of the results of the financial analysis. The results of the financial value chain analysis indicated that the case company had managed it working capital most efficiently, and systematically shortened the cycle times during the observation period. The case study deepens the analysis of financial figures by complementing and providing information behind the quantitative data.

The sample of the study consists of six companies operating as paper and board producers in the forest industry. The companies were selected by following the approach presented in the paper by Pirttilä et al. (2014), where working capital management in the value chain of the pulp and paper industry was studied. In this study, we focus on the paper and board stage of the value chain. Six companies providing similar products were selected from the study of Pirttilä et al. (ibid.). The companies also operate mostly in the same geographic area (i.e. Northern Europe).

The operational working capital, consisting of inventories, accounts receivable, and accounts payable, is measured by cycle times in this study. The cycle time for working capital, i.e. cash conversion cycle (CCC), is calculated as follows:

$$CCC = DIO + DSO - DPO = \frac{Inventories}{Sales} \times 365 + \frac{Accounts\ receivable}{Sales} \times 365 - \frac{Accounts\ payable}{Sales} \times 365$$

In addition to CCC, DIO, DSO and DPO, we also considered the DSO-DPO relation, i.e. net trade credit (Nadiri, 1969), in the analysis of cycle times. This variable describes the difference between payment terms towards suppliers and customers.

Results

Cycle time analysis within paper and board companies

The cycle times of working capital and its components were calculated for each year of the 2013–2016 period. Figure 1 shows the cycle times, the average values and the change in each component from 2013 to 2016.

The results show that paper and board companies have different working capital levels. The CCC varies from the average of 44 days (Stora Enso and International Paper) to 77 days (Holmen). In other words, Holmen ties up working capital over one month longer than Stora Enso. The difference between these companies results mainly from inventories, but the DSO-DPO is also one week longer at Holmen than it is at Stora Enso. When looking at the development of the CCC during the observation period, the results show that despite the same average CCC, the cycle times of Stora Enso indicate a shortening trend, whereas the CCC of International Paper has lengthened. Altogether four companies have shortened their CCC mainly due to changes in the DSO-DPO relation. However, while Stora Enso has made the change by decreasing their DSO, the other three companies have increased their DPO. This indicates that the companies have used different working capital strategies. The results of Stora Enso is partially caused by the use of factoring services, which has been announced in their annual reports, in addition to tightening up their payment terms with the customers. The other three companies may not have been that keen on factoring, but they have been able to extend the cycle times of accounts payables for over 20 days at best (Metsä Group). Usually this kind of change is done by negotiating longer payment terms with the suppliers. It is also possible that reverse factoring has been used to stretch the DPO. When compared to a previous study in the forest industry (Pirttilä et al., 2010), the results show that four companies have a CCC shorter than the average CCC (62 days) of the pulp and paper stage. The DIOs are on a similar level in all companies except for Holmen, which has the longest DIO of the sample. The other companies have fairly similar levels of inventories to the findings by Pirttilä et al. (2010), where the average DIO of the pulp and paper stage was 45 days.

Figure 1. Cycle times of working capital in paper and board companies in 2013–2016.

Figure 2 shows the working capital models of the companies consisting of the material and financial flows of working capital, i.e. DIO and DSO-DPO. In this analysis, the average figures for the observation period were used. The figure shows that companies have applied different working capital models. Three of the companies, Stora Enso, Billerud Korsnäs and Metsä Group, are relatively close to each other with similar inventory levels. They also have a similar net trade credit. However, Stora Enso is the only company in this research sample having a longer DPO than DSO. Holmen stands out with larger inventories, whereas IP has managed its inventory in the most efficient way. The working capital model of UPM is relatively far from the other companies. Its DIO is not long, but the DSO-DPO is clearly longer than in the other companies. The analysis shows that even when operating within the same value chain stage, companies have applied different working capital models.

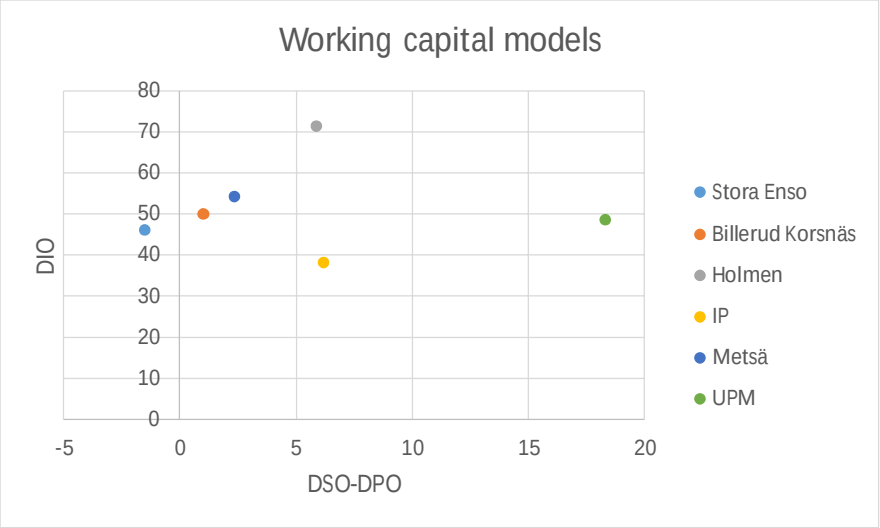

Figure 2. Working capital models of paper and board producers.

The results of the above analyses clearly showed that the importance of effective working capital management has been recognized in the companies. Most of the sample companies have

reduced their working capital remarkably during the four-year observation period. The results show that the DIO has remained on a fairly similar level. This may indicate that in the business of paper and board producers, certain inventories are required and they may have already reduced them to the optimal level. The reduction of working capital was done by adjusting the components of the financial flow, DSO and/or DPO.

Case Stora Enso

Working capital management in the company

The second part of the study is based on a semi-structural interview of the representative of the case company. The case company was selected on the basis of the results from the cycle time analysis. Stora Enso was an attractive target for a case study for two reasons. First, it had the shortest CCC of the sample companies, and second, the results indicated that the company has target-oriented and systematical working capital management. Thus, it was expected that an interview-based case study could deepen the results of this research and provide additional understanding of working capital management in the forest industry. In addition to the interview, the annual reports of the company have been reviewed and used to describe the working capital management of the company.

The interviewee had a leading position in one of the divisions of the case company, and has 15 years of experience from different functions within the company, including controlling, business development and supply chain. The interviewed person was selected through recommendations from other leaders in the company. The interview was conducted via Skype. Before the interview, the results of the numerical analysis of the cycle times studied in the first part as well as the cycle times of selected customers and suppliers were shared with the person. The results were also gone through at the beginning of the interview. The semi-structural interview focused on the present working capital management practices within the company as well as in the value chain.

The case company has performed systematic strategic work to decrease its working capital for over a decade now. This information is provided in the financial statements as well. The results of the analysis show that the company has succeeded in making its working capital management more effective: their working capital has been reduced remarkably during the last years. Within the company, this has required systematic leadership and management through target setting towards less tied-up working capital. The interviewee highlighted that these kinds of changes in the cycle times do not happen by accident. The reasons for aggressive working capital management and the reduction of working capital comes from the desired return of capital to the investors. Working capital can be affected faster than other items in the balance sheet in a capital intensive industry. There is constant pressure on both profit and the balance sheet. Operational working capital has been a key measure at different organizational levels. Managers responsible for the profit/loss have also targets related to working capital. It should also be acknowledged that the reduction of working capital is related to the structural change of the forest industry, including savings programs and decreasing the production of paper.

In the case company, working capital management is not separated from other financial results. The person responsible for the result is also responsible for the operational working capital. This way, sub-optimization is prevented. The responsibility and targets are implemented into all levels of the company from group to divisions and further to mill units. This way working capital is also taken into account in large investment decisions. The key question in business is: what is the optimal balance sheet that can be had without damaging the business and customer relations? In practice this is considered case by case. There is no other systematic

process to manage working capital in every decision, relation or unit. In the target setting, working capital is typically compared to sales. The key measure is relative, but cycle times (days) are not often used outside of inventory management, where the lead time is a common measure and followed already because of customer service.

Optimizing working capital is challenging, however. It simply cannot be minimized itself. The connection between the ability to make profit and working capital needs to be acknowledged. As the interviewed manager referred: "The best way to reduce working capital is to end the production and sales". By this, the interviewee highlighted the trade-offs in the management of working capital. The biggest challenge is to identify and consider the connection between the optimization of working capital and for example customer service, production efficiency, and production reliability (spare parts). Trade-offs between inventory levels and lead times, small receivables and cost of factoring, as well as long payment times and cash discounts are considered case by case on a daily basis. For example, when changing the service to a customer, it is considered what it requires from inventories and what is the effect of the change to the profits: are the consequences worth the increased working capital? There is still a long way for the holistic view and systematic process to do these kinds of assessments through all businesses and divisions.

Inter-organizational working capital management in the value chain
Even if largely emphasized in academic literature on working capital management and financial supply chains, inter-organizational working capital management is still quite new an approach. The case company faces a lot of challenges related to working capital collaboration. Working capital components, inventories and trade credit, are open in negotiations and can be settled case by case, but it is still far from actual collaboration. Still, the cycle times of trade credit and their development in the case company was seen as information that should not be shared with the suppliers and customers, even though the data is publicly available to anyone.

Some supply chain finance tools have been used in the case company. The clear major action that Stora Enso has taken in order to reduce working capital is factoring, selling their receivables to a third party that releases working capital and shortens the cycle time of accounts receivable. VMI inventory settlements are one example of collaborative working capital management actions that have been done with the customers. It has increased the working capital of the case company but, at the same time, the material circulates faster and the working capital of the customer is reduced, and thus working capital is released from the value chain.

Collaboration in working capital management through the value chain is challenging. It is a question of transparency and trust. The value chain structure prevents total transparency towards the end customers. Converters and merchants between Stora Enso and the final customers try to hold their positions in the value chain and prevent transparency. It is also a question of power in the value chain. The fight for the power in the value chain is strong and it makes the collaboration harder. This may also slow down new innovations and services regarding the optimization of working capital in the value chain.

Discussion and conclusions
A single company has limited options to reduce its working capital. The cycle times of trade credit are affected by the credit terms provided by the suppliers as well as the payment practices by the customers. The fact stands up for the value chain perspective of working capital. Factoring, i.e. selling accounts receivables to a third party in order to meet the immediate needs of cash, is an option that enables a company to affect its cycle time of accounts receivable, but

the service has its costs as well. Could it be a more sustainable option for an industry to collectively shorten their payment terms? One company cannot dramatically change the established payment practices within the value chain, and individually made actions regarding working capital management are slow. Which actors in the value chain are the most powerful ones that could lead the credit terms and working capital management to a new, more efficient era? An interesting issue arising from the interview was the sensitivity regarding the cycle times of trade credit components, DSO and DPO. The cycle times are linked with payment terms, and even though the balance sheets are publicly available to anyone, it was considered as information that should not be shared with the value chain partners. Do the companies not use this kind of data in their negotiations with suppliers and customers? Would this kind of data have an impact on the negotiations of payment terms?

Managing working capital is about seeking the correct balance between the optimization of cycle times and costs. In addition, there is a trade-off concerning sufficient material availability to fulfill the customer needs as well as sales increase via more generous payment terms. Working capital management is a complex issue even within one company, and responsibility for different working capital components is divided between different functions within the firm. Is value chain wide collaboration, suggested by several researchers, still a distant objective which works in theory, but, in practice, is too modern and complicated an idea to take into account? It seems to be a question of trust and power.

This paper concerned working capital management in paper and board companies and sought for an understanding on the practical challenges regarding intra- and inter-organizational working capital management. The results of the analysis of cycle times of working capital were complemented by conducting an interview in a case company. The findings showed that working capital has been reduced in the case company as well as in few other paper and board producers. This has been done by adjusting payment terms. In the case company, the reduction of working capital has been a strategic action, and factoring has been used to shorten the cycle time of accounts receivable. Moreover, the reduction of working capital is linked with the structural change of the forest industry. This working paper serves as a starting point for new studies regarding working capital management and financial supply chains, and provides several directions for further research. First, more interviews could be conducted in order to form a comprehensive picture of working capital management and its role in the case company. Second, the analysis of the cycle times of working capital in the stage of paper and board producers showed that there have been remarkable changes in working capital during the last years. It would be interesting to replicate the analysis in the total value chain of the forest industry to analyze current working capital management in comparison to studies by Pirttilä et al. (2010, 2014). Third, combining the numerical financial value chain analysis with interviews in the value chain could provide interesting information about how inter-organizational working capital management is seen at different parts of the value chain, and how the challenges regarding intra-organizational working capital differ from stage to stage.

Summary
This study aims at improving inter-organizational working capital (WC) management by developing a solution for managing the financial flows in supply chains. The paper presents the current state of the cycle times of financial flows and proposes a model for WC optimization in the supply chain via payment term adjustments. The model is tested with seven scenarios, which show that remarkable amounts of WC could be released by adjusting and harmonizing the payment terms in the supply chain. The introduced model provides a novel perspective on collaborative WC management in the supply chain by enabling win-win situations with a unique incentive system. The paper provides practical support for the optimization of WC at the supply chain level.
Keywords: Digitalization in purchasing, Working capital management, Financial supply chain management
Submission category: Working paper

Introduction and background

Financial issues and the management of working capital (WC) in the supply chain context have gained increasing attention in recent years, and the concept of financial supply chain management has brought the financial flow into the definition of supply chain (e.g. Wuttke, Blome and Henke, 2013). Companies experience pressure to extend their payment terms towards suppliers in order to release cash to be used for strategic investments and growth. At the most, payment terms tie up WC for 90 or even 120 days. For this period, many suppliers are forced to turn towards external funding sources in order to cover the expenses of their operations, which increases their financing costs. However, according to previous research (e.g. Kroes and Manikas, 2014), the increase of accounts payable at the expense of suppliers benefits the buying company only in the short term. In this study, our aim is to provide an alternative for the payment term extensions of individual companies by introducing a model for collaborative payment term adjustment in the supply chain in order to achieve a win-win situation and release WC from the supply chain for more productive use.

Supply chain finance solutions (e.g. reverse factoring) aim at win-win situations for buyers, suppliers and financial institutions (Liebl, Hartmann and Feisel, 2016). In reverse factoring, a buyer provides the supplier an access to cash on the buyer's credit rating, while the buyer benefits from the reduced WC by extending the cycle time of accounts payable without affecting the cycle time of the accounts receivable of the supplier (Grüter and Wuttke, 2017). The financial institutions benefit in terms of interest rate and service fee. But what if the companies collaborated to release WC from the supply chain without financial institutions? Would it be possible to find a win-win solution that benefits all supply chain partners? In this paper, we study collaborative WC management, consisting of the management of inventories and trade credit, i.e. accounts receivable and accounts payable. Our hypothesis is that by

adjusting and harmonizing payment terms, WC can be released from the supply chain in a way that all its members benefit. The objective of the paper is to develop and test the model for releasing WC through payment term adjustments. The two research questions of the study are as follows: 1) How could the optimization and standardization of payment terms be accomplished in the supply chain? 2) How do the adjustment and standardization of payment terms affect the WC in the supply chain?

The model is tested with scenarios in the context of an automotive supply chain. Previous research on WC management in the automotive industry has shown that the automotive companies have potential to release WC (Lind et al., 2012; Brandenburg, 2016). The results have shown that tightened payment terms required by the suppliers affected the ones provided for customers (Lind et al., 2012). The effect was visible throughout the value chain, as the changes in the cycle times of accounts receivable and accounts payable offset each other. Viskari et al. (2012) observed the connection between WC management and profitability in the automotive industry. Their results showed that a radical reduction in payment terms would improve the profitability of the whole value chain the most. This would require collaborative actions with the value chain partners, which has been emphasized by several studies (e.g. Randall and Farris, 2009; Viskari and Kärri, 2012), but the results of Vázquez, Sartal and Lozano-Lozano (2016) showed that WC in the automotive sector is not managed in a collaborative way. Even if the academic studies have reported benefits of inter-organizational WC management, the realization of such collaboration in practice is not a simple task. One major barrier in this is trust between the supply chain partners. Payment terms are negotiation issues between the companies, and they are not visible nor controlled at the supply chain level.

Digitalization provides opportunities for more efficient processes and cost savings in the supply chains. In FSCM, significant potential lies in the possibility of transparent and real-time information. Sharing accurate information in the supply chain, setting targets for WC management at the supply chain level, and monitoring the realized cycle times in real-time, are ways by which trust between the supply chain partners could be enhanced and tied-up WC in the supply chain released (see Figure 1). This would improve the overall efficiency of the financial supply chain.

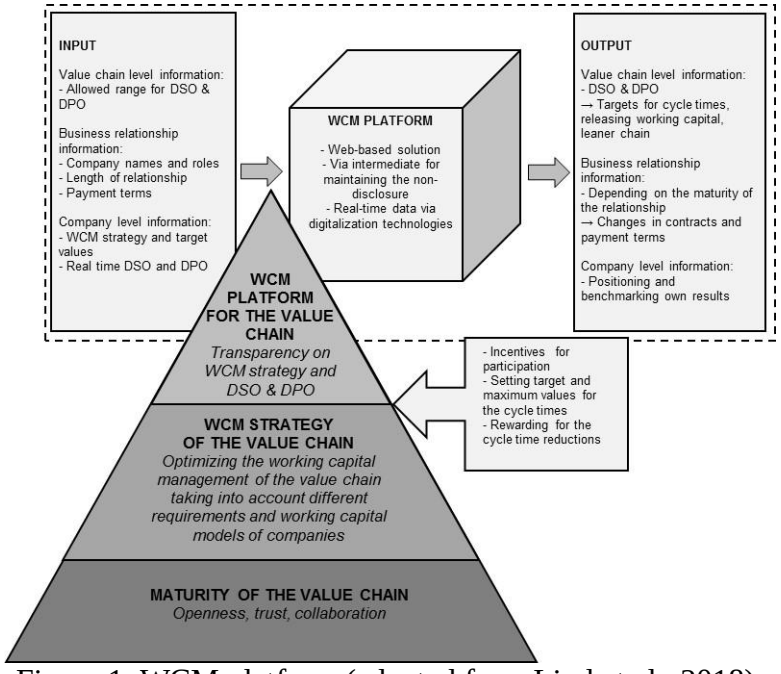

Figure 1. WCM platform (adapted from Lind et al., 2018).

Figure 1 describes the framework of this study. The figure is adapted from the study of Lind et al. (2018) according to the scope of this study and only considers the trade credit components of WC. The purpose of the WCM platform is to combine the WC data from the supply chain actors, and provide information for monitoring and managing inter-organizational WC. In this study, we study the potential benefits gained by applying the WCM platform in the supply chain.

The paper is structured as follows. The first section provided an introduction and background for the topic of the study, including a review of previous research and the objectives and research questions of the paper. The next section represents the data, measures and methods of the study. It is followed by a section introducing the model for payment term adjustment in the supply chain context. In the results section, the current state of the cycle times of WC in the sample companies is presented, and then this information is used as a basis for seven scenarios, which are used to test the model and to find the most optimal payment term configuration for the automotive supply chain. The final section provides the discussion, conclusions and objectives for further research.

Data, measures and methods

The effects of the optimization and standardization of payment terms is analyzed in the context of an automotive supply chain. The sample of the study contains 35 companies, and it describes the supply chain of the automotive industry consisting of four consecutive stages from refined raw material suppliers via component and system suppliers to car manufacturers. Each stage is represented by 4–16 companies. The sample companies were selected by following the approach by the study of Lind et al. (2012). The structure and the companies of the sample supply chain are provided in the results section.

The data for the analysis was collected from the official consolidated financial statements of the years 2011–2015. The values for inventories, accounts receivable, and accounts payable, i.e. the components of operational WC, were gathered and used to calculate the cycle times. Additionally, information on the actual shares of companies' sales concerning the automotive industry was gathered by reviewing annual reports and company websites. For most companies, exact or estimated shares were found from the official sources. For the remaining companies, the typical share of the stage was used in the analysis. Only car manufacturers were considered operating 100% in the automotive industry.

In this study, WC is measured by cycle times. We used the following formulas for the cycle times of WC (CCC) and its components:

$$CCC = DIO + DSO - DPO \quad (1)$$
$$DIO = Inventories/sales*365 \quad (2)$$
$$DSO = Accounts\ receivable / Sales * 365 \quad (3)$$
$$DPO = Accounts\ payable / Sales * 365 \quad (4)$$

In the analysis of the cycle times, average values of the observation period were used. This approach provides a more realistic view of the WC level of the companies by balancing the effects of possible exceptional years.

The analysis part of the study is twofold. First, the current state of the cycle times of WC in the supply chain is analyzed using the financial value chain analysis (Lind et al., 2012). This

analysis is used as a basis for the second part of the analysis, where scenarios are used to construct different possibilities for optimizing the WC of the supply chain with payment terms. This has been done by testing different values for the DSO and DPO in our model, and by analyzing their effects on the total WC of companies in regard to cycle times as well as monetary values. We present seven scenarios for the optimization of WC by modifying the trade credit components, i.e. DSO and DPO. The scenarios are introduced in the results section. The target of the payment term optimization in this paper is to find win-win solutions for all supply chain members. Therefore, sharing the benefits of the released WC is considered in the model.

Model for optimizing the financial flows of working capital in the supply chain

On the basis of the WCM platform (Lind et al., 2018), we developed a model which can be used to optimize the financial flows of WC in the supply chains by adjusting the cycle times of accounts receivable and accounts payable. The model is illustrated in Figure 2, and it describes the context in which the WCM platform can be used. The supply chain of the study has four stages that consist of companies operating in the same part of the chain. Except for car manufacturers, it is assumed that companies do not operate in the automotive industry only. Thus, the model considers the shares each company has with the supply chain partners. As described in Figure 2, the DPO of refined raw material suppliers as well as the DSO of car manufacturers are out of the scope of the model. This means that in this model, these components remain unchanged. The supply chain of this study cannot affect the cycle times of these WC components, as the suppliers of refined raw material suppliers as well as the customers of car manufacturers are not included in the study.

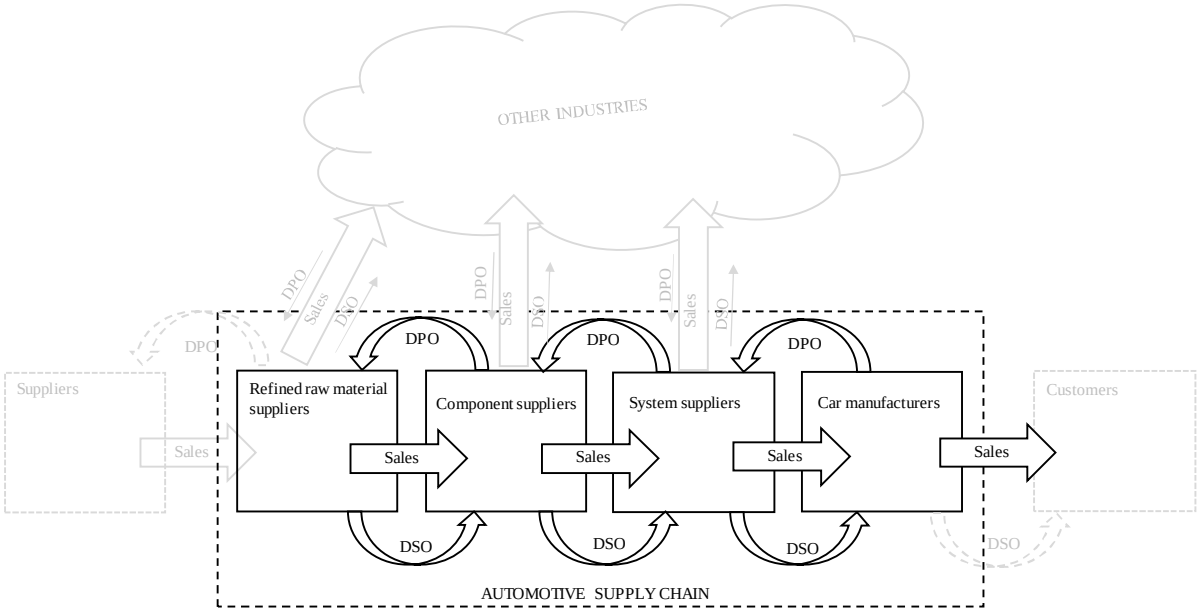

Figure 2. Model for optimizing the financial flows of WC.

When adjusting the DSO and DPO in this study, all companies within the stage will have the same DSO and DPO concerning the sales and purchases with other participants. In other words, the payment terms are harmonized in a way that all companies of the stage have the same payment terms in their business relationships with the companies of the previous stage, as well as with the companies of the following one. However, the payment terms may not be the same towards upstream and downstream. As the model represents the supply chain, the new DSO of

the suppliers defines and is equal to the new DPO of the customers, and vice versa. It is assumed that all supply chain partners participate in the optimization of the financial flows, and thus, new DSOs and DPOs can be set by the supply chain. The core idea of the model is to find a win-win situation by adjusting the DSOs and DPOs, ceteris paribus. However, with the restrictions concerning the harmonization of the cycle times within the stages, it is assumed that a solution in which every company would be able to "win", i.e. release WC, is not possible. Therefore, it was necessary to develop a settlement that also motivates these companies to participate in this supply chain wide payment term harmonization. In this study, we calculated a compensation for the companies whose WC increased. The compensation includes the amount of additional tied-up WC with a 15% interest. This is paid by the winning supply chain companies, who pay this in equal share (%) from their released WC.

Results

Current cycle times

Figure 3 shows the average figures for the observation period, and describes the current state of WC management in the sample companies. In addition to the cycle times, the table shows the average sales and WC of companies, as well as the exact or estimated share of the sales each company has in the automotive industry.

Stage 1: Refined raw material suppliers

	DIO	DSO	DPO	DSO-DPO	CCC	Sales (M€)	WC (M€)	Automotive share (%)
ArcelorMittal	81	20	53	-33	48	61 970	8 137	20 %
Dupont	80	61	50	11	92	26 012	6 528	20 %*

Figure 3. Current cycle times in the sample according to average figures from 2011–2015.

The results show that the beginning of the chain ties up relatively more WC, and the CCC gets shorter stage by stage towards downstream. However, when looking at the amount of WC in euros, the tied up WC of car manufacturers is remarkably higher due to the largest sales volumes. This means that when measured in euros, shortening the CCC by one day releases much more WC in the stage of car manufacturers than in the stage of component suppliers, for

example. A closer look at the trade credit components, DSO and DPO, reveals that the differences between the companies and within the stages are remarkable, varying from 12–84 days in the DSO and 20–76 days in the DPO. In most companies, the DSO is longer than the DPO, which indicates that the payment terms towards customers are usually longer than the ones towards suppliers. However, there are also 10 companies that have a negative DSO-DPO. The CCCs of these companies were also among the shortest in their stages, which indicates that they have been successful in their WC management. This kind of WC model is beneficial for the company itself, but not from the perspective of the supply chain as a long DPO is gained by stretching the DSO of the suppliers, and a short DSO requires fast payments from the customer. Thus, this WC model cannot be applied by every company in the supply chain.

Scenarios

Next, all scenarios and their results are introduced. All scenarios with adjusted DSO and DPO, their effect on the CCCs of companies, the amount of released WC, the amount of compensation paid or received by the company, as well as the eventual benefits of the payment term adjustment in euros, are shown in Appendix. Table 2 concludes the findings of the scenarios.

Table 2. Summary of the scenarios and findings.

Scenario 1: The least losers

The target of the scenario was to adjust the DSOs and DPOs by having as little companies increasing their WC as possible. The adjustment started from the upstream, where we selected 30 days as the new DSO for the automotive industry. This was seen as the best possible reasonable DSO value for the stage, as with this cycle time most companies release WC. The same logic was applied throughout the chain. The results show that Scenario 1 would release WC from the supply chain. Seven companies, all of them originally having a longer DPO than DSO, had to increase their WC.

Scenario 2: Same payment term through the chain

Scenario 2 also started from the upstream. The new DSO for refined raw material suppliers, 38 days, was based on the average DPO of these companies. The idea of the scenario was to test the consequences of the whole supply chain applying the same payment term. This scenario released less WC than the first one even if the number of losers was the same. The main reason for this was that the car manufacturers released less WC. From the perspective of the supply chain, it would be beneficial that the car manufacturers, who have the biggest sales volume, would be able to shorten their CCC.

Scenario 3: Happy upstream

Scenario 3 also started from the upstream. The aim of this scenario was to set new cycle times so that it would benefit companies in the upstream, but still keep realistic DSO and DPO values. Optimization was started by setting 35 days as the new DSO for the refined raw material suppliers. The results of the scenario showed that this option is not reasonable. The scenario released the least WC, and is not applicable, as the compensation to the losers was higher than the WC released by the winners.

Scenario 4: Happy downstream

Scenario 4 is the opposite of Scenario 3. As shown by the results of Scenarios 1–3, the supply chain benefits in total if the car manufacturers are able to release WC. Therefore, the adjustment was started from the downstream. The new DPO of the car manufacturers was set to 35 days, which was seen as a realistic option. In this scenario, only six companies had to increase their WC, which was the lowest number so far. However, the amount of released WC was lower than in Scenarios 1 and 2. Even if the payment term adjustments were started from the car manufacturers, they were moderate, and thus did not lead to a remarkable release of WC within the stage. In addition, the compensation required by company Renault was remarkably higher than in Scenarios 1 and 2.

Scenario 5: Long payment terms

In Scenario 5, long payment terms starting from the downstream were tested. The new DPO of the car manufacturers was 45 days, which led to remarkable reductions in the CCC for all companies in the stage except for Renault. This scenario released explicitly more WC than the previous ones. However, the number of losers was 10, which is the highest of all scenarios. This scenario causes increases in WC especially for the companies in the upstream.

Scenario 6: Short payment terms

Scenario 6 also started from the downstream. In this scenario, shorter DSOs and DPOs were tested. The DPO of car manufacturers was set to 35 days according to the second highest DPO of the stage. This scenario led to the second lowest WC release of the study. This resulted from the remarkable compensations required by the companies in the downstream. However, unlike Scenario 3, all companies gained benefits with this scenario, but the winners had to pay over 56% of their released WC to the losers.

Scenario 7: Bringing DSO and DPO closer together

The target of Scenario 7 was to make the difference between the DSO and the DPO shorter in each stage. The adjustment of the cycle times was started from the upstream by setting the new DSO to 45 days. With this value, the CCCs of most companies in the stage remain on the same level or reduce slightly. This scenario differs from the others by focusing on the relation between the DSO and DPO instead of concentrating on the components individually. The results show that this scenario was the most beneficial for the supply chain. It released over 32 billion euro of WC in total, and only six companies increased their WC. Also, the percentage of the released WC paid by the winners was the lowest.

Discussion and conclusions

In this paper, we presented a model for WC optimization through payment term adjustments. This model provides a solution for accomplishing the optimization and standardization of payment terms in the supply chain. The analysis of the current cycle times of WC showed that the cycle times of WC were longer in the upstream. However, shortening the cycle time of WC by one day releases more WC in the downstream due to a higher sales volume. The results of the scenario analysis showed that win-win situations (i.e. companies gaining financial benefits from the released WC of the supply chain) can be achieved by collaborating in terms of payment term adjustment and standardization within the supply chain. However, this was not possible without a compensation system that was included in our model. The most beneficial option was to bring the DSO and DPO closer together in all stages of the supply chain. This would release a remarkable amount of WC.

This study takes an initial step towards a practical solution for monitoring the financial flows in supply chains. By using the new technologies enabled by digitalization, a tool for managing WC in the supply chains could be developed. However, it should be carefully designed to ensure a certain anonymity and security within the system. Even if the system could provide visibility and transparency to the financial flows in the supply chain, it should be planned in a way that participants can trust the system as well as each other. Also, the legal aspects need to be considered when making a more detailed requirement specification for the system. Participants are required to enter fairly sensitive data into the system, such as payment terms and sales and purchase volumes with other participants, which may be a legal issue as well.

How should the implementation of such a system, as described in this paper, be accomplished? What would be the best way to have as many participants from the supply chain as possible? Of course, it depends on the position of the initiator. In the first tier (i.e. system suppliers), one possibility is to start the negotiations with one's own suppliers and their suppliers. Once they agree to participate, negotiations with one car manufacturer could be started, and the car manufacturer, in turn, would use its negotiation power to involve other system suppliers. The system could also be tested with a completely new business and new supply chain. As they would not have established practices that require changes, they could directly adapt to the collaborative WC management practices, and serve as a demonstration of the benefits of the system to others.

Future research

As a working paper, the paper still has several limitations which offer avenues for future research. The authors suggest future research regarding the development of the solution to be conducted in the following areas: 1) Supply chain visibility as a prerequisite for the tool implementation, 2) The limiting factors of such a WC management platform, e.g. legal restrictions or frame conditions, 3) Testing and further development of the application with pilot companies, and 4) A common WC management strategy for the supply chains the pilot companies are elements of, including motivation for participation. Additionally, it should be noted that WC management is not only about the management of trade credit, but inventory management is also an essential element in it. The following phase in the planning of such a system is to ensure that the corresponding material flow keeps up with the new, more efficient financial flow.

Abstract
The objective of this study is to examine whether supplier orientation and supply management innovativeness have positive impacts on a company's overall sustainability performance. This empirical study is based on a survey that targeted large- and medium-sized manufacturing companies in Finland. The results show that innovativeness in supply management considerably influences a firm's overall sustainability performance. Moreover, it is confirmed that supplier orientation positively relates to sustainability performance. The benefits of strategic supplier orientation and innovativeness of supply management are realized in sustainability performance directly. Supply management is a function where new ideas with the aim to influence supply markets are presented. For firm management recognizing this two-fold impact of supply management on sustainability performance is essential.

Keywords: Innovativeness, Supplier orientation, Sustainability performance

The impact of supply management innovativeness and supplier orientation on a firm's sustainability performance

Abstract
The objective of this study is to examine whether supplier orientation and supply management innovativeness have positive impacts on a company's overall sustainability performance. This empirical study is based on a survey that targeted large- and medium-sized manufacturing companies in Finland. The results show that innovativeness in supply management considerably influences a firm's overall sustainability performance. Moreover, it is confirmed that supplier orientation positively relates to sustainability performance. The benefits of strategic supplier orientation and innovativeness of supply management are realized in sustainability performance directly. Supply management is a function where new ideas with the aim to influence supply markets are presented. For firm management recognizing this two-fold impact of supply management on sustainability performance is essential.

Keywords: sustainability, innovativeness, supply management, supplier orientation, purchasing, supply chain

Introduction

In recent years, the movement towards innovative sustainable solutions and the adoption of cleaner technologies among companies has been evident. According to Eurostat's (2017) most recent innovation statistics, 52.7% of innovative companies in European Union (EU) member states introduced innovations with environmental benefits for the companies themselves or their customers. Hence, it seems that firms aim to improve their sustainability performance through innovations. Porter and van der Linde (1995) state that the sustainability requirements of the customers and other stakeholders force companies to innovate, which creates new business opportunities. Coping with sustainability requirements and creating innovations are closely related concepts (Eccles and Serafeim, 2013), and sustainability has been regarded as a driving force that increases the innovativeness of firms and supply chains (Porter and van der Linde, 1995; Nidomolu et al., 2009). Innovativeness is perceived as a prerequisite to the adoption of sustainability practices (Pagell and Wu, 2009), and it increases the utilisation of sustainable processes in supply management (Gualandris and Kalchschmidt, 2014). The growing requirements of sustainability also enhance the innovativeness of the entire supplier network (Nidumolu, Prahalad and Rangaswami, 2009), and sustainable innovations arise from supply chains where suppliers aim to satisfy their customers' needs. Thus, innovativeness and sustainability form a self-feeding cycle because on one hand, organisations need innovation capabilities to exploit sustainability; on the other hand, sustainability drives organisations to innovate. Thus, to gain the business benefits of the investments in sustainability, a company needs to enhance its own innovation capability, as well as utilise the innovativeness of its suppliers.

Supply management operates in the intersection of a company and its suppliers; therefore, supply management's participation in early phases of innovations, especially in terms of sustainability, is important (Hallstedt, Thompson and Lindahl, 2013). According to Hollos, Blome and Foerstl (2012), a company can have a strategic orientation towards suppliers in its upstream supply chain, which considerably enhances supplier co-operation in sustainability matters. This

strategic supplier orientation of a firm and the integration of interfirm capabilities of buyers and suppliers can increase innovativeness in supply chains (Hollos et al., 2012). Suppliers' ability to provide sustainable solutions and the development of integrated solutions in supply chains may also generate value, in terms of both sustainability and successful businesses (Windahl and Lakemond, 2006). According to Pulles, Veldman and Schiele (2014), suppliers' professionalism, specialisation and collaborative attitude, together with the characteristics of buyer-supplier relationships, such as supplier development programmes and buyers' status as preferred customers, increase innovativeness. Moreover, research has shown examples of innovations achieved through collaboration and partnerships (Darnall, Jolley and Handfield, 2008), and intensive buyer-supplier collaboration promotes interfirm learning and innovative ideas (Sofka and Grimpe, 2010). Overall, cross-organisational integration is a critical issue that should be connected to innovations (Rizzi, Bartolozzi, Borghini and Frey, 2013).

However, the more deeply suppliers are integrated into product design, the less visible the innovation process becomes from the buyers' perspective (Petersen, Handfield and Ragatz, 2005). Bönte and Dienes (2013) argue that companies following a co-operation strategy do not have higher environmental innovation performance. Consequently, there are contradictions in scientific discussions on the effects of inter-organisational collaboration on innovations, sustainability and performance. The existing research examining the connections between innovativeness and sustainability is still rare and mainly at a conceptual level (Gualandris and Kalchschmidt, 2014). Therefore, more research is needed to clarify the possible links between these concepts. This study's objectives are to clarify the meaning of supply management innovativeness, examine how it may affect a firm's sustainability performance, as well as how a firm's supplier orientation may contribute to its sustainability performance. Consequently the main research question in this study is: *What is the effect of firm's supplier orientation and supply management innovativeness on firm's overall sustainability performance?* The links between the concepts and their possible influence on a company's sustainability performance are examined by utilising the survey data collected from 113 Finnish firms in several industries. In the following section, the concepts are clarified, and several hypotheses based on the existing literature are developed. The methodological section follows. Finally, the results are discussed, and the conclusions are presented.

Theoretical background and hypotheses

A firm's sustainability performance

The increased sustainability awareness of a firm and its stakeholders has induced the company owners and management to consider how to create value from sustainability and to do so in a viable manner. If a company can create value and generate profit by utilising sustainable processes in its supply chains, it will strive for feasible strategies and business benefits. According to Waddock and Graves (1997), corporate social performance is associated with financial performance. Companies with strong financial performance are more conscious about or have more financial resources to spend on resolving sustainability issues (Waddock and Graves, 1997). Accordingly, it is acknowledged that a firm's size may influence its adoption of sustainability practices (Zhu et al., 2008). Large firms with high brand equity more likely implement sustainability practices and collaborate within their respective industries and with nongovernmental organisations (Plambeck, Lee and Yatsko, 2011). However, it is difficult to overstep the boundaries of a firm and dictate the sustainability rules to suppliers in upstream supply

chains. Thus, powerful companies should be role models (Amaeshi, Osuji and Nnodim, 2008) and use their strengths to boost the capabilities of weaker parties in the supply chain through education and collaborative value creation.

Improvement of corporate environmental and social performance requires clear actions, such as formulating strategies and designing and developing systems of sustainable performance. (Epstein and Roy, 2001). According to Montiel (2008), the main body of the corporate social responsibility (CSR) and sustainability studies builds on social, economic and environmental elements. While there are arguments that these three elements are actually interdependent, the majority of the empirical studies treat these dimensions as independent components and concentrate on a particular component (Montiel, 2008). The connection between sustainability performance and financial performance has been found, but only environmental performance has a direct effect on financial performance (Wagner, 2010), whereas the impact of social performance is moderated by advertising intensity. Additionally, by being a first mover in the market in terms of creating sustainable business cases, a firm can enhance its market share and image (Paulraj, 2011).

Although sustainability performance measurement is an essential part of corporate performance management, it has received little research attention (Searcy, 2012; Schaltegger and Burritt, 2014). The traditional way to measure firm performance only by means of financial and economic factors prioritises profits over people and the planet (Elkington, 1998). In terms of sustainability performance, the actions of the upstream supply chain should also be counted (Montabon, Pagell and Wu, 2016). The role of supply management is to prevent or mitigate sustainability-related risks by applying supplier selection, control and purchasing practices that ensure a company's sustainability efforts. Thus, the success of a firm's sustainability highly depends on its supply management, and it has been found that supply management directly and positively affects a company's sustainability performance (Gualandris, Golini and Kalchschmidt, 2014).

Innovativeness in supply management

Innovation is a largely examined concept in many studies, as Crossan and Apaydin's (2010) comprehensive literature review points out. According to Damanpour (1996, p. 694), "innovation is conceived as a means of changing an organization, either as a response to changes in the external environment or as a preemptive action to influence the environment. Hence, innovation is here broadly defined to encompass a range of types, including new product or service, new process technology, new organization structure or administrative systems, or new plans or program pertaining to organization members". Baregheh, Rowley and Sambrook (2009, p. 1334) complement the definition to consider business and company success as a main driver of innovations by arguing that "innovation is the multi-stage process whereby organizations transform ideas into new/improved products, service or processes, in order to advance, compete and differentiate themselves successfully in their marketplace". Crossan and Apaydin (2010, p. 1155) summarise innovation "[as] both a process and an outcome". For example, the existence of innovation capability and resources in a company, the detection of a market opportunity, business environment uncertainty and changes that force firms to innovate are found to be the drivers of innovations (Grossan and Apaydin, 2010).

Innovativeness refers to a company's collective openness to new ideas embedded in the corporate culture (Hurley and Hult, 1998). The company's ability to produce or adapt to new innovations, with the aim of influencing the markets where it operates, reflects its level of corporate innovativeness (Garcia and Calantone, 2002). According to Calantone, Cavusgil and

Zhao (2002), a firm's innovativeness can be measured by the frequency of activities through which the company tries out new ideas, seeks novel operating procedures, develops its operations creatively and succeeds in being the first to market new products and services. Innovativeness as a company's intra-organisational capability has been found to be one of the key antecedents of business performance and competitive advantage (Burns and Stalker, 1961; Porter, 1990; Hult, Hurley and Knight, 2004; Prahalad and Krishnan, 2008). Hence, a company's ability to introduce innovations can determine its future success and survival. In line with the works of Hurley and Hult (1998), Calantone et al. (2002) and Carcia and Calantone (2002), *innovativeness in supply management* can be defined as purchasing professionals' collective ability to innovate and their openness to new ideas, with the aim of influencing supply markets.

Christmann (2000) states that innovative organisations will be leaders in sustainability. The differentiation of products and services through contributions to the reduction in the unsustainability or the increase in the sustainability of the economy and society requires product development, product or service system innovations and value chain redesigns, which are led by sustainability criteria (Schaltegger and Burritt, 2014). The implementation of sustainability practices often leads to increased process innovations, and the innovative behaviour of employees creates greater organisational support (Hollos et al., 2012). Pagell and Wu (2009) find that organisational capability to innovate is a precursor of successful and sustainable supply chain management. They add that managerial orientation is the other organisational attribute that is a precursor of sustainable supply chain management, which means that firms need to be proactive and committed to ensure sustainability in their actions.

According to Gualandris and Kalchscmidt (2014), innovativeness increases the utilisation of sustainable processes in supply management. Pagell and Wu (2009) state that innovativeness is a prerequisite of the adoption of sustainability practices. Van Bommel (2011) argues that the capability to design sustainability strategies and approaches depends on a company's innovation power and supply network. Based on these views, the first hypothesis is proposed:

H1. Innovativeness in supply management positively influences a firm's sustainability performance.

Supplier orientation

Relatively enduring patterns of strategic behaviour that actively align a firm with its environment can be understood as its strategic orientation (Miles and Snow, 2003). Many studies have shown that a firm that successfully pursues a specific orientation will demonstrate better performance (Ruekert, 1992; Baker and Sinkula, 1999; Langerak, 2001), and a strategic orientation has been considered a firm's competitive edge. Strategic orientation defines a company's interaction and fit of its strategic choices towards its external resources, environment, competitors and customers (Zhou and Li, 2010). Companies choosing a specific strategic orientation to enhance their competitive advantage and performance must have adequate capabilities to implement the strategy in practice.

Mentzer et al. (2001, p. 7) state that one of the core characteristics of the philosophy of supply chain management is "a strategic orientation toward cooperative efforts to synchronize and converge intrafirm and interfirm operational and strategic capabilities into a unified whole". Hollos et al. (2012, p. 2974) define the strategic orientation of supply management as "the function's integration in strategic planning, its knowledge of and contribution to corporate strategic goals and the visibility of its contribution to these goals". Shin, Collier and Wilson (2000, p. 318) describe

supply management orientation as involving "management efforts or philosophy necessary for creating an operating environment where the buyer and supplier interact in coordinated fashion". In line with these definitions, in this study, strategic orientation is regarded as *supplier orientation*, that is, a firm's effort to co-operate with its suppliers by aiming for a strategic fit regarding its choices of external resources in the upstream supply chain. Hence, supplier orientation refers to the organisational activity of managing supplier relationships to achieve the firm's goals, and it is considered one of the possible strategic orientations of a firm.

Shin et al. (2000) find that supply management orientation constitutes a long-term orientation to supplier relationships, supplier involvement in product development, a reduced number of suppliers, and a quality focus. Min and Mentzer (2004) and Miocevic and Crnjak-Karanovic (2012) state that credibility, benevolence, commitment, norms, compatibility and top management support comprise supply chain orientation. Hollos et al. (2012) include adaptation to changing business plans, long-range planning and profound knowledge in their measurement of supply management orientation. Moreover, a firm's strategic orientation towards purchasing and supply management has a positive impact on sustainable supplier co-operation (Hollos et al., 2012). The firm's supplier base largely defines the level of sustainability of both the firm and the entire supply chain (Grosvold, Hoejmose and Roehrich, 2014). Bai and Sarkis (2010) argue that commodity- and price-based supplier relationships are no longer acceptable to suppliers of critical materials or organisations seeking to introduce innovative supply management, especially when the focus is on sustainability concerns. Thus, collaborative buyer-supplier relationships and strategic orientation towards suppliers need to be connected to a company's sustainability strategy. Based on this argument, the second hypothesis is proposed:

H2. Supplier orientation positively influences a firm's sustainability performance.

Interaction effect of supply management innovativeness and supplier orientation on sustainability performance

Buyer-supplier collaboration and supplier involvement in product development projects are widely studied research streams (Hoegl and Wagner, 2005; van Echtelt, Wynstra, van Weele and Duysters, 2008). However, mixed results about their influence on company performance or the success of product development have been presented (Wynstra, van Weele and Weggeman, 2001). Azadegan and Dooley (2010) show that suppliers' innovativeness (as the capacity to develop and introduce new products and processes) is positively associated with the buyer's manufacturing performance. Companies are increasingly utilising external sources of innovation management; thus, knowledge is needed about which suppliers are able to contribute to the firms' innovativeness (Schiele, 2006). Collaboration with suppliers has also been found as one of the best ways to enhance the transparency of supply chains and to mitigate sustainability-related risks (Multaharju, Lintukangas, Hallikas and Kähkönen, 2017). Therefore, companies should recognise the innovation potential of their suppliers and aim for collaborative and long-term business relationships with them to create value for both and finally, for the end customer.

Innovations linked to supply management have been studied in terms of collaborative actions between buyers and suppliers, such as early supplier involvement (e.g., Petersen et al., 2005; Johnsen, 2009) and supplier orientation (Kähkönen, Lintukangas and Hallikas, 2015). Early supplier involvement more likely occurs in collaborative than in arm's-length relationships (Bidault, Despres and Butler, 1998), and trust in suppliers has been found to increase innovativeness in supply chains (Panayides and Lun, 2009). The organisations' ability to manage

these collaborative operations and knowledge further increases innovations (Soosay, Hyland and Ferrer, 2008). Firms' supply management needs to participate in early phases of innovations, especially in terms of sustainability (Hallstedt et al., 2013). Sustainability-related risks and opportunities have spurred sustainability-oriented innovations in an increasing number of industries and markets and have become major competitive drivers among companies (Schaltegger and Burritt, 2014). The impact of supply chain innovativeness on supply chain performance has also been found to be mediated by supply chain integration (Seo, Dinwoodie and Kwak, 2014). Thus, it seems that supply management innovativeness and supplier orientation might be intertwined, and it is reasonable to study possible interaction effects of these two concepts on sustainability performance. Moreover, according to Russo and Fouts (1997) and Pullman, Maloni and Carter (2009), it is difficult to define the causality and the relationship between intangible resources, such as sustainability, and performance outcomes. Therefore, the third hypothesis is proposed:

H3. There is an interaction effect of supplier orientation and supply management innovativeness on sustainability performance.

Figure 1 presents the hypothesised model of the study.

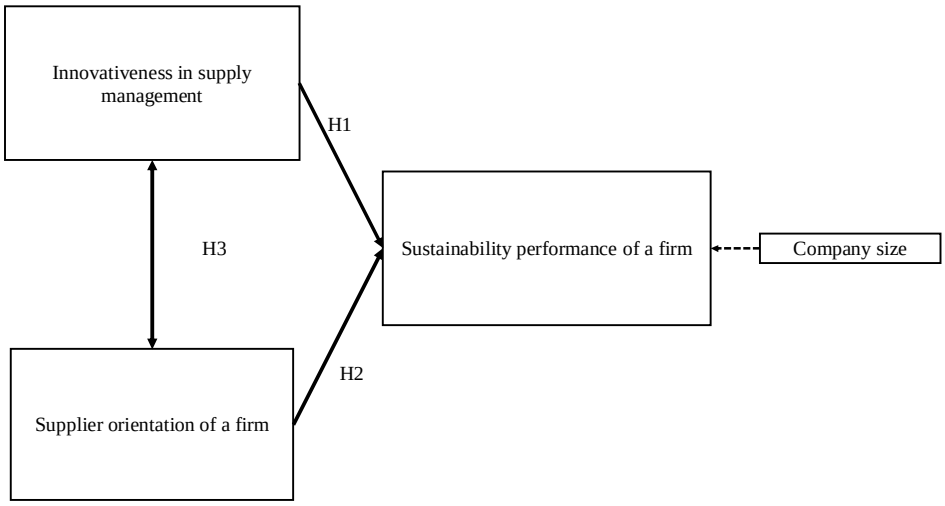

Figure 1. Research model.

Methodology

Data and sample

The objective of this study is to examine if supplier orientation and supply management innovativeness are connected to a company's overall sustainability performance. According to Creswell (2014), quantitative methods are the appropriate choices in empirical studies examining the relationships between concepts or the influence of drivers on an outcome. Therefore, a survey was designed to perform a quantitative analysis and to increase the generalisability of the results. The empirical study is based on a survey that targeted large- and medium-sized manufacturing and logistics companies in Finland. The choice of Finnish companies is justified because regarding investments in new technologies covering the 2012–2014 period, the share of novel sustainable innovations and technologies adopted in Finland's manufacturing industry was 71%, and the

service sector accounted for 50% (Official Statistics Finland, 2016). Moreover, the country's renewed innovation policy (Organisation for Economic Co-operation and Development, 2017) encourages Finnish companies to innovate in terms of sustainability by stating that coping with challenges in adapting to technological changes caused by sustainability, such as energy efficiency, water constraints, health issues and green growth, should become a permanent feature of firms' strategies. Hence, the Finnish context fits the research focus.

Firms with at least 30 million euros in operating capital, 100 employees and activities in Finland were extracted from the commercial AMADEUS (Bureau van Dijk) database. The sample consisted of 387 firms. All these companies were first contacted by phone to find the most suitable informants in the field of supply management, and the web link to the questionnaire was emailed to them. Reminder emails were sent to those who had not answered within two weeks. Finally, 113 filled-in questionnaires were received, with a response rate of 29.2% (113/387). However, the screening of the returned forms revealed two incomplete and non-usable questionnaires, which were removed from the data file, resulting in 111 usable responses for quantitative analysis. The non-response bias was assessed by comparing the early and the late respondents (Armstrong and Overton, 1977) in terms of industry, turnover and number of employees. Because no significant differences were found, it was concluded that non-response bias was not a concern in the data.

Of the respondents, 32% represented top management, 46% belonged to middle management, 4% occupied operative positions, 17% were experts in the field, and 1% held other positions. On average, the share of turnover expenses was 53%. Of all the purchases, 35% were manufactured abroad (11% of those came from low-cost countries) and on average, were sourced from 14 countries. The responses were grouped into six main industry categories, including construction; manufacturing of machinery, equipment, metal, non-metal, plastic and electronic products; chemical, paper and wood; logistics services; food; and other industries. Table 1 presents the basic information about the respondent companies.

Table 1. The sample's numerical data.

Industry	**N**	**Turnover (t€)**	**Employees**
Construction	23	176 521	458
Machinery, equipment and industrial manufacturing	39	388 969	1 696
Chemical, wood and paper	18	1 269 497	3 223
Logistics services	18	99 117	189
Food	4	613 046	1 371
Other	9	137 322	618
Total	111	428 404	1 344

Variables

Previous studies found that a company's size influenced its adaptation to sustainability practices (e.g., Zhu et al., 2008); therefore, the *firm's size* was included in the model as a control variable. The firm's size was measured by using the operating revenue of each respondent company. Logarithmic transformation was used to normalise the variable to meet the assumptions of regression analysis. The company's *sustainability performance* was assessed by asking the respondents to evaluate their current level of sustainability performance with six statements concerning reporting, organising, strategy and communication on 7-point Likert scale (from 1 = extremely low success to 7 = extremely high success). The *innovativeness in supply management*

measurement was based on the studies of Hurley and Hult (1998), Panayides and Lun (2009) and Seo et al. (2014). Six statements were provided regarding innovation capability in supply management, processes and operation models to collect ideas about supplier networks, participation in the company's innovation processes and coordination/facilitation of new ideas. To measure *supplier orientation*, the scale applied in the study of Kähkönen et al. (2015) was used. Table 2 shows the components, items and loadings.

Table 2. The items, loadings and reliability of the variables in this study.

Rotated Component Matrix	**1**	**2**	**3**
Supplier orientation (Kähkönen et al., 2015), α = 0.910			
Supplier collaboration is measured regularly.	0.822	0.118	0.180

Extraction method: principal component analysis
Rotation method: Varimax with Kaiser normalisation

To examine the unidimensionality of the model variables, a principal component analysis (PCA) with Varimax rotation was performed. The Kaiser-Meyer-Olkin (KMO) measure with a value of

0.879 confirmed the suitability of the items for PCA. A three-component solution was suggested, explaining 66% of the total variance. The reliability of the suggested scales was checked by calculating Cronbach's alphas. Composite measures were formed from each of the components. Table 3 presents the correlations among the composite variables.

Table 3. Correlations among the composite variables.

Variables (N = 111)	Mean	Standard Deviation	1	2	3	4
1. Sustainability performance	4.835	1.143	1.000			
2. Supplier orientation	4.866	1.150	0.359**	1.000		
3. Supply management innovativeness	4.072	1.140	0.348**	0.475**	1.000	
4. Turnover (ln)	11.351	1.472	0.154	0.072	-0.080	1.000

**p < 0.01

Regression analysis and results

The regression analysis (SPSS software) was performed to test the hypotheses. However, the small number of respondents (N = 111) did not make it possible to include the industry dummies (six different dummy variables) in the regression model. Therefore, the influence of the industry was checked separately by performing a one-way ANOVA analysis. The results showed no evidence that industries differed in terms of sustainability performance, innovativeness in supply management and supplier orientation ($p < 0.05$).

The regression analysis was performed in three phases. In the first phase (Model 1), only the control variable firm's size was included, and the results showed that it had no significant effect on sustainability performance ($R^2 = 0.024$). In the second phase (Model 2), the linearity of supplier orientation and innovativeness in supply management regarding each firm's sustainability performance was tested. The result was significant ($R^2 = 0.194$, $p < 0.01$). Third (Model 3), the interaction effect was included in the analysis. The interaction term was calculated by multiplying the variables supplier orientation and innovativeness in supply management. For the analysis, these interaction variables were standardised to prevent the possible problem of multicollinearity, which is common when testing the interactions between the independent variables. It turned out that the R^2 of change (0.013, Sig. of change =0.185) between Models 2 and 3 was not significant; therefore, no interaction effect was found.

To test for multicollinearity, the values of the variable inflation factor (VIF) scores were examined. The highest value was 1.403, which was clearly less than the cut-off level suggested by Cohen et al. (2003). The residuals of the regression varied between -3.22 and 1.79, showing that heteroscedasticity was not a problem in this case. The normality of the variables was estimated graphically from scatter figures. No violations of the assumptions of regression analysis were found, and it could be concluded that the test was performed successfully.

Based on the analysis, it can be concluded that innovativeness in supply management positively influences a firm's sustainability performance, as proposed in Hypothesis 1. Hypothesis 2, suggesting that supplier orientation positively influences a firm's sustainability performance, is supported as well. However, the argument in Hypothesis 3 is not supported. The interaction term does not provide significant improvement in the model, and thus, the proposed interaction effect of supplier orientation and innovativeness in supply management on sustainability performance is not detected. Moreover, in line with the results of the study of Zhu et al. (2008), it is found that a

company's size and sustainability performance are connected (Standardised $\beta = 0.167$; $p < 0.1$). Table 4 summarises the regression results.

Table 4. Results of regression analysis.

Discussion and conclusions

In this paper, the connections of supply management innovativeness and supplier orientation to a firm's sustainability performance has been examined. This paper's main contribution is finding and detecting the link between innovativeness and sustainability and between supplier orientation and sustainability. Innovativeness in supply management has been found to have a direct and positive influence on a company's sustainability performance (Unstandardised $\beta = 0.262$; Sig. = 0.012). A firm's supplier orientation also has a positive effect on sustainability performance (Unstandardised $\beta = 0.233$; Sig. = 0.022). However, there is no interaction effect between supply management innovativeness and supplier orientation on a firm's sustainability performance. Additionally, the results confirm that a firm's size influences sustainability performance, showing that large companies perform better in terms of sustainability than smaller ones. This finding is in line with those of Zhu et al. (2008) and Plambeck et al. (2011), who report that large firms and firms with high brand equity more likely adopt sustainability practices, which further contribute to their sustainability performance.

In Hypothesis 1, it is proposed that innovativeness in supply management positively influences a firm's sustainability performance. Several previous studies discuss about the critical role of the supply management function in a company's research and development and innovation

development; the benefits of cross-functional collaboration between product development and supply management are also widely acknowledged (e.g., Hallstedt et al., 2013; Rizzi et al., 2013). However, to the best knowledge of this paper's authors, there is no previous conceptualisation of what is understood as innovativeness in supply management. In this study, supply management innovativeness is defined as purchasing professionals' collective ability to innovate and their openness to new ideas, with the aim of influencing and developing supply markets. Several studies have pointed out the impact of innovativeness on supply chain performance (Panayides and Lun, 2009; Seo et al., 2014) and the sustainability of a supply chain (Gualandris and Kalcshmidt, 2014). However, in this study, innovativeness in the supply management function is defined and found to be linked to a company's overall sustainability performance. This finding supports the arguments that sustainability and innovativeness are linked, as suggested by Eccles and Serafim (2013), and that increased innovation capability may enhance a firm's sustainability performance, as suggested by Pagell and Wu (2009) and Van Bommel (2011). Innovativeness in supply management increases not only the supply chain performance but a firm's sustainability performance as well.

Hypothesis 2 suggests that supplier orientation positively influences a firm's sustainability performance. This hypothesis is supported by the empirical findings and is in line with the study of Hollos et al. (2012), who show that a strategic orientation contributes environmental and social sustainability practices. The present study's results enhance this view by showing the direct link of supplier orientation (as a firm's strategic orientation) with sustainability performance. In this study, supplier orientation is defined as a firm's effort towards co-operation with its suppliers and aim for a strategic fit regarding its choices of external resources in the upstream supply chain. In the long term, supplier orientation can have positive implications for company success and can provide competitive advantage by contributing to the development of sustainable business.

The proposed interaction effect of supplier orientation and supply management innovativeness on sustainability performance is not detected, as suggested in Hypothesis 3. This result contradicts those of previous studies that present the links between supplier collaboration and sustainability-related risk management and innovativeness in supply chains (Schaltegger and Burritt, 2014; Seo et al., 2014). However, the result supports the study of Kähkönen et al. (2015), who find that early supplier involvement and interfirm learning are concepts where innovation-related actions in supply management increase a buyer's dependency on its suppliers, whereas supplier orientation is a strategy for value-creating collaboration. Hence, the benefits of strategic supplier orientation and innovativeness in supply management are directly realised in sustainability performance without interaction.

Based on this study's findings, it can be concluded that supply management plays a vital role in boosting a firm's overall sustainability performance. This must be understood when formulating a company's CSR strategies and implementing sustainable values in practice. Supply management is not only a gatekeeper against sustainability risks arising from the supply base but is also a function where new ideas that aim to influence supply markets are presented. For a firm's management, it is essential to recognise this twofold impact of supply management on sustainability performance.

The results also show that if companies search for improvements in their sustainability performance, supply management innovations seem to be significant drivers. Companies seem to adopt sustainability requirements in their purchases to find innovative solutions as well. This implies that goals and measures related to innovations should be connected to the sustainability requirements set for suppliers. Consequently, it can be anticipated that sustainability performance

in purchasing and supply management can be improved by tightening sustainability requirements that foster innovations in supply management.

Similar to all research, this study has some limitations as well. The sample size is relatively small and only consists of Finnish companies. Therefore, more empirical research in other contexts is required. Moreover, the use of single informants in the data collection involves the risk of the common method bias. The study's cross-sectional design also means that the causal relationships are difficult to define. Furthermore, the relatively low explanation power (R^2 of 0.207) of the model clearly indicates that other factors can influence a firm's sustainability performance.

Abstract
The aim of this paper is to develop and describe the results of initial testing of a design for a strategic category management system. We align our research process with the constructive research approach. First, we develop an initial system with three phases based on design principles identified from the literature. Second we test the initial system with a group of purchasing professionals, and conduct a simple solution-market test. As future research, we suggest further iterative development for construct refinement, with stronger solution-market tests.

Keywords: category management, purchasing, strategy, constructive research

Introduction and research question

Although several strategic portfolio models and their variants have been suggested in the PSM literature (e.g. Kraljic, 1983; Olsen and Ellram, 1997; Nellore and Söderquist, 2000; Pagell et al., 2010; Luzzini et al., 2012; Drake et al., 2013; Cox, 2015), with the most notable ones subjected to extensive testing (e.g. Caniels and Gelderman, 2007; Terpend et al., 2011; Padhi et al., 2012), there are very few attempts to define and describe the strategic category management process more comprehensively, especially through a rigorously applied scientific process, and with a broader evidence-base (cf. O'Brien, 2012; Carlsson, 2015). The most notable exception is the work of Hesping and Schiele (2015), who propose a model with five levels of strategy development in purchasing, based on the strategic alignment -focused work by González-Benito (2007). The process starts from firm and functional level strategies, suggests alignment of category strategies, and focuses on the implementation of category strategies via a set of sourcing levers (Schiele, 2007, Schiele et al., 2011; Hesping and Schiele, 2016). Despite its theoretical foundations, the proposed model lacks testing in real-life contexts.

In order to lead the development of systems for category management, academic research must seek to enable the rigorous design of the 'artificial' (Simon, 1996), i.e. objects that do not yet exist, also for category management. In such design research oriented set-ups, the main question is about whether the suggested designs work, and the aim is to 'produce knowledge that is both actionable and open to validation' (Romme, 2003). In other words, the mission of design science is to develop knowledge for solving field problems (Denyer et al., 2008), which in our case would be related to how to design a strategic category management system for PSM, or what should be the design of such a system?

For addressing this research question, we align our research process with design science, and explicitly with the constructive research approach as suggested by Kasanen et al. (1993). The constructive approach involves phases, applied in varying order: (1) find a practically relevant problem which also has research potential, (2) obtain a general and comprehensive understanding of the topic, (3) innovate or construct a solution idea, (4) demonstrate that the solution works, (5) show the theoretical connections and the research contribution of the solution concept, (6) examine the scope of applicability of the solution (Kasanen et al., 2013). In line with this approach, we develop a construct for strategic category management (i.e. a set of 'models, diagrams, plans' and processes; Kasanen et al., 1993, 243), by obtaining a comprehensive understanding of the topic through reviewing the extant literature for identification of system design principles, and by innovating and constructing an initial system with practitioner engagement. We also conduct a first solution-market test for the construct, conducted in a management training context.

Development of the initial system

According to Rumelt (2011, 6), strategy can be defined as 'a coherent set of analyses, concepts, policies, arguments, and actions that respond to high-stakes challenge', with the 'kernel of strategy' comprising of diagnosis, guiding policies, and coherent action. From this it may be extrapolated that strategizing in PSM should follow the basic cycle of diagnosis, guiding policy analysis, as well as planning and implementing coherent action, and that such a cycle should first and foremost take place at the level defined by the basic unit of analysis for strategizing in PSM, namely the purchase category (Luzzini et al., 2012; Ateş et al., 2015). A strategic category management system design, according to this first principle, would allow a category manager to sense needs to reconfigure and transform, and further to seize opportunities to sustain and improve performance at the category level in a dynamic business and supply environment (cf. Teece et al., 1997).

Here we describe the required steps in each of these phases of strategizing. The development of the initial system is based on both the extant literature and practitioner engagement (Figure 1), as the system was developed together with an experienced procurement professional.

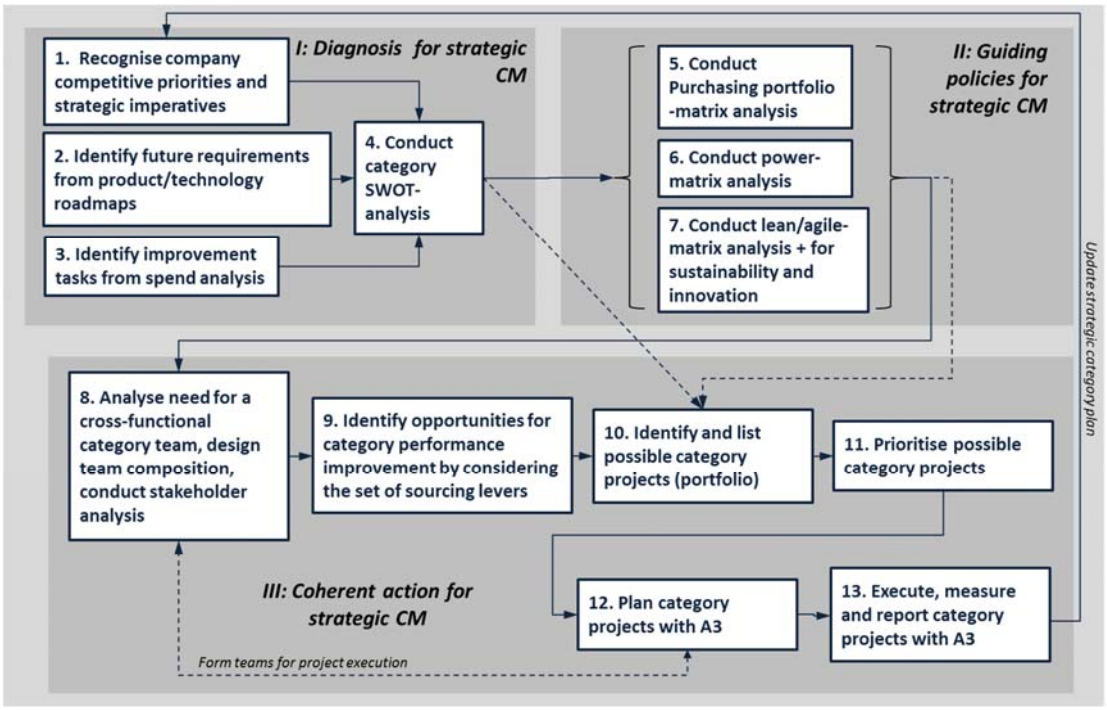

Figure 1 Initial system for strategic category management

The content of the diagnosis phase should aim to identify any challenges regarding the category (cf. Rumelt, 2011). The most high-level challenge for PSM could be suggested to be the problem of how to create value for the internal and the end-customer (cf. Amit and Zott, 2001)? The challenge of alignment between the competitive priorities of the company and the PSM function (Krause et al., 2001), has been discussed early on in the literature (e.g. Treleven and Schweikhart, 1988; Narasimhan and Carter, 1998), with evidence showing that strategic alignment of business strategy with purchasing strategy, as well as the alignment of purchasing strategy with purchasing practices, i.e. purchasing efficacy, is important for improving business performance (González-Benito, 2007; Baier et al., 2008). Therefore, we include element 1, i.e. the recognition of the competitive priorities and any strategic imperatives in the firm, into the initial system, enabled by for example a SWOT-analysis conducted at the company level. Element 2, identifying future requirements, may draw on available product and technology roadmaps (e.g. Phaal et al.). Element 3 draws on a spend analysis for identifying any challenges related to current procurement practices. In our system, we suggest that a key element in the diagnosis phase is a category level SWOT-analysis (element 4), which draws on the previously identified elements for identifying any issues and ensuring alignment, and essentially allows the brainstorming and identification, or diagnosis, of category challenges that may be addressed in the light of guiding policies or directly through coherent action.

We may conclude that the most high-stakes challenge for PSM is achieving alignment at the essential level of PSM strategizing, i.e. the purchase category. Value may be created by alignment in three respects: (1) in terms of strategic alignment with competitive priorities (e.g. quality, cost, time, flexibility, innovation, sustainability; Krause et al., 2001; Schneider and Wallenburg, 2012), (2) in terms of requirement alignment with category characteristics (e.g. profit impact, share of total cost, quality and logistics requirements; e.g. van Weele,

2010) and (3) in terms of supply market alignment with characteristics of the factor markets (e.g. supplier or buyer power, market structure; e.g. Kraljic, 1983; Cox, 2015).

What kind of guiding policies are offered for the proposed three-dimensional alignment? Selecting the Kraljic's (1983) matrix for requirement and supply market alignment (element 5), the power matrix of Cox (2015) for further supply market alignment (element 6), and the Drake et al. (2013) –matrix for strategic alignment (element 7), we may have three guiding policies for a category that should be jointly considered for a set of coherent actions (Figure 1). For example, an imaginary alignment analysis for the indirect category of office supplies, may suggest such guiding policies as 'noncritical items' (Kraljic, 1983), 'market / independence' (Cox, 2015), and 'non-strategic items' (Drake et al., 2013), and implying such coherent actions as (1) standardization, efficient processing and inventory optimization, (2) development of competence for bidding and negotiation, and (3) efficient purchasing, complexity reduction, standardization, automating transactions and using simple source selection processes to govern relatively short contracts, respectively. The recommended coherent actions seem similar, and the benefit of going through a process of using three separate analytical frameworks is not readily apparent. However, the benefits of more complex analysis are realized when there are imbalances of power, and more demanding or specific requirements from the business and internal customer. For example, the buyer may not be an attractive customer for the suppliers (van Weele, 2010), for example due to low volumes, and suppliers may have power resources over the buyer, for example due to buyer's switching costs, suggesting a dependency of the buyer, with supplier dominance (Cox, 2015). In effect, the Kraljic (1983) matrix may suggest a leverage strategy, but based on the power-matrix analysis, PSM may have to consider ways to reduce supplier's power resources or increase its own, for example by opting for a smaller supplier. Furthermore, if the competitive priorities of the company or internal customer requirements emphasize rapid design changes and short delivery times, i.e. agile supply (Drake et al., 2010), long-term relationships for information exchange and a proximate local supplier, again with smaller size for attentiveness and responsiveness, may be preferred over competitive bidding.

In the coherent action phase, we suggest that the need for a cross-functional category team is analysed, team composition is designed, and a stakeholder analysis is conducted (element 8), as the need for cross-functional approach in advance level procurement has been recognized for example in Schiele (2007), although there may be purchasing situations where procurement function dominates (low commercial uncertainty and low item complexity; van Weele, 2010), or serves as the primary owner of the category (Ellram & Tate, 2015). Next, opportunities for category performance improvement are identified by considering the set of sourcing levers (element 9; see Schiele, 2007 and Hesping & Schiele, 2015). In element 10 of the system, we identify and list category projects aimed at improving performance, drawing on the category SWOT, guiding policies, and the consideration of the sourcing levers in element 9. In element 11, the projects are prioritized with for example the simple approach suggested by O'Brien (2010) involving the consideration of ease of implementation and the potential benefits. In element 12, we suggest that the A3 report approach from Toyota is used for planning the projects (e.g. Shook, 2009), and finally, in element 13, projects are executed, measured and reported, also with the A3 formt. In planning and executing the category projects, project specific cross-functional teams may be formed, and the strategic category plan (outcome of the system) may be revised by restarting the process.

First test of the initial system

In order to demonstrate the applicability and validity of the proposed initial system we conduct a first solution-market test (Kasanen et al., 1993). The testing took place in training programme on strategic procurement management at the end of 2017 and early 2018, in two phases. First, the 13 participants of the programme (all procurement professional in their respective oragnizations, ranging from manufacturing to service provision and to utilities), spent a full day in getting familiar with the system and each of its elements. After introduction of the elements and the underlying concepts, such as the Kraljic-matrix, the participants applied the concepts in their own context, and therefore drafted a strategic category plan during the day. SWOT-analyses and matrix positions, as well as A3 reports were sketched with pens and markers on A3 size papers and discussed in smaller groups. The day ended with an assignment to develop chosen elements of the strategic category plan further, discuss and report within the organization, and prepare to discuss developments and experiences at the start of the next training next month.

Second, we design a simple online tool for allowing a "weak" solution-market test of our initial system, i.e. we sought to address the question put forth by Kasanen et al. (1993): "Has any manager responsible for the financial results of his or her business unit been willing to apply the construction in question in his or her actual decision making?" If application and adoption takes place, i.e. the construct "works", it may be inferred that the construct is valid, in addition to being linked to particular theoretical frameworks (Kasanen et al., 1993). The willingness of the participants to apply the system in their further category management work indicates usefulness or "truthfulness" of the design, comprising a "weak solution-market test" (Kasanen et al., 1993). In implementing such a test, we adapted the Juster-scale for predicting consumer purchase probability (Seymour et al., 1994) for our context, and implemented the test with the Qualtrics online survey tool. In essence, we designed a questionnaire in which each of the system elements separately (e.g. the Kraljic-matrix), as well as the entire system was displayed graphically to the respondent, and a question related to the probability of use was asked, such as the following: "On a scale from 0-10, how likely you are to use the SWOT-analysis in the diagnosis phase of category strategy planning?" Answers were prompted with a scale from 0 (Certainly would not use) to 10 (Would use certainly). Of the 13 participants in the programme, 8 submitted their responses to the questions probing the probability of use of each of the system elements. Verbal comments on the system and its usefulness were also received. As the small sample does not allow any advanced statistical analysis, we provide simple descriptive measures for the probability of use, which serves as our first solution-market test. Figure 2 presents the results of the test with the revised version of the system.

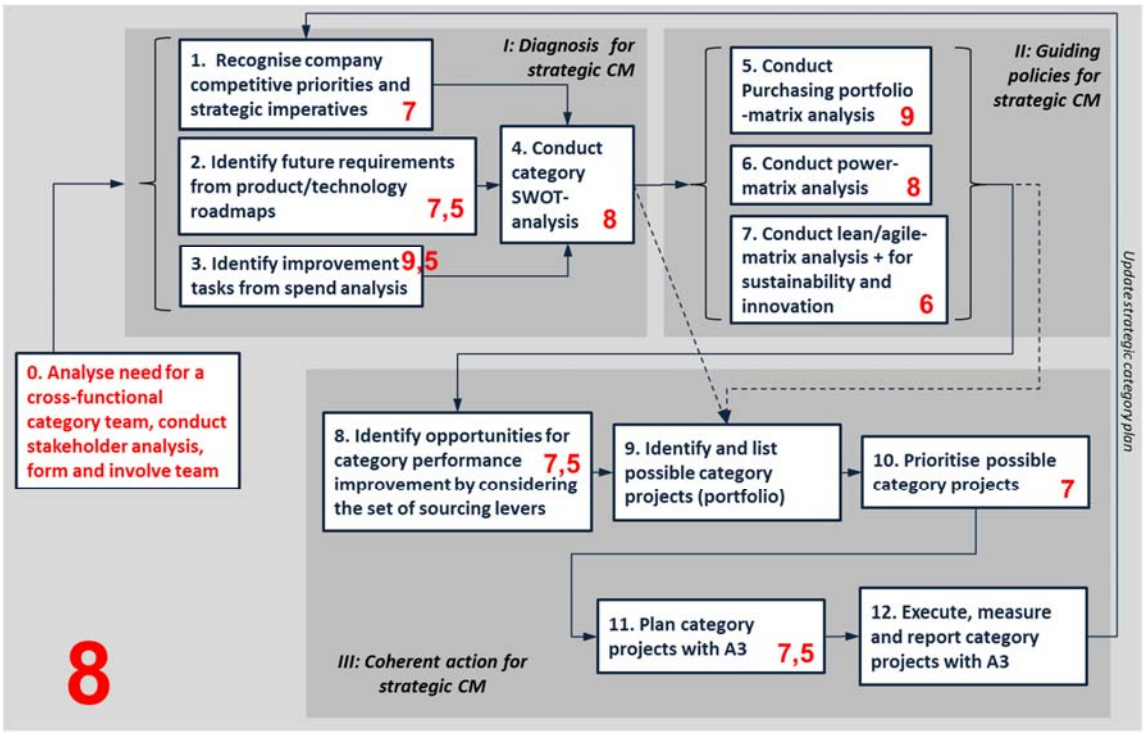

Figure 2 Revised system for strategic category management (with median values, scale 0-10; N=8)

The median values for the elements and the overall system (in the lower left-hand corner), indicate that the respondents are reasonably likely use the proposed system (median response is 8). Spend analysis and the Kraljic-matrix demonstrate strongest acceptance (median is 9.5 or 9), category-SWOT and Power-matrix are also likely to be used (median is 8), whereas the lean/agile-matrix has the lowest acceptance rate (median is 6).

The verbal comments suggested that the tools are very good, and that they allow valuable platform for evaluating existing tools. One respondent commented on the variety of the tools, and suggested that the challenge is demonstrating the value of the category approach in the organization. One respondent suggested that the process-model clarifies work and allows faster execution. This respondent also pointed out the need to have the analysis of the need for a category team more up-front, and even before the diagnosis, in order to draw appropriate competencies to the diagnosis phase, and ensure credibility and commitment of the organization. Based on this comment, the former element 8 has been moved as element 0, and now serves as a necessary enabler of the entire system and process. This revision emphasizes the cross-functional nature of the entire strategic category management process.

Conclusions and further research

The research question put forth in this paper was what should be the design of a strategic category management system? Based on literature and practitioner engagement, an initial system was designed, and then tested in training programme context. Support for the truth value of the construct, or its validity, was demonstrated by the means of a weak solution-market test, based on which the system was revised for greater emphasis on up-front cross-functional engagement.

As further research, we suggest further practitioner engagement for refining and testing the system, and efforts to demonstrate the applicability and validity of the solution through a multiple case-study with more advanced solution-market tests (Kasanen et al., 1993). One participant from the first test has already communicated willingness to apply the construct in the strategic category management of the company's indirect team. Furthermore, in order to accumulate knowledge on the association or even causality between the use of constructs for strategic category management and category or PSM performance, the framework suggested by Denyer et al. (2008) for analyzing the context, intervention, mechanism and outcome of strategic category management, could be used for conducting case studies.

ABSTRACT

The concept of behavioral supply management has attracted substantial research attention since its introduction in 2007. Nevertheless, it is still in a developmental stage, and the purchasing and supply management field represents a unique and fertile ground for more behavioral research. In this paper, we demonstrate the unchartered potential of behavioral supply management with a special focus on casual advice-giving, which is broadly present in everyday organizational interactions. The study differentiates three collegial advice types for buyers – to be honest, bluff, or lie – and investigates its influence on subsequent buyer–supplier negotiations. Scenario-based experiments show that advisees are prone to heed advice to be honest and to bluff, but not to lie in supplier negotiations. The findings are robust across both solicited and unsolicited advice and the advice-giver's job function. Finding that small talk can have a big impact, we conclude with a call for more behavioral research in PSM.

Keywords: Advice, Deception, Social learning theory, Social psychological theories, Behavioral experiments

Submission Category: Competitive Paper

INTRODUCTION

Since its beginnings, research in the purchasing and supply management (PSM) field and the broader supply chain management (SCM) discipline has been mostly grounded in the assumptions of rationality, self-interest, and utility-maximizing behavior on the part of the decision maker – a phenomenon epitomized by the sustained endeavor of scholars to integrate neoclassical economic theories and in particular transaction cost economics (Carter, Kaufmann and Michel, 2007). Numerous empirical studies, however, revealed a substantial gap between homo economicus-based theories and practices (e.g., Ribbink and Grimm, 2014; Stanczyk, Foerstl, Busse and Blome, 2015; Storey, Emberson, Godsell and Harrison, 2006). In order to make sense of this discrepancy, researchers pivot toward the tenet of *bounded rationality* where Tversky and Kahneman (1986) contend that "deviations of actual behavior from the normative

model are too widespread to be ignored, too systematic to be dismissed as random error, and too fundamental to be accommodated by relaxing the normative system" (p.52), and thus have recognized the importance of the behavioral dimension in SCM (e.g., Croson, Schultz, Siemsen and Yeo, 2013; Huo, Han, Chen and Zhao, 2015; Wieland, Handfield and Durach, 2016).

Starting with Carter et al. (2007)'s introduction of behavioral supply management as "the study of how judgment in supply management decision-making deviates from the assumptions of homo economicus" (p.634), researchers have increasingly adopted a behavioral lens in PSM studies. For instance, Moosmayer, Schuppar, and Siems (2012) reveal the power of reference prices in determining the ultimate B2B price negotiation; Hada, Grewal, and Lilien (2013) look into purchasing managers' perceived bias in supplier-selected referrals; Kull, Oke, and Dooley (2014) propose that various attributes of the purchasing situation affect cognition that in turn affects supplier selection choice; Stanczyk et al. (2015) demonstrate when and why intuition affects procedural rationality in global sourcing decision-making processes; Eckerd, Boyer, Qi, Eckerd, and Hill (2016) examine the impact of national culture on the responses of individuals to supply disruption resulting from psychological contract breach; Kaufmann and Wagner (2017) explore the potentially negative effects of affective trait diversity on sourcing team performance and how such negative effects might be mitigated through team members' emotional intelligence; and Reimann, Kosmol, and Kaufmann (2017) shed light on how cognitive, behavioral, and structural factors across the individual and organizational levels combine to bring about either dysfunctional conflict or constructive interaction in the aftermath of supplier-induced disruptions.

Whereas in the related field of behavioral *operations* management scholars draw upon both *cognitive and social psychological theories* to account for the behavioral deviations from the rationality assumption in operations (Gino and Pisano, 2008), behavioral PSM has largely relied on cognitive (e.g., with focus on biases, heuristics and personal traits) but only to a lesser extent on social psychology (e.g., with focus on national context and team traits) to better account for an array of PSM relevant phenomena.

The objective of this paper is to demonstrate that even casual collegial advice during everyday interactions can have significant impacts on the subsequent behavior of PSM professionals, an investigation which serves both as a showcase for behavioral research in PSM and at the same time as a call for more such research.

Our reasons to choose this specific research focus are threefold: *First*, in their role as boundary-spanners, procurement professionals' capabilities to interact with different stakeholders at each level of the purchasing process are assumed to be the most fundamental requirement (Tassabehji and Moorhouse, 2008). Extant studies demonstrate the relevance of communication in managing cross-functional team effectiveness and buyer–supplier relationships (Driedonks, Gevers and van Weele, 2014; Grudinschi, Sintonen and Hallikas, 2014). Nevertheless, the PSM literature has made very few inroads into addressing how procurement professionals communicate with colleagues *outside* the immediate team boundary (Driedonks et al., 2014).

Second, "small talk"— a common channel to communicate with non-close colleagues—is characterized as casual, spontaneous, and situational (Pullin, 2010; Subramanian, 2006). It can take place in various office locations—colloquially, at water coolers and copy machines in former times, and now in office kitchens and workout facilities—thus permeating organizational daily life. Small talk appears *omnipresent across all job functions*; and its potential influence is particularly relevant to those whose roles have a boundary-spanning nature, particularly procurement professionals. Further, according to Holmes and Stubbe (2003), small talk differs in terms of on-topic relevance, context-bound content, and

informativeness. Collegial advice giving is likely to occur via small talk, in the sense of a well-focused, referential talk with high information content.

Third, buyer–supplier negotiations represent one of the key means for the two parties to interact with each other (Kaufmann and Carter, 2004; Ramsay, 2004) and they have received increasing attention from PSM researchers (e.g., Thomas, Thomas, Manrodt and Rutner, 2013; Zachariassen, 2008) since the call extended by Wynstra and Knight (2004). Because buyer–supplier negotiations are also recognized as fertile *opportunities for deception* (Aquino and Becker, 2005; Tenbrunsel, 1998), companies typically draw on formal systems, such as codes of conduct (Handfield and Baumer, 2006), to mitigate the chances of ethical breaches. However, researchers argue that the efficacy of formal systems is generally nuanced and hinges also on informal systems. *Informal systems* consist of unofficial messages that convey organizational ethical norms (Smith-Crowe, Tenbrunsel, Chan-Serafin, Brief, Umphress and Joseph, 2015). Such communication also can be accessed and interpreted via (casual) conversation.

This study focuses on casual advice that comes from a non-close colleague via small talk. Based on two vignette-based experimental studies, we differentiate the advice content in terms of the perceived honesty of the advice giver, and investigate its implications for buyer–supplier negotiations. Scenario-based experiments first investigate whether the advice to engage in (dis)honest behavior toward a supplier influences a procurement professional's subsequent negotiation approach (*Study 1*). We follow the newly developed conceptualization of Kaufmann, Rottenburger, Carter, and Schlereth (2018) and make a distinction between two types of deception: a bluff and a lie. We test the effect of two situational factors on the receptiveness to the advice—namely, whether the advice has been actively solicited and what the job function of the advice-giving colleague is (*Study 1* and *Study 2*). Although the past decade has witnessed burgeoning interest in behavioral aspects of PSM by researchers, extant work pays scant attention to the influence of day-to-day activities beyond formal team settings, i.e., casual advice provided to purchasing professionals. With this paper, we aim to draw attention to the underexplored potential of the behavioral PSM by providing first insights into how receiving advice in a seemingly casual context overshadows purchasing professionals' subsequent interactions with suppliers in a negotiation. The observed effects in such a "light touch" setting indicate that there remains a dearth of behavioral research opportunities in PSM in general.

The remainder of the paper is organized as follows. In the next section, we discuss the relevant literatures and develop hypotheses on this basis. We then describe two vignette-based experimental studies and present our findings. Afterwards, we discuss the theoretical and managerial implications as well as limitations pertinent to our research. To conclude, we "zoom out" and consider the broader opportunities for behavioral PSM research, with *casual advice* as an example.

THEORIES AND HYPOTHESES

Small Talk and Social Learning Theory

Small talk is ingrained in organizational daily life. Taking the role of boundary-spanner, PSM professionals not only have to intentionally manage the communication process and content (Driedonks et al., 2014; Large, 2005), but also gain access to various types of information communicated during informal communications. As a form of informal communication (Pullin, 2010), small talk is spontaneous and situational (Subramanian, 2006) and usually starts with icebreakers such as greetings, general observations, and questions (Yang, 2012).

Anthropologists (Malinowski, 1946) define small talk as "phatic communion," which serves purely to establish a social bond and does not represent purposeful communication. However, this restrictive view—that the meaning behind small talk lies only in the speech act itself, and not in the content—has been contested by sociolinguists. Coupland (2000, 2003) argues that small talk is not necessarily devoid of information, but that it represents an intrinsic part of the talk. Holmes and Stubbe (2003) point to the dynamic nature of workplace small talk and conceptualize it in terms of a continuum, ranging from phatic communication on one end of the continuum, through social talk, and work-related talk, to core business talk on the other end; the continuum represents a stepwise increase in on-topic relevance, context-bound content, and informativeness. In this perspective, advice-giving and advice-taking are likely to occur via small talk, as a well-focused, referential talk with high information content.

Social learning theory posits that individuals generally do not possess innate repertoires of behavior, but rather acquire them over time (Bandura, 1977). Whereas this learning process typically consists of observing, imitating, and modeling the behavior of others (Bandura, 1977), researchers find that organizational ethical conduct can be learned in part through conversations with peers (Smith-Crowe et al., 2015). That is to say, actions of others being observed do not constitute a sine qua non for the social learning process, it can take place in social conversations. Therefore, we argue that procurement professionals are likely to acquire information embedded in casual collegial advice conveyed through small talk and this information in turn can have a bearing on their subsequent behaviors, such as negotiations with suppliers.

Advice and Buyer–Supplier Negotiations

In organizational studies, advice has been investigated as a special form of *social support* (e.g., Chentsova-Dutton and Vaughn, 2012; Deelstra, Peeters, Schaufeli, Stroebe, W., Zijlstra, F. R. and van Doornen, 2003; Feng and Magen, 2016) and *help* (e.g., Brooks, Gino and Schweitzer, 2015; Erdogan, Bauer and Walter, 2015). In this research, we follow the approach by Chentsova-Dutton and Vaughn (2012), and define advice as suggestions or directives intended to shape others' ways of thinking, feeling, or behaving.

In buyer–supplier negotiations, various factors, such as pricing, delivery terms, shipment schedules, and quality standards, are at stake (Thomas et al., 2013); hence, technical experts often are present both during the preparation and at the negotiation table to provide procurement professionals (i.e., negotiators) with advice upon request. However, whether collegial advice offered via small talk before the negotiation influences the buyer's negotiation approach remains unexplored. An empirical inquiry seems warranted in light of the ubiquitous nature and potential referential function of small talk in the workplace, and in light of the uncontestable importance of buyer–supplier negotiations for both the PSM field (Wynstra and Knight, 2004) and general organizational strategic benefits (Faes, Swinnen and Snellinx, 2010). Further, because extant studies have repeatedly demonstrated that boundary-spanners are often confronted with opportunities and incentives to intentionally mislead other parties (Bhattacharya, Singh and Nan, 2015; DeYong and Pun, 2015; Hawkins, 2013; Wang, Zhang, Wang and Sheng, 2016), we are particularly interested in the influence of collegial advice on buyer–supplier negotiations from the perspective of honesty. Moreover, we follow Kaufmann et al. (2018) and make a distinction between two types of active deception: bluffs and lies. Adopting a convention-dependent and norms-based perspective, they define a bluff as a deception which is palatable to both parties (and as such amoral) in a buyer–supplier negotiation and a lie as a deception which is not deemed acceptable to either of the parties (and as such immoral).

Peers are found to have a significant effect on (ethical) decision-making (Craft, 2013; Lehnert, Park and Singh, 2015; Westerman, Beekun, Stedham and Yamamura, 2007). Although social

learning theory lends strong theoretical support for this contention (O'Fallon and Butterfield, 2005) and as previously argued, behaviors could be acquired through both observations and conversations, it should be noticed that *advised* behaviors are not perceived, valued, and followed (i.e. *learned*) in the same way as *observed* behaviors because advisees are prone to ego-centrically discount advices (Bonaccio and Dalal, 2006; Yaniv and Kleinberger, 2000).

Ego-centric discounting is the most robust empirical finding in the advice-taking literature. Researchers have explored a plethora of factors to explain why advice receivers discount the advice they're given. Social psychology indicates that help in any form restricts the perceived behavioral freedom, which in turn leads to a negative psychological state called reactance (Brehm, 1966); more generally, the perceived restriction poses a threat to self-esteem and decision autonomy (Dalal and Bonaccio, 2010). In addition, although advice recipients have full access to internal justifications for arriving at a particular decision, they do not have access to an advice giver's reasoning and supporting evidence (Bonaccio and Dalal, 2006; Tzioti, Wierenga and van Osselaer, 2014). Advice discounting could also occur as a result of various cognitive biases, such as overconfidence, perseverance, or a confirmation bias (Yaniv and Kleinberger, 2000). Furthermore, predicting the motives of the advice giver is not possible (Sniezek and van Swol, 2001; Tzioti et al., 2014), and even well-intended advisors frequently recommend that others act differently than they would act themselves (Dana and Cain, 2015).

While extant empirical studies predominantly focus on advice about a *judgment task* which involves estimates or forecasts of a quantitative nature (Reyt, Wiesenfeld and Trope, 2016) (e.g., Gino and Schweitzer, 2008; Hooge, Verlegh and Tzioti, 2014; See, Morrison, Rothman and Soll, 2011), advice on a *choice task* with qualitatively different alternatives (Bonaccio and Dalal, 2006; Sniezek and Buckley, 1995) has received significantly less attention. More specifically, to the best of our knowledge, there has been no research dedicated to examine acceptance of the advice on a choice task, which not only includes qualitatively different alternatives but alternatives that are judged differently through an ethical lens (e.g., to be honest, to bluff or to lie). We therefore tentatively posit the following hypothesis:

> ***H1****: Collegial advice conveyed via small talk influences the advice recipient's behavior in a subsequent buyer–supplier negotiation.*

Solicited vs. Unsolicited Advice

In the relatively scant research on the reception and rejection of unsolicited advice, the consensus is that unsolicited advice is more often discounted than explicitly requested advice; unsolicited advice can be considered intrusive, inappropriate, and condescending, and it raises greater autonomy and self-esteem concerns (Fitzsimons and Lehmann, 2004; Goldsmith, 2000; Goldsmith and Fitch, 1997; Hinojosa, Gardner, Walker, Cogliser and Gullifor, 2017; Reinhardt, Boerner and Horowitz, 2006). Furthermore, although relational closeness typically is characterized by a high level of trust (Feng and Magen, 2016), which in turn represents an important precursor to advice-taking (Dalal and Bonaccio, 2010; Sniezek and van Swol, 2001), Feng and Magen (2016) caution that unsolicited advice even from a close friend still can engender negative reactions. We expect that this differential receptiveness to solicited and unsolicited advice also occurs in the context of advice offered by a colleague via small talk in relation to a subsequent buyer–supplier negotiation. Therefore, we hypothesize that:

> ***H2****: When given advice about a subsequent buyer–supplier negotiation in the context of small talk, the recipient is more likely to follow the advice if it has been actively solicited than if it is unsolicited.*

Departmental Thought Worlds

Differences in departmental thought worlds have received sustained attention from scholars of various disciplines, such as marketing (Homburg and Jensen, 2007), strategy (Frankwick, Ward, Hutt and Reingen, 1994), and operations and supply chain management (Niranjan, Rao, Sengupta and Wagner, 2014). Organizational roles lead to different thought worlds (Dougherty, 1992) with different perceptions and situated representations of the task environment (Boland and Tenkasi, 1995; Niranjan et al., 2014). Whereas studies repeatedly suggest a positive relation between (functional) diversity and idea generation (e.g., Dayan, Ozer and Almazrouei, 2017; Jehn, Northcraft and Neale, 1999), intergroup bias resulting from social categorization remains a stumbling block to fully reap the benefits of diversified workplaces (van Knippenberg, Dreu and Homan, 2004). Different thought worlds might impede knowledge transfer and integration in cross-functional teams (Kellogg, Orlikowski and Yates, 2006; Majchrzak, More and Faraj, 2012). Hence, we argue that people are less receptive to advice provided by a colleague from another function (i.e., one embedded in a different thought world). This response should hold particularly for PSM professionals, who frequently encounter colleagues with different functional backgrounds, including sales and R&D. Therefore, we hypothesize that:

> ***H3****: The job function of the advice-giving colleague moderates the advice recipient's receptiveness to the advice.*

The inter-relationships among the hypotheses are displayed in Figure 1.

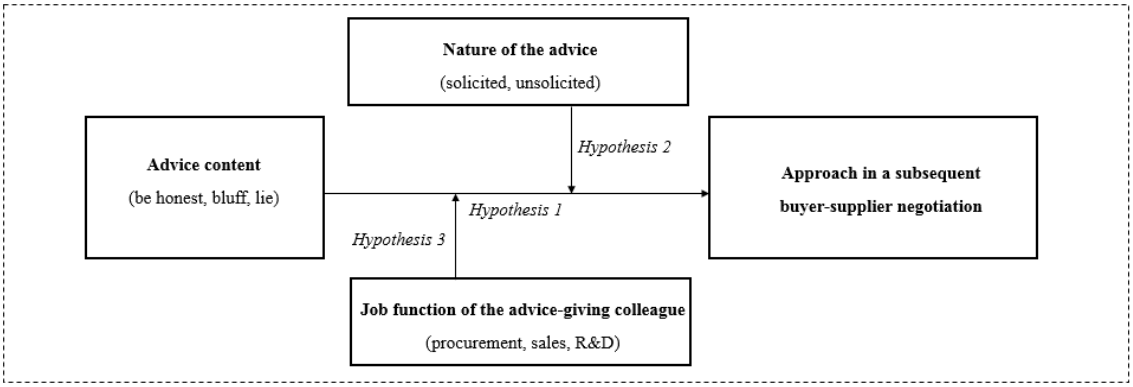

Figure 1: Research model

METHODOLOGY

We conducted two vignette-based experimental studies (Bachrach and Bendoly, 2011; Eckerd, 2016; Rungtusanatham, Wallin and Eckerd, 2011) to assess our hypotheses. The vignette methodology is well-suited for our research purpose for four reasons. First, vignettes allow researchers to examine sensitive topics where individuals are usually reluctant to share information (Pilling, Crosby and Jackson, 1994), such as indicating whether they will engage in (dis)honest behavior in the subsequent encounter with suppliers. Second, vignette experiments help generate more valid and reliable data by standardizing the social stimulus across respondents (Alexander and Becker, 1978). Third, vignette design has proven conducive to understanding how and why individuals make decisions in the SCM discipline (Tangpong, Hung and Ro, 2010; Thomas, Davis-Sramek, Esper and Murfield, 2014). Fourth, researchers have adopted vignette experiments to investigate buyer-supplier negotiations (Kaufmann et al., 2018; Thomas et al., 2013). In addition, to avert carryover effects on the part of the participants, both studies used a between-subjects design.

Study 1

This study used a 3 x 2 design (*advice content*: be honest, bluff, lie; *nature of the advice*: solicited, unsolicited), plus two control conditions.

Vignette design. Participants assumed the role of a buyer who would soon enter into the last round of a negotiation for marketing services to be provided by an agency. The only remaining objective in the last round of negotiations was to convince the supplier to reduce the price from the previous offer. Before entering the negotiation, participants met a colleague who was a manager for an unrelated spend category in the procurement department.

Depending on the assigned treatment group, each participant received one piece of advice from the colleague about how to convince the supplier to reduce the price, drawn from the 3 (i.e., be honest, lie, bluff) by 2 (i.e., solicited, unsolicited) study design. In addition, we included two control groups: In *control condition A*, participants actively sought advice but were told to make their own decision; in *control condition B*, no colleague was present. Participants then answered the survey question about the approach they planned to take in the final negotiation round. They had three options: being honest, bluffing (false threat), and lying (false promise), according to the taxonomy of Kaufmann et al. (2018).

Because participants' correct understanding of the situation was crucial for them to accurately interpret whether each of the three options represents an honest approach, we purposefully designed instruction questions to identify and exclude participants who chose to bluff or to lie without knowing that their chosen approach was to be dishonest.

Vignette validation. We closely followed the steps outlined by Bachrach and Bendoly (2011), Rungtusanatham et al. (2011), and Walker (2014) to ensure that our vignette was realistic, believable, interesting, and effective. In order to increase the external validity of our research, we chose people with at least two years of work experience in either a sales or supply management position as our unit of analysis for both the pilot test and the final data collection. During the design stage, we pre-tested an initial version of our vignette with n=340 participants from two business schools (M_{age}=21.9 years) and incorporated their feedback to refine our design. In the post-design stage, we conducted two pilot tests with practitioners. The first pilot test included a sample of n=246 professionals ($M_{work\ exp}$=17.2 years; $M_{negotiations}$=31 B2B negotiations), and the second included n=122 professionals ($M_{work\ exp}$=16.4 years; $M_{negotiations}$=22 B2B negotiations). Based on the feedback obtained from the pilot tests, we made final adjustments to our vignette.

Sample. The initial sample consisted of n=447 North American purchasing and sales professionals, recruited using a U.S.-based survey research firm. The data were collected in one survey period. Of the 447, 14 participants were excluded for failing to answer the instruction checks correctly. Another 18 participants were excluded because they finished the exercise in less than five minutes or more than one hour, which we interpreted on the basis of our pilot tests as either a lack of careful reading and considered decision-making or as getting distracted during the exercise, respectively. The remaining 415 participants (90.6% usable rate; 191 male; M_{age}=38.0 years; $M_{work\ exp}$=17.6 years, $M_{negotiations}$=74 B2B negotiations) were randomly allocated to eight conditions.

Results. Participants were asked whether they found the scenario realistic and were able to imagine themselves in the situation (Dabholkar, 1994). With M= 5.98 on a seven-point Likert-type scale, the realism check indicates that perceptions of the scenario were adequate to induce authentic responses (Reimann, Shen and Kaufmann, 2017; Thomas et al., 2014; Thomas et al., 2013).

We conducted a univariate analysis of variance (ANOVA) on the aggregated perceived honesty measure (α=0.97), which revealed a significant effect of condition on the perceived honesty of the advice ($F(2,301)=602.44$, $p<.001$). A planned difference contrast demonstrated that advice to lie (M=1.85, SD=0.81) was perceived as significantly less honest than both advice to bluff (M=2.54, SD=1.22) and advice to be truthful (M=6.26, SD=0.81) ($t(220)=-2.547$, $p<.001$), and that advice to bluff was perceived as significantly less honest than advice to be truthful ($p<.001$) ($t(220)=-3.73$, $p<.001$). Taken together, these results indicate that the manipulations for *advice content* were successful. In addition, participants could only proceed if, depending on the assigned condition, they correctly answered whether the advice had been actively solicited or not, ensuring a successful manipulation for *nature of the advice*.

For *hypothesis 1*, we explore whether casual advice influences the advice recipient's subsequent negotiation approach. A cross tabulation analysis revealed a statistically significant association ($\chi^2(8)=98.01$, $p<.001$, *Cramer's V*=0.344). However, a pairwise χ^2 association analysis demonstrated that no non-random difference occurred – neither between the *lie* and *control condition A* ($\chi^2(2)=4.63$, $p=.10$), nor between *lie* and *control condition B* ($\chi^2(2)=0.70$, $p=.70$), nor between two control conditions ($\chi^2(2)=1.79$, $p=.51$). Taken together, the findings showed that advice to be honest and to bluff is related to the participants' subsequent negotiation approach, but advice to lie was fully discounted.

Because we found no pairwise difference between *lie, control condition A*, and *control condition B* in terms of the subsequent negotiation approach, and because the best way to assess the influence of advice is to juxtapose it with a decision-making context devoid of advice, we then limited our focus to *honest*, *bluff*, and *control condition B* (i.e., no presence of a colleague) and conducted a multinomial logistic regression, with the *advice content* (i.e., be honest, bluff, and no presence of a colleague) as the predictor, and the subsequent negotiation approach (i.e., be honest, bluff, lie) as the dependent variable to be predicted. The results indicate that the *advice content* significantly predicted whether the advice recipient chose to behave honestly, to bluff, or to lie ($\chi^2(4)=86.155$, $p<.001$). In addition, in comparison with those who had no interaction with a colleague and made their own decision, those who had been advised to behave honestly were 3.32 times more likely (p=.013) to behave honestly than to bluff. Meanwhile, those who had been advised to bluff were 7.12 times more likely (p<.001) to bluff than to behave honestly but also were 7.03 times more likely (p<.001) to bluff than to lie. Thus, our findings provide *partial support* for *hypothesis 1*.

For *hypothesis 2*, we investigate whether the receptiveness to advice is determined by whether the advice had been solicited or not. We computed a dummy variable, "Match/No match," to measure the outcome of *receptiveness to advice*, following Sniezek and Buckley (1995). "Match" indicated the cases in which participants in the *honest condition* chose to behave honestly, participants in the *bluff condition* chose to bluff, and participants in the *lie condition* chose to lie. All other cases represented a "No match." The dummy variable, "solicited/unsolicited," is the predictor. Furthermore, factors identified in the literature as predictors for advice-taking – i.e., *task difficulty*, *perceived advice quality*, *self-confidence*, *dependent decision-making style*, and *decision-making anxiety* (Dalal and Bonaccio, 2010; Gino, Brooks and Schweitzer, 2012; Gino and Moore, 2007; Tost, Gino and Larrick, 2012) – were controlled for in the analysis. The scales were either self-developed or adapted from previous studies, and all scales achieved a reliability score greater than .80. We also controlled for the influence of participants' age and gender. Because the hypothesized differential effect of solicited and unsolicited advice can only be convincingly measured and interpreted when the advice is the same, we conducted three independent binary logistic regression tests based on the *advice content* (i.e., *honest condition*, *bluff condition*, and *lie condition*). The results showed that regardless of the advice content, the advice-taking behavior was not affected by whether or not the advice had been solicited (*honest condition*, p=.16; *bluff condition*, p=.60; *lie condition*, p=.07). Thus, *hypothesis 2* is *rejected*.

Study 2

In the second experiment, we shifted the focus from the *nature of the advice* to the *characteristics of the advice-giving colleague* and deployed a 3 x 3 design (*advice content*: be honest, lie, bluff; job *function of the advice-giving colleague*: procurement, sales representative, development engineer), with one control condition of *no presence of a colleague*.

Vignette design. The scenario description strongly resembled the first experiment. Participants assumed the role of a buyer who would soon enter into the last round of negotiations over a special tone wood for a musical instrument producer. The only remaining objective was to convince the wood supplier to reduce the price. Before entering the negotiation, participants met one colleague who offered a piece of advice. Participants then answered the survey question about the approach they would take in the final negotiation round. The options were identical to those in the first experiment, with a minor adaptation to the spend context. Participants in the nine treatment conditions also were asked to indicate their overall perception of the advice-giving colleague. Participants in the treatment conditions were then informed that they would work with the advice-giving colleague in a cross-functional sourcing team, and were asked to indicate their relational expectations for this colleague and for the cross-functional team.

Sample. The initial sample consisted of n = 510 North American purchasing and sales professionals, recruited using a U.S.-based survey research firm. Participants had to have at least two years of work experience in either a sales or supply management position. The data were collected in one survey period. Of the 510 participants in the initial sample, 32 were excluded for failing to answer the instruction checks correctly. Another two participants were excluded because they completed the survey within five minutes, which we assumed to be indicative of non-attentiveness, given the length of the survey. The remaining 476 participants (93.3% usable rate; 182 male; M_{age} = 38.0 years; $M_{work\ exp}$=18.6 years, $M_{negotiations}$=84 B2B negotiations) were randomly allocated to the 10 conditions.

Results. Participants indicated that they perceived the scenario as realistic (M=6.04). Similar to the first experiment, both the ANOVA test and a planned difference contrast showed that the manipulations for *advice content* had been successful. In addition, participants could only

proceed if, depending on the assigned condition, they correctly identified the *job function of the advice-giving colleague*, ensuring its successful manipulation.

The test of *hypothesis 3* was very similar to that of *hypothesis 2*. We first computed a dummy variable, "Match/No match," to measure the outcome, *receptiveness to advice* (Sniezek and Buckley, 1995). *Job function of the advice-giving colleague* served as the predictor, and as in the first experiment, we controlled for *task difficulty*, *perceived advice quality*, *self-confidence*, *dependent decision-making style*, *decision-making anxiety*, and participants' age and gender. All scales achieved a reliability score of greater than .80. We then conducted three independent binary logistic tests on the basis of *advice content* (i.e., *honest condition*, *bluff condition*, and *lie condition*). Results showed that regardless of the advice content, the job function of the advice-giving colleague did not affect the advice-taking behavior (*honest condition*, p=.95; *bluff condition*, p=.50; *lie condition*, p=.41), causing the *rejection* of *hypothesis 3*.

DISCUSSION AND MANAGERIAL IMPLICATIONS

Taking the role of boundary-spanners, procurement professionals deal with internal and external suppliers and organizational customers on a daily basis. Consequently, a structural hole (Burt, 2009) often appears between buying organizations and their suppliers, giving procurement professionals ample opportunity to play one party off against the other for their own benefit. Companies conventionally resort to formal control systems, such as compliance programs and codes of conduct, to curb dishonest conduct. Nevertheless, researchers cast doubt on the effectiveness of formal systems and advocate for informal systems as another component of the organizational ethical infrastructure. The norms espoused by informal systems might or might not be ethical (Smith-Crowe et al., 2015). Tenbrunsel and Messick (2004) note the danger of mixed signals from formal and informal systems, arguing that uncertainty breeds opportunistic actions. From this perspective, casual advice involving ethical issues represents one manifestation of informal systems. One objective of this showcase is to bring casual advice to the forefront by examining its influence on purchasing professionals' subsequent negotiations with suppliers.

We differentiated the advice content in terms of advice to be honest, advice to bluff, and advice to lie. In general, our results showed that a piece of collegial advice via small talk influenced the advice recipient's behavior in subsequent buyer–supplier negotiations. However, a closer inspection revealed a differential effect of the advice. Compared with those who had not engaged in any advice giving or taking but had made their own decision, advice recipients who had been advised to be honest were 3.3 times more likely to behave honestly than to bluff. Those who had been advised to bluff were 7.1 times more likely to bluff than to behave honestly, but also were 7 times more likely to bluff than to lie. In addition, advice to lie was fully discounted, and participants made their decision as if they had received no advice.

We contribute to the theoretical advancement of the use of deception in buyer–supplier negotiations, highlighting the effect of a situational variable—casual advice—which permeates organizational daily life but has so far slipped under the radar of researchers. Further, we contribute by offering the first indication, to the best of our knowledge, that business bluffing needs to be further reconceptualized. Kaufmann et al. (2018) consider lying and bluffing to be two distinct constructs, and they attribute the main difference to the consequences for their targets. They argue that the targets of lies perceive the actor as being *im*moral and are unwilling to negotiate with the actor again, while the targets of bluffs perceive the actor as being *a*moral and *are* willing to negotiate again in the future. Our findings suggest that the difference between bluffing and lying might also be reflected in the advice recipient's different acceptance of bluffing advice and lying advice.

We suggest that managers pay more attention to their organizations' informal control systems. Although actively shaping these systems takes effort, our results reveal that even small talk with a non-close colleague during lunch time could influence procurement professionals' preferred approach in negotiating with suppliers. Working in a compliance culture, exemplified by an environment where honest actions are both modeled and advocated via informal communication systems, can indeed motivate procurement professionals to follow suit. Moreover, the influence of advice to bluff seems to be unclear: while the advice can move buyers away from truth-telling behavior (being honest), it also might prevent buyers from engaging in unethical behavior (lying). However, our results demonstrate that buyers seem unwilling to follow advice that advocates lying. One possible explanation is that they can't predict all the motives of the advice giver (Sniezek and van Swol, 2001; Tzioti et al., 2014) and are unsure of the benevolence of this advice. This uncertainty becomes more salient when the advice-giving colleague suggests lying, leading the recipient to fully discount the advice.

Our results also demonstrate that, regardless of the advice content, recipients treat B2B negotiation-related solicited advice and unsolicited advice equally. This finding illustrates a boundary condition (Busse, Kach and Wagner, 2016) of the extant advice literature, which posits that unsolicited advice is discounted to a greater extent than advice that is explicitly asked for (e.g., Fitzsimons and Lehmann, 2004; Reinhardt et al., 2006). One potential explanation is that advisees are rather indifferent to whether the advice is solicited or not because organizations increasingly embrace an open communication culture and hail it as a boost to organizational performance.

In addition, we found that another situational variable—the job function of the advice giver—does not influence receptiveness to the advice. Procurement professionals likely see the advice from sales colleagues as equally credible to advice received from procurement professionals, probably because sales colleagues are experienced negotiators (i.e., they know "how"); and similarly, advice from R&D colleagues also has credibility probably because these colleagues are familiar with the product (they know "what").

For managers, the robustness of the results showing how these two critical situational variables influence the effects of advice on subsequent negotiations further underscores the need to monitor advice-giving in casual contexts. The maturity of the compliance culture surrounding a PSM function does seem to affect supplier negotiations.

LIMITATIONS AND FUTURE RESEARCH

In our studies, we operationalized advice acceptance as "matching" in terms of consistency between an advice recipient's decision and the advice giver's recommendation (Sniezek and van Swol, 2001). Researchers contend that this method of measurement is misleading because it does not consider the advice recipient's pre-advice choice; the argument is that advice-taking occurs or "counts" only when it causes the advice recipient to *switch* from his or her pre-advice choice to the alternative recommended by the advice-giving colleague (Bonaccio and Dalal, 2006). We admit that first asking for participants' pre-advice choice and then providing them with the advice could yield further insights. However, we examined various treatment conditions on a group level and compared their choice patterns with that of the control condition, in which a choice was made without the influence of advice. Therefore, the decisions reached by those in the control condition provide similar data to that of the pre-advice choice and might convincingly serve as a basis for comparison.

We limited our focus on participants from North America and did not consider those with other cultural backgrounds. While the macro-level national culture represents a significant variable

influencing an individual's intention to behave ethically, researchers consistently demonstrate that the *micro-level peer influence* exerts a greater effect (Westerman et al., 2007). Therefore, we argue that casually given collegial advice may also influence one's negotiation approach in a different culture. Yet, it would be interesting to find how such qualitatively different advices (i.e. to be honest, to bluff, or to lie) will be perceived and to what extent they will be followed, because certain cultures attach more importance to humility (Taras, Kirkman and Steel, 2010), which might reduce ego-centric discounting and impact advice-taking behavior (Kausel, Culbertson, Leiva, Slaughter and Jackson, 2015). By the same token, industry and organizational culture overshadow individual decision-making but are unlikely to override the influence of proximal social referents (i.e. reactions to collegial advice) – although this is another potential area for future research.

With our findings providing evidence that collegial advice offered in a casual manner takes its toll on buyers' subsequent negotiation approach, we strive to shed light on the under-tapped potential of behavioral PSM research. As a complementarity to the already largely adopted cognitive psychological lens, we would like to specifically draw attention to the *social psychological perspective*. Entrusted with various strategically important tasks, such as mitigating supply risks, improving cost savings, ameliorating product quality and processes, and boosting innovative capabilities (Azadegan and Dooley, 2010; Azadegan, Patel, Zangoueinezhad and Linderman, 2013; Day and Lichtenstein, 2006; Feisel, Hartmann and Giunipero, 2011; González-Benito, 2007; Zsidisin and Ellram, 2003), PSM professionals interact with internal organizational customers and external suppliers on a daily basis. These frequent interactions with different stakeholders provide ample opportunities for research with a social psychological approach.

Using our empirical studies as an example, we adopt the "5W and H" approach (Cao and Lumineau, 2015) and highlight in Table 1 how a specific behavioral focus (i.e. casual advice) might be incorporated in both *intra*- and *inter*-organizational PSM research and thus help advance our understanding of various PSM activities. For instance, while our studies focus on advice-recipients, future studies may focus on advice *givers* as the unit of analysis by investigating their emotional and behavioral reactions to the advice recipient if their advice is not followed. Building on our empirical setting, the effect of casual advice-giving may go beyond the advice-related buyer-supplier negotiation. Since in social interactions, people engage in information processing to form and update impressions (Asch, 1946; McArthur and Baron, 1983), previous advice-encounters in casual contexts may well set the initial tone for how the procurement professional interacts with the advice-giving colleague in a *future collaboration*, and the same applies to the advice-giving colleague. Empirical studies in this arena are much needed, because many organizations employ cross-functional teams for critical PSM tasks (Driedonks, Gevers and van Weele, 2010; Kaufmann, Meschnig and Reimann, 2014). A dyadic perspective, taking into consideration both advisor and advisee, including various dispositional variables (e.g., personality traits and role identity) pertaining to them, may shed additional insights into the dynamic advice-giving and -taking process as well as its implications.

Further, researchers could look beyond the boundary of the organization. Procurement professionals often represent the most important, if not the only, touch-point for suppliers. Because companies increasingly rely on external sources to advance knowledge and innovation (van Echtelt, Wynstra, van Weele and Duysters, 2008), future research might examine how and when procurement professionals transfer, e.g., a supplier's advice into the buying organization. In particular, there would be value in exploring how cognitive (e.g., rational or emotional information processing), structural (e.g., power distribution between buying company and

supplier) and situational (e.g., advice-content related) variables combine in complex ways to facilitate or inhibit this advice transfer. Beyond that, questions of how advice passes from lower-tier suppliers to the buying organization are of particular relevance, because they may help better account for critical PSM activities such as supply risk mitigation. This line of inquiry invites studies adopting a supply chain view (Carter, Kosmol and Kaufmann, 2017; Carter, Rogers and Choi, 2015).

Having provided an empirical investigation of the effect of casual advice on buyer-supplier negotiations, and expanded upon how researchers may incorporate this specific behavioral focus in future studies, our hope is that this paper highlights the still underexplored potential of behavioral research in PSM and helps guide future work in this field.

Table 1: Exemplary Research Agenda

	What? **Area to investigate**	**Who?** **Dispositional Variables**	**Where?** **Contextual Variables**	**When?** **Temporal Variables**	**Why?** **Relevance**	**How?** **Managerial Interventions**
Key concepts	**Topic area:** Advice-recipients' perception of the advice-giver and its implications Advice-givers' reactions to the advice-recipient's behavior and its implications Process of advice-transferring **Advice-related factors:** qualitative vs. quantitative nature, solicited vs. unsolicited	**Individual-level:** role identity, personality traits, cultural background **Team-level:** team composition, role assignment	Power asymmetry, industry dynamics	Time criticality of the advice-related decision-making, transferring the advice (soon or late), history between the advice-recipient and -giver	What could casual advice-giving bring about in the PSM field?	Measures to make use of the omnipresent causal advice-giving/taking activities
Possible research questions	• Does previous advice-related encounter impact the advice-receiving buyer's perception of the advice-giving colleague? And in which contexts will these perceptions play out? (e.g. cross-functional collaboration, sustainable SCM initiatives) • What could be the social rewards and	• How do personality traits influence boundary spanners' intention to accept, reject or transfer the advice? • How do different functional level "thought worlds" reveal themselves in the advice-giving/taking process? • Does certain cultural	• To what extent does the power asymmetry between the boundary spanners (i.e. buyer vs. supplier) impact the advice-giving/taking process? • Do highly dynamic industries profit as a whole from frequent inter-organizational advice-giving activities?	• Are advice-recipients more willing to heed the advice when the related decision-making is imminent? • What factors influence buyers' speed to transfer suppliers' advice into the buying organization?	• What types of and how do casual advices pass from lower-tier suppliers to the buying organization and backwards? • What could be the facilitating and inhibiting factors in the above process?	• Which archetypes of advice do buyers receive from colleagues in casual context? Do they complement or undermine the formal communication and control system? • How can buying organizations structure incentive systems to encourage suppliers to

	What? Area to investigate	Who? Dispositional Variables	Where? Contextual Variables	When? Temporal Variables	Why? Relevance	How? Managerial Interventions
	costs for the advice-giver? • Do advice-giving colleagues/suppliers punish the buyers if their advices are not followed? And how (refrain from offering advice in the future or execute more severe ones)? • When do buyers transfer a supplier's advice to the buying organization?	background (e.g. value social harmony vs. value self-enhancement) make the advice-recipient more or less likely to heed the advice? • Does a team react more open (e.g. due to reduced ego-centric discounting) or reluctant (e.g. due to "not invented here syndrome") to advice from outsiders? Does the level of diversity play a role here?				actively provide advices?
Promising theories	Social learning theory, social perception paradigm, social network theory	Social identity theory, role identity approach, institutional theory, work-group diversity	Complex adaptive system, theory of reasoned action	Temporal orientation, deferential association theory	Information processing view, supply chain practice view	Ethical infrastructure, organizational commitment, supply chain practice view

Abstract

Digital tools are shaping today's sales and purchasing. The majority of the current tools are used within a single company, but some tools and solutions can be used collaboratively across the company borders. The goal of this research is to analyze these collaborative situations to identify both the drivers and the challenges of building digital purchasing tools. By conducting a multiple-case study of industrial manufacturers and their distributor partners, we have received rich data that gives insight into this topical issue. The main contribution of the research is a model that distinguishes the drivers and challenges of the collaborative tools.

Keywords: Purchasing tools, digitalization, sellers, distributors

Working paper

1 INTRODUCTION

Sales and purchasing are among the critical functions in a firm. Digital tools and digital information are transforming sales, not least because the buyers use new tools in their role. The nature of organizational buying in business-to-business setting is shaping also the nature of selling (Ulkuniemi, Araujo and Tähtinen, 2015). The role of human interaction in sales cannot be underestimated but, it is not the only way how companies can give information and convince customers about the company's offering. People use frequently different digital tools in searching and comparing different products and services.

The sales/purchasing interface is facing many changes in the industrial companies. The globalized arena of buying and selling is one of the reasons for more complex settings in the relationships. In the fierce competition and development of new IT solutions, it is evident that many business practices and processes are changing and the dynamics between the companies in the distribution channel face some challenges. Sales especially at B2B context is an area where the traditional view of face-to-face salesmen has been challenged during the last decade. The sales force automation (SFA) and configure-price-quote (CPQ) -systems are examples of this change in selling.

One of the critical customer development tasks is the development of SFA tools targeted to buyers. For that reason the benefits of SFA tools is an important research topic. Even though that many of the SFA tools are used collaboratively by sellers and buyers, majority of the research regarding SFA benefits focuses on mainly the selling company (Holloway, Deitz, and Hansen, 2013; Bush, Moore, and Rocco, 2005; Barker et al., 2009) and in limited way to the customer (Boujena, Johnston and Merunka, 2009). This research tries to address this research gap by examining the benefits and challenges of SFA use in situations where the tools are used collaboratively by both seller and buyer.

Sales configurators are a SFA tool that can be used in the sales process in providing product information on different product options and feasible configurations. Sales configurators can be used to also to provide pricing and availability information. Developing sales configurators requires deep understanding of the customer requirements and preferences and can be categorized as a customer development activity.

In this paper we address the following two main research questions. 1) What are the benefits of sales configurators in collaborative use between buyer and seller 2) What are the challenges of sales configurator use in collaborative use .While we are mainly interested in the usage of sales configurators in collaborative setting, we are not limiting the inquiry to those situations. In order to gain deeper knowledge of the benefits and challenges we extend the research focus to situation where the tools are used internally in the seller or buyer company. We hope that this gives us additional information to analyze the phenomena more comprehensively.

To address the research questions, we develop a two-wave qualitative research design. All together 41 dyadic in-depth interviews were conducted. The first wave of interviews were conducted in selling companies and consecutively the second wave in buyer companies. Datasets of 25 seller side and 16 buyer side interviews were analyzed to answer the research questions.

The main contribution of this study is the identification of both benefits and challenges of collaborative sales force automation tool use. We also make a distinction of the benefits and challenges in six different context. For both seller and buyer three situations: internally, pre-relationship and during the relationship. The study contributes to the SFA literature by adding to the results of Holloway et al., 2013 and Boujena, et al., 2009.

2 LITERATURE REVIEW AND THEORETICAL FRAMEWORK

Understanding how current sales in a B2B context are changing because of digital tools requires exploration of two theoretical aspects: digitalization of sales and seller-distributor relationships, which are discussed next.

2.1 Digitalization of Sales and purchasing processes

Sales is one of the areas that is changing due to new digital tools. Most of the articles in this field look at the adoption of sales technology within one company (e.g., Schillewaert et al., 2005). There is a silent revolution occurring now related to how purchasers behave, and this behaviour has an evident effect on the sales side. Many things change the complexity of selling in the B2B context. For example, in the global arena, there is an increasing need for more complex products and services, and entities related to these areas are selling value. These

ventures require deeper understanding of the underpinnings related to customer value creation. Traditional selling, in many cases, has turned towards consultative selling.

The challenges around marketing have started from consumer businesses. The new digital forums, social media, and mobile marketing are typical examples of the contexts that have revolutionized marketing (Lamberton and Stephen, 2016). These types of media and their development has intensified the need to look at the issue of market intelligence in new ways.
The use of IT solutions in inter-organizational relationships has increased during the last few decades. Most articles look at these issues from the seller's side, but material from the buyer's perspective also exists. For example, Presutti (2003) studied e-procurement and defined it as "a technology solution that facilitates corporate buying using the internet." After the intensive e-procurement and e-supply period, there has been much discussion concerning IT and the Internet, and their roles in decision-making about purchasing and e-purchasing in different contexts (Centobelli et al., 2014; Walker & Brammer, 2012; Gunasekaran et al., 2009).

From the seller's point of view, IT tools enable a new way of interacting with critical parties in the distribution channel. Mirani et al. (2001 p.101) pointed out that "suppliers have traditionally managed their relationships with resellers using inefficient, fragmented, and labor-intensive communications processes." Their basic message is that multiple benefits can be received not only through improved efficiency and productivity, but also from improving profits by enhancing "front-office" activities. In many cases, including ours, this requires collaboration with distributors. Distributors do sometimes act as gatekeepers between manufacturers and customers. In this situation, it is extremely important to find solutions that are beneficial to all parties in the distribution channel.

Sales Force Automation (SFA) provides digital tools for the use of distribution networks. Jobber and Lancaster (2009) identified SFA as one of the major forces affecting selling and sales management. One SFA tool is the sales configurator. These configurators play a crucial role among companies with rather complex and technical products. In these situations, it is crucial to find the best possible product and service configurations from both the customer's and the company's perspectives. SFA refers to the use of technology by salespeople in their selling and administrative tasks (Morgan & Inks, 2001). SFA can be defined as the application of information technology to support the sales function (Buttle et al., 2006). SFA is meant to support the sales function, not to replace it; in other words, SFA means adapting technology to support the sales activities of a certain company to enhance the company's sales process.
An SFA system is often part of an enterprise-wide information system that integrates sales activities with the information systems across the whole organization (Barker et al., 2009). Therefore, SFA is vital for the whole organization. Technologies used may include, for example, computer hardware, software, and mobile devices such as tablets and mobile phones. SFA promises to free salespeople from their compulsory time-consuming administrative tasks in favor of relationship-building tasks that better suit the skills and abilities of the sales force (Eggert & Serdaroglu, 2011).

Sales configurators can be used in various ways. A typical situation involves the selling company's personnel using these configurators in their selling tasks. Distributors use them when configuring products per requests of end customers and when finalizing the product orders sent to the selling company. The most far-reaching application for the sales configurators is when sellers let the end customers define their preferences for the product attributes, thereby configuring the product themselves. Enabling the end customers be involved in the configuration process has been found to increase customer satisfaction (Huffman & Kahn,

1998). At the same time, more information can be gathered from the customers (Berman, 2002). Zanker and Tiihonen (2008) stated that a configurator creates valid configurations of a requested item based on specified criteria and limitations to ensure compatibility and customer requirements.

Although sales and product configurators are frequently viewed as interchangeable, they can have different meanings. Pimiä (2002) said that a sales configurator is a product configurator adapted for the needs of sales personnel. It is software, either an independent application or a part of another one, such as ERP, CRM, or Product Data Management (PDM), that helps the sales force to create a quotation. Then again, Kopra (2003) identified three entirely different usage scenarios for a sales configurator application: (1) internal use by a sales person to create quotations, (2) dealer use of the application, and (3) direct external use by end-customers.
According to Haag (1998), a sales configuration is a high-level configuration in which an external user, usually a sales person or a customer, interacts with an application to make a creative decision on the offering. Kopra (2003) argued that, more often, the customer accesses the configurator through the Internet to generate a configuration detailed enough for automatic quotations. More recent studies, such as that of Abbasi et al. (2013), support this claim and note that the configurator offers a graphical user interface (GUI) to guide customers through the entire process. During this process, the configurator verifies the feasibility of a configuration and handles possible conflicts (Abbasi et al., 2013).

In addition to the basic benefit of the configurator—a product that fits the customers' needs—research shows that customers can attain value from experience-related benefits (Trentin et al., 2014). According to Trentin et al. (2013), other customer-related benefits of sales configurators in business-to-consumer markets are (1) benefit-cost communication, (2) user-friendly product-space description, (3) easy comparison, (4) flexible navigation, and (5) focused navigation. In an empirical study, Baharati and Chaudhury (2006) found that both system and information quality influence the user satisfaction with sales configurators.

El Kadiri et al. (2015) have studied trends in ICT technologies and enterprise information systems (EIS). They presented four challenges of EIS: (1) data value chain management, (2) context awareness, (3) usability, interaction, and visualization, and (4) human learning and continuous education. These issues also must be considered in guided selling projects. In addition to typical IT systems like ERP, CRM, and maybe SFA, new concepts and systems have emerged in the discussion, such as Partner Relationship Management (PRM). Mirane et al. (2001) saw these systems as "helping suppliers treat resellers as virtual extensions of internal sales teams."

2.2 Development of Seller – Distributor Relationship

The relationship between seller and distributor is often critical for the success of the distribution channel. Tsai et al. (2013) stated that "in the e-Retail industry a well-designed IT infrastructure is essential in creating a tightly integrated value chain and delivering high quality service." Their article concentrates mainly on information systems and technology (IST) sourcing and underlines the essential role of IT in retail business. This may be especially critical for e-retailers, but similar performance effects can be realized in manufacturer–distributor relationships. The relevance and need to develop IT solutions that support both efficiency and effectiveness goals is evident. Osmonbekov and Gruen (2013) stated that "firms are increasingly using e-business tools to transform channel relationships in order to achieve competitive advantage." They also divided the systems into categories: (1) reseller-supplied,

(2) third-party supplied, and (3) manufacturer-supplied. In addition, they postulated that companies should be aware of perceived inequity in sharing benefits of e-business technology. The general assumption is often that benefits accrue to all parties due to effects such as lower costs, improved communications, streamlined processes, web-based accessibility, and issues surrounding channel power. Mirani et al. (2001) also discussed the IT tools in supplier-reseller partnerships.

Wilson and Daniel (2007) underlined the importance of rapid and dynamic changes in the distribution channel to be able to compete successfully. Their findings stated that there are challenges in both creating new innovative channels and at the same time ensuring that the "organisation works as a single, coherent entity" delivering consistent service.

3 METHODOLOGY

3.1 Research Design and Case Selection

The research data includes semi-structured interviews in five Finnish industrial cases. In this paper, we analyze 45 interviews that are coming from a dyadic company – distributor context. The data gathering focuses on five focal industrial case companies; two of them were offering goods and services in the field of electronics industry, while one was a machine manufacturer producing equipment used mainly in the construction industry. In addition, two workshops were aimed at professionals, and were also arranged around the research topics.

Four companies are small- and medium-sized enterprises (SMEs), and one company is considered large. Companies operate in the field where the end-products are complex and modular. All the companies market and sell products and services to global markets. Configuration is often needed according to customers' needs. The companies in the study also differ in their reliance on distributors. One company sells nearly all of its products through resellers. Two of the companies make approximately half of their sales through resellers. One company makes only a small part of its sales through resellers.

The electrical components companies sell products that are clearly configurable; this quality is critical to satisfy end-customer needs. Still, many of the products are off-the-shelf products. In those cases, the configuration is done by the distributor, the manufacturer, or a collaboration of both.

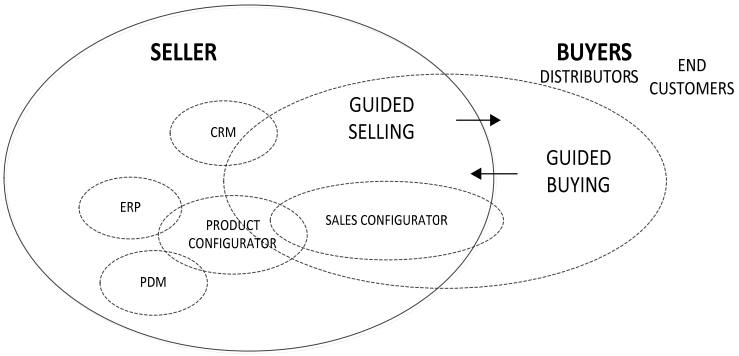

Figure 1. The setting of the study and relevant IT systems

The dyadic scope of the research can be seen in Figure 1. The selling companies (i.e., focal companies) and the buying companies (i.e., distributors) are the main foci of the study. Figure

1 also illustrates the different information systems used for guided buying and selling. In the current study, we look at the sales configurators under investigation in our study and only marginally use the term guided selling, which is a broader concept of sales using IT tools and personal selling in the distribution channel relationships.

3.3 Data Analysis

The research data was analyzed by the researchers according to the methods used in qualitative data analysis. The themes were created according to interview material in order to answer the research aim. The data included rich and colorful text by the practitioners, and this may have included some biased views and personal opinions. We tried to find the possible biases and not make any far-reaching interpretations based on these comments.

The basic data consisted of the comments made about the benefits and challenges of sales support tools by suppliers and distributors. Also, the comments related to the nature and importance of the supplier-distributor relationships were valuable. In the analysis, it was clear that the different businesses had certain similarities but also some clear differences. These interesting findings will be analyzed in the results section herein.

4 RESULTS

4.1. Benefits Driving the Development of Digital Sales Tools

The companies' representatives saw the development of the guided selling positively, and they saw many possible benefits from the use of the IT tool. The process itself enabled the development of business processes and more effective results in the whole distribution channel. The end-customer also benefited from more systematic configuration in the sales process. The nature of the tool as a checklist of important issues in the sales process was often mentioned by interviewees. Other widely mentioned benefits were the increase in product knowledge and many operational elements. When the product information is presented in a customer-friendly manner, it is cognitively more accessible. The importance of presenting technical and product information in an accessible way is particularly important in cases where the complexity of the products is great. There were examples where companies needed to go through the technical details of the order iteratively.

> *"Someone who does not know the products so well could still make the configuration so that solution is a functioning product."*

As with the selling company, the distributor would benefit from the increased information about the customers' needs, market distribution, and market potential. The benefits could come to all parties through this more transparent chain from the end-customer to producer. Easier and more efficient handling of orders is yet another benefit to the selling company. In many cases, the interviewees said that the most obvious benefits came from more efficient operations. Sometimes, the distributors stated that the most of the benefits would inure to the supplier's side:

> *"It is useful for you guys…."*

The suppliers believed there were also benefits for the distributors, as it was easier to assess the financial outcome of certain solutions. The value and cost of customizing products was revealed:

> *"The distributors could see easily in the offering phase what is their profit when including different features into the offering. They would see if it's useful to customize the products (if customer is not wishing it)."*

> *"If, for example, you buy a machine with some additional features the system would help you to specify the configuration correctly and you would avoid difficult negotiations when adding the features afterwards."*

There was also a difference between the companies already using sales configurators or electronic purchasing from the case suppliers. These companies were able to give both positive and critical feedback about the functionality and usability of the systems. On the other hand, their opinions may have been fixed on their current experiences, and it may have been difficult to solicit more visionary ideas for systems development.

The distributors' benefits can be inferred from the idea that the configurator tool would make their lives easier and support their business goals. Resellers are quite often the parties who influence the configurations suggested to the end-customers. A digital configurator could make ordering easier and faster, and it would support sales. Businesses could obtain statistical data from the sales and technical data about the products sold and their profitability, for example. Distributors could also enhance their knowledge of the products, as well as the end-customers' needs. Two benefits would be a clear view of the total offerings and an easier comparison among the different solutions.

4.2 Challenges Complicating the Development of Digital Sales Tools

When considering the pressure to transform operations, the interviewed rental company representatives saw that their roles and positions would remain largely the same as before. The IT capabilities and tools would help some operations, but would not change the business logic in a radical way. Our distributor interviews were done only in Finland, and the material discusses mainly this market area. We received some indications in internal interviews that market areas are highly different. In some markets, the role of rental companies is not as important, and the willingness and active use of IT and modern information sources (e.g., social media) differs a lot. In addition, the view of how things will be changing in the future varied widely. Some interviewees thought that there would be changes in the buying patterns and practices, while others saw the conservative business staying as it is.

In both machinery and electricity cases, it was clear in the most complicated cases—including customization and complex solutions—the expertise of the manufacturer was needed. In those situations, there is often the need for face-to-face contacts that may include all parties: distributor, end-customer, and manufacturer. The use of configuration tools is supported in the middle of the continuum, off-the-shelf products, and fully customized solutions. The view was rather similar in internal interviews, where the salespersons saw that the tools may have an effect on their work but would not eliminate the need for the salespersons' personal expertise. This opinion was supported by comments when interviewees discussed the role of face-to-face contacts:

"No configurators or IT systems can replace it (face-to-face contact)."

The use of IT and other changes in current operations are quite challenging for the manufacturing companies. There are different fears and resistance to change that make the new solutions hard to implement, even internally, for manufacturing companies. Interviewees also mentioned that the challenges can be even greater when directed towards external companies. At least the company cannot force the partners to use the systems:

"Change is a very difficult thing to us and breaking the change resistance. We should look forward and develop things even though it is difficult."

When talking about the changes in the distribution channel during the internal interviews, the general opinion was that tools have to be developed in order to keep the competitive edge in the future. There were huge differences among the current distributors and in their IT :

"I don't see it possible with current customers, but I know that things will change."

"If we want to be an active and modern company, digitalization is a must. World has developed to this direction and if we don't follow this development we are definitely out!"

The roles and positions of different companies in the distribution network may change and there may be conflicting interests.

"We try to handle things so that we are not fishing at the same place with the manufacturer. If there is a mutual customer the manufacturer deals with larger projects and we'll manage the daily needs."

The distributor's perspective is critical in most of the companies. The new tools and active use of modern IT are seen as ways of developing the distribution network. Many of the old ways of distribution are still working fine, but there has to be an ability to see future development and changing buying patterns. There is not a great risk of radically losing the business in the short term, but in the long term, this can happen. On the other hand, by implementing new tools and innovative ways of presenting offerings, new customers and new geographical areas can be found.

4.3 Summing Up Results

The study includes both sellers' and resellers' (i.e., buyers') opinions on IT tool use in their sales and purchasing operations. The natural result is that it is easier to implement the system internally with one's own salespeople than to put it in the hands of resellers and ensure active use there. This point is obvious, but it highlights the importance of developing a system to provide the benefits to different parties and users. In this context, businesses cannot rely on the systems that are released merely hoping to bring some benefits. The tools must be extremely useful. Table 1 summarizes the Benefits and challenges of sales tool implementation at different parties.

Table 1. Benefits and challenges of sales tool implementation at different parties

	B2B-Seller	B2B Seller-Distributor Relationship				B2B-Distributor
	Internal	Pre-relationship	Relationship	Relationship	Pre-relationship	Internal
Benefits and Drivers	▪ Operational efficiencies ▪ Order handling becomes easier ▪ Improved market information ▪ More resources to customer development tasks	▪ Sales tool becomes a marketing communication channel ▪ Attracting better distributors ▪ Improved market visibility	▪ Improved sales because of better customer service ▪ Sales tool supports traditional selling activities ▪ Easier and improved order generation ▪ If customer uses the tool, the customer commits to the seller	▪ More relevant information from supplier (options, profitability…) ▪ More technically oriented customers receive tools they require ▪ Information is not dependent on salesperson or time of day	▪ Supplier selection becomes easier ▪ Relevant information is available ▪ Willingness to use a sales tool can give an access to "better suppliers"	▪ Pricing becomes easier ▪ Product know-how increases ▪ Customers are easier to serve
Challenges	▪ Master data handling ▪ Updating the information ▪ Developing and Implementation of the system	▪ Information open to competitors ▪ Too much information to distributors & end customers ▪ More difficult to differentiate to different segments	▪ Educating and motivating the distributors to use the tool take resources ▪ Technological issues	▪ Learning of many information systems take resources ▪ Technological issues	▪ Initial access to sales tools can be difficult ▪ Technical know-how is required	▪ Resources need to be allocated to utilize the tools ▪ Using a specific tool can be a risk if personnel changes are expected

ABSTRACT

Consumers often tend to store non-functional and old electronic products for a period of time before they are discarded. The storage behaviour may cause by unclear communication concerning the importance of immediate return. In discussing undesired storage behaviour among consumers, this research provides insightful product return knowledge by studying the idea of ideal timing and quality of return and the effect of different message framing on consumers' Immediate Return Intention (IRI). Therefore, this research presents a conceptual framework underpinned by social marketing theory highlighting product return knowledge as a factor that influences consumers to immediately return their used products. The proposed framework also visualised the relationship between message framing and consumers' IRI that moderated by these consumers' traits; environmental knowledge and environmental motivation, resulting in facilitating the establishment of effective business-to-consumer information sharing.

Keywords: Product Return Knowledge, Message Framing, Immediate Return Intention (IRI), Social Marketing Theory

Paper Category: Working Paper (WP)

INTRODUCTION

Over the years, manufacturing activities have been mostly confined to extracting raw materials from the earth to produce end products. The products then will be disposed into landfills or incinerated after its end-of-life. However, this unsustainable approach is no longer acceptable because of the rising concern for clean and safe environment. Realizing the magnitude of this problem, various initiatives have been undertaken by industries, governments and scholars and they have tried to analyse this issue from the perspective of the supply chain and more particularly in the context of Closed Loop Supply Chains (CLSCs) (Guide and Van Wassenhove, 2009; Rubio et al., 2008; Jimenez-Para B et al., 2014). CLSCs are related to End-of-Life (EoL) and End-of-Use (EoU) products. The aforementioned research is focused on the supply side of End-of-Life (EoL) and end-of-use (EoU) and it highlights various key activities such as product acquisition, reverse logistics, inspection and possible product disposition (Blackburn et al., 2004). Focusing on value-added recovery material use cycle, one of the common problems encountered in CLSCs is uncertain quantity and quality of the return.

In the CLSCs, Original Equipment Manufacturer (OEM) or remanufacturer may decide to handle the return process individually (Madenas et al., 2014). Guide and Jayraman (2000) mentioned that 82% of firms collect the used products directly from the customers. Manufacturers know that the retailers are the closest players to the market and thus they can influence customers, create knowledge and awareness of environmental concerns, and educate them to return the products in good conditions (Giovanni, 2014; Hong and Yeh, 2012). One of the major challenges in CLSCs research is to understand its relationship with the market and consumers (Jimenez-Para et al., 2014). Particularly, (re)manufacturers are interested to know the relationships of various factors with return attitude and intention, and how these factors can motivate consumers' to immediately return their used products. Nowadays, (re)manufacturers motivate the consumers to return their EoU and EoL products through benefits such as warranty, incentives, and exchange offer. However, they are still unable to collect sufficient amount of used products from the market (Jena & Sarmah 2015). In respect of that, firms want to know the key factors which impact mostly the return attitude and intention of the consumers. Moreover, these questions are likely to be encountered by the (re)manufacturer in practice, and they have not been adequately addressed in the literature.

In discussing consumers' immediate return intention, this research investigates product return knowledge development and delivery. Product return knowledge development highlights the types of information (information content) and product return knowledge delivery highlights information presentation (information context) as independent variables. The chosen variables are derived from work by Philips (2004). Philips (2004) stated that successful environmental education depends on its design and delivery. Additionally, rational choice theory suggests that individuals base their choices on the attributes of the choice set (information content), the way information is being presented (information context) can also have a strong effect on consumers' use of and reaction to information (Avineri and Owen, 2013). Thus, this research explores the effect of types of information and information presentation on consumers' Immediate Return Intention (IRI) of durable household waste. The proposed information contents are ideal timing and acceptable quality of return. The proposed information context is message framing; positively and negatively framed messages.

Therefore, the aim of this research is to propose a conceptual framework leading to consumers' Immediate Return Intention. This framework provides information on how the identified variables influence consumers to immediately return their used products. The product return activity is discussed based on these scopes:

- Where the product return is initiated by consumers and not by curbside collection initiated by collectors (local government agencies, industrial collectors, third-party recyclers).
- The end-of-use and end-of-life product return and not focused on other types of returns (e.g. commercial return, warranty return).
- Product return that involved the returning activity of household waste such as broken and obsolete small electronic kitchen appliances, office equipment and toys and is not focused on food and beverage packaging, apparels and container.

LITERATURE REVIEW

Consumers' Storage Behaviour

According to Sabbaghi et al. (2015), consumers often have a tendency to store their used, old or un-functional electronics for a period of time before they discard them and return them back to the waste stream. Numbers of previous research highlighted this issue. Saphores et al. (2009) presented the first survey-based which estimates of e-waste items stored by US households. They found that by the end of 2005, US households stored at least 470 million

small and 277 million large electronic waste (e-waste) items, which substantially exceeded 2008 official estimates (EPA, 2008). Tackling the same issue is, Milovantseva & Saphores (2013b), who found that US households stored approximately 84.1 million junk TVs at the end of 2009. Milovantseva & Saphores (2013b) also reported that consumers tend to retain their e-waste (television) between the range of 5 to 16 years. The latter research reported a particular range of retention period based on these demographic factors: educational level, gender of household head, marital status, household income and geographic location. Recent research of Sabbaghi et al. (2015) explored storage behaviour among consumers. One of the findings reported that consumers tend to store the unwanted Hard Disk Drive (HDDs) for 1.11 years on average. Sabbaghi et al. (2015) also found that household consumers tend to keep electronic waste longer in storage when they use them less than the normal time.
Such prolonged storage behaviour as reported in the extant research leads to problems such technology obsolences for product recovery, low-efficiency disposal treatment that could danger human health and uncertainty problem in product return and recovery inventory. Regardless of functionality, the obsolete used products are not likely to be reusable (Babbitt et al., 2016). This behavior increases the obsolescence rate of used still-functional products which will directly affect the further treatments such as reuse, upgrade, and refurbishment. The obsolete waste then might be dumped in landfill sites or recycled with low-efficiency such as being burnt for valuable metals which results in releasing of hazardous toxics into the environment and harmful effects on human health (Jang and Townsend, 2003, Kolias et al., 2014). These are the reasons why immediate post-consumption return is vital. According to Guiltinan (2015), consumers need to know time delay in collecting and processing products makes them unusable, obsolete and even completely unsalvageable. This means that knowledge about technological obsolescence should be transferred to consumers so that they will initiate immediate post-consumption return. Consumers need to know that the sooner a used product is processed, the higher value is recovered. Optimal recovery value is beneficial for businesses and also helps in minimizing the risk to human health. It is time to view this issue from a social-good point of view. Understanding the nature of the used electronics in terms of quality and timing will diminish the risk of unprofitability of recovery system as well as avoid hazardous disposal that could harm our health (Sabbaghi et al. 2015).

Despite the fact that producers come up with numerous strategies to respond to reverse logistics, such as product take-back policy, extending the scope of producer responsibility, incentive-based scheme (refund payment) to encourage more return, it still insufficient. Consumers' willingness to commit in immediate return after usage phase is necessary. Any kind of motivation and knowledge sharing could be one of the solutions to encourage willingness and participation. Additionally, Sabbaghi et al. (2015) also suggested that manufacturers should play vital role in motivating consumers to return their household waste, especially e-waste.

Business-To-Consumer (B2C) Information Sharing in EOU and EOL Return
In B2B information sharing, accurate, timely, and consistent information about material flows and processes through the supply chain can reduce operating costs and increase the productivity of individual companies and the entire supply chain (Timpe, 2006; Uusijarvi, 2010). In the other hand, for B2C information sharing, consumers value detailed product information, especially in pre-purchase processes, e.g. product origin, quality, sustainable characteristics (Regatteri et al., 2007) and post-consumption processes (Appelhanz et al. 2015). B2C information sharing can reduce consumers' information asymmetries and associated information costs (Hobbs, 2013; van Amstel et al., 2014), thereby increasing product trust and purchase intentions (Chen et al., 2012; Clemens, 2013; Ortega et al., 2014;

Ubilava and Foster, 2012). The provision of these types of information enhances trust in products as well as preferences for eco-friendly and abstinence from non-eco-friendly materials (Gleim et al., 2013). Good pro-environmental messages not only draw the customers closer to pursuit long-term and profitable relationship (Bendapudi & Leone, 2003; Payne, Storbacka, Frow, & Knox, 2009), but it ultimately results in positive behavioral intentions from consumers (Viet & Cass 2013). Hence, it will result in consumer engagement in pro-environmental behaviours, such as sustainable consumption and disposal.

Products return knowledge with immediate return information is expected to respond the exponential growth of durable household waste, for example, e-waste. It is easier to solve the exponential growth of e-waste by using drop-off method, instead of take-back program and curbside collection. By definition, drop-off recycling method means that consumers willingly drop their waste at the provided facilities. On the other hand, take-back program and curbside collection are the collection method that initiated by (re)manufacturers, government or other third parties. Drop-off recycling is easier to implement than take-back or other programs involving manufacturers and the required facilities are typically less expensive to operate than curbside collection programs (Saphores et al. 2012). In order to amplify return initiated by the consumer, awareness is vital. According to Jena & Sarmah (2015), to spread awareness among the consumers for returning their used products is a challenging issue for the (re) manufacturer. Nonetheless, this issue is challenging yet attainable. It is attainable with the support of adequate and accurate information throughout educational programs and campaigns, plus the familiarity of general environmental knowledge among consumers. Since today's consumers appreciate general environmental knowledge more than ever, the distribution of this type of specific environmental knowledge is possible.

CONCEPTUAL BACKGROUND AND PROPOSITION DEVELOPMENT

Product Return Knowledge

Generally, return product knowledge is an individual's knowledge and familiarity about returning the used products. It can be measured in terms of objective or subjective knowledge, which is very difficult to separate operationally (Rao and Monroe, 1988). Thus, a composite multiple scale knowledge on subjective and objective analysis is used to measure the return product knowledge as quality, performance, and price (Rao and Monroe, 1988). To fit in this research context, return product knowledge is extended by considering some special features of returned product knowledge like availability of collection of used products centre, recovery process and existence of toxic material in electric and electronic equipment. These special features are related to information derived from Guide and Van Wassenhove (2009), which highlighting time and quality of return. Specifically, knowledge about the existence of toxic material in electric and electronic equipment reflects the importance of returning electronic waste as soon as possible (ideal timing of return). For the acceptable quality of return, it will be implicitly conveyed in knowledge about recovery process of electronic waste.

There is evidence that general environmental knowledge is not always a sufficient condition to predict environmentally conscious consumer behavior (e.g., Laroche et al., 2001; Polonsky et al., 2012). This suggests that product specific environmental knowledge such as environmental labels providing appropriate and accurate information is also an important requirement to allow consumers for making environmentally conscious and reasoned decisions (Polonsky et al., 2012; Testa et al., 2013). For this, consumers must know about the existence of environmental knowledge, understand their meaning, and trust the information presented (Thøgersen, 2000). Bougherara and Combris (2009, p. 321) define environmental

knowledge as information tools that "aim to internalize the external effects on the environment of the production, consumption, and disposal of products". Based on these findings, this research attempts to highlight the usage of specific environmental knowledge, which is product return knowledge as a tool to affect consumers' action in products disposal.

Here, the construct 'knowledge' is meant to measure consumers' familiarity with the functional aspects of environmental message (Taufique et al., 2014) and the meaning of different terms used in. Based on this discussion, the following is proposed:

P1: Product return knowledge is positively related to attitudes towards EoL and EoU immediate return

Immediate Return Attitude

Many studies establish attitude as one of the strong antecedents influencing behavior (e.g., Ballantyne & Packer, 2005). In most models of pro-environmental behavior, attitude is placed as the central variable between environmental knowledge and behavior (Davies et al., 2002; Polonsky et al., 2012) where environmental knowledge and pro-environmental attitudes are highly interconnected (Bamberg, 2003). In this research, attitude towards the environment is measured in terms of consumers' degree of agreement in the inclusion and availability of relevant information (ideal timing and acceptable quality) of EoL and EoU return.

Immediate Return Intention

Intention is an individual's planning of action to perform the behavior, and also captures the motivational factors that influence the behavioral attitude. A person's behavioral intention is conjointly determined by attitude and subjective nor norm, which assists to measure the actual behavior of a person (Fishbein and Ajzen, 1975; Wang et al., 2013). Return intention has been in discussion, for example in Jena & Sarmah (2015), which highlight numbers of construct that affect return attitude and intention. Examples of construct that derived from qualitative literature reviews are perceived benefit, perceived risk, return product knowledge, social awareness, subjective norm and market characteristic. Based on the finding from qualitative literature reviews, this research adopts two of the constructs; return product knowledge and social awareness. Return product knowledge for this research covers extended features from previous literature. Previous literature cover the features like availability of collection centers and energy saving. Additionally, this research covers the extended features like recovery process. Therefore, it is suggested that:

P2: Attitudes toward EoL and EoU immediate return is positively related to immediate return intention

For this research, social awareness is another construct that can influence immediate research intention. In this research context, social awareness is defined to assess the information about immediately return the used products from different sources. Consumers' assessed this information from various sources such as friends, advertisement, and education (Raziuddin et al. (2016); Chang & Wu (2015); Lai et al. (2014)). Based on this, social awareness is implicitly presented in the message framing part of this research. Relevant information and different information presentation play an important role in making awareness among the consumers about the return of used products (Jungbluth et al. 2012). Therefore, this research intends to answer this question:

"How does consumers' immediate return intention change after being manipulated by two differently framed awareness messages?"

Message Framing in Product Return Knowledge

Literature presents two methods of presenting environmental information and knowledge, such as *environmental labels* (Mackenzie, 1991; Harris and Cole, 2003; Horne, 2014), and *message framing* (Avineri and Owen, 2013; Chang and Wu, 2015). An environmental label is a visual method that companies and manufacturers use to display the environmentally preferable features of a product in the marketplace (Goggin, 1994). As for message framing, scholars define it as a theoretically grounded persuasive communication strategy aimed at promoting perceptions, judgments, attitude and behavioural changes through the presentation of equivalent appeals, framed in terms of either the benefits gained or negative consequences incurred (Chang and Lee, 2009; De Velde et al., 2010; Gerend and Cullen, 2008; Krishnamurthy et al., 2001; Levin et al., 1998).

Message used in communicating environmental impact of particular products when they are not properly treated and disposed could be presented in positive and negative ways. In this study, consumers' participation in product return activity can be promoted by emphasizing the positive consequences of doing so (for example, *"if you decide to return your no-longer used appliances for proper treatment and disposal, you will help the environment"*) or the potential negative consequences of not doing so (for example, *"if you decide not to return your no-longer used appliances for proper treatment and disposal, you will harm the environment"*). These two approaches have the same goal, which is encouraging participation in product return activity.

The rationale of having these two ways of information presentation is both of them having different effects on individual behaviour. Considering this fact, marketers design different advertising methods and products to tackle different segmentation in their commercial marketing. Segmentation aims to identify whether unique groups (segments) exist along with key needs and motives that distinguish each group to inform different marketing and promotion mixes accordingly (Andreasen, 1995).

In the study of charitable activities and environmental protection, scholars tend to be inclined to believe that a negative message is more influential, as there is a negativity bias when processing information (Chang and Lee, 2009; Davis, 1995; Levin et al., 1998). Taylor (1991) indicates that negatively framed messages are more direct, differentiated, and contagious than positively framed messages, and make people feel fear, anxiety, unhappiness, and strong and rapid physiological, cognitive, emotional, and social responses. These reactions, however, are not created in the same intensity by positive message framing (Banks et al., 1995; Van't Riet et al., 2010). When proprietors provide a negatively framed message, the consumer's emotions are aroused because the messages contain information regarding potentially negative consequences (Chang and Lee, 2009; Mayer et al., 1992). Hence, based on the aforementioned discussions the following is proposed:

P3: A negatively framed message will be more effective than positively framed message when promoting immediate return of electronic waste

The Moderators

This paper presents a conceptual framework that investigates the relationship between product return knowledge and consumers' EoL/EoU immediate return intention. Two moderator roles are highlighted which are *environmental motivation* and *environmental knowledge*. These moderators will be used to define consumers' segmentation. Previous literature defined

environmental motivation as individual's level of motivation toward environmentally friendly behaviours (see e.g., Osbaldiston and Sheldon, 2003; Pelletier et al., 1998; Villacorta et al., 2003). Deci and Ryan (1985) noted that concept of environmental motivation stems from the innate psychological needs for competence and self-determination. Individual practices pro-environmental behaviour for different reasons. Therefore, motivation has been proposed as a means to gain insight into varieties of behavioural persistence (De Young, 1986; Pelletier et al., 1998).

As for environmental knowledge, scholars define it as a general knowledge about environmental issues or problems, such as the problems the earth is now facing (Benton, 1994; DeChano, 2006; Martin and Simintiras, 1995). Additionally, Petty and Cacioppo, (1986) noted that environmental knowledge can be defined as an individual's ability to interpret and process information. The selection of moderators, which are environmental motivation and environmental knowledge, is based on attributes of intrapersonal level in an individual. According to Frias et al., (2008), individual motivation and ability affect the outcome of message processing. Ability is another definition of environmental knowledge as noted by Petty and Cacioppo (1986). Fewer studies have investigated whether the differences in personal motivation and ability interfere with the emotional reaction of the individual when reading positive and negative messages, and subsequently influence behaviour (Chang and Wu 2015). Therefore, environmental motivation and environmental knowledge are selected as the moderator based on the following assumption:

Where there is a sense of environmental motivation and environmental knowledge (even in very low level), consumers will spend time to read environmental information of products.

When motivation is high, the individual will need to employ a greater proportion of cognitive resources in order to assimilate the message. Furthermore, if the individual received a negatively framed message, he or her emotions will generate an additive effect, because people have more motivation to avoid a loss than to attain a gain of equal magnitude (Krishnamurthy et al., 2001; Meyerowitz and Chaiken, 1987). Therefore, they will prefer information about potential negative consequences and ways to avoid their occurrence (Chang and Lee, 2009). Consequently, he or she will be more concerned over the message content, and relevance to environmental protection will be processed in more detail when a message is negatively rather than positively framed (Kanouse, 1984; Maheswaran and Meyers-Levy, 1990; Steward et al., 2003). Hence, the negativity bias will exert its influence. Based on this discussion and to achieve the aforementioned objectives of this paper; to examine the two-way interaction effect between message framing and environmental motivation, the following hypotheses are proposed:

P4: A negatively framed message is more persuasive for immediate return in situations of high environmental motivation

P5: message framing has no differences in persuasiveness effect for immediate return in situation of low environmental motivation

This study also attempts to achieve this objective; to decide whether positively or negatively framed message is more effective in appealing for electronic waste immediate return (controlled by environmental motivation and environmental knowledge). When an individual with high motivation and more knowledge performs a behavior, he or she prefers engaging in environmental goals and also has the ability to select information with higher relevance to his

or her needs, and so understanding will be more efficient and with less effort. Hence, the individual will have confidence in his or her ability to perform the specific behavior (Ajzen and Madden, 1986; Frías et al., 2008; Kidwell and Jewell, 2008). Because the individual already has relatively high environmental knowledge, he or she can effectively deal with the message. Therefore, there is not much difference in pro-environmental behavior intention whether the message is framed positively or negatively.

On the contrary, an individual with high motivation and low environmental knowledge is likely to systematically or thoroughly process the given information. Because they (him or her) concerned environment, and have high environmental motivation, therefore, him or her carefully attends, evaluates, elaborates, and integrates task relevant environmental informational inputs, and base their environmental awareness on their understanding of such information. In other word, negatively framed message is more effective for individual who has high environmental motivation and low environmental knowledge. Hence, the following hypotheses are proposed:

P6: message framing has no differences in persuasiveness effect for immediate return in situation of high environmental motivation and high environmental knowledge

P7: negatively framed message is more persuasive for immediate return in situations of high environmental motivation and low environmental knowledge

Conceptual Framework

The proposed conceptual framework covers the aspects of information content (types of information) and information context (the way information is being presented). These aspects belong to two level of supply chain communication, which are from point of origin (producers or manufacturers) to point of consumption (consumers). At manufacturer level, the Product Return and Recovery Management (PRRM) takes place in order to achieve one ultimate goal; profitable return and recovery operation. Profitable return and recovery mean that the operation achieves operational cost minimisation and profit maximisation. At consumers' level, environmental knowledge and environmental motivation are selected to be the additional factor to modify their current return practice. This means that consumers willingly commit to immediate return, instead of storing the used products. The modification in consumers' current return practice; from return to immediately return the used products is based on behavioral change, one of the benchmark criteria suggested in social marketing theory. The ultimate goal of social marketing should be to change people's behaviour, not only to inform and educate them about social problem (Kubacki et al. 2015).

In the context of the proposed conceptual framework as seen in Figure 2, the process of translating return and recovery information (information content) into persuasive and understandable context (presentation) is to promote the action of immediate EoL and EoU return among consumers. The identified research gap (as shown in Figure 1) in this translation process is regarding the right timing of return and acceptable quality of return. At present, environmental product information that available for consumer covers only the environmental effects caused by the products in the phase of manufacturing and use (Jungbluth et al., 2011a). Immediate EoL and EoU return is expected to be attainable if consumers are provided with the correct and clear information of product return and recovery. The correct and clear information is expected to encourage consumers' willingness to return their used products to the provided drop-off sites, not in domestic waste bins.

The benchmark criteria, formative research, as suggested by social marketing theory (Andreasen, 2002), is used to identify consumer preference towards return and recovery information (time and quality of return) in product return creation. The identification of relevant product return and recovery information, then, will lead to the process of translating the information into understandable environmental message format. The rationale of understanding types of information that valued by consumers is to avoid information overload. It has been noted that providing a huge number of product information items might result in an information overload; it therefore becomes necessary to identify the items consumers especially value (Kehagia et al., 2007; Pieniak et al., 2013; Salaün and Flores, 2001; Verbeke, 2005, 2008). As the information consumers demand might vary between consumer segments, the valued information items also should be determined for different target groups (Dimara and Skuras, 2003; Verbeke, 2005, 2008). Based on this, the proposed framework is considering the segmentation, as one of the fundamental elements suggested in social marketing theory. Formative research also used in identifying consumers' preferred information presentation. The information presentation is required to influence and convince consumers to take further action in product return activity. Considering the fact of interpretation difference, two presentation methods and two personal moderators are included in the framework. The positively and negatively framed messages are the presentation methods suggested by framing message concept. The aforementioned moderators, environmental motivation and environmental knowledge are derived from previous environmental behavioural studies (Chang and Wu 2015; Weinstein et al., 2015; Lois et al., 2015).

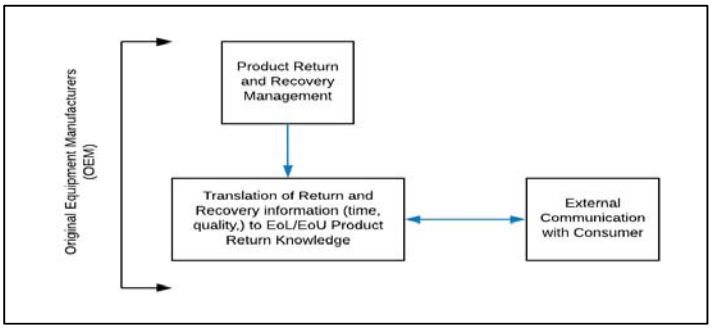

Figure 1: Research Gap

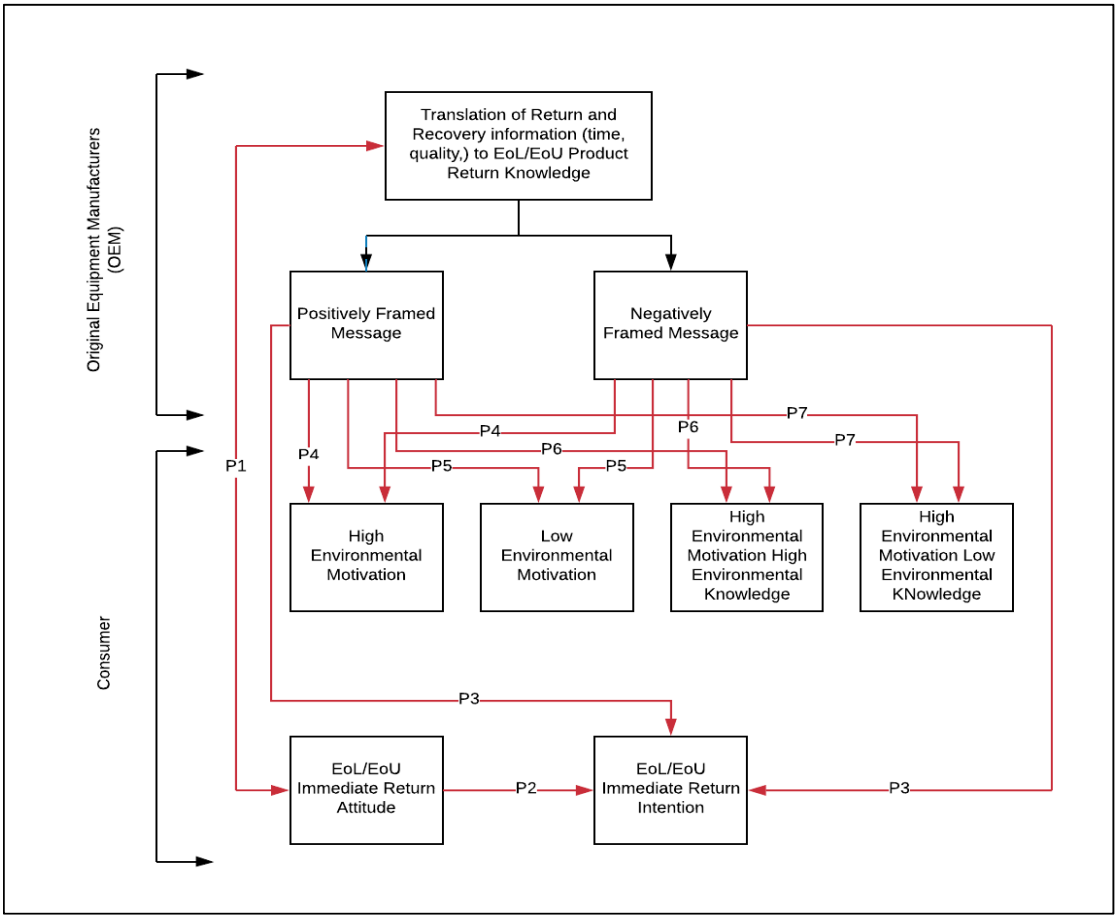

Figure 2: Conceptual Framework

RESEARCH DESIGN

The first thing that will take place in order to collect primary data for validation purpose is designing the framing message. Briefly, there will be two short messages of approximately 150 words, conveying the advantages (message 1: positive frame) and disadvantages (message 2: negative frame) of returning the acceptable quality used products at the right time. Messages post-validation phase will include the design of a survey that completed by these influential measures; demographic, environmental motivation, environmental knowledge, product return knowledge, immediate return attitude and immediate return intention.

Influential Measures

- **Demographic:** According to Chang and Lee (2009), these factors may influence the likelihood of green initiatives; age, gender, and educational level. These related demographics were deliberated as potential variables that might influence the survey's results.
- **Environmental Knowledge:** Environmental knowledge is an individual's skill or proficiency in interpreting the information contained in a given stimulus (Frías et al., 2008; Maclnnis et al., 1991). To do this, the Roper Group assessment on basic environmental literacy (Coyle, 2004; DeChano, 2006) and scale from the 1997 survey administered by the

National Environmental Education and Training Foundation (NEETF) are referred. To measure respondents' proficiency, the proficiency criterion at 75 percent correct will be used, as suggested by NEETF.

- **Product Return Knowledge:** product return knowledge will be assessed based on four items which cover the idea of EoL and EoU return, respondent's familiarity with the collection center and why they need to return the used electric and electronic equipment. The four items use 6-point Likert-style scale. The four items adapted from Hazen et al (2012) and Jimenez-Para et al. (2014). The items were reworded to meet the context of this research.
- **Environmental Motivation:** Environmental motivation assessment will be conducted by using six subscales of motivation toward environmentally friendly behaviours as suggested by Osbaldiston and Sheldon, (2003), Pelletier et al., (1998), and Villacorta et al., (2003). On a seven-point scale, respondents will be asked to rate the degree to which they agree with the elements. The scale and all elements are derived from Pelletier et al., (1998). The intended outcome of this section is an environmental motivation index. The index is expected to help in exhibiting two levels of environmental motivation, which are high and low.
- **Informative Measure:** Participants indicated how true, objective, convincing, relevant, believable, useful, and interesting the message was to them. Ratings were made on seven-point scales (Chang and Lee, 2009; Van't Riet et al., 2010). An index was created by calculating the mean of the seven items.
- **Immediate Return Attitude:** In this study, attitude towards immediate return is measured based on four items that were developed by Lee (2011) on six-point Likert-style scale. Adapted items were reworded, where necessary, to maintain the semantic properties of the context of the study.
- **Immediate Return Intentions:** Assessment for immediate return intentions covers the respondents' likelihood of supporting immediate return. The five-point scale of "always willing", "sometimes willing", "unsure", "rarely willing", and "never willing" (Kilbourne and Pickett, 2008) will be used for this assessment.

CONCLUSIONS

This paper has pursued to bridge the literature void in terms of B2C information sharing that is expected to influence consumers' participation in product return activity. The aim of this research has been achieved by proposing a conceptual framework to explore how product return information and its presentation could possibly influence the information processing at consumers' level, so that it is understandable and influential to encourage participation in immediately returning used products after end-of-use and end-of-life phases. The framework was developed based on social marketing theory. The next step as part of this research is to empirically validate the conceptual framework and its respective propositions.

Theoretical Contributions

This research is expected to contribute to the introduction of subsets in segmentation as the addition to geographic (e.g. cities, countries) and demographic (e.g. sex, age, education) segmentation in social marketing theory. In addition to demographic segmentation suggested in social marketing theory, this research explores the propositions that use environmental motivation and environmental knowledge for segmentation purpose. The propositions will be tested by using motivation index and environmental literacy calculation. These formulas show

that intrinsic elements (motivation) and ability (knowledge) are measurable and they are relevant to be used as the basis of segmentation.

Practical Implication

Additionally, this research initiates the exploration of Business-to-Business (B2B) related information; ideal timing and quantity of return, into B2C communication and its potential to amplify drop-off recycling. Last but not least, this research contributes in introducing the concept of Immediate Return Intention, which based on behavioral change, one of the benchmark criteria suggested in the social marketing theory.

Abstract

A redefinition of sustainability considers the natural environment and society as constraints to firms. The food sector is characterized by buying firm power and experiences pressures from food scarcity on the environment side and transparency demands on the societal side. This paper postulates that sustainable supply chain management should incorporate new theoretical lens to understand the dynamic shifts of network governance modes occurring in the food sector. Drawing upon global value chain, resource-dependence theory and embeddedness, this essay proposes a research agenda for the analysis of global and local solutions to food supply and the impact onto sustainability diffusion.

Keywords: Sustainability, Food Supply Networks, Network Governance

Introduction: Sustainable supply chain management and the food sector challenges

Current definitions of sustainability within the Sustainable Supply Chain Management (SSCM) literature have been predominantly based on a temporal perspective (Matos & Hall, 2007; Reuter et al., 2012; Schrettle et al., 2014), a multi-dimensional perspective (Seuring & Müller, 2008), or both (Carter & Rogers, 2008). The temporal perspective is grounded in the Brundtland Commission's definition of sustainable development: *"development that meets the needs of the present without compromising the ability of future generations to meet their needs"* (WCED, 1987, p. 8). From a business perspective, this definition suggests that firms need to consider both short-term and long-term results. As a result, the strategic management of resources must consider not only short-term efficiency but also long-term continuity of supply (Pagell et al., 2010).

The multi-dimensional perspective has often been grounded in the triple bottom line concept (Elkington, 1998), which defines sustainability as a three-dimensional construct balancing the dimensions of economic, environmental and social impact. Nevertheless, preliminary SSCM frameworks have often taken a two-dimensional focus to explore tensions either between the economic and environmental dimensions, or between the economic and societal issues (Wang & Sarkis, 2013). The former approach often uses the term 'green', such as in 'green supply chain management' (Srivastava, 2007), whereas the latter focuses on corporate social responsibility, such as in 'socially responsible supply chain management' (Hoejmose et al., 2013). The year 2008 became a milestone in the definition of SSCM based on the three-dimensional concept of sustainability, as captured by two influential reviews by Carter and Rogers (2008) and Seuring and Müller (2008), respectively:

SSCM by Carter and Rogers (2008, p. 368): "*The strategic, transparent integration and achievement of an organization's social, environmental, and economic goals in the systematic coordination of key inter-organizational business processes for improving the long-term economic performance of the individual company and its supply chains* ".

SSCM by Seuring and Müller (2008, p. 1700): "*The management of material, information and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development, i.e., economic, environmental and social, into account, which are derived from customer and stakeholder requirements".*

The food sector is particularly pressured by health and environment protection requirements that raise challenges such as food security, water security, clean energy and biodiversity (Griggs et al., 2013). As such, it has been increasingly the object of studies in the SSCM field. Moreover, a recent redefinition of sustainability questions the balanced perspective proposed by the triple bottom line and reframes the three pillars paradigm as a *nested concept* (see Figure 1). This new paradigm sets the natural environment and social development as constraints to economic performance (Griggs et al., 2013).

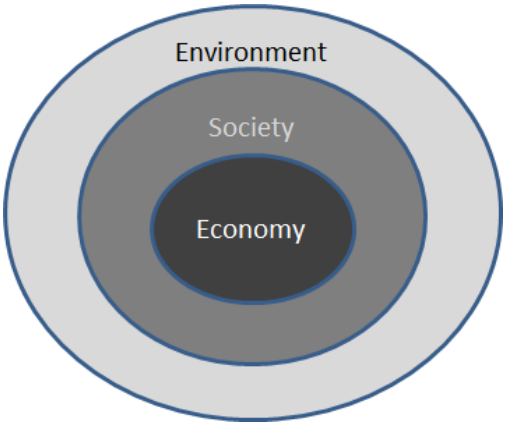

Figure 1: The nested concept, adapted from Griggs et al., 2013.

The food sector has been largely affected by increasing social and environmental constraints, in particular regarding the threat of food scarcity. On one hand, forecasts suggest that as population growth continues, by 2050 the world will need to feed more than nine billion people, requiring nearly 70% more food than what is consumed today (Denis et al., 2015). On the other hand, because food production requires vast amounts of natural resources, such as water, land and energy, it represents a particularly significant challenge regarding energy consumption (Mena et al., 2014). Moreover, in the US alone, the increase in coastal storms will cause US$ 3-7 billion in annual damages to food businesses by 2030 (Paulson Jr., 2015). As society becomes aware of growing concerns on food scarcity and food safety, governments have been closely observing the practices of the food industry, and the sustainability of the food system has been under increasing scrutiny from the public (Beske et al., 2014).

Although current definitions still emphasize the 'chain' perspective, recent studies have indicated that the increasing complexity and fragmentation of supply systems suggest the need to reframe SSCM in at least two main aspects. Firstly, by expanding the scope of SSCM

from the linearity of direct buyer-supplier relationships to multi-tier and multilateral studies (Walker et al., 2014). Secondly, by exploring the differences across local and global systems, in order to capture the inherent complexities of global supply networks (Tachizawa & Wong, 2014) and to provide further understanding of SSCM phenomena outside the context of large-to-large firms (Touboulic & Walker, 2015a).

This paper takes an essay format to first, reflect on the limited debate regarding the differences between global and local solutions to food supply, then set theoretical foundations based on theories that have so far have seen limited application in the SSCM field, namely, global value chains, resource-dependence theory and embeddedness. Finally, the essay draws from anecdotal evidence in food supply networks in the US and Brazil to illustrate the research questions that compose a future research agenda for the field.

The incipient debate on global versus local food supply

Global solutions to sustainability in the food sector

Food supply networks are predominantly characterized by concentration of power within a small set of buying firms (Gereffi & Lee, 2012). The rise of global food supply networks has resulted from the co-evolution of the geography of consumption and the geography of production (Gereffi et al., 2005). The former has been shaped by the increasing purchasing power of emerging economies, which has expanded the consumer market available to large (and global) firms, previously restricted to rich countries. The latter has been shaped by the increasing costs of land, labor and capital, which have set large firms on a continuous quest for low-cost sources of goods and services, moving their sourcing targets from rich countries to emerging countries (Rodrigue, 2012). The resulting configuration is a fragmented and globally dispersed supply network. Food distribution is particularly representative of this trend, creating the equivalent of a *supply funnel,* where *large buying firms*[i] are in the center of consumer goods distribution, channeling food products from a globally dispersed supply base to an even wider base of end-consumers around the globe (Gereffi & Lee, 2012).

The continuous search for low cost sources of supply and the fragmentation of the upstream side of global food supply networks (i.e. the supply base) have led to a multi-tiered structure composed of *direct suppliers*, often geographically close to the buying firm; and *sub-suppliers*, mostly concentrated in emerging economies, thus distant from Western buying firms (Rodrigue, 2012). The increasing participation of emerging economies in global trade has drawn attention to the socio-environmental impact of sub-suppliers, pushing buying firms to improve sustainability standards not only within their boundaries and direct suppliers but also throughout their extended supply networks (Grimm et al., 2014). Moreover, because sub-suppliers are often globally dispersed small and medium-sized suppliers (SME suppliers[ii]), large buying firms have often turned to the adoption of global codes of conduct in order to improve sustainability standards (Turker & Altuntas, 2014). In such global supply networks, major buying firms may be deemed to be no more sustainable than their suppliers (Krause et al., 2009). As such, a buying firm's sustainability profile is constituted not only by its own practices, but also by those of its direct suppliers and of its extended global supply chain (Miemczyk et al., 2012). This reality is perhaps most starkly demonstrated by the reputational (and financial) damage caused to a number of organizations by media exposure of unsatisfactory ethical behavior or environmental performance by key suppliers (Svensson, 2009).

SSCM research has put most of its recent attention on global supply networks, as well as on the discussion of obstacles to the management of suppliers from emerging countries (e.g. Awaysheh & Klassen, 2010; Chen & Hung, 2014; Ehrgott et al., 2011; Gold et al., 2013; Hall

& Matos, 2010). As sustainability pressures show no signs of abating and firms have insufficient knowledge and capabilities to tackle all sustainability issues, these must cooperate with stakeholders across the broader supply network (Zhu et al., 2008). Moreover, buying firms are being increasingly impelled to lead the diffusion of best practices throughout their global supply networks (Nair et al., 2016).

Local solutions to sustainability in the food sector

Triggered by public scrutiny of global food supply networks and the disappointing responses from large buying firms, solutions based on local food production and distribution have been increasingly presented as a sustainable alternative to global systems. In many countries, local food producers are organizing cooperatives and local markets that can directly access end-consumers and offer them an alternative to mainstream food distribution. As food cooperatives are often led by entrepreneurs and small-sized firms, these systems face multiple difficulties inherent to their size, financial constraints, and limited access to resources and knowledge possessed by larger firms (Capo-Vicedo & Capo, 2011).

Small firms are more likely than large firms to encounter significant obstacles when attempting to introduce SSCM practices (Barnes & Liao, 2012). Cooperation with other similar sized firms is a strategic alternative that can offer smallholder farms a better competitive position (Capo-Vicedo & Capo, 2011). Cooperative systems are based on the principles of autonomy and self-direction. Autonomy means that the supply network runs with no single company deliberately orchestrating the totality of its activities (Choi et al., 2001). This means that governance within supply networks may be a self-organized and emergent process (Nair et al., 2016). In opposition to the centralized coordination seen in global supply networks led by large buying firms, self-directed networks may exhibit higher levels of participation, offering a low cost alternative to monitoring and formal controls (Alvarez et al., 2010).

The unstable nature of emergent cooperatives produces a transient aspect in business relationships, which may vary between adversarial and collaborative (Bastl et al., 2013). Cooperative members, which are competitors to some extent, may interact among themselves by means of autonomous relationships (Choi et al., 2001). The analysis of interactions among suppliers may reveal how they can cooperate and jointly organize economic action, despite being competitors (Mena et al., 2013). Co-opetition has been defined as *"the inherent tension of cooperation and competition: in other words, increasing gains through collaborative synergy while at the same time fighting for larger shares of the gain"* (Wilhelm, 2011, p. 663). Although originally focused on the economic dimension, co-opetition can entail *"cooperation among competing entities to achieve economic, environmental or social goals"* (Pathak et al., 2014, p. 266). SCM scholars have begun to explore co-opetition, but often within the context of dyadic buyer-supplier or supplier-supplier relationships (Wu & Choi, 2005). There is limited research looking beyond the dyad and examining coopetition in supply networks (Kim et al., 2011). Moreover, the network composition of such cooperatives differs greatly from supply networks led by a central buying firm, yet they are almost unmapped by the SSCM literature.

Tensions between global and local solutions to sustainability in the food sectors

The differences sketched above have led to the emergence of a 'local' versus 'global' debate concerning world food distribution. Nevertheless, the extant SSCM literature has been shy in addressing this research avenue (Touboulic & Walker, 2015b). To address this research gap, this essay elaborates on how the global value chain framework (Gereffi et al., 2005),

resource-dependence theory (Pfeffer & Salancik, 1978) and the concept of embeddedness (Granovetter, 1985) can work as complementary theories to discuss how future research can address the alternative governance modes in local and global food supply networks in order to understand how they influence sustainability diffusion.

Theoretical foundations to inform a research agenda

Supply network dynamics are underexplored in SSCM literature and have received little research attention (Nair et al., 2016); hence, the SSCM field may lack adequate theorization to investigate alternative governance modes with very different network compositions which represent the differences between global and local solutions to food sustainability. Theory choice in SSCM studies has favored mostly transaction cost economics (TCE), the resource-based view (RBV) and stakeholder theory (Touboulic & Walker, 2015c). Influenced by these theories, the extant SSCM literature has predominantly taken a dyadic perspective (Miemczyk et al., 2012) and assigned a protagonist role to major buying firms, assigning a secondary role to suppliers, and particularly to sub-suppliers (Grimm et al., 2014).

This essay subscribes to calls in the SSCM field to: (a) explicitly state the theory informing research (Touboulic & Walker, 2015c) and (b) benefit from the richness of general theories under-explored within the SSCM field (Sarkis et al., 2011). The tradition of borrowing theoretical perspectives from other disciplines and the mother field of general management has influenced the way in which SSCM has been conceptualized, but there are still unexplored opportunities, as well as unanswered questions (Sarkis et al., 2011). Drawing from established theories within general management literature can avoid 'reinventing the wheel′ (Touboulic & Walker, 2015c). Moreover, this approach enables a twofold theoretical contribution: (i) applying an established theory to SSCM phenomena offers a new context to elaborate on the original theory to address idiosyncrasies of the new context; and (ii) using a new theoretical lens to investigate SSCM phenomena is an opportunity to contribute to the SSCM field.

Global value chains

Global value chains (GVC) is a theoretical framework developed to explain value appropriation and the dynamics of geographical configuration of global supply networks (Gereffi et al., 2005). GVC studies have been often published outside traditional OM journals, such as the Journal of Business Ethics (e.g. Lim & Phillips, 2008; Rotter et al., 2014), and little SSCM research has been conducted adopting the GVC lens (Gereffi & Lee, 2012). Drawing from the TCE framework, the GVC framework proposes *market* and *hierarchy* as the two extremes of a governance mechanism continuum (Williamson, 2008). Differently from the TCE framework, in between the two poles of market and hierarchy, the GVC framework discusses alternative governance modes and power asymmetries between buyers and suppliers according to three variables: (i) complexity of transactions, (ii) the ability to codify transactions, and (iii) the capabilities in the supply network (Gereffi et al., 2005). The framework posits that higher levels of complexity, low levels of ability to codify transactions and lack of capabilities within the supply base favor buyer-driven supply chains, i.e. buying firm control over the supply base; whereas an opposite scenario favors an equilibrium between buyers and suppliers (Gereffi et al., 2005). Depending on the level of buying firm control over the supply base, governance may assume *relational*, *modular* or *captive* modes (Gereffi et al., 2005). A *modular* governance reflects a reasonable coordination balance between the buying firm and suppliers, skewed towards the buyer; a

captive governance reflects full coordination by the buying firm, whilst the *relational* mode rests in between (Sturgeon et al., 2008).

GVC explains shifts of governance mode through top-down and bottom-up movements. Top-down movements reflect global buying firms' imposition of practices and profit distribution, whereas bottom-up movements reflect responses from local producers, associations, and other stakeholders in search for upgrading, i.e. accessing value-added activities and improving economic results for the local economy (Gereffi et al., 2005). The food sector is a major focus of GVC literature, and has been historically characterized by buyer-driven supply chains and a captive governance mode, meaning major buying firms such as retailers and brand-name food manufacturers dictate guidelines and define profit margins upstream and along the supply chain (Gereffi & Lee, 2012). GVC posits that buyer-driven supply chains emerged from the shift of power from producers to buyers, resulting from the consolidation of major retailers and brand-name manufacturers in the food sector (Gereffi et al., 2005). Nevertheless, the GVC literature so far has not considered movements where local producers gather to form cooperatives to reach out directly to final consumers, and in what ways such movements could reshape governance modes and provide new opportunities for social upgrading.

We conjecture that these movements are related not only to value appropriation, but also to sustainability diffusion. Therefore, we resort to GVC as an adequate theoretical background for understanding the local versus global debate, but also posit that such research avenue can contribute to the development of the GVC framework, as they might lead to a swing back to supplier-driven supply chains. Furthermore, we also suggest that this pendulum between buyer-driven and supplier-driven governance can be seen through the lens of resource dependence and response to constraints, which we explore next.

Resource-dependence theory

Resource-dependence theory (RDT) explains how the business environment affects and constrains firms as well as how they respond to these external constraints (Pfeffer & Salancik, 1978). When the environment changes, firms face the prospect of either not surviving or changing in response. According to RDT, behind every constraint there is an interest (stakeholder) group. What stakeholder theory (which is out of the scope of this study) defines as stakeholder pressure, RDT labels as an external constraint. Hence, RDT can help to explain large buying firms' reaction to food scarcity as well as food suppliers' reaction to lack of access to final consumers and well as reduced margins, hence RDT can contribute to the global versus local debate.

RDT suggests the level of resource dependence depends on two elements: resource importance and concentration of resource control. In order to reduce uncertainty, firms increase coordination with key stakeholders, increasing interdependence, which in turn reduces uncertainty (Pfeffer & Salancik, 1978). Hence, the threat of supply scarcity imposes an external constraint for the buying firm that, according to RDT, will make it invest in closer relationships with the supply network. Additionally, excessive concentration of resource control will see the buying firm increasingly moving beyond the first tier of suppliers to develop supplier loyalty with upstream producers. Furthermore, RDT proposes two responses to external constraints: *advocator* (influencing the environment) and *processor* (adapting to the environment) (Pfeffer & Salancik, 1978). While the former reflects an active approach to mitigating or eliminating constraints, the latter refers to a more passive response to changes in the environment.

We conjecture that the previously-mentioned pendulum between buyer-driven and supplier-driven supply chains might reflect opposite responses on each side, from a RDT perspective. In other words: large buying firms have been adopting an active/advocator

approach for the last decades, resulting in a reactive/processor approach by suppliers, where recently, the rapid expansion of local cooperatives signifies an active/advocator approach by suppliers, possibly resulting in the buying firms shifting to a reactive/processor approach. However, despite the promising contribution that both GVC and RDT might offer to SSCM in the food sector and more specifically the global versus local debate, the inherent complexity, messiness and decentralization of supply networks characterized by SMEs call for a third theoretical perspective, namely the concept of embeddedness.

Embeddedness

An insightful view for understanding the contrast between well-established networks and emergent networks is the concept of *embeddedness* (Granovetter, 1985), which posits that firm behavior is embedded in, or partially determined by ongoing systems of interfirm relations. The word "partially" in the description is important, because it signals the view that firms' economic behavior should be seen as neither under-socialized nor over-socialized (Simsek, 2003). Emergent networks are fragile systems, and in opposition to established clusters, they are more exposed to unethical behavior (Eckerd & Hill, 2012). Local clusters develop a system of norms over time that influences the decision-making process and favors group-level over individual benefits (Dyer & Nobeoka, 2000). As a result, dense clusters are influenced by non-economic logics of association, since supply network members are embedded in culture, values and beliefs. Such a process is defined as cultural embeddedness; hence, non-economic forces can counter-balance market forces during the decision-making process (Wu & Pullman, 2015). Within embedded networks, there is active and widespread participation of all members, negotiating and collaborating towards a common goal.

In this essay, we infer that decision processes in centralized supply networks led by large buying firms will differ largely from those in decentralized food cooperatives. In addition, given that the GVC framework has been developed with a focus on the role of buying firm, it may fail to explain messy dynamics in food cooperatives. Hence, we propose to resort to embeddedness in order to complement the picture initially drawn using GVC and RDT.

Towards a research agenda on network governance and sustainability diffusion

A combined lens to analyze global food supply networks

Initially, we suggest a GVC lens to get a better understanding of governance and sustainability diffusion in global food supply networks. When studying such networks, the SSCM literature has extensively investigated relationships between focal buying firms and their direct suppliers by contrasting two alternative approaches: monitoring and collaboration (Gimenez & Sierra, 2013; Gimenez & Tachizawa, 2012; Tachizawa et al., 2015; Vachon & Klassen, 2006, 2007, 2008). When broadening the scope from local to global supply networks (and managing sub-suppliers), SSCM research has suggested that managerial practices have similar characteristics to those applied to direct suppliers (Grimm et al., 2014).

When expanding monitoring mechanisms to sub-suppliers, buying firms have often adopted indirect or third-party solutions (Tachizawa & Wong, 2014). Generally in a dominant position, large buying firms have adopted a centralized strategy of sustainability targets and guidelines for suppliers (Banterle et al., 2013), imposing global standards and targets onto the supply base (Caniëls et al., 2013). However, there are two main challenges that make managing sub-suppliers unique. The first is incomplete traceability due to the lack of transparency about the existence and involvement of sub-suppliers in a buying firm's supply base (Grimm et al., 2014). The second is the lack of contractual relationships with sub-

suppliers, limiting the buying firm's ability to put direct pressure on them (Grimm et al., 2014).

Collaborative efforts involving globally dispersed sub-suppliers have faced as much resistance as monitoring mechanisms. The geographic dispersion of global supply networks adds complexity to collaborative efforts due to differences in culture (Grekova et al., 2014), economic background (Hall & Matos, 2010) and institutions (Parmigiani & Rivera-Santos, 2015; Silvestre, 2015). Such heterogeneity hinders collaboration (Hall & Matos, 2010). Furthermore, the more globally dispersed the networks become, the less buying firms can influence sub-suppliers (Hoejmose et al., 2013). Barriers to the diffusion of best practices are amplified when considering the relationships between a large corporation and SME suppliers (Lee & Klassen, 2008). Hence, whilst collaboration seems an effective pathway to SSCM, how to develop a collaborative environment remains an answered question, particularly when considering the large share of SME suppliers (Touboulic & Walker, 2015a) and the geographic dispersion of contemporary supply networks (Alvarez et al., 2010; Rotter et al., 2014). Previous research has emphasized the significant challenges faced by large buying firms engaging with globally dispersed SMEs, such as in the cases of Nestlé (Alvarez et al., 2010) and Danone (Gold et al., 2013).

In brief, collaboration between large firms and globally dispersed SMEs seems a complex yet under-explored aspect in SSCM. On the positive side of SME involvement, despite the investment capacity of large firms, SME suppliers are often in a better position to innovate due to their inherent agility (Balch, 2016). On the negative side, many SME suppliers face difficulties in meeting the increasing social and environmental guidelines of their customer firms, given their limitations in financial funds and human resource expertise (Lee & Klassen, 2008).

The GVC literature has characterized food supply networks with low levels of ability to codify transactions and lack of capabilities within the supply base, hence leading to the formation of captive governance (Gereffi & Lee, 2012). In captive supply networks, large buying firms should be able to impose sustainability standards onto their supply base of SME suppliers. Nevertheless, recent research shows high levels of supplier resistance within supply networks characterized by the presence of strong buying firms (Muller et al., 2012). There is a dark side of excessive buying firm coordination, where sustainability efforts that (a) are characterized by uneven distribution of benefits/risks and (b) are implemented in a mandated fashion suffer resistance from the dominated suppliers (Brockhaus et al., 2013). Moreover, existing buyer-supplier tensions in periodic commercial negotiations are also a barrier to collaboration (Touboulic & Walker, 2015a). Furthermore, SME suppliers often do not possess the skills, resources and time to comply (Touboulic & Walker, 2015a).

The limits to sustainability diffusion in global food supply networks might be explained by RDT (Pfeffer & Salancik, 1978). First, despite being in a captive mode, SME suppliers may succeed in impose some level of external constraints to the buying firm. Second, the imposition of sustainability standards onto captive suppliers may backfire and increase resistance, hence increasing external constraints. Third, the threat of food scarcity may be promoting a shift of power, which may impose in a governance shift from captive to relational or modular governance alternatives. In other words, SME suppliers may experience a power rebalance due to food scarcity, increasing their strength and imposing onto buying firms the need to shift from an advocator approach to a processor approach. Moreover, SME suppliers seem to realize they can use this power to gather into cooperatives, which may either lead to the emergence of an equivalent of modular governance in food supply networks, or some new form of governance, unmapped by the existing GVC framework and characterized by the predominance of local solutions to food supply.

A combined lens to analyze local food supply networks

Through the GVC lens, the emergence of local food cooperatives directly accessing end-consumers may be rebalance of coordination mechanisms, which will lead to a rebalance of value appropriation by smallholder farms. In other words, the emergence of food cooperatives reflects a process of disintermediation (Mena et al., 2013), which can cause buying firms to lose the broker position in the supply networks. Nonetheless, the resulting emergent reconfiguration may differ from governance modes currently offered in the extant GVC literature. To RDT lens, this shift is more specifically a power shift, where suppliers can now act as advocators, thus reshaping the environment.

Despite the lack of understanding of the emergent process of new cooperatives of SME suppliers, a recent study by Wu and Pullman (2015) analyzes a 22-year old US cooperative of beef producers. According to the authors, throughout the years, the decision-making process has been largely influenced by the strong cultural ties among cooperative members (Wu & Pullman, 2015). Hence, the emergence of new cooperatives may suffer from a lack of cultural ties if cooperative participants do not share common backgrounds. Ultimately, the level of embeddedness within such cooperatives may define the success of such local solutions to food supply.

Besides the US, Brazil is also experiencing the emergence of many food cooperatives. Between 1995 and 2012, Brazil has gained 15 places in McKinsey's globalization index (Manyika et al., 2014), hence a proof of increased globalization in general across economic sectors. But, at the same time, looking at the food sector, sales of local food cooperatives have grown close to US$ 1 billion in 2015 (Fischberg, 2015). The ascending trend is in part driven by a growing, although still slow, interest in organic/bio foods, especially in larger, more sophisticated urban markets, like São Paulo and Rio de Janeiro, and sales of organic products have allegedly reached US$ 1 billion in 2016. By recent expert accounts (Liu, 2017), while 82 percent of US families consumed organic food in 2016, this proportion drops to 15 percent in Brazilian market. The US figures are not surprising and help to explain the recent widely publicized acquisition of the Whole Foods chain by Amazon. This scenario suggests a strong tension between global and local solutions to food distribution not only in the US, but also in Brazil, and most probably in other countries.

One exemplar is the Brazilian-based cooperative Junta Local (which in Portuguese has a similar meaning to "Local Cooperative"), which is one of the many emerging local food cooperatives that offer end-consumers direct access to farmers in Rio de Janeiro, the second largest city in Brazil, with over 8 million inhabitants. Junta Local was initiated in 2014 by three founders that felt difficulties in obtaining access to organic food farmers in an urban city such as Rio de Janeiro. The cooperative faces the challenge of establishing a participative and collaborative governance mechanism that gives voice to the multiple farmers, whilst providing a winning experience for end-consumers. Currently, Junta Local represents over 200 local farmers and sells products directly to end-consumers through two complementary channels. In the first option, end-consumers may buy online and collect goods once every other Saturday in a temporary hub in a rich neighborhood of Rio de Janeiro. The second options results from food fairs that the cooperative organizes every month, where end-consumers can be face-to-face with producers.

Another recent experience in Brazil is the Clube Orgânico (Organic Club), founded in Rio de Janeiro in 2014 by two advertising professionals interested in expanding the local organic equitable food market. After experimenting with different approaches for their venture, they came upon a "Community Sustaining Agriculture" model. In this high involvement model, consumers and producers undertake an obligation respectively to consume a fixed weekly

amount of produce and to produce under strict sustainable practices, with the club providing the link between consumers and producers. They initially gathered over 100 members.

In terms of the environmental dimension, in both examples the distance from *'farm to fork'* is significantly reduced, hence most probably reducing the carbon footprint of the food supply network. In terms of the social dimension, farmers, under different formats, engage in upgrading opportunities by adding services and advancing onto the retailing function previously monopolized by the large buying firms. If benefits in both social end environmental dimensions are sustained, and economic growth continues, such local solutions to food supply may offer a challenging alternative to large buying firms. A significant force of local cooperatives is the embeddedness resulting from the transparency culture where end-consumers meet farmers and buy food whose origin they trust.

Combining multiple theories to inform a research agenda

Table 1 offers a research agenda resulting from the combination of GVC, RDT and Embeddedness applied to the debate between global and food solutions to sustainable food supply.

Table 1: Food supply network governance structure and sustainability diffusion: Local versus global solutions

Theory	Construct	**Global food supply / Weak supply base**	**Local food supply / Powerful supply base**
GVC	Complexity of transactions	High	Shift to low (Less intermediates)
	Ability to codify transactions	Low	Medium (Less complexity)
	Capabilities in the supply network	Low	High (Empowered suppliers)
RDT	Prevalent governance mode	Captive	- Does this shift represent a change to Relational/ Modular governance or new governance modes?
	Response to external constraints	Buyer: Advocator Supplier: Processor	- Does power rebalance mean a swap of roles between buying firms and suppliers?
Embedded-ness	Main logic of association	Economic logics: Strong	- What is the influence of cultural/ non-economic logics onto sustainability diffusion?
	Heterogeneity of actors	High heterogeneity	- Can local cooperatives produce widespread embeddedness across the supply network?
Sustainability diffusion	Social dimension	- Limited compliance to global standards	- To what extent do local cooperatives offer social upgrading opportunities for suppliers?
		- Unbalance in value appropriation	- What is the new configuration of value appropriation?
			- What are possible positive/negative social outcomes, when compared to global solutions?
	Environmental dimension	- Limited compliance to global standards	- To what extent do local solutions reduce the carbon footprint?
		- High carbon footprint	- What are possible positive/negative environmental outcomes, when compared to global solutions?

Conclusion, limitations and future research

As the definition of sustainability has been recently revised (Griggs et al., 2013) and current SSCM theorization has been challenged (Matthews et al., 2016), this paper raises awareness to unexplored research questions regarding the trade-offs between global and local solutions to sustainable food supply. Given the current challenges of the food sector, where the environment imperative offers scaling challenges and, on one side, major firms and power concentration have been exposed to public scrutiny; and on the other side, alternative governance modes based on local supply continue to spread, there is a lack of theoretical frameworks that can help unveiling the extent to which alternative governance modes affect sustainability diffusion in different ways.

On the theoretical front, this essay offers a research agenda to motivate studies to map how different governance modes can affect sustainability diffusion. The essay builds on the logics of GVC, RDT and embeddedness to compare global food supply networks led by major buying firms with local direct-access food cooperatives. By organizing the global versus local debate through a multi-theoretical lens, this conceptual piece raises a key set of research questions that, once answered, can help unveil the extent to which alternative governance modes can set new directions to food sustainability diffusion.

In terms of managerial implications, this paper posits that the investigation of alternative governance is key to unveil the extent that local solutions to food supply can provide upgrading opportunities for farmers when they incorporate value-adding activities such as retailing and service, hence increasing their share in the value chain. As many farmers increasingly adopt the local cooperative as their sole access to market, the proposed research agenda becomes critical to provide practical recommendations not only to entrepreneur farmers, but also to funding agencies and regulators.

Despite the promising potential of 'theoretical cross-fertilization'(Gold et al., 2013), special attention must be paid to the relation between theory and context. Moreover, every theory is grounded in epistemological and ontological assumptions; hence, specific theories amplify certain concepts and relationships whilst ignoring others. This essay has purposively emphasized constructs from the three-selected theoretical lens, such as governance, transactions, response to external constraints and logic of association. Nevertheless, before considering the addition of other constructs, the framework should be exposed to empirical testing in future studies.

Most importantly, future research can provide a social contribution by supporting the empowerment of local farmers and an alternative system that may serve many end-consumers eager to understand where their food comes from and whether the price they pay for their food is equally distributed among the involved economic actors.

---

[i] *This study adopts the term 'buying firm' as a standalone noun and 'buyer' when addressing widely used expressions such as 'buyer-supplier relationships'. In all cases, the term refers to the firm, not the individual purchasing professional. Furthermore, instead of adopting the terms 'multinational corporations' or 'multinational enterprises', this study uses the term 'large buying firm' to emphasize the focus on the upstream movements of large multinationals.*

[ii] *This study adopts the expression 'SME suppliers' instead of the general term 'SMEs' to highlight both (a) the size difference between large buying firms and suppliers and (b) the focus on the upstream relationships between large buying firms and their supply bases.*

Supply Chain Disclosure Drivers and Outcomes: 16 Case Studies

Abstract
This study focuses on the growing phenomenon of public supply chain information disclosure. As this literature is still in its infancy, we adopt an inductive approach to build theory. The paper draws on data from 16 in-depth case studies across four industries to present a conceptual model of supply chain information disclosure including the drivers, barriers and outcomes of supply chain disclosure.

Key words: Supply Chain Disclosure, Sustainable Supply Chains, transparency, abductive research.

Acknowledgements: We would like to thank the Irish Research Council for their support and funding for this research #LoveIrishResearch.

Introduction

This paper draws on the emerging supply chain information disclosure literature to understand the present state of supply chain disclosure. Supply chain information disclosure is a relatively new phenomenon and is gaining traction in terms of research and managerial interest. Research suggests supply chain reporting is done in a messy, complex and, sometimes, incomprehensible manner (Van Der Ploeg and Vanclay, 2013; Wilson, 2013). The data is also gathered at considerable cost to both a buying firm and its extended supply chain (Marshall et al., 2016) leading to claims of exclusion and imperialism especially when reporting is demanded by large multinational companies (Mol, 2015). Given the new nature of this research area, we need to improve of understanding of the nature and dynamics of supply chain information disclosure.

To aid conceptual clarity we locate our work within the existing field: Transparency. Transparency, as a construct, was explored intermittently in the organizational sciences beginning in the early 1990s (Schnackenberg and Tomlinson, 2014). Schnackenberg and Tomlinson (2014) highlight a number of core features of transparency: it involves internal and external information exchange; it is an intentional activity; it is a perceptual process governed by the perceived adequacy and accessibility of information; it is deemed to have a positive

effect on performance, and in particular stakeholder trust. Disclosure is similar to transparency but is different in one fundamental way: disclosure occurs publicly. We use Etzioni's definition of transparency as "*the principle of enabling* ***the public*** *to gain information about the operations and structures of a given entity*" (Etzioni, 2010: 1).

Within this broad construct, we delve into one of its associated dimensions: disclosure with a specific focus on the public disclosure of supply chain information. Disclosure, along with clarity and accuracy, is generally regarded as a central dimension of transparency (Schnackenberg & Tomlinson, 2014: 1792) and encompasses a range of processes including analysis, interpretation, documentation and communication (Williams, 2008). The concept of disclosure is based on the idea that information must, at minimum, be openly and timely shared if it is to be considered transparent.

A useful starting point here is Williams' definition of corporate disclosure as "*any purposeful public release of information – financial, social or environmental, required or voluntary, qualitative or quantitative – that is likely to have an impact on the company's performance and on the strategic decision making of its internal and external audiences*" (2008: 237). While there is a considerable literature on the topic of information disclosure in general, there is no unifying theory and there are a range of ongoing disagreements about what disclosure is and what should be the proper disciplinary and theoretical focus, e.g. stakeholder theory, legitimacy theory or a communication perspective (Williams, 2008). This is attributed, in part, to the eclectic disciplinary heterogeneity of disclosure studies ranging from accounting, finance, economics, and latterly management sciences such as corporate governance and supply chain. Definitional problems also exist particularly with regard to forms of disclosure, for example, the distinction between mandatory and voluntary disclosures (Gray *et al*., 2001); types of disclosure (social, environmental and financial); their manner of the release formal written disclosures; informal disclosures (e.g. sustainability reports or websites); or inadvertent disclosures (e.g. whistleblowing) (Williams, 2008). The growing use of voluntary disclosure is deemed to be a way for firms to differentiate themselves from competitors and potentially generate financial and social outcomes for the firm through their legitimacy-enhancing or preserving effect (Cheney and Christensen, 2001). Currently, most social and environmental reporting remains voluntary (Deegan, 2002). There is also the added complication that top managers have discretion in making decisions about what information to disclose and this level of strategic choice needs to be factored into any explanatory model.

Turning to the supply chain literature, the issue of disclosure is addressed in an eclectic manner since the early 2000s. In general, we find that the supply chain literature tends to conflate the terms transparency and disclosure or subsume disclosure as part of the definition of transparency. For example, Egels-Zandén *et al*., define transparency as "*disclosure of information*" (2015: 95), with supply chain transparency encompassing information disclosure on traceability, sustainability and purchasing practices. Within this definitional perspective Egels-Zandén *et al*., differentiate between internal supply chain transparency (the degree to which a firm is transparent to itself) and external transparency (the degree to which a firm makes itself transparent to external stakeholders) (2015). In a similar vein, Mol define transparency as "*environmental governance by disclosure*" (2015: 154), with four types of supply chain transparency: management, regulatory, consumer and public transparency (2015: 155). It is the latter two forms that we encompass under the term supply chain information disclosure. Other authors use different labels for supply chain information disclosure including supply chain reporting (Mol, 2015; Wilson, 2013); or, the most prevalent nomenclature, supply chain disclosure (Deegan & Islam, 2014; Doorey, 2011; Van Der Ploeg and Vanclay, 2013).

Within the transparency literature there is a predominant focus on internal supply chain information disclosure (usually information exchange between a buyer and a supplier) and a relative neglect of external supply chain information disclosure. Although internal supply

chain transparency is well explored, the dynamics underpinning the public disclosure of supply chain information is poorly researched and understood and it is this gap we wish to address.

Methodology

Given the nascent stage of supply chain information disclosure research, we conducted an exploratory study to help develop a theoretical foundation and to understand the dynamics of the motivation, barriers and outcomes of supply chain information disclosure. A case study methodology was chosen as it allows us to investigate a contemporary phenomenon within its real-life context (Yin, 2003: 3). We chose this exploratory approach to make sense of unstructured data and gain understanding of this under-explored phenomenon. Having found no existing theory that suitably explains supply chain information disclosure we follow Eisenhardt and Graebner's (2007) protocol on building theory from case studies. This allows us to generate theoretical constructs from multiple case studies, thus developing theory inductively using replication logic (Eisenhardt, 1989; Eisenhardt and Graebner, 2007).

We explore the key questions of 'why' companies are disclosing information into the public domain (what are the drivers and barriers) and what are the outcomes (Eisenhardt and Graebner, 2007).

Sampling

Multiple cases are generally accepted as providing a stronger base for theory building (Yin, 2003). Through this approach, we are better able to argue for replication and more robust theory building (Eisenhardt and Graebner, 2007). 16 multinational companies with multi-billion euro revenues were selected as cases from the following four industries apparel (A), electronics (E), medical devices (M) and pharmaceuticals (P). These companies were selected from the Forbes list of companies on the advice of an EY report (2014) that stated that companies with multi-billion-dollar revenues were disclosing sustainability information publicly, as no report has evaluated supply chain information, we assume this to hold for supply chain information. Annual reports were examined for revenue (above €1 billion in turnover) and industry (from one of four industries of interest) with at least one company in each industry reporting some supply chain information in the public domain.

Data was gathered over a period of two years from September 2013 to September 2015 in order to evaluate companies supply chain disclosure during and after this period. The period of time was of particular interest as many companies had begun disclosing supply chain information that had not been disclosed before. Acknowledging the importance of time and context (Meredith, 1998), the chosen time frame, in our view, is critical for supply chain disclosure research.

While we expected our choice of companies to produce similar results, we were aware that institutional pressures would likely create disparities across industries due to varying institutional pressures. Using multiple cases allows for greater external validity and more robust theory building (Eisenhardt and Graebner, 2007; Yin 2003). Industry groupings allowed for further understanding of those that disclose supply chain information, who are customer facing and have been involved in a number of scandals (Apparel and Electronics) and those that are more business facing, disclose minimal amounts of information, have had fewer scandals and are heavily regulated (Medical Devices and Pharmaceuticals).

For each company we purposefully targeted and interviewed those who were responsible for supply chain information disclosure, the choice of such knowledgeable informants allows us to limit bias. In total 33 respondents were interviewed as detailed in Table 1. 15 interviewees are in companies that do not disclose any supply chain information to the public, 7 have limited information mentioning their supply chains, while 11 are in companies

that publish multiple types of supply chain information. Ethical considerations allow for the names and titles to be changed to protect the anonymity of sources.

Data collection

A semi-structured interview protocol was used to collect the data, questions were loosely structured around the shift to information disclosure looking at antecedents, types of information disclosure and outcomes. 33 interviews between 1 and 2 hours in length were conducted and recorded. Levels of information disclosure were probed in terms of depth of information gathered and released and the number of tiers of suppliers from which information was gathered and publicly disclosed. We worked within a very broad spectrum of topics. Although there are numerous advocates of unstructured fieldwork (Spradely, 1979) for clarity and to avoid information overload we followed a more structured approach. Eisenhardt and Graebner (2007) illustrate the difficulties in suspending knowledge of the subject.

Data analysis

The research team gained access to multiple companies in four different industries leading to both theoretical and literal replication and the ability to test themes and insights are they emerged (Yin, 2003).

All the interviews were transcribed verbatim coding over 1,300 pages of transcripts. Three researchers worked in isolation following a thematic analysis approach which offers a systematic, yet flexible and accessible, approach to analyse qualitative data (Braun and Clarke

2006). This allows for an inductive approach where themes are derived from the data. To reach a consensus on what was emerging from the data we followed a rigorous, iterative approach encompassing constant comparison techniques and interpretive analysis.

This constituted the open-coding process where data was allowed to dictate emerging codes. Following Strauss' (1987) approach we were able to work within broad categories to guide the process. After the initial coding allowed us to perform the first level of analysis we met to discuss codes, refining and collapsing as we progressed. We returned to analysis establishing relationships between codes searching for links and themes within the data. Over a series of meetings, we worked to reach a consensus on what was emerging from the data.

Findings

The model in Fig. 1 depicts the initial findings of the case studies. The cross-case analysis demonstrates a consistent view of supply chain information disclosure. The majority of constructs depicted are the topics most often discussed by the interviewees with between 30%-96% agreement. The circle size shows the order of magnitude of the number of interviewees who discussed the theme, those in **bold** are over 50% agreement. We group the themes into meta-categories of driving, barriers, not driving and outcomes. We capture inter-relationships as much as possible. Within the meta-categories, where circles overlap, the same interviewee has discussed the constructs as linked in some way. Unfortunately, sometimes this was not possible to capture fully due placement and complexity. The colour of the circles is for visual clarity only.

Driving supply chain information disclosure

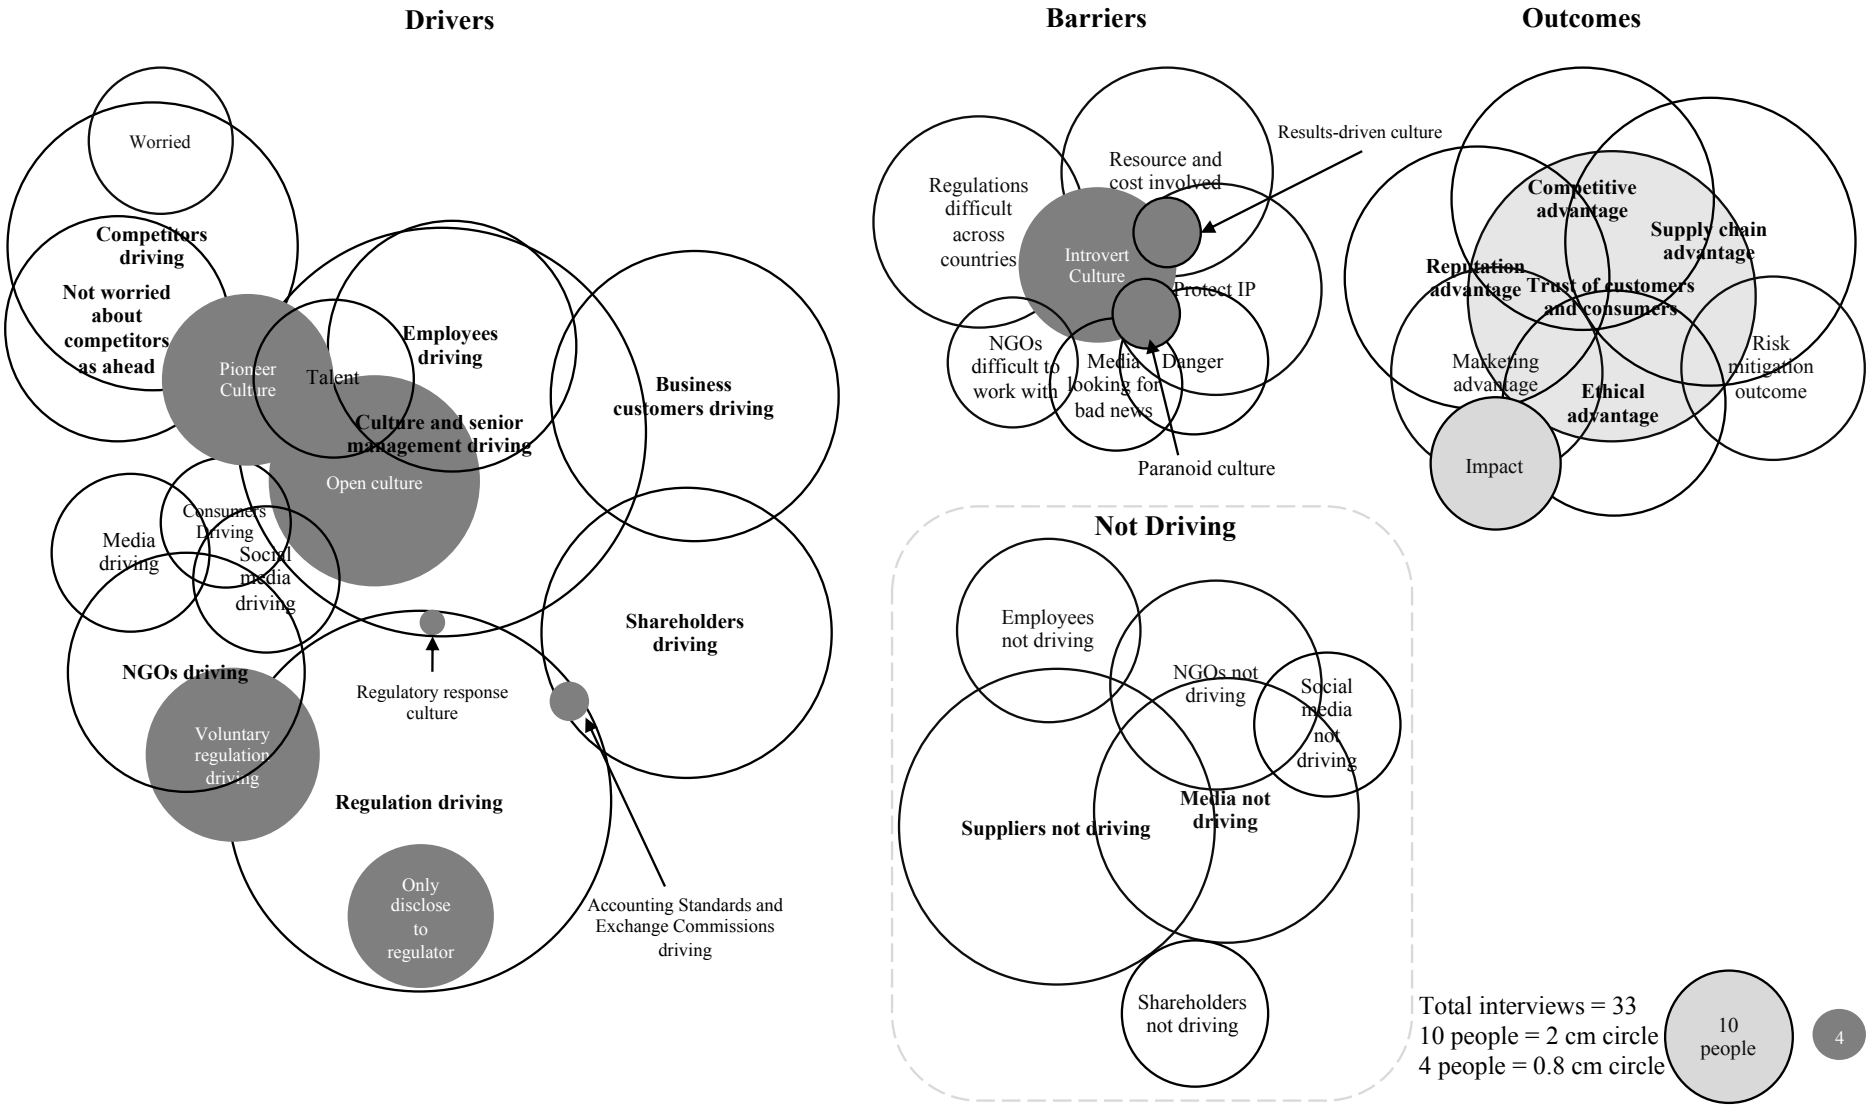
The only driver mentioned by all the interviewees was corporate culture and senior management. Previously separate constructs for senior management and culture were collapsed when 93% of respondents stated that senior management and culture together drive supply chain information disclosure. Several constructs provide detail on the types of culture: open and pioneer cultures drive disclosure, with respondents stating that building culture through multiple methods needs to happen. This also links with employees driving disclosure. In companies with a culture and senior management team who prioritise disclosure, employees are demanding more information and want to be associated with an ethical company. The need for both talent attraction and retention drives companies to disclose material issues in their supply chains.

Competitors are an important driver with some worried and others not worried about competitors as they are ahead of the competition and only use them to benchmark and pioneer new initiatives. This links competitor pressure with an internal pioneer culture, a sense that competitors are driving elite companies to be even better or more innovative in their disclosure.

87% of respondents stated regulation drives disclosure and, within this, voluntary regulations are important, particularly global initiatives such as the United Nations Global Compact and NGO-driven initiatives such as Sedex, Electronics Industry Citizenship Coalition, Fair Labor Association, Ethical Trade Initiative and Sustainable Apparel Coalition.

This links with NGOs driving disclosure and social media, consumers and media providing a compelling force for opening supply chain information. Interestingly, respondents overwhelming favour the use of social media, which is regarded as much more controllable as opposed to the unpredictable and, seemingly malevolent, nature of traditional media.

Figure 1: Supply Chain Information Disclosure Model Development



The difference between the interviewees descriptions of consumers and business customers is marked. Many more companies are under pressure from business customers to supply information, when these customers are large, sophisticated public or private sector companies. The pressure from consumers is much more amorphous with the real push for disclosure coming from NGOs who then drive consumer awareness and activism.

Four constructs are included due to their interesting nature. They are mechanisms which motivate or discourage disclosure. Cultural types that motivate disclosure: regulatory response culture; or create barriers to disclosure: paranoid and results-driven cultures. A further construct describing the impact of Accounting Standards and Exchange Commissions also intersects shareholders and regulation driving disclosure.

Barriers

The barriers to disclosure are mentioned by fewer interviewees than the main drivers. The barriers mentioned most often are the need to protect competitive advantage and intellectual property (IP), the resource and cost involved in disclosing and the difficulty in following regulations across different countries. Again, these constructs are interconnected, particularly costs and protection of IP. Several cultural constructs are also mentioned, notably an introvert culture, where the company is not used to 'broadcasting' lots of information but in some cases has used this culture to its benefit by ensuring data integrity before disclosing. However, other interviewees report this culture stems from a sense of disclosure as dangerous, the media only looking for bad news, the difficulties of working with NGOS and two other cultural attributes: an orientation for financial results and a culture of paranoia where interviewees feel that the media and NGOs attack them. This combination is a powerful deterrent to disclosure.

Not Driving

Suppliers are the stakeholder group most likely not to be driving disclosure. Multiple respondents spoke of suppliers wanting marketing as a result of sustainability initiatives, but many buyer companies are reluctant. Suppliers, on the whole are regarded a group who 'do' the disclosing rather than driving customer companies to disclose. Furthermore, a much bigger group stated that media was not driving disclosure than the group stating media was driving disclosure. This group split into two camps: one, the regulated companies and the second, the companies who feel targeted by the media. This group focused on the negative aspects of media and both groups described the harmful and vindictive nature of traditional media. Social media was evenly split between those who thought it was driving and those who didn't, again, like the NGOs not driving, this split was driven by industry. A much smaller group stated shareholders did not drive but these were mainly in family-owned companies where the family made strategic decisions.

Outcomes of disclosure

Five outcomes of disclosure were stated by 50% of the respondents. This is interesting as only 30% of interviewees are in companies that are disclosing supply chain information. The most common advantages stated are: trust and loyalty of customers or consumers, competitive advantage, supply chain advantage (where visibility in the supply chain confers multiple benefits) and a related risk mitigation advantage, as disclosure can act as an 'early-warning system' for issues in the supply chain. When the company discloses, it gains a reputational advantage. It is regarded as forward-thinking and innovative with greater insight into the opportunities and problems across its operations and supply chains. Ethical advantage, is quite different. This is where other companies, NGOs, customers, consumers and talent know they are working with or for a company that is meeting or exceeding societal expectations. This is

also linked with actual impact, where supply chain disclosure is leading to initiatives in the supply chain that positively impact the planet or the people in the supply chain.

The outcomes are tightly overlapped and interconnected. Interviewees see advantages as virtuous circles where insight into supply chains brings multiple benefits. These include marketing advantage, where companies can use storytelling and differentiation to increase attractiveness and differentiation leading to increased sales revenue.

Discussion

This initial grouping and modelling of the constructs from the 16 cases has thrown light on some very interesting dynamics in the supply chain information disclosure process.

The most prominent driver of supply chain disclosure, the same as the sustainability literatures is internal: senior management and corporate culture (Fraj Andres et al., 2009; Pagell and Wu, 2009) and also employees.

Similar to the sustainability literature on institutional theory (Zhu and Sarkis, 2007; Zhu, Sarkis and Lai, 2008), but which has not, to our knowledge been used in the supply chain disclosure field, we find coercive, mimetic and normative drivers of supply chain information disclosure: regulatory, shareholder and business customers; competitors; and NGOs with influence from media, social media and consumers, who appear to coercively or normatively increase pressure on disclosure through concerted action (MacMillan et al., 2004; Deegan and Islam, 2014). In the supply chain disclosure field much more attention is paid to stakeholder theory (Doorey, 2011; Wilson, 2013; Egels-Zandén et al., 2015; Mol, 2015; Van Der Ploeg and Vanclay, 2013), so combining these theories may give additional insight.

In this research, we have also uncovered some new constructs including different types of culture that hinder or motivate disclosure: pioneer, open, regulatory-response, introvert, paranoid and results-driven cultures, some of which have not been previously identified or linked with supply chain information disclosure.

The outcomes are very much in line with the current literature on both corporate responsibility reporting and supply chain information disclosure. Outcomes such as competitive, reputation and brand advantage (Chen and Slotnick, 2015; Doorey, 2011; Egels-Zandén et al., 2015; MacMillan et al., 2004; Waddock et al., 2002; Van Der Ploeg and Vanclay, 2013); and supply chain advantage (Egels-Zandén et al., 2015; Mol, 2015) are described by supply chain disclosure researchers.

However, this is the first large scale case study research to provide evidence across multiple industries. We provide a robust view of the interlinkages between the diverse types of advantage, with reputation and supply chain advantage interdependent with competitive advantage. Ethical advantage is linked more with reputation advantage and impact. Importantly, sustainability improvements through disclosure are discussed in the supply chain disclosure literature but only to say that there is no link between disclosure and sustainability improvements (Doorey, 2011; Egels-Zandén et al., 2015; Mol, 2015). So, this research is the first to make the link between disclosure and impact with multiple respondents describing how their disclosure initiatives have made a qualitative difference to environmental or social issues.

Furthermore, trust and loyalty of customers and consumers (Waddock et al., 2002; MacMillan et al., 2004) appears to underpin all the other advantages and is the most cited outcome. This is surprising as our focus is on the supply chain, so one assumption is that the supply chain will not only be at the forefront of interviewees minds but will also be most impacted by disclosure of its information (Egels-Zandén et al., 2015; Mol, 2015). One outcome we did not find was that disclosure legitimises company behavior and shifts the risk and blame for issues in the supply chain onto the suppliers (Egels-Zandén et al., 2015; Mol, 2015). However, legitimacy may be linked to multiple outcome constructs including ethical, reputation and trust and needs to be explored further.

Our constructs also differ on ethical advantage and risk mitigation advantage. Ethical advantage is the idea that the company is behaving well and is meeting or exceeding societal expectations, which many respondents link to the long-term survivability of the firm. Risk mitigation advantage works as an early-warning system for the company to let decision-makers know if there are issues in the supply chain about quality, process, product, environmental, working conditions or human rights issues.

The outcomes of disclosure are clear and although the interviewees were given opportunity to discuss negative outcomes from disclosing these were rarely mentioned but include audit fatigue, the high expectations when you start to disclose and the risk of other companies 'free-riding' on your initiatives. Although these is not depicted in the model, due to few respondents mentioning them, it is interesting to note that not all outcomes were positive.

Other interesting barrier constructs that are new to the field include the dangerous nature of disclosure, NGOs being difficult to work with and media only looking for bad news, which all appear to either stop or discourage disclosure.

In terms of practical and policy implications, the internal drive for disclosure and the parallel link to sustainability is something that managers and policy makers can be creative in harnessing. Through incentivising pioneer and open cultures in companies through awards, recognition and other intrinsic motivations for senior managers and employees in companies that are pioneering disclosure initiatives or who have excelled despite obstacles in disclosure can create foundations for stories and legends to bring lasting change in companies. One of the main goals of disclosure is informed choice for investors, consumers, customers and society and with parallel external motivation from role model competitors, regulators, shareholders, business customers and NGOs, companies will understand that supply chain information release will become a hygiene factor in many industries. If companies want to have the advantages of supply chain information disclosure they need to overcome introvert and paranoid cultures, and an overly narrow definition of IP and 'results'.

There are some strange results in the research, for instance, NGOs, employees, and shareholders are both described as driving disclosure and not driving disclosure. An initial within case analysis shows that there are industry and company reasons behind these differences and will be the subject of further investigation.

Naughty but nice: Communications in controversial industries

Abstract

The premise of this paper is that buying companies have to make themselves attractive (buyer attractiveness) in order to attract high-quality suppliers in the industry. We investigate the corporate communications of the largest companies in a unique context: controversial industries. We explore 24 cases in six different industries in order to understand if they discuss the main controversial issues in their industries and, if they discuss these issues, what do they say. We discuss the potential impact of these communications on supplier attraction and business model sustainability.

Keywords: supplier attraction, reporting, disclosure

Paper Type: Working Paper

Introduction

This paper explores how companies in controversial industries make themselves attractive to a potential supplier market. This is particularly important within these industrial contexts, as it may be more difficult to attract suppliers and then to keep them satisfied to maintain competitive advantage (Ellis et al., 2012). As buying organisations become increasingly reliant on their supply chain partners, greater levels of resources are engaged to ensure attraction and supplier satisfaction.

Unfortunately, in the purchasing field, the research on the task of attracting suppliers is almost completely neglected unlike that of attracting buyers, which dominates marketing. The prevailing attitude that the customer is key to the transaction, while the supplier has to do all the work means that researchers have neglected the methods and impact of attracting high-quality suppliers. A key factor across this body of work is the identification of whether the customer has a good reputation for trustworthiness and fairness (Pulles et al., 2016) and can be intrinsically trusted (Ellegaard & Ritter, 2007; Hald et al., 2009). By looking specifically at how organisations within controversial industries portray themselves and communicate their controversial issues, this paper contributes to the development of the supplier attraction field by building on work which determines the components that make up the supplier attraction concept and the specific factors that generate attraction.

Once a relationship has been established between a buyer and supplier, ongoing efforts are needed to ensure that satisfaction levels remain high. Again, the marketing literature focuses on buyer satisfaction, in this case, consumers (e.g. Lam et al. 2004; Luo et al. 2010; Perkins, 1993). Consumer satisfaction leads to better supplier performance, as consumer satisfaction leads not only to loyalty but also the competitive advantage from that loyalty in terms of increased revenues and profitability (Hallowell 1996; Lam et al. 2004, Luo et al. 2010). This link is so prevalent in the marketing literature that satisfaction is used as a proxy for performance (Hallowell 1996; Luo et al. 2010). Although, supplier satisfaction in the purchasing literature is not as developed, a number of antecedents of supplier satisfaction are identified, with much of the focus on the role of trust (Nyaga et al., 2010).

Communication with suppliers comes in many forms. One of the most visible and easily accessible forms of communication, especially if a supplier has no experience with a buyer is through corporate communication: websites and publically-available reports. However, currently the corporate communication landscape is heterogeneous with different

communication methods used including integrated reporting, stand-alone sustainability reports, downloadable pdfs and non-downloadable webpages. What is reported is also varied with little standardisation, order or context (Kozlowski et al., 2015; Okongwu et al., 2013; Van Der Ploeg and Vanclay, 2013). Some companies offer very little information on any aspect of their operations and supply chains, while others provide a large volume of information. This can be either negative reporting where companies discuss lessons learned and goals for the future, aimed at an audience of legitimising stakeholder groups or positive reporting of performance and goals for commercial purposes (Marshall et al., 2016).

This study will examine the corporate communication of firms in controversial industries, which are defined as industries excluded from responsible investor lists, that are morally questionable and that negatively impact the environment and/or society. We propose that buyers in these industries are not as attractive as buyers in other industries and make up for this by developing robust communications strategies for demonstrating trustworthiness to attract and satisfy suppliers. This leads us to our research questions:

RQ1: How do companies in controversial industries communicate the controversial issues in their industry?

RQ2: How do companies in controversial industries portray their suppliers?

By highlighting the practices of a number of companies within controversial industries, we want to show managers how they can use communications to effectively attract and satisfy suppliers.

Literature review

Supplier attraction and supplier satisfaction

Supplier attraction refers to a supplier's positive response to a buyer's perceived characteristics and behaviour. "Attractiveness is judged by knowledge of the alternatives and by the eye of the beholder, and the expected value ...in which each individual evaluates the rewards and costs gained through interaction with others…" (Mortensen and Freytag, 2010, p. 6). We use the terms 'supplier attraction' to refer to this affective state and its effects on the behaviour of suppliers.

Supplier attraction begins before a buyer-supplier relationship takes place and focuses on the buyer's attempt to engage the services of the supplier. The buyer displays their attractiveness by demonstrating how a supplier can maximise benefits and minimise costs by establishing a relationship with the buyer. Attraction will also be determined by how the supplier perceives anticipated satisfaction from the buyer's competitors and how well they demonstrate relationship benefits and costs (Ramsay, 1994). Extant literature identifies a series of antecedents of supplier attraction. Huttinger et al. (2012) for example, identify key drivers of attraction including risk, technological development, market growth, revenue generation and positive social aspects (2012).

Supplier attraction comes from a combination of costs and benefits and is subject to the effects of comparison with the supplier's prior expectations and expectations of competitor offerings. Therefore, if a supplier values the offerings displayed by the buyer the more likely they are to work with them. Therefore, the better the quality of the buyer's purchase offering, the more attraction the supplier will perceive. Although there are conceptual similarities between supplier attraction and supplier satisfaction, such as the role of trust, satisfaction is experienced after the exchange and all costs and benefits have been experienced. When it comes to prospective buyer's supplier attraction refers to the satisfaction the supplier anticipates

experiencing from working with the buyer. Therefore, it is of particular importance for organisations to portray themselves in a positive, trustworthy manner both before and after the exchange begins. In a similar way to the antecedents of supplier attraction, the anticipation of satisfaction derives from the reputation the company, experienced through the brand, image and communications of the company (Chicksand & Rehme, 2018) and its ability to engender trust (e.g. Nyaga et al., 2010).

While marketing has focused on the attempt to influence the behavioural intentions of consumers our focus is to understand how to influence the behavioural intentions of suppliers in order to enhance supplier attraction and supplier satisfaction. Doing this could lead to minimising external resource costs and maximise profitability, but perhaps, more importantly, could lead to the buyer being a preferred customer for the supplier (Huttinger et al., 2010) leading to preferential resource allocation (Pulles et al., 2016). This can include access to the supplier's proprietary technologies (Ellis et al., 2012), access to better pricing and/or greater levels of flexibility (Nollet et al., 2012).

If a company is in a controversial industry, they have the added problem of dealing with issues that are regarded as undermining the basic societal contract and need to be much better at communicating relationship benefits and attracting suppliers. We want to understand if other companies can learn from the practices of controversial companies regarding how they confront the issues they are faced with and how they communicate these issues to demonstrate they are legitimate and worthwhile companies for suppliers to work with.

Methods

To answer the research questions, we use a case-based approach, drawing on secondary data. The choice of using secondary data was logical as it is invaluable for operations and supply chain management research (Boyer and Swink, 2008) and because of the sensitive nature of the study, which makes primary data collection difficult. The rationale for selecting organisations deemed as controversial, is that need to work harder to demonstrate that they can be trusted in order to attract prospective suppliers and to maintain supplier satisfaction. We make use of Yin's (1994) extreme case study method in order to obtain multiple perspectives via multiple cases of different organisations in a variety of industries.

We based the selection of cases on several criteria: companies had to be in industries that were judged as disapproved on responsible investor lists Triodos Bank (2013) and Domini Responsible Investor list of excluded industries (2017). These controversial industries were agricultural chemicals, alcohol, armaments, coal mining, oil & gas and tobacco. In order to identify the most valuable companies, and the most likely to communicate publically (EY, 2014), we used the Forbes 2000 list (2017) of most valued companies. Finally, the company had to have either over 30% of revenues derived from the controversial activity or be regarded as the market leader in the activity.

We identified the controversial issues in each industry using the descriptions in the Domini Responsible Investor list (2017). The primary issue for each industry and the secondary issues for each industry are given in Table 1 below.

Table 1 - Controversial Issues

Controversial Issues	Primary	Secondary
Agricultural Chemicals	Impact of chemicals on individual health, soil health and biodiversity (harmful and addictive products DRI)	Working conditions and human rights, including conflict minerals
Alcohol	Impact of alcohol on individual health (harmful and addictive products DRI)	Drink driving; working conditions and human rights, including vulnerability of developing world farmers
Armaments	Death, arming risky groups (harmful and addictive products DRI)	Working conditions and human rights, including conflict minerals and arming conflict groups
Coal	Impact of oil and gas on environment including pollution and climate (fossil fuel owners and producers DRI)	Working conditions and human rights, including health and safety of miners
Oil & Gas	Impact of burning oil and gas on environment including pollution and climate (fossil fuel owners and producers DRI)	Working conditions and human rights, impact of oil spills
Tobacco	Impact on tobacco individual health (harmful and addictive products DRI)	Working conditions and human rights, including green lung disease

DRI: Domini Responsible Investor category

Report analysis

We systematically downloaded and analysed the web communication, annual reporting and sustainability report of 24 companies using the factors presented in Table 2. An excel spreadsheet was used to capture the researchers' analysis. The key areas for data collection were organised under the headings 'Controversial Issue Reporting', 'Supplier Reporting', and 'Reporting Strategy' and were chosen in order to help answer the research question:

RQ1: How do companies in controversial industries communicate the controversial issues in their industry?

RQ2: How do companies in controversial industries portray their suppliers?

Findings

The details of the case findings are not presented in this paper, rather a summary of the key findings is given in Table 2 below. This summary lists the key factors and a high-level analysis of how each case company dealt with the factors and this enabled us to perform a within case for each company and cross-case analysis for each industry and across the industries.

Table 2 - Case Findings

Discussion and Conclusions

We identified three strategies companies adopt when communicating their main controversial issue: directly, indirectly and avoid. For alcohol and tobacco companies, it is almost a necessity to *directly* address health issues since these issues are well known in the public domain. We would also expect to find this in industries where impacts are also common knowledge and in the public discourse.

The coal and oil & gas companies in our sample *indirectly* refer to global warming and admit to their role in climate change but only at an operational level rather than a product level. For example, the main focus is the operational ways they reduce CO2 emission, however, they do not tackle the issue of the burning of their product and the harm it does to the environment. Although the coal companies state other renewable fuel sources they are investing in. The main focus of their communication, however, is other operational issues such as health and safety of workers and disaster impact reports. According to Mol (2015), this could lead to loss of legitimacy for these companies and eventually their licence to operate.

Agricultural chemical and armament companies tend to *avoid* their main controversial issues and provide solutions to other issues in their companies, which are not regarded as the dominant societal issue.

Companies within our sample have the added pressure of scrutiny by a number of stakeholders including the media, NGOs, academics and unions. The media and NGOs, in particular, and resourced and well equipped to develop creatively destructive campaigns and boycotts and bring to light poor practices (Deegan and Islam, 2014). Therefore, since they are in the public eye, these companies have to show how they are mitigating their impacts on society as poor practice will be made public, leading to reputational damage (MacMillan et al., 2004; Waddock et al., 2002). It is interesting to note that the companies who tackle their controversial issue head on have also developed solutions to these issues and have created substitute products. For companies who do not address these issues directly there are no readily available substitute products.

Certain companies have turned controversy into opportunity, not least by defusing the controversy by describing the efforts and measures they are taking to solve the controversial issue. This is evident for the alcohol and tobacco companies, who claim to have solutions to their controversy impact. They directly admit the impact they have on society and provide descriptions of products or initiatives that they claim alleviate these impacts. For alcohol companies, non-alcoholic beverages are an obvious solution to their controversial issue, whereas the tobacco companies claim that e-cigarettes are a solution to theirs. Therefore, substitute products can be promoted to customers and stakeholders, replacing the harmful ones.

Arguably it appears as though tobacco companies devote less coverage than alcohol companies to their controversial issue and it is less prominently displayed in their reports. The focus of their argument is that consumers should be given choice and that this needs to be balanced against conclusive scientific evidence of the health risks. However, their solutions are centred around the development of new products, and thus offer a wider choice to their customer. From these findings our first proposition is:

Proposition 1: Companies will focus on controversial issues if they can market a substitute product as part of the solution to the issue

It appears when there is little scope for substitute products, and where the companies are not willing to advocate less consumption, they *avoid* their main controversial issue, instead they will emphasise dealing with them indirectly through their operations. For instance, companies in armaments are not seen to be tackling issues pertaining to 'death and injury to

people' but they invest in technologies, infrastructures, products and services which posit them as leading or cutting-edge innovators in their industry, thereby seemingly contributing to the wider welfare of society. Therefore, our second proposition is:

Proposition 2: Companies will avoid a dominant controversial issue if it is part of their core business (if they have no substitute product) and will give prominence to another controversial issue

It is evident that in controversial industries we cannot argue that all firms have developed robust communications strategies for attracting suppliers. A focus on supplier attraction i.e. the proactive management of the satisfaction the supplier anticipates experiencing from the act of exchange through communication and reporting, was more developed in companies located in the US or Europe and that were listed on US or European stock exchanges. In contrast, professional report was not as developed in the semi-state or developing world reports. India Coal, China Shenhua Energy and PetroChina, appear to be at the early stages of reporting. We, therefore, conclude that sophisticated sustainability communication and reporting is essential for companies in the developed world, which can lead to the attraction of suppliers:

Proposition 3: Reporting and communication is essential for controversial companies in the developed world to maintain their social contract and attract suppliers.

Proposition 4: Controversial companies, with previous semi-state ownership, from developing countries, will have less focus on reporting to maintain their social contract and attract suppliers.

It appears that companies in controversial industries understand their dependence on suppliers to their core businesses or capabilities and have focused on different suppliers depending on their industry context. This dependence is a potential risk or vulnerability to them. Companies in agricultural chemicals, armaments and oil & gas appear to manage this vulnerability by working with numerous, small-scale, diverse and a financially-weaker pool of suppliers who are selected and scrutinised by their in-house supplier codes of conduct. These codes of conduct whilst guiding supplier selection can also be perceived as straitjackets that can undermine the smaller supplier's operational autonomy over the long term. It can also be a tool to steer suppliers to depend on the larger buying company instead. Our review of these guidelines suggest that these 'codes of conduct' are so elaborated, sophisticated and scrutinised that once a supplier has gone through the selection process, it is locked in to a long-term service agreement with the controversial buyer. Companies in controversial industries appear to align their supplier codes of conduct to their perceived controversial issue. However, this alignment becomes less significant over time as the relationship deepens and the suppliers become more dependent on the controversial buyer.

Proposition 5: Buyer companies in controversial industries will align controversial issues to their own codes of conduct to create, maintain and sustain their attractiveness.

In conclusion, buying companies in controversial industries can be delineated quite clearly by the industry they are situated. Alcohol and tobacco companies appear to have found a sustainable model for supplier attraction and business survival. The other companies in the sample would do well to understand the strategies of these two industries to be attractive to suppliers and avoid an unsustainable business model.

Abstract

This research identifies potential solutions for supply market analysis and improvement in purchasing category management. Supply market development contains several practices that have effect on purchasing effectiveness. The empirical research is based on two expert focus group surveys, interviews and two workshops, which were executed in the Finnish Transport Agency. The preliminary results show that development areas of *purchasing planning instructions*, *market dialogs and networking with suppliers and buyers* were estimated to have the most supply market development potential in the case agency.

Keywords: Supply market development, Purchasing development, Public procurement

Submission category: Working paper

Introduction

Supply market development and analysis is a topical theme in the public sector. The decline in the resources of the public sector has prompted governments to look for new innovative solutions that can produce legislation-defined mandatory services with fewer resources and greater efficiency (Hartley, 2005). The public agencies are trying to avoid supply side monopoly situations via supply market development actions because monopolistic or oligopolistic suppliers often do not have incentives to act efficiently from the buyer point of view (Van Weele, 2005). Supply market development actions can mitigate supply chain risks (Sodhi and Tang, 2012).

In this study, we aim in investigating the most valuable development actions for supply market development. We-illustrate how the organization may find and prioritize potentially efficient and effective supply market development actions in their purchasing categories. The identified supply market development actions are especially suitable for organizations which utilize purchasing category management model that has purchasing categories with only few suppliers. The contribution of this paper is to provide impact and feasibility estimations of different supply market development actions which were recognised by purchasing category (PC) managers of the public agency. In the literature, it has been remained mostly unaddressed that which PC activities have the most impact on effective development of supply markets.

Background and literature review

Companies are trying to improve competitive advantage, purchasing performance or purchasing innovativeness with supply market analysis and development. Agencies have similar targets with performance and innovativeness. Nowadays supply market development is taken seriously also in the public sector. Supply market development can be part of the performance aims of the public

organization. In this paper *supply market development* term is used, because in the literature alternative *supplier market development* term is less frequently used.

Supply market development may improve public sector purchasing innovativeness and increase purchasing innovations. Supply market development may lead to improved communication and collaboration between buyer and suppliers. *Early supplier involvement* (ESI) and collaboration have been sources of certain innovations (Wynstra et al., 1999; Schiele, 2010). In the recent years considerable attention has been given to innovation and in the public purchasing management area (e.g., Moore and Hartley, 2008; Pollitt, 2011, Bekkers et al., 2011; Edler and Georghiou, 2007). The EU countries are setting targets for innovative procurement and making efforts to measure innovations made in the governmental organizations (Hughes et al., 2011; Arundel and Huber, 2013; Bloch and Bugge, 2013; European Commission, 2012). It is acknowledged challenge to measure and quantify performance of purchasing innovations (Kattel et al., 2013). Despite of innovation measurement challenges, the results of this study include concrete high impact actions for supply market development in the case agency (Table 2). These supply market development actions of this paper may have positive effect on purchasing innovations and innovativeness. The knowledge of previous supply market development actions (Table 1) may also be utilized by new purchasing categories or even by other organizations. Supply market practices may be considered as *purchasing innovations* (Walker, 2008; O'Toole and Lawrence, 1997) if supply market practices or development actions are considered as new to a unit of adoption and bring new value to the customers of purchasing.

Supply market and other supplier development can be considered as part of Supply Chain Management (SCM), which manages the flows of information, materials, and services from suppliers through production to the end customer. It is said that the SCM aims to reduce uncertainty and risks in the supply chain. From the buyer perspective in the SCM risk mitigation it is important to guarantee that supply markets are working healthily and providing expected services and products on time to their purchasing customers. If supply markets are too narrow and too few suppliers can only provide services or products, then supplier may act in a monopolistic way and cause unwanted cost, availability or quality level changes to its customers. (Leenders et al., 2006).

Supply market development related topics like supplier development (e.g. Handfield et al., 2006; Krause et al., 1997; Krause, 1999; Leenders et al., 2006; Monczka et al., 2002), supply market analysis (SMA) (e.g. Parniangtong, 2016) and supply base development (e.g. Monczka, 1993) have been covered in the earlier research. However, there is a research gap concerning how the supply market analysis results are transforming into supply market development actions especially in public sector purchasing organizations.

Empirical study

The case organization, the Finnish Transport Agency purchases annually with 2100 million euros. Several purchasing categories of the FTA have a high impact especially on the infrastructure supply markets. The FTA is the only purchaser in certain purchasing category areas in the Finland. However, purchases of majority of the categories do not have dominating position in the markets.

In the empirical part of the study, we identify the appropriate development actions to guarantee functioning markets and to improve quality and cost effectiveness of supplier provided products and services in the case organization. The case study covers all 17 purchasing categories of the

FTA. Each PC is composed of one to seven PC products. The PC managers are the focus group in this study.

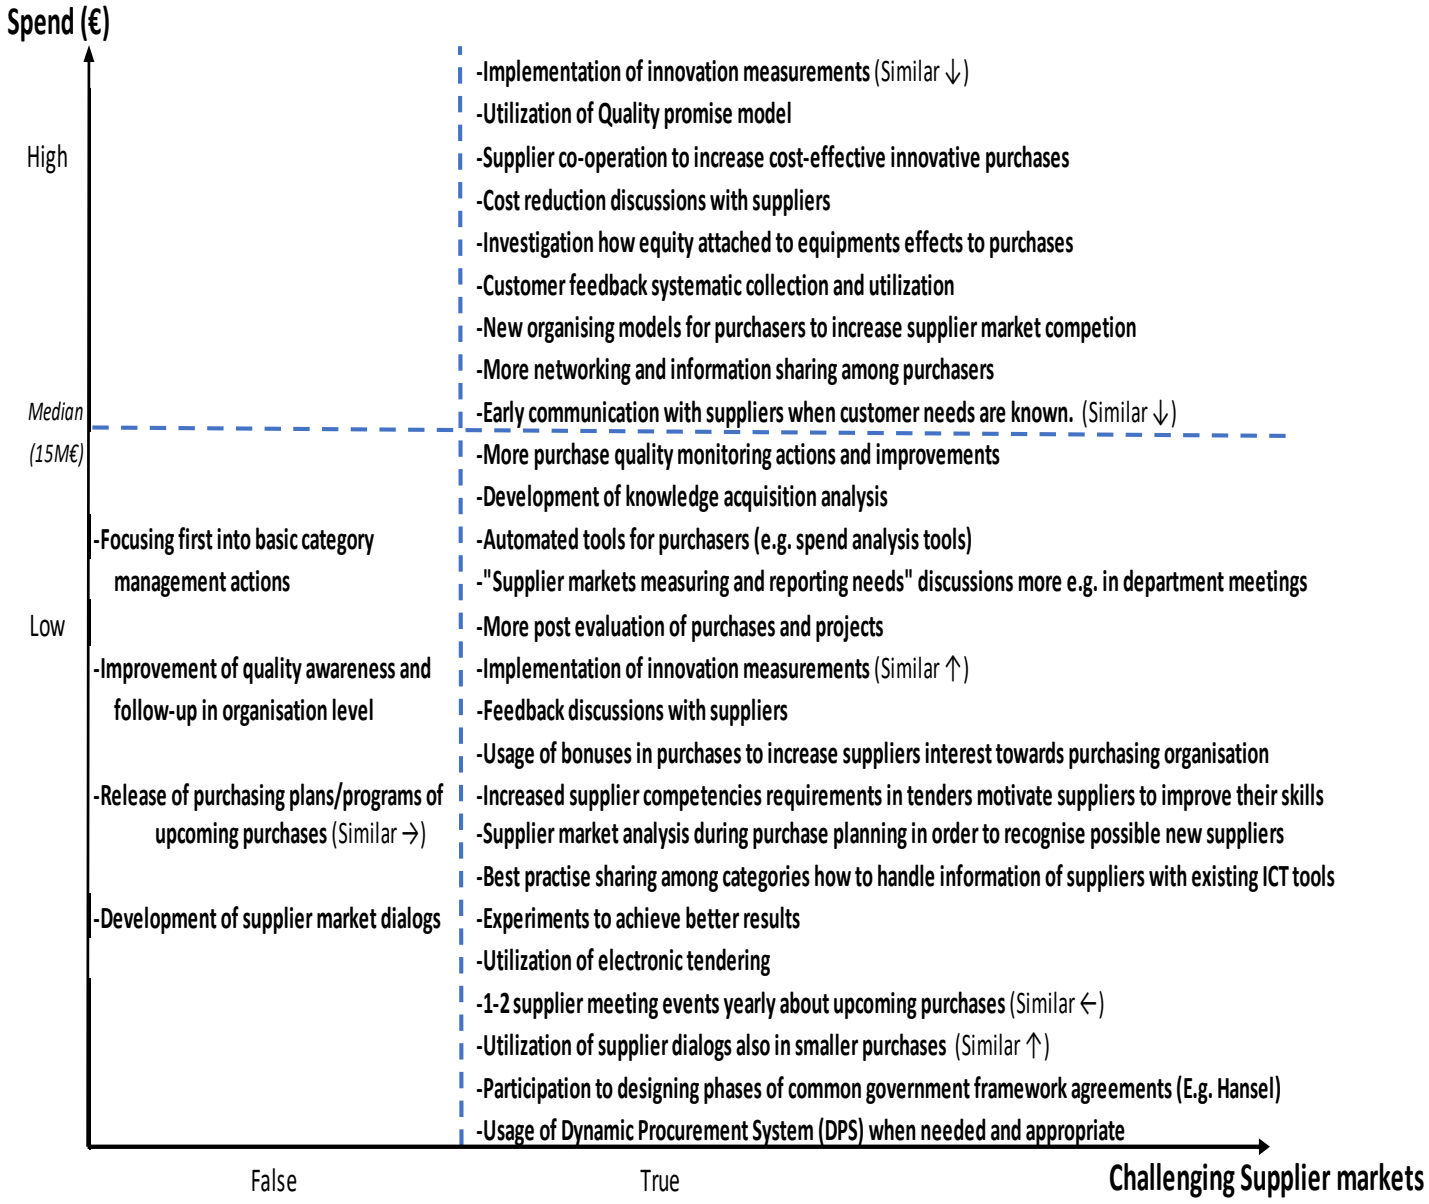
In the first stage of the study, we conducted the survey and asked from the focus group e.g. about the supply market development importance and features in their category. The survey included questions covering also purchasing strategies, purchasing performance, purchasing operations, category continuous improvement and supplier risks. 17 answers were collected from the survey. In the second stage, we carried out semi-structured empirical 16 interviews for each focus group member. One interview covered two PCs because one person was responsible of two categories. The interview themes covered the previously mentioned survey topics. By interviewing it was searched the reasons why certain survey claims were either above or below organization's average in the interviewed category. Interviews provided supply market understanding e.g. about challenges, best practices, supplier/purchaser benchmarking, as well as characteristics of supply markets and beneficial development areas.

The third stage of the study contained two workshops. In the first expert workshop was found nine supply market development areas or actions which had the most impact to categories of the agency according to group of the PC managers. The first workshop was implemented by using semi-structured focus group method. The second workshop with ten attendees prioritized proposed top supply market development actions by valuating impact and feasibility of each action. In the latter workshop we used the structured focus group method. In the second workshop the group of the PC managers were asked to report new supply market development actions if something was missing from earlier identified supply market development proposal list. This list was formed mainly based on focus group interviews and the results of the first workshop. In the next phase of prioritization workshop participants voted the impact and feasibility values of each development action proposal from the agency's point of view. Likert scale (1-5) was used in voting of impact and feasibility values of development actions. (Value 1 meant that action had very low either impact or feasibility from the whole agency point of view. Value 5 meant the opposite, meaning that action had very high impact or feasibility.) At the end of second workshop it was discussed the managerial explanations and the implications of the results. In the workshop the PC Managers were instructed to make supply market development plans from the perspective of their own categories.

Findings and implications

The results of the focus group interviews can be seen from Table 1 which contains experiences of supply market development actions and methods in the different purchasing categories. Y-axis describes the spend of the category which was interviewed. X-axis shows that did the interviewed category manager of development action report to have supply market challenges in his/hers category. Information of X- and Y-axis were gathered from the implemented survey of the category managers.

Table 1. Previous both supply market experiences and development actions based on the focus group interviews.



The ideas of supply market development prioritized in the second workshop are shown in Table 2. The table contains workshop participants' opinions about the supply market development actions from impact and feasibility from agency purchasing categories point of view. Table 2 includes ID information of each development action. Figure 1 shows how development action IDs are positioned in a XY-matrix where X-axis describes impact and Y-axis describes feasibility values of each development action.

Table 2. The second workshop results of the supply market development actions.

ID	Prioritized supply market development actions	Impact	Feasibility
1	Purchasing planning instructions are developed in decentralized categories. Decentralized categories have purchases which are divided to different departments and units in the organization.	★	★
2	Market dialogs are utilized systematically more often and in larger scale.	★	★
4	It is verified that purchasing models and document templates of purchasing products are renewed systematically by utilizing both supplier and purchaser feedback information.	★	★
5	Open purchaser-suppliers meeting days are arranged more often.	★	★
3	Presence in Buyer – Supplier and Buyer – Buyer -collaboration networks are developed in each category.	★	☆
8	Standardized automated tools are developed to support purchasing and supplier monitoring in existing ICT systems.	☆	★
6	More resources for implementation of quality measurement during purchasing contract period.	★	☆
7	Organization decision makers makes sure that purchasing category managers have sufficient resources and support.	★	☆
9	Utilization opportunities of framework agreements are investigated in categories with few suppliers.	☆	☆
12	Peer support networks are created for categories having monopoly or oligopoly supplier situation.	☆	★
14	Survey for suppliers is implemented to get information how interested are suppliers about the agency as a purchaser.	☆	★
10	Purchasing requirements are becoming harder in a long run in purchasing category products (e.g. more value for money, higher quality requirements).	☆	☆
13	Categories with decentralized purchases develop training of their important supplier. Training is about how consults are expected to work in the agency environment and what instructions to follow.	☆	☆
15	Participation to networked competency centre of central government.	☆	☆
16	General and category specific supplier disqualification and dependency	☆	☆
11	Dynamic Purchasing System (DPS) is utilized more often in the selected categories.	☆	☆

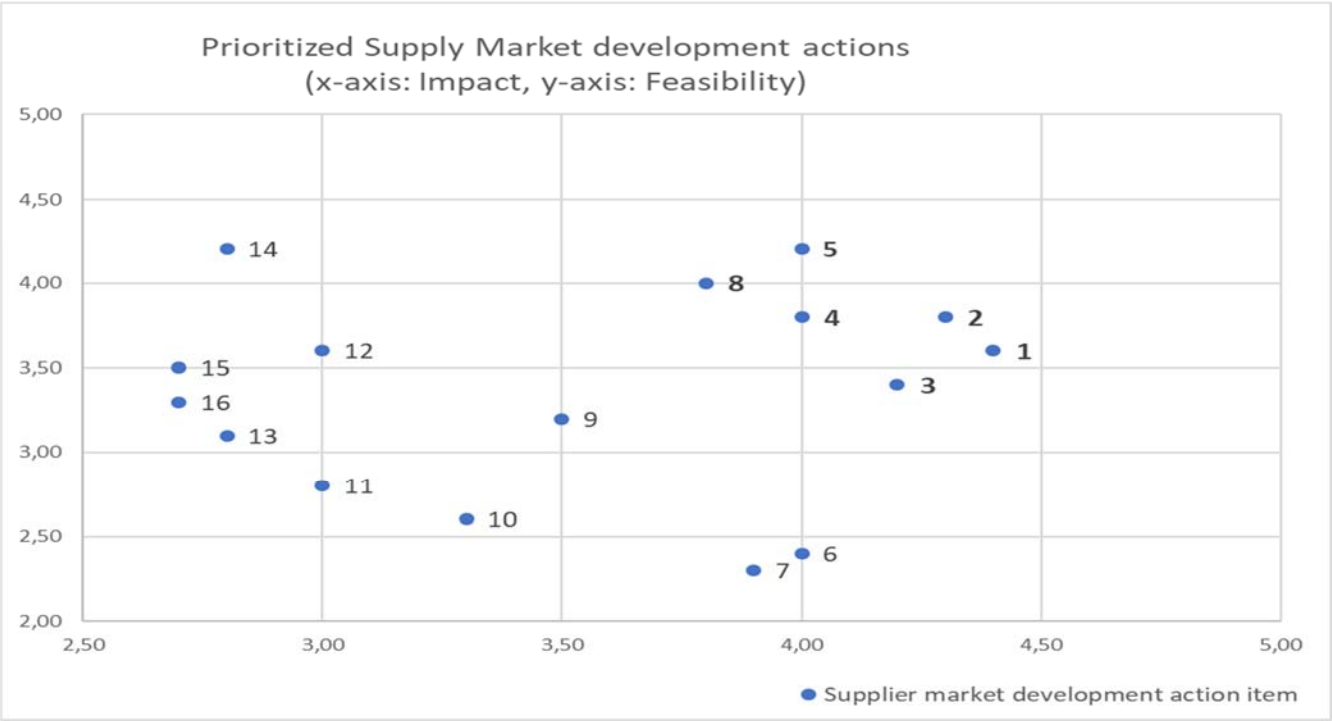


Figure 1. *Impact and feasibility of the supply market development actions in XY-matrix based on the prioritization workshop.*

The main managerial impact of this study is that potential supply market development themes were found. The actions in these themes received high impact and high feasibility scores in the FTA. The main themes were roughly *supplier and buyer communication* (Figure 1 and Table 2: ID2, ID5, ID3, ID12, ID14), *standardization of procedures and tools* (ID1, ID8, ID9) and *continuous improvement* (ID4, ID6).

The action with highest impact score (ID1) was related to purchasing planning instruction creation in decentralized purchasing categories. These purchases of the decentralized categories were implemented in different departments and units of the organization. The buyers of the decentralized PCs can especially benefit about best practises containing purchasing planning instructions because they less often get PC specific instructions or advices from the nearby co-workers.

In the literature standardization of purchasing procedures (like ID1, ID8 and ID9) has been recognized to have positive effect on quality of material, on-time delivery from suppliers, inventory performance and to a business performance (Sánchez-Rodríguez et al., 2006). Purchasing instructions may contain standardized procedures of purchasing planning and supplier-buyer communication. Purchasing planning instructions with supply markets information of the category can be valuable to the new buyers of the PC. Purchasing planning instructions of the PC (ID1) can explain how to implement the most valuable supply market development actions like supplier-buyer communication related market dialogs action (ID2). Market dialogs can be considered a form of ESI.

Continuous improvement related actions were ranked to third position (ID4) and to seventh position (ID6) in impact evaluation. PC managers considered that it is important to verify that purchasing models, procedures and documents are upgraded based on supplier and the buyer information (ID4). Assurance of quality measurement resources during contract period was considered to have high impact but this action was difficult to implement in the case organization because of low feasibility score (ID6). The most feasible development action was ID5 which proposed that supplier-buyer meeting days should be arranged more often.

Conclusions and suggestions for future research

The neglection of supply market development may lead to a situation where number of suppliers is too few and a true competition among suppliers during tendering is missing. Monopolistic or oligopolistic supply markets may raise cost level of purchases and quality of purchases may decrease. This study listed supply market development actions and themes which may also mitigate the risk of monopolistic and unhealthy supply markets. The findings of this study may benefit purchasing category managers and other purchasing professionals who are planning to make effective and efficient supply market improvement actions. In the supply market development planning of PCs it is possible to learn from other categories by using supply market development interviews results (Table 1) and workshop findings (Table 2) of this study. This study found, besides potential high impact supply market development actions (Table 2: e.g. purchasing planning instructions, market dialogs, improvement via supplier and buyer information), potential bottleneck areas (two actions) which can avert the development of supply markets.

One potential future topic for future research is to study the reasons why two topics were estimated to be difficult to implement but still had high impact scores in the case organization (Table 2). Firstly, according to the workshop results the decision makers should guarantee sufficient resources and support to PC managers. In case the PC managers are not allowed to spend sufficient working time for the PC development work and they do have enough management's support, supply market development work may not be as effective as it should. Secondly, another future investigation topic is to think how to guarantee appropriate resources for quality control activities during the contract periods of purchases. We propose that organisation should guarantee that resources of category management and quality measurements are sufficient. Supply market development efforts of PC managers can be inefficient and ineffective without appropriate support of management in the organisation.

Abstract

The aim of this study is to identify the antecedents of purchasing innovations. This paper introduces a framework for best practices and categorizing the innovations of purchasing. A conceptual model for purchasing innovations was constructed based on a literature review. Empirical study is based on interviews and a survey in a public agency. The empirical analysis of the conceptual model showed that the constructs for sustainable supplier development and purchasing support exert a statistically significant effect on the purchasing innovations. By improving areas of the previous constructs, organizations may improve its innovativeness in purchasing.

Keywords: Public procurement, Purchasing innovations, Finland

Introduction

Public sector innovativeness and innovations are the sources of economic and industrial competitiveness in the European Union (European Commission, 2010). The EU invests 24% of world expenditure on research and the EU dominated earlier global research and innovation field together with the USA and Japan (European Commission, 2012). The western EU countries contributes also circa 20% of GDP to the public sector (Eurostat, 2018). These high contributions mean that public sector innovations can have a high impact to the industrial competitiveness. Similarly, in a high-impact public purchasing organization, such as the Finnish Transport Agency (FTA) (2100 million euros annually) the value potential of purchasing innovations is considerable. The public sector innovations, including purchasing innovations, aim for improved productivity, the efficiency, and the quality of public services. The decline in resources in the public sector has prompted governments to look for new innovative ways to produce and improve agency-provided services (Hartley, 2005). Meanwhile, agencies re-evaluate existing service production processes and attempt to find novel solutions that can produce legislation-defined mandatory services with fewer resources and greater efficiency.

Innovation and innovativeness in the public sector have been widely discussed in the academic literature, but, for the most part, the antecedents of purchasing innovations in public procurement remain undefined and unaddressed (Bekkers et al., 2011; Uyarra and Flanagan, 2010; Hommen and Rolfstam, 2009). This paper attempts to cover a gap in the literature concerning the sources of the purchasing innovations of the public sector. This paper describes a search for the antecedents of purchasing innovations in the FTA. This paper asks the research question of which antecedents explain most of the purchasing innovations in the studied agency. The knowledge about the antecedents and examples of purchasing innovations can be utilized, e.g., when improvements in

purchasing innovativeness and innovations are planned in the different purchasing categories of the FTA.

The first and second chapters of the paper introduce the main terms and concepts of this research study. The second chapter outlines the forms of innovations and innovativeness in the literature. The third chapter depicts the purchasing innovations in the literature and the fourth chapter describes the conducted empirical interviews, the survey, the analyses, and the findings of the survey. The fifth chapter draws conclusions and discusses the managerial implications of the found results. A literature review was conducted to create a conceptual model for purchasing innovations. The empirical interviews of the research focused on the best practices implemented in purchaser-side purchasing and issues related to innovation sources. The interviews gave indications that the created conceptual model for purchasing innovations was suitable for the researched organization. A framework for best practices of this paper is an example how purchasing experiences can be categorized. Interview observations and a created framework of this study may be valuable for category managers of the FTA when actions of purchasing innovation development are planned. In the final phase, the empirical survey featured questions regarding purchasing, purchasing innovations, and supplier innovativeness. The survey results were analysed with an exploratory factor to structure and confirm the conceptual model constructs. The conceptual model was then tested by regression analysis.

Innovation and innovativeness

In the recent years considerable attention has been given to innovation generally and in the public purchasing management area in recent years (e.g., Moore and Hartley, 2008; Pollitt, 2011, Bekkers et al., 2011; Edler and Georghiou, 2007). Like many other popular terms, there is no widely accepted or common definition for "innovation" (Dunleavy et al., 2006). The term is often understood as pointing to originality and effectiveness. Originating from the Latin *novare*, it means renewing or introducing something new (Schiele, 2006). According to Schumpeter (1939), *innovation* can be understood in short as doing things differently in the realm of economic life. Schumpeter (1912) has defined product and process innovations that include the introduction of new products, quality, method of production, or method of handling.

Nowadays, innovating work means creating and implementing a new or significantly improved solution to a meaningful problem (Rogers 1995). In general, innovations do not have to be new to the world, but they should be a novel introduction to the market or industry where such innovations are intended for use (Edquist et al., 2000; Keeley et al., 2013). The studied FTA is a distributed organization that was formed from three agencies in January 2010. According to Schiele (2006), organizational mergers are another source of innovation, along with imitation, the purchase of innovations, the development of new products, and continuous improvement. In the newly merged organization, a single solution may be interpreted as either innovative or standard, depending on the previous experiences of personnel in certain divisions of the organization.

Innovativeness is a major force behind the development of innovation and new products (Droge et al., 2008). Joint product development activities between buyers and sellers may lead to the long-term success and survival of supplier firms. Inemek and Matthyssens (2013) suggested that buyer assistance-giving routines effectively enhance supplier innovativeness in the relationship between an international original equipment manufacturer (OEM) buyer and a first-tier supplier; this enhancement, however, is not as significant with respect to lower-tier supply networks. Improving supplier performance may necessitate that a buying firm invests directly in a supplier's operations

by providing direct assistance through visits, training programs, or assistance from employees in improving the supplier's process efficiency (Krause et al., 2000). Interfirm information-sharing activities constitute imitation, which is considered a source of innovation (Schiele, 2006). An example is Toyota, which as a buyer has provided assistance to its suppliers over a period that is twice as long as that offered by its U.S. competitors (Dyer and Hatch, 2006). This increased buyer assistance to suppliers has resulted, on average, in improved supplier performance in terms of quality and cost (Dyer and Hatch, 2006).

Innovations can be seen as a process wherein new ideas, objects, and practices are created, developed, or reinvented and that are new to a unit of adoption (Walker, 2008; O'Toole and Lawrence, 1997). Public organizations may also innovate in search of legitimacy, thus highlighting the importance of treating innovation as implementation and not merely as an idea (Walker, 2008; Boyne et al., 2004; Damanpour and Evan, 1984). The innovation process includes phases such as understanding, solution idea creation, solution creation and commercialization. Aside from being categorized into processes and services, innovations can also be classified as ancillary (Damanpour, 1987) and inter-organizational (Mandell and Steelman, 2003) types. Process innovations can be divided into technological and management innovations. Walker's (2014) review of the process innovation implemented by governments showed that the internal antecedents of process innovation matter more than their external counterparts.

A further classification of innovations is as incremental and discontinuous types. As explained by Phillips et al. (2006), close supplier relationships favour incremental innovation, whereas new and temporary relationships favour discontinuous innovation. Innovation is important not only in supply chains for physical products but also in processes and services; innovation in both dimensions plays an essential role in innovation management. Innovation may be also affected by organizational factors and characteristics such as industry area, production (manufacturing/service), profitability model (for-profit/not-for-profit), or sector (public/private) (Damanpour, 1991).

Purchasing innovations and innovativeness

In recent years, innovations in the purchasing management field have elicited managerial and academic attention (e.g., Luzzini et al., 2015; Arundel et al., 2015; Schiele, 2006). In various purchasing categories, innovativeness more effectively enables improved performance outcomes than does reducing purchase price. In this paper *purchasing innovations* term is related to practices or actions which are considered as new to a unit of adoption and bring new value to the customers of purchasing (Walker, 2008; O'Toole and Lawrence, 1997). This section briefly outlines the forms and sources of *purchasing innovations*. To identify the nature of purchasing innovations, we reviewed the existing research on this matter.

As discussed previously, the term "innovation" can be seen as broadly defined. Value- and performance-adding innovations may originate from an organization itself because organizational mergers are a source of innovation (Schiele, 2006). *Purchasing innovations* may be also related to supplier innovativeness, which can be enabled by actions and practices of the buyer (Schiele, 2006). Purchasing innovations and innovativeness may be learned from an organization through the best practices that it implements. Best practices are a collection of valuable experiences that may have been accumulated from agencies where employees had previously worked. Valuable purchasing experiences may remain mostly unknown in an organization if best practices are not shared across the possible vertical silos in the organization. The findings of previous studies were

used as bases in developing the conceptual model proposed in the current research study. In the empirical survey chapter of this paper is explained *purchasing innovation* construct meaning in the constructed conceptual model.

The literature review showed that several purchasing and supply innovation sources have practices or solutions that integrate suppliers closely to purchasing organizations (e.g., Wynstra et al. 1999; Schiele, 2010). This integration and supplier innovativeness is often enabled by the changes implemented in a purchasing organization (Schiele, 2006). Lorenzoni and Lipparini (1999) reported that buyers may look for innovation potential among suppliers and try to leverage such potential to create value for their own customers. Innovativeness is also part of the design and implementation of sustainable products and service procurement. Nidumolu et al. (2009) claimed that sustainability is the key driver of innovation. Sustainable procurement takes into account the environmental, social, and economic effects of purchases (Australian Government, 2013). In the healthcare sector, for example, the rationalization of packaging has generated innovations that exert positive environmental and economic effects without compromising product performance (Green et al., 1998). Isaksson et al. (2010) argued that supply chains generally present considerable innovation potential for sustainable development. Green et al. (1998) mentioned that a critical type of power in the buyer–supplier context is a firm's ability to innovate and become a source of new ideas for its partners. Miemczyk et al. (2012) described how sustainable purchasing components, such as ethical behaviour, have been incorporated in the measurement of innovativeness in the literature.

According to Inemek and Matthyssens (2013), purchasing assistance from a buyer may enhance supplier innovativeness in the presence of certain buyer and supplier characteristics. Supply risks are relevant to purchasing because the complexity of purchased services and products is often considerable. The increasing complexity of solutions drives buyers and providers to consider approaches that include risk and benefit sharing. The complexity of purchases is equally relevant to supply chain innovation (Harland et al., 2003).

Calantone et al. (2002) demonstrated that innovativeness is related to firm performance, while Petroni and Panciroli (2002) studied innovation as a determinant of supplier performance. Bringing innovations to the purchase process re-engineering and automation innovations involved in supply chain processes may affect the structure and effectiveness of purchasing (Croom, 2001). As described by McGinnis and Vallopra (1999), the development and improvement of production and operations processes substantially contribute to competitive advantage; in these initiatives, purchasing is likely to play a major role.

Other important sources of purchasing innovations are e-commerce and information and communications technology (ICT) applications in supply chains (Croom, 2001; Min and Galle, 1999; Monczka et al., 2010). Incremental innovation focuses only on the reduction of administrative costs by automating manual processes (Croom, 2001), whereas more sophisticated innovation approaches encompass the use of the Internet to seek new suppliers (Croom, 2001) and the use of e-systems to acquire innovation ideas from suppliers (Monczka et al., 2010). Suppliers can serve as important sources of innovation by bringing in new ideas and concepts and considerably reducing the development time of services and products (Min and Galle, 1999).

Early supplier involvement (ESI) and supplier innovativeness in product and service development emphasize collaboration with suppliers in developing or implementing certain innovations

(Wynstra et al., 1999; Schiele, 2010). ESI seeks to develop collaborative processes for the early involvement of suppliers and supplier innovations. The advantages presented by early involvement include the reduction of the time required for product development cycles, improvements to product quality, enhancements to the use of supplier expertise, improvements to cost management, and reduced supply risks (Zsidisin and Smith, 2005). Supplier base management helps purchasers concentrate on supplier organizations that exhibit a strong potential for innovativeness (Schiele, 2006).

Traditional supply-side innovation policies are insufficient to satisfy the challenges posed by promoting competitiveness and therefore give rise to the need to create an innovation-seeking demand and market. Edler and Georghiou (2007) identified several areas where innovation can be applied, namely, the sectors of transport and logistics, e-health, pharmaceuticals, energy, environment, security, and digital content. The recent trend of sustainability in product development should be taken into account when considering the ability of organizations to use market mechanisms in persuading suppliers to innovate or increase the environmental performance (Green et al., 1998).

Recent research conducted by Monczka et al. (2010) addressed the importance of integrating supply management in the innovation strategy and R&D roadmap of an organization. Schiele (2010) stated that technology roadmaps can be used to bridge new product development strategies and sourcing strategies. Such bridging is achievable by including supply network design as a step in roadmap formulation and involving purchasing professionals in the formulation of the design. Monczka et al. (2010) discussed the importance of carrying out a business analysis of the tradeoff between price and innovation and organizing innovation workshops with key suppliers.

Purchasing innovations may also improve the performance outcomes of public organizations more than focusing on price reduction (Edler and Georghiou, 2007). Innovation in the supply chain involves making changes to products, processes, or services to either reduce cost or improve efficiency and thereby increase customer satisfaction (Bekkers et al., 2011). Innovative public purchases may also create new viable private sector solutions to market issues through either the *public procurement of innovation* (PPI) or *pre-commercial procurement* solutions (PCP) (Edquist and Zabala, 2012; Edquist et al., 2015; Bos, 2016). *Purchasing innovations* are also considered as new by the purchasing personnel (Edquist et al., 2000; Rogers 1995).

The findings of the conducted literature review are summarized in Table 1 which contains literature findings that may explain purchasing innovations in organizations. The literature review indicated that purchasing performance is not regarded as a possible source of purchasing innovations. According to the literature, innovativeness has a positive relationship with performance (Calantone et al., 2002; Petroni and Panciroli, 2002). We presumed that the literature would show that well-performing organizations have resources and practices that increase organizational innovativeness. Table 1 also presents the framework that we developed for the categorization of best practices and purchasing innovations. Table 1 includes hypotheses, which potentially drive purchasing innovations. These hypotheses is used in the following phases of this study.

Table 1. Possible sources of purchasing innovations and the framework for the categorization of best practices and purchasing innovations.

Possible source of purchasing innovations
• H1: Supply risk (Monczka et al., 2010; Harland et al., 2003; Zsidisin and Smith, 2005) • H2: Purchase support (Inemek and Matthyssens, 2013; Krause et al., 2000; Dyer and Hatch, 2006) • H3: Supplier sustainable development (Isaksson et al., 2010; Nidumolu et al., 2009; Green et al., 1998) • H4: Supplier base management (Lorenzoni and Lipparini, 1999; Green et al., 1998; Schiele, 2006; Phillips et al., 2006; Monczka et al., 2010) • H5: Customer need fulfillment (Monczka et al., 2010; Edler and Georghiou, 2007; Lorenzoni and Lipparini, 1999) • Purchasing performance

Based on literature review the initial conceptual model for *purchasing innovations* was created. Figure 1 represents the conceptual model. The model is explained more in the following chapter.

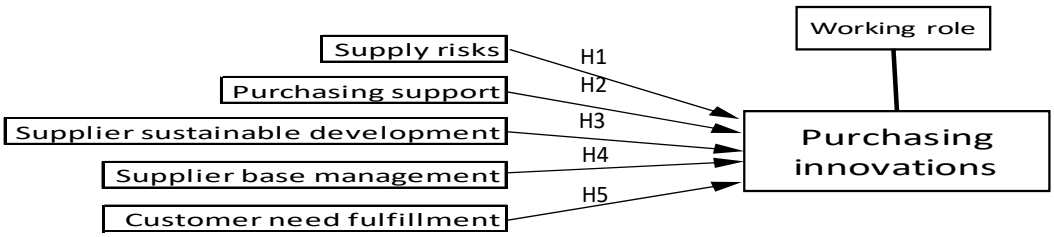

Figure 1. Initial conceptual model for purchasing innovations.

The EU commission and individual countries, including Finland, have plans for government purchasing innovativeness improvement. The Finnish government is aiming that 5% of public sector procurement is innovative. In the same time European countries are making efforts to measure government innovations (Hughes et al., 2011; Arundel and Huber, 2013; Bloch and Bugge, 2013; European Commission, 2011). A challenge for the governments is to measure and quantify performance of purchasing innovations (Kattel et al., 2013). Many countries plan to improve the procurement innovation situation but, in many countries, concrete innovation measurement systems and measurement guidelines do not yet exist (OECD, 2016).

One example about innovation measurement is the Department of State procurement of France (Service des Achats de l'Etat, SAE) which has an innovation indicator in their procurement performance measurement system. This innovation indicator describes a portion of amount of procurement for innovation contracts. Innovation indicator of SAE is reported by the buyer at the time of purchase and no impact or evaluations were done concerning procurement for innovation (OECD, 2016). Currently in Finland the buyer reports in procurement notice that does the used purchasing method consider innovation aspects. It is not self-evident that which criteria buyer uses in evaluation of innovation aspects of his/hers purchase. This paper studies that what are the antecedents of purchasing innovations in the studied organization based on purchasing survey results which was answered by employees in different purchasing roles. These antecedents give information that which topics influences on decision of the buyer when purchasing is considered

as innovative or not. Recently it has been given a proposal about the measurement areas of purchasing innovations, so the antecedents of purchasing innovation topic is contemporary in Finland (Valovirta et al., 2017).

Empirical study

The first phases of the empirical study involved interviews with the employees of the FTA. The empirical interviews were done in order to get confirmation that the literature findings of purchasing innovation sources apply to the studied case organization. Based on the empirical interviews and literature review results, an initial conceptual model for purchasing innovations was created. In the last phase of the study, an organizational survey was administered, and the survey data were analysed against the developed conceptual model.

The motivation for selecting a mixed-method approach to the empirical study included complementary and triangulation purposes in order to accomplish a richer and deeper understanding and a higher validity of the results (Greene et al., 1989). The primary qualitative interviews analyses were supplemented with quantitative data based on the survey data and statistical analysis.

Despite of the ongoing debates of *common method bias* (CMB) (Spector, 2006; Doty and Glick, 1998), the CMB may be a potential problem in the study because empirical interviews and survey results are from a single organization. The empirical survey and interviews results may be influenced by a desire to appear consistent or by a tendency for interviewees/respondents to agree with assumptions (Podsakoff et al., 2003). The CMB problem may be tested with Harman's single-factor test (Harman, 1967). The CMB exists if a single factor will emerge from a factor analysis of all survey items or one general accounting for the common variance existing in the data will emerge. In this research we loaded items into an EFA and examined the unrotated single-factor (Podsakoff et al., 2003). The single-factor explained only 37% (<50%) of the variance in the items. In *principal component analysis* (CFA) tree factors had eigenvalues greater than 1.0. This implies that CMB is not present our research data.

Empirical interviews

The first part of the research study comprised semi-structured empirical interviews. The formulated interview themes revolve around successful purchases, information quality, origin and application with respect to best purchasing practices. A total of 23 people, who are procurers, managers, or staff involved in purchase tasks, were interviewed individually or in groups. The interviewees whose purchases belong to the same category or resemble one another were classified under one group. The interview observations were organized, documented and revised by two authors. During the interviews the organizers noticed that the outputs of group conversations started to resemble previous conversation results. After interviewing 23 persons, the authors decided that additional interviews were not needed it was judged that such would not bring enough new value to the study.

On the basis of the interview results, over 100 items about best purchasing practices, improvement proposals, training proposals, bottlenecks, successful purchasing cases, and other purchasing-related observations in different procurement categories were formulated. In the next phase, affinity diagrams were drawn to find groups that exhibit similarities, as determined from the

documented observation items. The results of a previous interview analysis showed that many of the best practices for purchasing and supply management in the FTA can be classified under the following categories: *purchasing performance*, *supply risks*, *purchase support*, *supplier sustainable development*, *customer needs,* and *supplier base management* (Table 1). This categorization framework may be used for future purchasing development purposes. One of the goals of the interviews was to identify those procurement categories that are the best sources of up-to-date information concerning best purchasing practices. The categorization of the identified purchasing innovation and best practices may reveal, for example, opportunities for joint development between different purchasing categories or organizational entities.

The interviews indicated that a purchasing history database that contains previously implemented best purchasing practices and experiences may improve the FTA's purchasing process. Having a repository of best practices may improve purchase performance and reduce project risks because experiences regarding similar projects are available in the initial phase of the purchase process. Several of the interviewees believe that examples of successful purchases can be instructive to procurers. A given purchase is often characterized by unique project-specific characteristics, but procurers or project managers can use examples as references in applying new practices within a given project context.

The interviews also highlighted the need to consider purchasing risks during the purchasing preparation phase. The benchmarks used by other organizations in the preparation phase may decrease the probability of problem and risk occurrence during purchase implementation.

Innovative solutions are often associated with supplier-side innovations. The interview observations indicated that enabling supply and purchasing innovation necessitates sufficient capability to purchase support resources. The necessary support resource skills may be specific to a project context. The interviewees acknowledged that additional purchasing training programs, such as training on pragmatic contract reviews or professional service procurement processes, may improve quality and shorten the lead times of purchases. Another observation from the results of interviews was that reported purchasing best practices (Table 2) were discussed as purchasing best practices of buyers. However, it is possible that innovative new practices of interviews were originated from the supplier-side.

Table 2. Examples of purchasing best practices and proposals from the interviews.

Best practice category	Example purchasing best practice or proposal from interviews.
Supply risk	- Supply risks should be identified, and risk management activities should be implemented. Risks exist always and purchasing personnel should be able to live with those when appropriate risk management actions have been followed. - Risk management and responsibilities tables should be defined in contract if more complex purchase at hand. - Benchmarking of own agency and other agencies similar purchasing experiences may be valuable in risk mitigation. - Continuous systematic learning from purchases should be applied in order to improve quality and mitigate risks. Purchasing category responsible can share previous purchasing knowledge and experiences e.g. by arranging purchase kick-off meetings for procurers.

Purchase support	- Purchasing support persons of procurement unit collect and share purchasing best practices across the organization. - Purchasing support persons should reserve time for processing of emergent support issues. - Purchasing training needs from different topics like how to purchase professional services easily. - Important to find a person who has implemented similar purchase and have possibility to get sufficient support from him at the right time. - Need for an internal purchasing service which takes care of purchases of certain domain.
Supplier sustainable development	- Projects must plan and implement project hand-overs during a life cycle of the service or the product. Life cycle management can include economical or environmental topics. - Process efficiency improved in projects when onsite processes taken into use. E.g. printing and signing of documents right away after the meeting reduces unnecessary waiting and travelling of people.
Supplier base management	- Important to have supplier network practices in order to hear and collect new value adding proposals from new potential suppliers. - Good communication to suppliers is important. - External organizations have capabilities and knowledge which can provide e.g. innovative financing solutions for tendering. - Good tendering schedule enables to get sufficient number of suppliers to competitions. Healthy competition can increase innovativeness of offers. - Communication and appropriate co-operation with supplier side central organizations can be beneficial.
Customer need fulfillment	- Technical dialogs during purchasing process improves outcome of provider selection process. Customer needs can be described during technical dialogs and providers can propose new solution proposal to purchaser. - Customer requirements and needs should be recognized before start of tendering process. - Psychological tests can be part of supplier selection in order to find motivated persons. - Important to recognise the stakeholders of the project in early phase. Involvement of stakeholders during the project should be guaranteed.
Purchasing performance	- Need for a database containing purchases information: who carried out the last purchase/what good and bad experiences they had and what they learned. Usage of previous purchasing experiences may increase amount of value adding work. - Lessons learned and retrospective meeting at the end of projects may improve learning. Appropriate project documentation may help future projects. - A database of previous purchases can accelerate information searching. - Purchasing experiences are shared via collaboration networks where purchasing personnel shares their knowledge of previously implemented purchases with co-workers.

Many of the interview responses revolve around communication with the stakeholders of a project. An important stakeholder group in both private and public procurement comprises the intended

customers of a project. A customer can be defined and interpreted in different ways, but it normally refers to an entity that receives value from purchase results. In the private sector, the end-customer is often willing to pay for the value received from a service or product. In this study, the construct *customer need fulfillment* was especially highlighted from the perspective of end-customers (Table 3). The interview respondents also stated that improved implementation often translates to the presence and involvement of purchase customers at the beginning of a project, during purchase, and during implementation. Without customer involvement, it is difficult to verify that a supplier solution or delivery has generated the targeted positive value for customers.

Sustainable procurement entails thinking about economic, social, environmental, and ethical aspects over whole-of-life costing, which is also known as life cycle costing or *total cost of ownership* (Australian Government, 2013). The interview results showed that best purchasing practices encompass life cycle thinking. Life cycle observations focus on project improvement practices that concern the minimization of lead time and the reduction of unnecessary work. These are achieved, for example, by quick onsite project meeting practices, such as contract signing. Planned handover periods for information sharing between projects are also encouraged. Previous practices improve professional service results because these avoid, for instance, unnecessary traveling and trial-and-error learning.

Another interesting finding from the interviews is that good and innovative bids require working markets and a sufficient number of capable suppliers. A procurer can make decisions during competition planning, which can affect a number of received bids. One of the observed best practices implemented in the case organization is the year-round scheduling of competitions, which enables more bidders to participate in requests for quotations.

To sum up, the literature review and interviews were aimed at confirming an initial conceptual model for *purchasing innovations*. We found that best purchasing practices of interviews (column 2 of Table 2) can be categorized into similar typologies and categories, as determined from the literature review (Table 1).

Empirical survey

To understand the factors that underlie purchasing innovations, we conducted a web survey in the FTA, from which 115 answers were received. Table 3 shows Likert propositions of the survey and the seven areas targeted by the survey measurement. The survey measurement areas were developed with factor analysis. Table 3 lists the related constructs identified in an exploratory factor analysis (EFA). The *purchasing innovations* construct in Table 3 signifies the enabling of supplier innovativeness either through methods and processes or assistance from suitable contractual agreements and proposal requests.

Table 3. The constructs and their measures in the survey (1-7) Likert scale.

Model constructs measures and their measures	Cronbach alpha	Mean
Purchasing innovations	0.6	
Supplier innovativeness is enabled by the methods and processes utilized in the purchasing category.		3.9
Contractual agreements enable innovative solutions from suppliers		3.8
Request for proposals allow suppliers to offer innovative solutions		3.6

Customer need fulfillment	0.6	
Customer needs are considered in the planning of purchases		5.4
Changing end-customer needs are considered during the contracting period		4.8
End-customer satisfaction for need fulfillment is assured after the purchase		4.6
Supply risks	0.7	
Delivery risks		4.4
Quality risks		4.6
Cost and price risks		4.3
Environmental hazard risks		2.7
Risks related to supplier unethical behaviour		2.5
Legal risks		3.6
Risks associated to supplier financial problems		3.1
Purchasing support	0.6	
Juridical support resources are available for purchases		4.9
Support resources are available for purchases		3.6
Supplier sustainable development	0.6	
Supplier information is collected systematically inside the purchasing category		3.2
Suppliers are developed based on evaluations		3.4
Supplier sustainability is considered in all purchases		5.5
Social and economic sustainability targets are considered for purchases		3.9
Green sustainability targets are considered for purchases		4.3
Supplier base management	0.6	
Knowledge in the purchasing category about the most important suppliers		5.7
The number of suppliers in the category is sufficient for maintaining competition		4.5

In the survey, responders estimated given survey arguments with a 1-7 scale (Table 3). In the supply risk area questions, the highest value 7 meant that the risk of a given argument was considered as high. The value 1 was given to the risk arguments when the risk of argument was low. In the other survey measurement areas, the value 7 meant that a survey argument reflected very well, and the lowest value 1 meant that a given argument reflected very poorly, the reality according to the responder. Each survey respondent categorized himself/herself under one or more *working role* groups, namely, *full-time purchasers*, *part-time purchasers*, *decision makers,* and *other* individuals involved in the purchase process. A *working role* group variable was selected as a control variable for the *purchasing innovations* in the concept model because different purchasing *working role* groups may have a different interpretation of purchasing innovations. *The working role* control variable is shown in the created initial conceptual model for *purchasing innovations* (Figure 1). The distribution of responder types is illustrated in Figure 2. Approximately 300 officers are estimated to serve different purchasing roles in the FTA. This means that the response rate in the survey was 35% for the personnel working with purchases.

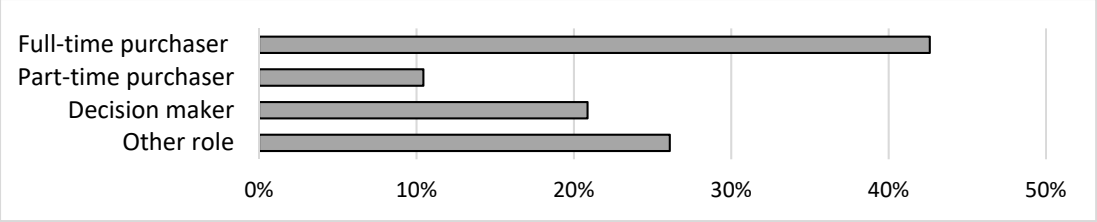

Figure 2. The distribution of responder types.

An exploratory factor analysis of the survey data was conducted to structure and confirm the model constructs. The reliability of the constructs was determined by using Cronbach's alpha values and a correlation analysis was performed on the grouped measures. IBM SPSS (v23) was used in main quantitative analyses. Data imputation methods were not applied because the respondents were required to provide answers in accordance with a Likert scale.

The differences in responses among the purchasing working role groups of respondents were examined using analysis of variance (ANOVA). The possible biases of the respondent groups, outliers, extreme values, and the skewness of responses were also examined using box plots. The responders' *working role* group variable was used as a control variable. Working role types are listed in Figure 2. The ANOVA shows that the only statistically significant difference ($p < 0.05$) between *working role* groups was between *part-time*- and *decision maker*-role types. This difference occurred in the *supply risks* measurement area. The *decision makers*-group evaluated *supply risks* to be more significant than the *part-time purchaser* -group.

The constructs identified in the factor analysis are shown in Table 3. The lowest Cronbach's alpha value was .6 and excluding the constructs with this value from the tested conceptual model was unnecessary. In exploratory factor analysis research, the Cronbach's alpha lower limit may be at the .6 level (Robinson et al., 1991; Hill et al., 2006, 139). To group the measures for the identified constructs, we performed a correlation analysis; the results are shown in Table 4.

Table 4. Correlation analysis results of group measures.

Variables	Purchasing innovations	Customer need fulfillment	Supply risks	Purchasing support	Supplier sustainable development
Customer need fulfillment	0.213* (0.022)				
Supply risks	0.038 (0.686)	-0.012 (0.900)			
Purchasing support	0.375** (0.000)	0.218* (0.019)	0.122 (0.193)		
Supplier sustainable development	0.453** (0.000)	0.337** (0.000)	0.008 (0.930)	0.310** (0.001)	
Supplier base management	0.260** (0.005)	0.277** (0.003)	-0.255** (0.006)	0.248** (0.008)	0.339** (0.000)

a Pearson correlation coefficients, P-values in parentheses.
* Significance at the 0.05 level (2-tailed).
** Significance at the 0.01 level (2-tailed)

The results of the correlation analysis showed that *purchasing support*, *supplier sustainable development, customer needs,* and *supplier base management* exhibited statistically significant correlations with *purchasing innovations* ($p < 0.05$). *Supply risks* (correlation analysis p-value = 0.686) was excluded from the conceptual model (Figure 1) because *supply risks* did not correlate with *purchasing innovations.*

The conceptual model was formed on the basis of the literature review, interview observations, Cronbach's alpha values, and the correlation analysis results. According to the literature,

purchasing performance does not explain purchasing innovations and was therefore excluded from the conceptual model. The model features *purchasing innovations* as the dependent variable and *customer need fulfillment, purchasing support, supplier sustainable development,* and *supplier base management* as the independent variables.

Survey results and findings

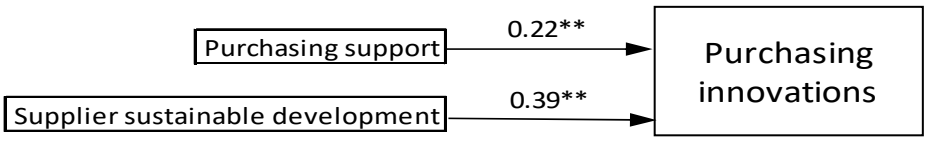
The results of the regression analysis are presented in Table 5. The R square value of the model was 0.272. We tested the multicollinearity of the model using the variance inflation factor (VIF), as shown in Table 5. A VIF value lower than 2 indicates low multicollinearity. Because all the VIF values in this work were below 2, multicollinearity was not an issue in the developed regression model.

Table 5. The results of the regression analysis.

Term	Coef	SE Coef	T-Value	P-Value	VIF
Constant	0.75	0.61	1.22	0.225	
Supplier sustainable development	0.39	0.10	3.74	0.000	1.28
Purchasing support	0.22	0.08	2.80	0.006	1.15
Customer need	0.03	0.11	0.26	0.796	1.18
Supplier base management	0.08	0.09	0.87	0.387	1.19

As illustrated by the regression analysis results, *supplier sustainable development* and *purchasing support* exert a statistically significant effect on *purchasing innovations* ($p < 0.05$). No other factors in the conceptual model demonstrated a statistically significant effect on the dependent variable.

The conceptual model of this research (Figure 1) was developed based on the literature, the empirical interviews, and the factor analysis results of the empirical survey information (Table 1 & 2). This model was further developed with the correlation and regressions analyses of the survey data. The findings of concept model analysis showed that the constructs for *sustainable supplier development* and *purchasing support* exert a statistically significant effect on the *purchasing innovations* in the studied agency. The results of the regression analysis are seen from Table 5 and Figure 3.



** Significance at the 0.01 level (2-tailed)

Figure 3. Conceptual model for purchasing innovations

Conclusion and discussion

This study provides information about possible sources of purchasing innovations in the public sector. The empirical study focused on buyer perspective of a non-profit public transportation agency that procures a broad range of services and materials. One future research topic is to study purchasing innovation and best practices from the supplier perspective in the public sector**.** The conclusion to the research question based on the study findings is that *supplier sustainable*

development (coef .39) and *purchasing support* (coef .22) explain statistically significantly *purchasing innovations* in the studied public sector organization. The *supplier sustainable development* finding aligns with the research of Nidumolu et al. (2009), who stated that sustainability is the key driver of innovation. The finding that *purchasing support* is significantly related to purchasing innovations is the novel contribution of this research.

Interesting result of this research is that *customer need fulfillment* and *supplier base management* did not explain statistically significantly *purchasing innovations* in the created conceptual model (Figure 3). The measures of *purchasing innovations* (Table 3) focused mainly either on enabling supplier innovativeness or on innovative solutions in competition phase. The measures of *customer need fulfillment* were instead related either to planning, delivery or ending phase of the purchase, which may explain why *customer need fulfillment* does not explain *purchasing innovations* in the conceptual model of this study. The measures of *supplier base management* are related to sufficient number of suppliers and to the knowledge of current the most important suppliers. The requests for tenders of the EU public sector are open for all suppliers in the member countries of the EU. One goal of the public sector target is to treat suppliers equally and fairly in tendering also because of the EU procurement legislation. This means also that supplier base management usage in the public sector tendering is limited. In empirical interviews were told that supplier base management related decisions may occur during the competition planning phase because competition planning results can affect to the number of received bids.

The interview results of this study (Table 2) had similarities with the literature findings. According to interviews, technical dialogues with suppliers enabled innovation of suppliers. Supplier innovation potential is discussed e.g. in Lorenzoni and Lipparin (1999) and Min and Galle (1999). Interviewees thought that customer needs and requirements should be recognized before the tendering process. Early customer and supplier collaboration in service and product development had been a source of innovation (Wynstra et al., 1999; Schiele, 2010). Interview observations included supplier development and supplier development base management actions which improved supplier-buyer communication and buyer's chance to have sufficient amount of proposals. Early supplier involvement with the buyer have seen as a source of innovations (Wynstra et al., 1999; Schiele, 2010). In the conducted interviews were not reported practices, which would have helped purchasers to concentrate to a few suppliers that exhibit a strong potential for innovativeness. This practice has been mentioned in the literature (Schiele, 2006). In the EU a public buyer may use e.g. negotiation or restricted procurement procedures, defined by the procurement law. These procurement procedures may help the buyer to concentrate on and have more buyer-offeror dialogues with certain suppliers during the tendering process. Negotiation procedures require often substantially more purchasing support resources than conventional open or restricted tendering procedures. Sufficient purchasing support resources were considered also as a good practice in the interviews and in the several papers (Inemek and Matthyssens, 2013; Krause et al., 2000; Dyer and Hatch, 2006).

The current work corroborates this perspective by providing evidence of the connection between sustainability and innovation in the procurement context of the public sector. From a managerial perspective, sustainable procurement is aimed at evaluating the economic, environmental, and social aspects of purchasing. Unsurprisingly, then, new environment-friendly materials and energy sources that require purchasing solutions may be thought of as falling under innovative procurement that creates additional value. The values and strategies of an organization may, to some extent, explain why sustainable procurement solutions are regarded as value-adding

components by personnel. Responsible procurement may be associated with corporate social responsibility, which revolves around social, economic and environmental effects on society. The effects of responsible actions improve competitiveness, risk management, transparency, and open communication with stakeholders.

Sustainable purchasing takes environmental aspects into consideration. *Supplier sustainable development* explains the *purchasing innovations* in the studied public organization possibly because public organization procurement must take into consideration the environmental and legal restrictions of a project during a purchase life cycle. In the FTA, the possible environmental, social, ethical and lean values held by purchasing personnel may partly explain why a new and improved sustainable solution is considered innovative or not. In public procurement, social sustainability factors are considered also for legislative reasons. For example, a purchaser is required to verify that a tenderer has fulfilled the labour obligations in accordance with the Contractor's Obligations and Liability Act.

In practice, innovativeness and value creation in purchasing can be a challenging task. This study indicated that considering issues related to *supplier sustainable development* and *purchasing support* in innovative purchase planning is beneficial. Similar directives are stipulated in general purchasing policies that mandate adherence to sustainable purchasing principles and the adequate consideration of supplier markets in all the purchases of the studied agency. The results suggest that value-adding *purchasing innovations* are enabled by sufficient and skilled *purchasing support* resources. Sufficient and skilled professional support resources, including juridical, are equally valuable in the different purchase process phases, as determined from the interviews. Without sufficient skilled professionals, public purchasing innovation would likely occur less often and with less positive effects on society. Fortunately, procurement professionalism and know-how have received attention from the Finnish government and the Finnish purchasing sector. In this context, purchasing services are frequently seen as value-adding services.

As with any study, the current research has certain limitations. First, the applicability of the results is restricted given that the study is based exclusively on a large public sector organization. Therefore, generalizability may not extend to other types of public organizations. Second, the results on the identified antecedents of purchasing innovations may be beneficial to an organization similar to the FTA but not necessarily applicable to public sector organizations that differ from the studied agency. Because the sources of *purchasing innovations* may vary from one public sector organization to another, these antecedents require further study.

Summary
This research explores the importance of perceived organisational justice in times of crises, when supplier commitment and strategic orientation have the potential to offset the negative impact of external pressures on business performance. We draw data from a survey of 117 suppliers of a major Greek grocery retailer. The retail sector in Green has been under enormous pressure during the recession. This provides a very interesting setting for exploring the implications for buyer-supplier relationships. Results show that higher levels of perceived justice by the suppliers are associated with higher levels of commitment and long-term business orientation, which in turn, leads to higher performance outcomes. Moreover, the strength of relationships appears to offset the potential (negative) impact of the financial crisis on performance.

Keywords: buyer-supplier relationships, organisational justice, Greek financial crisis, retail supply chains

Introduction

The "Marmite shortage crisis" in the UK, and Volkswagen's dispute in Germany with two of its suppliers in 2016 illustrated the important role of justice in managing buyer–supplier relationships in supply chains. Both incidents showed how fragile buyer-supplier relationships can be and also how seemingly strong, functioning, long-term relationships can quickly become weak and dysfunctional bringing severe disruption. Conflicts and tensions between buyers and suppliers are not uncommon and yet in the literature there is not much empirical research about the role of justice in buyer-supplier relationships particularly in times of economic crisis. Trkman and McCormack (2009) for example, explored the issue of supply risk management for car manufacturers within the context of an economic crisis. Using contingency theory they proposed a framework for the assessment of supplier risk of disruption. Blome and Schoenherr (2011) building on their work investigated how severe developments like the financial crisis affect risk management and they explored both negative and potentially positive impacts on the buying firm. In both cases however the emphasis was on risk management and not on how the buyer-supplier relationships may be affected. The research by Servais and Jensen (2012) investigated the role of buyer-supplier cooperation, conflict and trust in customer satisfaction by using data collected in a period of recession, but without considering organisational justice. More recently, Ellram and Krause (2014), explored how long-term relationships responded to an economic downturn and their results suggested that the balance is delicate; a stressful event, like the recent financial crisis, may reveal surprising relationship vulnerabilities.

In this research we add to this body of literature, providing empirical evidence, by focusing on the relationship between a grocery retailer and its suppliers in times of acute economic crisis. The primary purpose is to empirically investigate how the perception of fairness (or justice), in a buyer-supplier relationship influences suppliers' commitment and their performance. We examine the above in the context of the Greek food retail sector, which has been affected by one of most severe and long lasting financial crisis in Europe due to the unprecedented reduction in household consumption (Eurostat, 2017). This potentially creates an environment where conflicts and disagreements are more likely to happen and escalate.

We anchor our research on the theory of organisational justice in order to explain the relational linkages between buyers and suppliers and we draw data from a survey of 117 suppliers of a major Greek retailer (hereinafter referred to as Retailer-Co). Results show that that higher levels of perceived justice by the suppliers are positively associated with higher levels of commitment and long-term business orientation, which in turn, leads to higher performance outcomes. It is also shows that during the crisis the conflicts and disagreements have increased. The paper proceeds as follows. In the next section we provide a review of the literature focusing on the key elements of organisational justice and the link to performance. The paper then presents the data collection process, followed by the results and discussion where we present both managerial and research implications.

Literature review and conceptual framework

The retail sector during the global financial crisis: the case of Greece

The retail sector was one of the sectors affected the most during the recent global financial crisis, which put an end to 15 years of uninterrupted prosperity (Flatters and Willmott, 2009). This was largely because of consumers restraining themselves from excessive spending (Burt et al. 2010), often through a more price-conscious orientation, buying less expensive brands in order to reduce household expenses and save money (Bowmer, 2011). In a similar vein in Greece, the dramatic depreciation that followed the outbreak of the financial crisis drastically reduced consumer incomes and spending. After a decade of rapid growth (2000-2008), retail trade in Greece contracted by 5 per cent per year in terms of volume during the recession (Mylonas and Tzakou-Lambropoulou, 2016). Food sales dropped by 18 percent since 2009 (13.15 billion euros), in 2016 alone, food sales dropped 4 percent with a further 2-3 percent decrease estimated for 2017 (Nielsen report, 2017). In parallel to the economic crisis, the Greek retail sector also went through a period of consolidation with a number of companies being pushed out of the market (e.g. the number of SME retailers during the period 2008-2013 dropped by circa 30,000 stores) or entering into strategic mergers and acquisitions in order to survive the pressures of the recession (Mylonas and Tzakou-Lambropoulou, 2016, Euromonitor, 2018). Not surprisingly the impact of the crisis in many cases was cascaded down to suppliers. For example, the bankruptcy of Marinopoulos (Greece's largest supermarket chain) left 2,000 suppliers unpaid with 50 percent of Marinopoulos's debts to them been written off. Several suppliers, mainly small businesses, were on the brink of bankruptcy.

Organisational justice and performance

In examining the nature of buyer-supplier relationships, a well-established stream of literature identifies a continuum ranging from discrete to relational behavior (Dwyer et al 1987; Siguaw et al. 2003). However, firms are struggling to develop and sustain collaborative initiatives towards the end of the relational continuum (Spekman and Carraway 2006) as many buyers continue to abuse their position of power and strangle suppliers with short term, cost-driven decisions (Rossetti and Choi 2005), particularly with regards to retailer-supplier relationships (Corsten and Kumar 2005). Ultimately, Giunipero and Eltantawy (2004) warn that this is

detrimental to long term competitiveness given that the full capabilities of a supplier will be undermined. Therefore, effective collaboration requires more than just co-ordination at the operational level of the relationship, but intent on the part of boundary spanners in buyer organizations to build strong relationships, whereby attitudes such as trust and commitment can exist. This positive behavioral intent is critical to developing and sustaining collaborative initiatives, as it encourages partners to dedicate assets on behalf of others in the chain, thus creating economic value (Spekman and Davis 2004).

One important dimension affecting an individual's actions and reactions is how fairly they perceive treatment by the other, often more powerful party. The theory of organizational justice (or fairness) has been used extensively in the intra organizational literature, where the traditional focus has been on the role of fairness in the workplace. The assumption is that employees' perceptions of fairness will impact upon their behavior, and therefore on organsational outcomes and performance (Colquitt 2001; Konovsky 2000; Masterson et al. 2000; Thiabaut and Walker 1975). Employees who perceive they are treated fairly contribute to performance through positive behaviors, such as long term commitment or discretionary behaviors. Likewise, for those employees who feel they are being treated unfairly, resultant damaging retaliatory behaviors will negatively impact upon organizational performance (LePine et al. 2002; Podsakoff et al. 2000). In the context of this study, the theory of organisational justice is applied to inter-organisational relationships. It is proposed that the concept of fairness, or justice, will influence the strength of buyer-supplier relationships and in particular, supplier commitment – in good times as well as bad.

Greenberg (1993) and then Colquit (2001) conceptualised organisational justice in four distinct components: a) distributive justice, b) procedural justice, c) interpersonal justice and d) informational justice. Previous research on organisational justice comes with shortcomings and gaps. For example, Lusch (2000) and Brown and Cobb (2006) focused exclusively on the consequences, but only for limited number of justice dimensions. The implications for firm performance have also not received much attention and very few studies (Griffith et. al, 2006) have examined the impact of fairness on firm performance. The research by Chad and Golicic (2010) with participants from the construction industry also aspired to link the performance with the perception of justice using the social capital theory, however, their model did not consider variables tied to relationship strength such as information sharing and commitment.

In addition to the four components of organisational justice and in line with the study by Hornibrook et al. (2009), we consider commitment as a mediator between perceived organisational justice and performance. In addition, we recognise the importance of strategic alignment and the categorisation of customers (buyers) on the part of suppliers (sellers). In line with the study by Zanquetto and Fearne (2003) we argue that suppliers who perceive a relationship to be of strategic (long term) importance are more likely to allocate resources to support the development of that relationship, will be reciprocated by the buyer, in the way they treat them – distributing the financial benefits fairly (distributive justice), giving them a voice (procedural justice), explaining their decisions (informational justice) and treating them with respect (inter-personal justice).

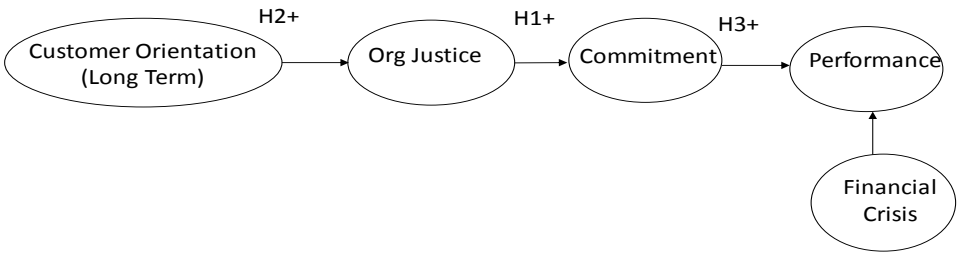
The resulting conceptual framework is illustrated in Figure 1 and the hypotheses we seek to formally test are as follows:

H1: Organisational justice positively influences commitment.

H2: Customer orientation (a supplier's perception of the strategic importance of the relationship) is an antecedent of organisational justice.

H3: Commitment positively influences performance.

Figure 1. Conceptual Framework



Methodology

Data was collected during the summer/autumn of 2016 via a survey of Retailer-Co's suppliers. At the beginning of the research, we established a database of 250 food manufacturers and processors operating in the sector through industry associations. These companies operated in different food sub-sectors (e.g. processed fruits and vegetables, dairy products, fresh and processed salads and dressings, bakeries, snack and confectioneries). Almost all (98.3%) of respondents regarded the supermarket as a key customer. A total of 119 questionnaires were completed, representing a response rate of 47.2%. Out of the 119 questionnaires completed two were excluded from the sample due to missing values and so a total of 117 questionnaires were analysed. The average time to complete the questionnaire was 20 minutes. Questionnaires were sent to through a link to an online survey. There were two rounds of data collection. The participants received the first reminder about three weeks after sending the survey link. The second reminder was sent in about three weeks following the first reminder. The participants were also given the opportunity to receive the results of the survey.

The survey included 25 questions both closed (using 1-5 likert scale) and open ended including questions about the company. The questionnaire consisted of five parts. The first one included questions that referred to the profile of the respondents and of the company. The following section emphasised on information sharing issues (e.g. the level of perceived trust and reliance). The third part aimed at identifying suppliers' perception about their relationship with the buyer their level of commitment. In this section the main aspects of the distributive, procedural and interpersonal justice were being assessed and the constructs were based on previous research (Colquitt, 2001; Griffith and Lusch, 2000). Section four captured the implications of economic crisis and how it influenced the buyer-suppliers relationship. Finally, the sixth section contained questions related to operational and financial performance where we gathered data about the following four key performance indicators: i) The supplier's sales revenues related to last year's sales and compared with the current year's performance of the rest market competitors, ii) the service level related to the proportion of out of stocks situations compared with the previous year's performance and iii) the volume of quality issues that is being observed during the year, iv) the on – time delivery to Retailer-Co's distribution centres. For the development of these questions and the agreement on the relevant key performance indicators we interviewed the director of procurement from Retailer-Co and also the logistics director for one of the main distribution centres.

Organisational performance refers to how well a firm achieves its goals. Past researches have measured organisational performance using primarily financial indicators such as return on investment (ROI), market share, profit margin on sales (Sánchez and Pérez, 2005). This has been particularly the case in the innovation literature where the amount of sales (or sales turnover) generated from innovations has been one of the most common measures of business performance (Griffin, 1997). In this research, in addition to growth related indicators (e.g. market share growth, sales growth, new customers) we consider profitability-based measures

(e.g. profitability, return on sales) but also the manager's perception of the organisation's overall performance.

Findings

Sample description

Table 1 presents the sectors represented in the sample with canned food products having the highest frequency of responding companies, followed sausages and dairy products and non-food products. There were also 5 companies, participants from which responded they did not belong to any of the listed food subsectors.

Table 1 Food sub-sectors represented in the sample

Sector	Frequency	Percentage
Canned food products	53	45.3
Sausages and dairy products	23	19.6
Non-food products	23	19.6
Fresh produce	7	5.9
Fresh meat	6	5.1
Other	5	4.5

Table 2 presents the years the company has been in operation at the time of data collection and the great majority of companies represented in the research are well-established business with more than 10 years in operation.

Table 2 Participant companies' years in operation

Sector	Frequency	Percentage
Less than 5 years	4	3.4
5 to 10 years	8	6.8
10 to 20 years	18	15.4
More than 20 years	87	74.4

The measurement model

Partial Last Square (PLS) path modeling was chosen for the data analysis using the Smart PLS 2.0 software. The internal consistency and the convergent and discriminant validity of the measurement model were assessed by using the PLS approach (see Table 3). It is important to note that the construct 'customer orientantion (long term)' was considered as a dummy variable in the model. Furthermore, organisational justice was considered as a second-order construct taking into account its dimensions (distributive, procedural, informational, inter-personal).

Table 3. Construct-level measurement statistics

Constructs	Cronbach alpha	CR	CustOr	OrgJustice	Commitment	Perf
Cust Orient	1.00	1.00	**1.00**			
OrgJustice	.94	.95	-0.11	**.74**		
Commitment	.88	.91	-0.21	0.60	**.77**	
Performance	.83	.88	-0.21	0.44	0.52	**.77**

Note: Bold numbers on the diagonal show the squared root of AVE; CR = composite reliability

The results showed in Table 3 exceed the recommended threshold values of .70 for Cronbach's alpha, .70 for CR and .50 for AVE (Bagozzi and Yi, 2012). Additionally, the values of square root of AVE were greater than the highest correlation between one construct and the other constructs which suggest discriminant validity (Fornell and Larcker, 1981). In table 4 we present the results of the proposed model.

Table 4. Results of the hypotheses test

Hypothesis and Path	Coefficient (β)	S.D.	t-value	p-value	Status
H1. OrgJustice -> commitment	0.596	0.059	10.060	0.000	Supported
H2. CustOr -> OrgJustice	-0.109	0.097	1.133	0.257	Rejected
H3. Commitment -> perf	0.483	0.074	6.523	0.000	Supported

S.D. = standard deviation

The results of the hypothesized model (see table 4) revealed that organisational justice strongly influences commitment. The coefficient of 0.596 and t-value of 10.06 lead us to accept H1. In addition, higher levels of are strongly associated with higher levels of performance of suppliers. The coefficient of 0.483 and t-value of 6.523 confirm H3. However, results did not support the hypothesis that the strategic categorisation of the relationship as long term would result in higher levels of perceived organisational justice. The non-significant influence of this perspective on organisational justice lead us to reject H2 (β = -0.109; t-value=1.133). Regarding the potential impact of the financial crisis, the results revealed no significant impact on performance, leading us to conclude that the strength of relationships served to 'mediate' the impact of the financial crisis on suppliers performance with this particular retailer.

Discussion/Conclusions

Our results support the findings from previous research regarding the benefits of strong inter-organisational relationships for business performance (Liu et al 2016, Yilmaz et al. 2004). Specifically, they suggest that (even) in times of crisis suppliers who perceive themselves to be fairly treated by their customers will devote additional resources to 'go the extra mile' for the benefit of both partners in the trading relationship. The commitment that comes from being fairly treated pays dividends in 'normal' trading environments by facilitating the sharing of risk, joint decision-taking and the collaborative allocation of resources. However, as previous research has suggested, it is in times of crisis that the citizenship behaviours of committed suppliers are most appreciated and duly rewarded, through reciprocal risk sharing and corrective actions designed to ease the pain.

The theory of organisational justice is an attractive lens through which inter-organisational relationships can be explored. The separation of organisational (distributive and procedural) and personal (informational and inter-personal elements of relationships) is particularly valuable in the context of supermarket supply chains and fast moving consumer goods, where transactions are many and margins are tight and individuals (buyers and account managers) are under significant pressure to deliver results over short time horizons. This pressure can only intensify in times of economic uncertainty and financial austerity. Yet, the results of this study suggest that, with the right strategy, suppliers can withstand these pressures, provided they are treated fairly by their (more powerful) trading partners.

Not withstanding the novel context of this study and the significance of the results reported here, the study is not without its limitations. First of all, the research was restricted to

one retailer and their relationship with a small number of suppliers, which limits to some extent our ability to make broader generalisations to other contexts. In addition, the sample size in this research was relatively small which limited our ability to do further analysis. Further research may include data collection from other suppliers to Retailer-Co, but also from the buyers within the supermarket involved in the study. This will hopefully shed light on the specific initiatives undertaken to counter the effects of the financial crisis without recourse to the use of power and the (unfair) extraction of concessions from their suppliers.

R&D collaboration in the supply chain: involving customers and suppliers in green product development

Abstract

The aim of the paper is to illustrate how collaboration in the supply chain enables green product development. A single case study is conducted at a world leading industrial tool manufacturer. The project under study is the development of a product that is new to the firm, a new application, that involves a world leading automotive manufacturing customer as well as two specialized suppliers. The study points to the importance of managing knowledge sharing with external partners as well as within the focal firm. In addition, relationships with external partners are managed differently depending on their scope of contribution in the product development project.

Keywords: innovation; supplier involvement; cross-functional

Submission category: competitive paper

Introduction

Sustainability is a growing concern around the world for governments, citizens and firms. By addressing sustainability issues, firms find opportunities to both be more competitive and address climate issues more effectively (Porter & Van der Linde, 1995). The rapid use of digitalization in industrial settings has enabled development of products aimed towards more sustainable operations. Technological developments, new regulations as well as increased push from customers and consumers for greener products require firms to develop more sustainable products. In this paper, sustainability refers to environmental sustainability and sustainable innovation is also referred to as green product development.

Green collaboration with external partners are beneficial to firms' performance (Dangelico & Pontrandolfo, 2015). To succeed in developing green products, firms need to collaborate with external organisations, as no firm can have all knowledge in-house. Prajogo et al. (2014) point to the need for collaboration beyond the firm's level, primarily to involve customers and suppliers in green development efforts. In fact, studies point out that collaboration seems to be more important in green developments than in other types of developments (Horbach, 2008; Petruzzelli et al., 2011). There is extensive literature on supplier involvement (Bengtsson et al., 2013; Johnsen, 2009; Melander & Lakemond, 2015) and customer involvement (Eslami & Lakemond, 2016; Laage-Hellman et al., 2014; Öberg, 2010) in product development. However, fewer studies have investigated collaborative green product developments. Collaborations in green product developments are important, as these products are characterized by higher levels of complexity and novelty, requiring a number of knowledge bases to be integrated (Petruzzelli et al., 2011). Studies show that involving suppliers and customers in green developments bring economic benefits to firms (Zhu et al., 2012). In joint developments, supplier and customers contribute with new knowledge. Suppliers tend to be included in collaborative efforts to provide new technology and new material (Foster & Green, 2000; Geffen & Rothenberg, 2000). Similarly, customers provide knowledge about markets, products and services (Dai et al., 2015).

Few studies have included customer and supplier collaborations in the same green product development project while also studying internal organizational issues. In fact, Mazzanti and Zoboli (2009) point out that industrial relations in green developments is highly under

investigated. Hence, there seems to be a shortage of studies combining the study of multiple external and internal considerations in collaborative green product development. The aim of this paper is to illustrate how technological developments through digitalization and collaboration in the supply chain enables green product development. The paper takes a qualitative approach and is based on a case study which illustrates customer and supplier involvement in green product development. Cross-functional collaborations within the focal firm are also investigated.

The paper is structured as follows. First, theory on collaborations in product development are presented, focusing on external and internal collaborations. Thereafter, the methodology is described. The case of DigiQual is presented, followed by the analysis. Finally, conclusions are presented.

Theory

Collaborative product development

In collaborative product development, organisations jointly develop new products. Several studies point to an increased need for firms to involve external actors in product development (Chesbrough, 2003; Gupta & Wilemon, 1990). Inter-organisational collaborations can involve a number of actors, for instance suppliers, universities, customers, competitors or other organisations. Faems et al. (2005) show that the more firms collaborate with different external partners, the more likely they are to create new or improved products that become a market success. Similarly, Becker and Dietz (2004) point out that external collaborations in product development enhance the probability of creating new products.

External collaborators in the supply chain are important sources for product development. Research point to suppliers' importance (Bengtsson et al., 2013; Cuervo-Cazurra & Un, 2010), and the importance of customers (Belderbos et al., 2004; Laage-Hellman et al., 2014). A study comparing collaboration in product development with suppliers, customers, competitors and universities show that collaborations with suppliers have the highest positive impact on product development, followed by university collaborations (Un et al., 2010). The authors also find that customers do not appear to affect product development, while competitors seem to harm the firms' product development. It is shown that collaboration with partners that are similar to the focal firm gives fewer benefits than partners that are diverse since similar firms provide a less diverse pools of information and know-how (Baum et al., 2000). However, it may be more difficult to collaborate with firms that are different than with firms that are similar, since similar firms share knowledge bases and pre-understandings (Melander, 2014). Proximity is a concept that has been identified as important in external collaborations (Knoben & Oerlemans, 2006). These authors suggest three types of proximity dimensions for inter-organisational collaborations: technological proximity, geographical proximity and organisational proximity.

Green product development

Involving external partners in green product development projects provides benefits such as access to knowledge, enabling the development of new products and faster introduction to the market. These collaborations provide opportunities for new designs that are more energy efficient and environmental friendly (Florida, 1996). By collaborating, firms access diverse knowledge resources, which is important in order for firms to improve their green design capabilities (Lenox & Ehrenfeld, 1997). Studies show that accessing knowledge and increasing the firm's knowledge is an important reason for collaborating in green product development (Chadha, 2011; Chen & Hung, 2014; Dangelico et al., 2013; Melander, 2017).

Studies show that collaborative partners in green product developments often are suppliers and customers (Melander, 2017; Prajogo et al., 2014). By collaborating with suppliers, firms can improve their environmental performance (Geffen & Rothenberg, 2000). Supplier often contribute with new technologies and designs that decrease the use of energy and CO_2 emissions. Suppliers also contribute with more environmental friendly material and by providing material with less toxic waste. Collaboration with customers enables firms to increase their knowledge about the market and changes in green products and services (Dai et al., 2015). Firms involve external partners at different times during the development project. However, Lee and Kim (2011) suggest that external collaborators should be included from the concept stage to the prototype stage.

Literature on collaborative green product development reveals some tensions. There are disagreements on the importance of collaborating with external partners. Many studies show to the importance of collaborating with external partners in green product development (Dangelico, 2016; Horbach, 2008; Melander, 2017; Segarra-Ona et al., 2014; Wu, 2013). In fact, a study by De Marchi (2012) point out that collaboration with external partners are more important in green product developments than for regular product developments. In the same line, a study by Petruzzelli et al. (2011) shows that green product developments in fact have higher degrees of collaboration compared to other developments. In contrast, a study by Cuerva et al. (2014) point out that collaboration is not important for green product development. Whether inter-firm collaboration is beneficial or not, firms still need a well-functioning intra-firm collaboration. Therefore, it is not surprising that many scholars claim that firms need not only to manage external relationships, but also internal cross-functional relationships (Chadha, 2011; Walton et al., 1998; Wu, 2013; Zhu & Sarkis, 2006).

Cross-functional collaboration

Internal collaboration within firms between functions are important, as these are identified as mechanisms for both incorporating knowledge from external collaborations as well as initiating new external collaborations (Hillebrand & Biemans, 2003). There are many studies focusing on cross-functional collaboration in product developments (see e.g. Lovelace et al., 2001; Sethi et al., 2001). There are a number of studies identifying important factors for cross-functional collaboration. In collaborative efforts, physical proximity facilitates coordination and interaction between functions (Okhuysen & Bechky, 2009). Similarly, alignment of multiple functions within the firm is important (Storbacka et al., 2011). Internal facilitators that have effect on cross-functional collaboration in NPD are identified as a firm's evaluation criteria, reward structures and management expectations (Song et al., 1997). Goals, rules and procedures and physical proximity impact collaboration in cross-functional teams (Pinto et al., 1993).

McDonough (2000) reviews literature on cross-functional collaboration in new product development and identifies a number of factors influencing team success. These factors are categorized into "stage setters", "enablers" and "team behaviors". Stage setters include project goals, empowerment, human resources and climate. Enablers consist of team leaders, senior management support and champions. Finally, team behaviors include cooperation, commitment, ownership and respect/trust. Teams with greater levels of functional diversity tend to have greater level of disagreements (Lovelace et al., 2001). The authors show that the effect of that disagreement on the team's performance depends on three things: how the disagreement is being communicated, how free the team members are to express doubts and how effective the team leader is perceived to be. Sethi et al. (2001) investigate cross-functional development teams and identify contextual influences and team characteristics that affects innovativeness. Contextual influences include extent of project monitoring, customers' influence and

encouragement to take risk. Team characteristics include social cohesion, superordinate identity and functional diversity. However, the authors find that functional diversity has no effect on innovativeness. Although many studies have been made on cross-functional collaborations and what makes these collaborations successful, there is no clear answer on how firms should act. That is due partly to that internal collaboration between functions in projects is a complex and dynamic process (Calamel et al., 2012).

Methodology

A qualitative case study was conducted as it allows for capturing the phenomenon in a real-life context (Halinen & Törnroos, 2005) and allows for understanding dynamics in a specific setting (Eisenhardt, 1989). A firm called IndTool (fictitious name) was selected as it is a leading global manufacturing firm that is used to collaborate with customers and suppliers in green product development. IndTool has customers with high demand on sustainable development and IndTool's suppliers are leading in new technologies and sustainability efforts. IndTool is a manufacturer of industrial tools. A purposive sampling strategy was used to select a case that was particularly instructive for this research, aimed to understand green product development involving customers and suppliers (Patton, 2002). In addition, the case involves a number of internal functions and organizations at different geographical locations at IndTool. Hence, the case aims to illustrate contributions from customers and suppliers in green product development as well as internal relationships (Siggelkow, 2007). To ensure that rich data could be attained, IndTool participated in the case sampling.

The product under study is a quality product aimed towards automotive manufacturing plants. IndTool develops a number of quality products, but this product, here called DigiQual, has an application that is new to IndTool. Hence, collaborations with customers and suppliers were very important to access knowledge about the new application as well as new technologies. An interview guide was made that incorporated the main topics (external and internal collaboration) while allowing for flexibility and follow-up questions. Semi-structured interviews were conducted with nine knowledgeable individuals at IndTool. The respondent and their organizational belonging is shown in Table 1.

Respondent	Organizational location
Sales manager	US
Sales zone manager	US
Product marketing specialist	US
After sales specialist	US
Product specialist	US
R&D manager	Sweden
R&D project manager	Sweden
Voice of the customer manager	Sweden
Business manager	Italy

Table 1Respondent and their organizational belonging

All interviews were made face-to-face except one interview that was made by phone. The interviews lasted between one to three hours. Two individuals were interviewed multiple times to follow-up the project's progress. In addition, documents were studied. These documents consisted of project reports, internal documents and practices for external collaborations. A case report was written where narratives were presented to include rich and detailed descriptions of the project.

A within case analysis was conducted where data was analyzed, organized, categorized and coded (Eisenhardt, 1989). Data was coded and structured according to time perspective and external involvement as well as cross-functional collaborations to create a story from the occurrences in the project (Miles & Huberman, 1984). By using interview-data, microanalysis was made that took the interviewees' interpretations of the project into consideration (Strauss & Corbin, 1998). Empirical data and theory were systematically compared in an iterative process (Dubois & Gadde, 2002; Eisenhardt, 1989). Key variables from theory was used to categorized data that was displayed in a meta-matrix. A case study database was used to store collected and analyzed data (Yin, 2009).

DigiQual: a green product development

Organizations involved in the development of DigiQual

One of IndTool's most important products is a hand-held tool used in various production lines for manufacturing in for instance the automotive industry. The product under study is an accessory that belongs to a product group closely associated with the hand-held tool. The product is a measurement tool that can be described as having a hardware part and a software part that are integrated. The product, DigiQual, is classified as quality equipment. IndTool is a large global company with clear boundaries for their products, where it is clear within IndTool which organizations that owns which type of products. However, there is some flexibility as well, as it is possible for organizations to do developments for their national market. For example, a specific factory is responsible for a product range globally. But a national entity is allowed to develop a product within that range for their own national market if needed.

For this case story, three different organizational locations have been involved: US, Italy and Sweden. The headquarter is located in Sweden, where the hand-held tool is developed and manufactured. For the hand-held tool, there is a global market team and a global product owner also located here. The global product owner is mainly concerned with the technical aspects of the product, future development, production and quality. The global market team supports local market teams around the world. They contact the different local markets and gather information about the customers' needs. The global market team makes sure that IndTool has the right product offerings and collaborates with the global product owner to ensure that R&D efforts are focused on what the market requests. The factory and R&D team for quality assurance products is located in Italy. They also have a global market team and global product owners for their products. The US organization consists of application center, service, administration and market support. There is a local market team and product support in the US. Within IndTool, US is the biggest customer center. It was IndTool's US organization developed the DigiQual product, which is in the product range belonging to the Italian organization.

External collaboration partners in the development of DigiQual are a customer and two suppliers. The customer is one of the world's largest automotive manufacturers. The customer's manufacturing plant that was involved is located in the US. The customer has close collaboration with IndTool's US organization, with almost daily communication between the two firms. The suppliers are two small specialized suppliers located in the US. One supplier provided hardware, where specifications are quite clear. The other supplier provides software for DigiQual, here the relationship is of a more collaborative nature, where IndTool and the supplier has a strategic partnership. The supplier is leading in the field of wireless handheld communication devices for industrial applications.

The product development

Sales representatives in US visit their customers on a daily basis and have very good contacts within these firms. When visiting the customer in this case, sales representatives identified the potential for the new sale, a measurement instrument. In order to further develop the idea of this product, IndTool started a partnership with the customer. The customer provided input and influenced the development of DigiQual. The customer pushed for a sustainable product and explained the needs from the factory and manufacturing processes. The customer also described what the customer would like to be able to do with the new product and which applications that would be useful, as well as technological limitation in the plant. Together with the customer IndTool developed a set of needs and features for the product. The customer also participated in the test phase of DigiQual.

Previously, most data collection tasks were done manually within the customer's automotive plant. Existing technologies have made it possible for digital data collection, but there was limited use of software for this purpose. Before DigiQual, IndTool did not have a product for this type of data collection in their product portfolio, and thus R&D investments were needed. The main enabling factors for this product was technical development and the transformation in digitalization happening at the customer's factories. The customer wanted to integrate software into handheld hardware to be used in a number of data collection processes. IndTool also knew that the customer wanted flexibility in the product and that its quality operations should be more sustainable. DigiQual is a little hand-held device with software, scanner and Bluetooth connection.

The development of DigiQual within IndTool was not a clear path. Sales representatives presented the idea of a new product, DigiQual, to the US sales group. By developing this product IndTool could provide quality assurance to more areas in the automotive plant. Before, IndTool provided quality measurement tools for torque, but with a new product they could provide quality measurements in other areas of the plant as well. The US sales contacted the global product owner in Sweden to ask them to start a development project for this new product. However, this product was not within the product range for the Swedish factory and R&D. It was another subsidiary in Italy that made the accessories, which has close collaborations with the Swedish organization.

The US organization then contacted the Italian global product owner and asked them to develop the product. There was limited response from the Italian organization. The US organization got some backing from the Swedish organization, but was not able to influence the Italian organization. The Italian R&D was not interested in developing this product, pointing out that they did not have the time for this R&D project as they are busy focusing on their other products. After several attempts to get attention to this new product idea without response, the US organization decided to develop the product themselves.

Since IndTool's US organization had formed a partnership with the customer and had a good idea of what type of product they wanted to develop, they decided to develop the product in the US limited to the US market. By developing it themselves they could to get a product faster to the customers. By involving the customer and two expert suppliers to provide the hardware and software for the product, the US organization managed to develop DigiQual for the local US market.

A local product becoming global

DigiQual was introduced to the US market, first to the customer who participated in the product development, and then to other customers. DigiQual sells well in the US for being new to the

market. It has been a very good development for this type of product. The customer that participated in DigiQual's development wants to buy this product for their factories in other countries. But IndTool only allows for DigiQual to be sold to the US market. However, for the customer, IndTool is a global company who should be able to sell their products globally.

The success of DigiQual and future potential of digital quality product has gotten IndTool's Italian R&D's attention. After DigiQual's introduction to the US market, IndTool's Italian R&D has now started their own R&D project to develop a similar measurement tool for the global market. The Italian R&D is developing software for the new hand-held tool where the US sales provide input from their experience with DigiQual and input from customers. The new product will be more complex than DigiQual and will be able to complement a wider range of products. It is a big undertaking for IndTool, as the product needs to be able to communicate with a number of different applications and software. Once the new product has been developed it will replace DigiQual in the US, and it will be sold globally to automotive manufacturers, as well as to similar industries.

Analysis: collaborative product development

Digital technologies

DigiQual is a new product enabled through digitalization with the aim to have clear sustainability gains for the customer. Through close customer collaboration, IndTool managed to develop a product that was new to the firm, had new applications and provided a number of benefits for the customer. Hence, IndTool created a new product category and thus entered a new market, something which has been pointed out as important for green product developments (Dangelico et al., 2013). DigiQual, the quality assurance product in automotive operations, was able to replace a number of manual data collection tools and operations.

The customer performs a large number of inspections, data collections and documentations in the production processes at the automotive factory. Prior studies have identified technological opportunities as enablers for green product developments (Chavez et al., 2016; Dangelico & Pujari, 2010). Before DigiQual, the customer applied a very limited use of digitalization for quality operations, although the technologies for digital data collection and documentation were available. Instead, pen and paper were used for visual inspection documentations. DigiQual has replaced these manual proceedings and enabled higher quality documentation by providing bar code scanning, camera for taking pictures, Wi-Fi for providing locations and uploading forms and pictures. Previously, data as well as visual defect descriptions were manually loaded to computers for storage. Hence, DigiQual has provided better logging of defect products.

For quality assurance, the customer conducts a number of measurements manually during the manufacturing process. These were previously written on paper and later transferred manually to a computer for uploading in the system. DigiQual can conduct some of these measurements and log these directly to the network. Other measurements can be read by DigiQual and uploaded, or put manually in DigiQual for direct upload to the network. Similarly, inspections are made in vast carparks of newly produced cars. Operators have to locate a specific car and check some specific aspects of that car. Previously, there has been a problem of finding the correct vehicle and operators have cheated the system by simply claiming to have performed an inspection without actually having located the vehicle. By using DigiQual, operators can easily locate the vehicle by tracking it. Photos of the vehicle ensures that the operator has located the correct vehicle as well as ensures that inspections of specific parts have been conducted by uploading photos of these parts. Hence, DigiQual has improved quality and accuracy of inspections. DigiQual has improved quality assurance as well as traceability of

repairs by using barcode scanner, where date, time, repairs, spare parts and operators are logged into the system. Hence, the new product improves productivity, reduces costs and risks, which is in line with what is pointed out as important in previous studies of green product developments (Florida, 1996). Quality assurance uses digitalization to improve quality and reduce manual labor. Similarly, prior studies have pointed to the importance of green product developments to be a valuable investment and economically beneficial (Lee & Kim, 2011; Porter & Van der Linde, 1995; Steward & Conway, 1998).

Collaboration in the supply chain

The customer, one of the world's largest automotive manufacturer located in the US, was very important for the product development and a driver for the development (Guoyou et al., 2013). Previous studies have shown that customers provide valuable input to product development projects (Eslami & Lakemond, 2016; Öberg, 2010; Von Hippel, 1986). The customer allowed IndTool to get access and in-depth knowledge of their operations on the factory floor of assembly. IndTool has a long relationship with the customer, not only in the US, but globally as well. This study points to the importance of existing customer relationships, as IndTool got the idea for the product from meeting with the customer and spending time on the customer's shop floor and discussing sustainability aims. Hence, this is similar to previous studies, which has shown the importance of existing customer relationships in product development (Laage-Hellman et al., 2014).

Customers are very useful in the early phases of the product development (Blazevic & Lievens, 2008; Coviello & Joseph, 2012). In the early phases, the customer was a part of the idea generation for the product as well as providing IndTool with access and detailed insight into the quality assurance processes. The customer also had a list of requirements and desires for features of the new product. During the development project the customer was available for gathering information, specifying requirements and feedback on the product. Studies have shown that customers are important contributors in the end-phase of development projects (Kandemir et al., 2006; Kaulio, 1998). At the end-phase, the customer tested the product and was the first buyer of the product. Hence, the customer was involved throughout the project, and had different roles and contributions at different times in the development project. The customer also pushed for the introduction of the product to their global factories, which provided additional incentives for IndTool to develop a product that was to be available for the global market.

Suppliers have been identified as important collaboration partners in green product development (Hofmann et al., 2012; Sarkis et al., 2011). Two suppliers were involved in the project, one provided hardware and the other software. The relationships with the two suppliers were of a different nature, depending on their delivery into the product. The hardware supplier had clear specifications on what was to be delivered and thus this relationship was of a more distant nature with clear boundaries and design requirements with limited knowledge integration. This relationship can be described as being an arm's-length relationship where the supplier could quite easily be exchanged for a new supplier. The software supplier on the other hand had a relationship with IndTool that was described as a partnership (see e.g. Bonaccorsi & Lipparini, 1994; Ragatz et al., 1997). The development and integration of the software required extensive communication, collaboration and knowledge sharing between the two firms. Also, the customer's requirements and requests during the development provided additional in-put during the project that needed to be transferred to the supplier.

The relationships with the two suppliers were of a different nature, although they both contributed to the development project. The scope and nature of their contribution was an important factor for the choice of relationship (Rosell et al., 2017). The hardware supplier delivered according to quite clear specifications and could more easily be exchanged for another hardware supplier. The software supplier needed to understand the quality assurance processes at the customer in order to develop the software. For the software supplier to be able to provide suitable software, IndTool and the supplier needed close collaboration where the supplier understood IndTool's business as well as IndTool's customer's varying needs in the quality assurance. During the development project, the firms developed trust and increased both of their knowledge bases. The software supplier had a partnership with IndTool and could not easily be exchanged for another supplier without the project losing time and consequently adding cost to the project. However, IndTool was not locked-into the supplier (Handfield et al., 1999), as the software was not proprietary to that specific supplier. Hence, the software development could have been made by another expert supplier.

Internal collaboration

This project has involved a number of internal organizations within IndTool. In line with previous research, this study also points to the importance of internal coordination (Praest Knudsen & Bøtker Mortensen, 2011; Takeishi, 2001). First, the US organization was responsible for the development of DigiQual. In order to make sure that DigiQual was a suitable complement to the firm's main product, the hand-held tool, the US organization collaborated with the Swedish organization that is responsible for that tool. In addition, the Italian organization is running the development of the product that will replace DigiQual and are collaborating with the US organization regarding their experiences with DigiQual. Hence, there was geographically cross border collaborations within IndTool regarding this product. This study shows that geographical, technological and organizational proximity (Knoben & Oerlemans, 2006) influences intra-firm collaborations as well as inter-firm collaborations. There have been some internal struggles, as the US organization wanted the Italian organization to develop a global product, but they showed limited interest in that product from the start. Despite pushing the Italian organization as well as getting support from the Swedish headquarter, the US organization did not get any commitment for their product idea. Hence, they decided to develop the product by themselves for the national market.

The project involved collaborations across organizations and functions. It is shown that coordination within large firms which have specialized departments can be particularly challenging (Clark & Wheelwright, 1992). In this project, sales and marketing have been vital for the development of DigiQual through their good relationship with the customer. Purchasing has had an important role in managing the supplier relationships in this project, similar to studies of supplier involvement in product development (see e.g. Luzzini & Ronchi, 2011; Melander & Lakemond, 2014; Schiele, 2006). These functions have collaborated with R&D in order to develop DigiQual. Knowledge needed to be transferred between the functions, in particularly customer in-put needed to be described not only within IndTool, but also to the suppliers involved. A success factor for this project was the ability to create an understanding for the customer's processes and needs, as well as limitations for applying new technology in the automotive plant. Alignment between functions and across organizations has been challenging, but an important factor in order to succeed in the development of the new global product.

Conclusions

This paper illustrates the importance of customer and supplier involvement in green product development. This study shows that by understanding customers' operations, firms can develop green products using new digital technologies to replace manual operations. The study points to numerous green, operative and economic gains by applying digital solutions in an automotive plant. In addition, this study has pointed to a number of benefits from collaborating with customers in product development projects. The customer provided ideas, requirements and insight in the early phases of the project. During the development, the customer provided the firm with detailed insight into its quality assurance processes and helped deciding the features of the product. During the end-phase the customer provided feedback on the product and was the first buyer of the product (see e.g. Coviello & Joseph, 2012). By having existing relationships and much interaction with the customer, the firm was able to understand the potential of a new product for applications that were new to the firm. Hence, the good existing relationship was an enabler for the development project (Laage-Hellman et al., 2014). Other studies have shown that having a strong relationship with a customer is beneficial in development projects, as it increases efficiency and effectiveness of the development project (Lin & Huang, 2012). Close relationships facilitate knowledge transfer but may limit a broader range of knowledge. However, there are drawbacks to having close customer relationships. Studies point out that close relationships may harm innovativeness (Lin & Huang, 2012). In contrary, this study has shown that the close customer relationship was an enabler for the firm to enter a new product category and a new market. Other drawbacks found in the literature shows that collaborative development including customers that require a high level of interaction results in delays of the development process (Fang, 2008). However, no evidence of delays due to the customer was found in this study.

This study demonstrates two different approaches to involving suppliers in product development. One the one hand, a distant relationship, with the format of a traditional arm's length relationship with limited knowledge exchange, was created where the interface and design of the supplier's contribution was clear from the start. On the other hand, a close partnership with knowledge exchange during the project was developed with the supplier where the content of its contribution to the product could not be specified from the start. This is similar to much of recent literature on supplier involvement in product development (see e.g. Bengtsson et al., 2013; Johnsen, 2009). The supplier's contribution required the firms to build a shared understanding of the customer's processes and needs, which were transferred into the product.

This study confirms previous findings that cross-functional collaborations are important when involving external organizations in product development (Chadha, 2011; Takeishi, 2001). As this project involved both customer and suppliers, both sales and purchasing were important functions that needed to collaborate and share knowledge. As suggested by Curwen et al. (2013), it was important to have a clear goal and organizational capabilities. Functions within the firm that usually did not collaborate, namely sales and purchasing, had extensive communication and shared knowledge. As suggested by Wong (2013) the firm needed to develop knowledge management practices. Research often point to the importance of sharing knowledge with external partners (Rosell et al., 2017), but in this project, sharing knowledge within the firm was also important. For the future development, the firm shared knowledge it had gained from the development of DigiQual in the US to the Italian team that is developing the global quality assurance product. To access the customer's knowledge, sales was an enabling function, and very important for gathering information about what had been successful with DigiQual and which features that need further developments. Previous research has pointed out the green supply chain management focuses on external relationships in procurement, production, distribution, reverse logistics and packaging, as well as innovation in

these processes (Sarkis, 2003). This study adds to that stream of research by demonstrating how a firm involves both customers and suppliers for the development of sustainable quality assurance products.

This study has some limitations. Interviews have been made with the focal firm, individuals at the customer and the suppliers have not been interviewed due to limited access to these firms. A single case cannot be generalized. However, the aim of this study is not to provide statistical representativeness but to provide a rich description and understanding of a specific phenomenon. Future research could investigate how firms integrate and share knowledge with additional actors in the supply chain when developing sustainable solutions.

Let and forget: a dilemmas perspective on contract governance in healthcare procurement

Abstract
There is a lack of contract management in healthcare procurement, despite pressure to cut costs and drive value. Through an in-depth case study, we reframe the 'problem' of the paucity of contract management as a decision dilemma to unpick the causes by exploring underlying attitudes of procurement. Resources focus on cost improvement plans; the role contract management plays in ensuring value is delivered is not recognised. A lack of consequence for not managing contracts dilutes the pressure to take responsibility. Attitudes become entrenched and the dilemma of where to focus resources loses its power to induce 'stop and think' behaviours.

Keywords: Healthcare, decision dilemmas, contract management

Introduction

Healthcare procurement covers purchasing of care (commissioning of healthcare providers) and purchasing for care covering the procurement of clinical and non-clinical goods and services (van Raaij, Schotanus and van der Valk, 2013). This research concerns the latter, purchasing for care. Procurement third-party spend in England on the National Health Service (NHS) totals over £27bn per annum, with goods and services (excluding pharmaceuticals, agency staff, estates and facilities management) accounting for £9bn per annum (Carter, 2016). The NHS is facing severe financial strain and the constraints are amplified as the demand for services have increased significantly over the past decade. To illustrate, latest figures show that in 2015/6, 46% more operations were conducted compared to 2005/6 (10.1 million up from 7.2 million), and hospital admissions rose by 28% to 16.3 million (NHS Digital, 2017). A government-commissioned report into the NHS in England cites a number of procurement problems that collectively cost an estimated £700million per annum; lack of value extracted from contracts, price variations, hidden costs, inefficiencies, poor compliance, lack of cost containment and poor inventory control (Carter, 2016). In this context, creating and extracting value through procurement becomes increasingly necessary (Meehan, Menzies and Michaelides, 2017).

The positive relationship between procurement and organisational performance is well documented (Sánchez-Rodríguez, Hemsworth and Martínez-Lorente, 2005, Schiele and McCue, 2006) and the potential for mainstream value contribution is clear (Cousins, Lawson and Squire, 2006, Ellram and Liu, 2002). Despite its strategic relevance as a policy tool,

public procurement is often not aligned to policy initiatives limiting its ability to drive broader societal value (Rolfstam, 2015). Procurement maturity demands a functionally integrated and coordinated activity that contributes to value and firm-level competitive advantage (Foerstl, Hartmann, Wynstra and Moser, 2013), covering structures, relationships, processes and systems (Van Weele, 2010). In the PSM field, gaps still exist in our knowledge of the role and importance of internal relationships, supplier development and corporate performance (Zimmermann and Foerstl, 2014). Contract management is a core activity linking value capture with internal and external relationships. Although not empirically validated, it has been suggested that contract management is classified in the Purchasing and Supply Management (PSM) literature as operational and functional, rather than strategic and organisational in nature (Matopoulos, Bell and Aktas, 2016).

Contracts are legal agreements that detail the work or transaction to be completed and the terms applicable, ranging from standard boilerplate clauses to highly customised, complex terms and outcomes (Schepker, Oh, Martynov and Poppo, 2014). Contract management is a continuous process that systematically ensures the delivery of agreed outcomes, KPIs, service levels, and contract compliance. Procurement, suppliers and other stakeholders work collaboratively through the contract life to ensure appropriate execution of deliverables and to analyse opportunities to improve and drive further value for all parties, increasing the potential for learning. The majority of extant studies focus on contract design and pre-purchase rather than contract delivery (Nullmeier, Wynstra and van Raaij, 2016). The pre-purchase stage of contract negotiation covers the operational terms of the agreement and can set out each party's value outcomes, relationship expectations, strategic intent, and organisational contributions. Many contracts, particularly those with key suppliers, or in high value/risk spend areas, can be complex and cover long timeframes. Value needs to be considered throughout the life of a contract (Pinnington, Meehan and Scanlon, 2016) as contract outcomes and expectations can change over time and in dynamic, complex environments. The importance of effective, value-focused contract management is often assumed, in practice and in the academic literature, yet in the UK's NHS the procurement teams lack engagement and influence over this part of the procurement cycle and contracts once let are often not actively managed by procurement (Meehan et al., 2017). This paper aims to explore why this is.

Contract management can eliminate some problems of opportunism in contracting (Brown and Potoski, 2003), and is important for effective governance (van der Valk, Sumo, Dul and Schroeder, 2016). Governance lacks a common definition, but in essence it relates to the agreed norms, rules and behaviour used to manage and guide how performance is sustained and how parties are held accountable for their actions. Two core concepts - steering and shared responsibilities – are implicit in governance. In considering contract management as an issue of governance, the lack of NHS procurement involvement raises important risks, as this can side-line the influencing of commercial issues of value, create gaps in accountability, and fail to create shared buy-in for broader issues involving consequences of economic power, market development, innovation, and network learning.

Literature review

Contract management

Contracts in business-to-business markets vary enormously. The academic literature around contracts is equally varied, although transaction cost economics (TCE) (Williamson, 1996) is the dominant conceptual framework adopted in many empirical studies (Schepker et al., 2014). TCE is useful as it provides parameters to manage ex-ante incentives in contracting

arrangements – dealing with forecasts and the potential for contracts to deliver particular outcomes, and ex-post governance – providing flexibility to manage performance based on actual metrics (Williamson, 1996). Although there are resource costs associated with contract management, these can be small in comparison to the savings achieved through effective supplier motivation (Turner and Simister, 2001). Effective management can counter issues of incomplete contracting (Brown and Potoski, 2003), which most contracts are, as many risks are unforeseen and rationality at the contract formation stage is bounded (Turner, 2004).

Empirical studies of contract management in the PSM literature are grounded in TCE as its constructs are deemed to 'explain' contracts (Schepker et al., 2014, Spina, Caniato, Luzzini and Ronchi, 2016). However, prior studies tend to largely focus on the mechanisms for contracting at the start of the process, rather than the on-going performance management of suppliers against the contractual agreements. Implicit in this view is a rational, economic view of markets and contracts that assume a 'good contract' will deliver agreed outcomes, a position that can mask behavioural or other factors involved in contract success. Moving to value outcomes is a major challenge in healthcare business-to-business relationships (Porter, 2010). The extant contract literature largely focuses on the assumption that the most efficient choices are made upfront and remain static, in contrast to value-based procurement, which is contextualised, temporal and multifaceted (Meehan et al., 2017). Approaches rooted in narrow cost and control ideologies can limit the potential for adopting longer term value based procurement strategies in healthcare (Meehan et al., 2017). Additional dimensions of contract management are needed (Schepker et al., 2014) to understand not just the outcomes within a contractual agreement, but to unpick and consider the longer term consequences of inter-organisational exchanges on other stakeholders from an ethical perspective (Piercy and Lane, 2007).

Governance and dilemmas

The potential for public procurement contracts to be used as a policy tool to achieve societal outcomes (Grandia and Meehan, 2017) and to add wider value to its environment (Telgen, Harland and Knight, 2007) is a common policy theme across Europe, USA, China and Brazil (Lember, Kattel and Kalvet, 2015). While compliance to effective legal regimes can promote accountability and value, contracts need to be effectively managed as the mere presence of a legal or regulatory framework does not guarantee success (Ibrahim, Bawole, Obuobisa-Darko, Abubakar and Kumasey, 2017). Market governance alone is not sufficient to drive changes in suppliers' commitments (Jiang, 2009).

The suggestion in the public procurement literature is that contracts should go beyond operational performance measurement to engage the supply chain in delivering broader policy outcomes over time. In this role, procurement requires maturity and strategic influence to balance supplier developments, internal relationships, and policy drivers. A buying organisation's involvement in contract management can co-determine supplier's performance as they become involved in service design and can reduce operational barriers (Nullmeier et al., 2016). Contractual governance is a term gaining attention in the inter-organisational literature (Benton and Maloni, 2005, Cao and Lumineau, 2015, Schepker et al., 2014, van der Valk et al., 2016), where attention is focused on the interplay of contractual and relational governance. Although these studies centre on governance, the studies are still often rooted in rational decision-making models, and can lack consideration of the complexities of competing demands, heterogeneous drivers and interests, political pressures, and power structures.

In etymological terms, governance refers to steering and guiding, not just control. At its most

abstract, conceptual level, governance is concerned with the delicate balance between the state and civil society (Stoker, 1998). In the broader governance literature complexity is taken as a core condition of the environment, particularly related to public sector governance (Schillemans and van Twist, 2016), and the need to reconcile diverse values is recognised (Chen, 2009). A number of ethical dilemmas emerge in the conceptualisation of governance (Stoker, 1998). Even at a basic, operational level, the question of which contracts should be managed raises dilemmas for procurement. The resource implications of managing all contracts actively (Brown and Potoski, 2003) could prevent this approach, particularly if many contracts are only transactional in nature, and resources are severely constrained, as in the NHS. A strategic account management strategy, whereby only key suppliers are managed is common in practice yet also raises ethical issues. Key NHS suppliers are defined in the latest Government-commissioned review (Carter, 2016) by levels of contract spend rather than a supplier's quality, criticality, innovation or value initiatives (Meehan et al., 2017), providing no incentive for suppliers to work collaboratively to reduce spend on contracts. Further, this approach favours the already powerful few, and if contract management improves a supplier's competitiveness, then it reduces the ability of smaller spend suppliers, typically SMEs, to compete and survive, distorting markets and power in the longer term (Piercy and Lane, 2007).

Tensions emerging when dealing with contract management are not discussed in the PSM literature. For instance, if suppliers, or other stakeholders are found not to be performing against agreed metrics or against the spirit of the contract, or if contract aggregation is considered to be leading to inequities in the supply chain, what should procurement do? Escalation and resolution procedures for operational issues might be contained within the contract documentation. What is less clear is who carries ownership, responsibility and accountability, and who leads this process, particularly in complex cases and for longer-term unintended consequences. Multiple, competing expectations of performance create conflicting legitimacies and dilemmas (Klingner, Nalbandian and Romzek, 2002). Public organisations have been shown to view contracting as a method to reduce responsibilities through passing accountability to suppliers (Brown and Potoski, 2003). Relationships can become increasingly charged in risk shifting activities (Benjamin, Nisim and Segev, 2015), exposing deeper dilemmas and debates on the responsibilities, political role, and ethical implications of contract governance steering by public procurement that goes beyond the provision of efficient and effective goods and services (Steinfeld, McCue and Prier, 2017).

To explore the lack of contract management in the NHS's purchasing for care (van Raaij et al., 2013), we utilise the concept of decision dilemmas (Bowen, 1987). Dilemmas relate to people's experience of having to make a choice between mutually exclusive alternatives, where each option creates emotional and personal concerns and challenges that are difficult to reconcile (Ozkaramanli, Desmet and E Özcan, 2016). Decision dilemma theories look at how people make decisions when the results and feedback on performance of actions are unclear. The difficult decisions people must make are usually not about isolated choices but the series of decisions that have consequences to an entire course of action (Staw, 1981). Emotional duality exists in dilemmas when the set of choices available each contain potential benefits and losses.

A diverse range of early psychology theories seeks to explain decision 'errors'. In the management literature, escalation of commitment (Drummond, 2014, Staw, 1976, Staw, 1981) has been a prominent development in the dilemmas research stream and describes how decision-makers' fail to disengage from a failing course of action, effectively throwing good

money after bad. Decision theories are useful but often do not capture the central nature of why the dilemma is created. This research builds on prior studies that identify a lack of contract management in NHS procurement (Meehan et al., 2017). In this research, we are interested in understanding the nature of dilemma in NHS procurement to address why there is a very low level of contract management, despite the significant pressure to find efficiencies and manage costs. Reframing the 'problem' of the lack of contract management as a decision dilemma enables our research to unpick the causes of the issue through exploring the underlying behaviours and attitudes. Our research questions, bounded by the empirical context of the NHS Trust examined, are:

RQ1: What are the resource priorities for NHS procurement?
RQ2: Do NHS procurement professionals see a broad potential of contract management?
RQ3: What are the levels of procurement maturity to manage contracts in an NHS Trust?

Methods

This research was conducted using a rich case study with one NHS Trust, in order to develop a deeper understanding of procurement professionals' attitudes towards contract management. In the UK, an NHS Trust is an independent legal entity that manages hospitals and operates under unique governance arrangements (NHS Choices, 2017). Attitudes are impacted by a multitude of factors such as culture, governance structure, internal and external perceptions of procurement, procurement maturity and leadership, which vary from Trust to Trust. A case study is valuable to explore context, dynamics and emerging issues in PSM (Dubois and Salmi, 2016). The case was selected in conjunction with a procurement development organisation. This particular Trust is excelling in many other aspects of procurement maturity but, crucially, contract management activities remain lacking.

Methods employed included both open interviews and observations. Previous research has attributed the paucity of contract management in the NHS to a lack of resources (Meehan et al., 2017), so the procurement team were observed to identify how their time is used and what activities are prioritised. The 'real-world' problem related to the lack of contract management was the starting point for the research, which drove the choice of a case method, and the various appropriate conceptual domains were iteratively explored as the research findings and analysis progressed (Brinberg and McGrath, 1985). Semi-structured and open interviews were conducted with senior procurement professionals from the team.

Participants selected had been at the Trust for 2years+ to enable comment on changing priorities and the culture, and all had roles sufficient to have an understanding of the strategic role of procurement. The researchers also spoke to internal end users including clinicians and non-clinical (e.g. IT) service managers to ascertain their role in ensuring suppliers were meeting contractual obligations. Observation notes were collected throughout and the semi-structured interviews were recorded and transcribed verbatim.

The data were coded and analysed thematically (see Table 1). Two of the researchers coded the data to achieve greater analytical richness (Eisenhardt, 1989). Coding was compared and discussed until consensus was reached, in order to improve the rigor of the analysis (Pemer and Skjølsvik, 2016). From the results, conflicts and accountability emerged as core issues experienced by NHS procurement staff. A serendipitous grounded approach explored conceptual explanations using dilemma theories and a governance lens to explain the lack of contract management. This approach was critical in our learning of the implications of the

original research problem, from academic and practitioner perspectives (Dubois and Salmi, 2016).

Findings and discussion

The results of our initial thematic analysis (see Table 1) centres on the current position of contract management and attitudes towards it from key stakeholders in the NHS trust. Our discussion centres on the three research questions to evaluate contract management in relation to concepts of decision dilemmas and governance to offer a new, rich insight in the complexity of contract management in the healthcare context.

Table 1: Stakeholders' views of contract management

Topic	Theme	Representative Data Examples
Procurement Activities	Cost improvements	*"Generally, I'd say maybe...70- 80% of time is cost improvement plan projects."* *"It's sort of time issues and when mainly our focus at the moment is CIP [Cost Improvement Plans], savings for the trust, it is difficult to dedicate so much time to contract manage all of the contracts awarded."* *"We do contract manage where we can but a lot of our time at the moment is cost improvement."* *"We are coming to the point, where there isn't much we haven't looked at, to be fair [under CIP]. We have pretty much looked at everything now. So it's difficult to come up with, now, projects that, erm, that is sort of viable and realistic."*
	Compliance	*"We are the experts to advise the people out there to say yes, we have a requirement, we've got to do x,y,z, to make a legally compliant procurement"* *"My personal experience is that compliance doesn't always go hand in hand with cost improvement because we can get much [emphasis] better savings going direct to our supplier."*
	Pre-award contract management	*"When I said light focus on contract management, that is, after we have initiated the contract. In the beginning side of the contract, procurement... we will do as much as we can to smooth the contract management process"* *"We try to manage as much as we can. We cover the information on that by anticipating some problems on the future.... It is about the contract management conflicts we can erase in most of the cases"*
	Post-award contract management	*"We don't contract manage the small value contracts. Large value ones, we will have regular contract management meetings with the provider".* *"In terms of contract management whenever we can do... delivered the project, it seems to be put to bed then because we don't have the time to go back and monitor it but I think more and more now [emphasis] we have to go back and monitor it because half of that delivery is ensuring that's realistic.*
Attitudes towards contract management	Aspiration	*"I think contract management is something that we have been trying to introduce on a more formal basis."* *"I'd say it's something that we are very aware that we need to do."* *"I think it's the aspiration. It's what we'd love to do, you know, we'd love to be able to properly manage all of the contracts that we have in the department."*
	Discomfort at lack of contract management	*"We have to think about the contract management side of things when we start the process. Some might...some might not..erm..and once we have the contract in place, then we only get limited time.... to manage a contract..."* *"Contract managing is really key to what we should [emphasis] be doing but again its just having that time because we are so under pressure at times where the amount of projects we've got to deliver because procurement is seen as a ...support function"*

	Time consuming	*"One of our buyers does contract manage those contracts that he awarded. He probably has quarterly meetings. There have been some performance issues so he has had to have a couple more meetings which has taken up a lot of his time, and a lot of work has come from that."* *"It is difficult to dedicate so much time to contract manage all of the contracts awarded. It really is something that we'd need a lot more time and resources to do really."*
Purchasing Triad	End users	*"We ask others to evaluate the quality. The experts; the end users, the clinicians, doctors....so they will evaluate, but we will carry them, contact them to say how we have to do it. So, they will do that and we will support and guide and mentor them to do it."* *"The clinicians are so busy, they wouldn't be able to spend enough time, to clearly track the requirement that is a problem in itself."* *"The ownership will sit with the end user in conjunction with procurement. They usually do the day to day management of the contract because we are not there on the shop floor, they will do the contract monitoring. We will come in when there is a problem, when there is confusion...a friction."* *"Our approach now is focussed upon the end users, making regular meetings with them as well, and that's key."*
	Poor supplier performance	*"We realised that the supplier had bitten off more than they could chew. Supply then started to really take a nose dive."* *"The supplier did not inform us that they could provide these pumps anymore. So, we had to very quickly put in another plan to ensure that we got them in from another supplier."*
	Distrust of suppliers	*"Our reps policy throughout the Trust, that a supplier isn't allowed to approach any clinician or anybody really in the trust without first coming through procurement".* *"Other trusts may have done tenders and got better prices. There's a whole host of reasons why but at least we have visibility on that now. So pricing now is transparent throughout the NHS... So suppliers are having to be a lot more transparent now in their prices. Which is great. For us."* *"These suppliers have been milking us for years when the pound has been really strong, and now they are saying it's got to this, and they are now saying we've got to put prices up. So it's hard really to have sympathy."*

Contract Management Activities

The most common barrier to contract management cited in the interviews was a perceived lack of resources to deal with the contracts and manage the ongoing actions arising. Participants predominantly defined resources in terms of capacity and staffing levels, rather than expertise and skills. Only limited contract management activities take place and are reserved for large contracts, typically valued in the £millions. For these contracts multidisciplinary teams comprising of procurement, finance, end users, and suppliers meet quarterly to discuss progress against contractual targets yet there was little evidence of a steering governance role to deliver wider value initiatives or health policy outcomes. Contract meetings are chaired by procurement, placing them firmly at the centre of the contract management activity, and providing potential opportunity for linking internal relationships management, supplier development, and organisational performance (Zimmermann and Foerstl, 2014).

An issue identified in the case is that the significant majority of contracts fall below the spend value that would warrant contract management. One participant clarified that despite

managing “hundreds” of contracts, they attended “no more than five” contract management meetings a month. The strategic management of contracts based purely on spend has been linked to ethical dilemmas (Piercy and Lane, 2007), particularly if the consequence of inequitable management leads to favouring the already powerful in a market. Although the contract management activity witnessed in this NHS Trust involved a range of different stakeholders, the focus tended towards operational KPI compliance and monitoring, rather than active steering towards longer-term value-based improvements to health outcomes, commercial agreements, or to analyse the consequences of contract arrangements on markets.

RQ1: What are the resource priorities in NHS procurement?

The analysis revealed the dominant priority for NHS procurement is to support end users to achieve their Cost Improvement Plans (CIP), set by finance, whilst also ensuring regulatory process compliance at the sourcing stage. Procurement performance is measured on its ability to support departments to meet CIP targets. Contract management is not perceived as a core activity in achieving this. Participants viewed resources in terms of limited capacity and low staffing levels rather than a broader consideration of resources (skills, capabilities, IT etc), and staff resources are focused on pre-award contract activities such as establishing key performance indicators, delivery schedules, etc. For contracts not actively managed, procurement pass the management responsibilities on to the end users, which is perhaps understandable given the clinical nature of some products, although this does not apply to all spend categories. There is a presumption made by procurement that the end users as “experts” will monitor whether the contract terms are being met, although critically this is not followed up by procurement, or even checked to see if these activities are completed. Given the high risk of some of the clinical products end users confirmed that they did actively assess product quality (if not necessarily contract performance), although for non-clinical areas the end users taking responsibility for this could not be identified.

There is an acknowledgement, at least by some procurement staff, of the resource pressures on end users that suggests expecting them to manage contracts, which sits outside of their official roles and responsibilities, is unrealistic. The lack of clear governance structures both inter-organisationally within contracts, and intra-organisationally across the contract management activity creates gaps of accountability. An interesting finding is how procurement positioned, and defended their lack of contract management. Their rationale is rooted in the belief that they sufficiently state the goals of the contract in early stages, which negates the need for procurement to be involved in post-award contract management activities. Procurement also refers to end-users as the experts to further shift responsibility and justify their own lack of contract management.

A clear and consistent message from the findings is that for procurement teams the activities related to securing cost reduction at the contract agreement stage are the priority. However, it was acknowledged frequently that the opportunities for savings are dwindling making CIP goals more difficult to achieve, suggesting a growing need for procurement to think more creatively. Procurement perceives freeing resource for contract management conflicts with their sourcing/contract negotiation priorities. Procurement do not recognise the full potential of contract management to reduce costs, certainly when compared to the potential cost reduction opportunities in contract negotiation. In terms of decision dilemmas, we trace the resultant lack of contract management to these conflicting priorities, as this is where the initial resource dilemma is rooted.

At the heart of the dilemma we find two conflicting paths. Procurement can: 1) use their

limited resource to drive for ex-ante CIP savings at the contract negotiation stage, set against 2) use their limited resource to work with suppliers in the longer term through contract management to deliver value potential and identify further improvement areas. This dilemma supports previous studies that confirm the resource implications of contract management (Brown and Potoski, 2003), but our findings importantly highlight the difficulties that people face in resolving this issue. The restricted resource in the NHS (NHS Digital, 2017) prevents them from merely increasing capacity to attend to both activities, heightening the dilemma.

The personal dilemma emerges because CIP savings are only recorded when contracts are agreed and there is no provision for recording additional value beyond the current annual accounting period. From a behavioural perspective, dilemmas often require a prioritisation between conflicting long term considerations and immediate concerns (Hoffman, Baumeister, Förster and Vohs, 2012). Evidence suggests that people weigh present events more heavily than those in the future (Frederick, Loewenstein and O'Donoghue, 2002). Social forces experienced in the environment shape and constrain decision dilemmas. Given the heavily pressurised NHS environment focused on saving money (Carter, 2016, Meehan et al., 2017), peoples' decision to prioritise sourcing in the short term at the expense of providing resource to manage contracts is perhaps understandable. However, this 'let and forget' approach is not compatible with value-based procurement, that moves from efficiency solely based on price, to broader, long term value measures based patient health outcomes achieved per pound spent (Porter and Teisberg, 2006). Short termism can have consequences that damage longer-term value-based approaches (Lindgreen and Wynstra, 2005), potentially further exacerbating the dilemma.

RQ2: Do NHS procurement professionals see a broad potential of contract management?
Our findings support the view suggested in the literature that contract management is predominantly viewed as operational rather than strategic (Matopoulos et al., 2016). Contract management and the broader relational concept of contract governance (Benton and Maloni, 2005, Cao and Lumineau, 2015, Schepker et al., 2014, van der Valk et al., 2016), however have strategic potential for assessing suppliers' performance and contract compliance, capturing agreed value, and identifying additional value sources. Our results show that there is a general recognition that contract management is recognised as important, but the language used by participants reveals that it is seen as a longer-term rather than an immediate priority.

The dilemma stemming from how to best utilise limited resource is indicative of conflicting legitimacies of competing expectations (Klingner et al., 2002). Decision dilemmas create mutually exclusive alternatives with challenges and choices that are difficult to reconcile, which are the hallmarks of a dilemma (Ozkaramanli et al., 2016). The emotional duality of a dilemma was evidenced in the apparent unease amongst participants when discussing the paucity of contract management in the NHS, manifested through broken sentences, unfinished justifications and hesitant responses. The majority of participants acknowledged that contract management is something they "should" be doing, however current resources and time pressures mean it is not possible to manage more than a few contracts each often in a cursory way. Participants were noticeably evasive around their choices, and the dilemmas experienced were palpable. The language used to describe the number of contract management meetings a month ["no more than five"] suggests that this activity is viewed as something to be minimised.

Interestingly, some contradictory rationales for not engaging with contract management emerged from the interviews. Some buyers failed to identify its potential and considered it to

be purely as a time-consuming drain on resources. Managing contracts creates more work as, once they are being managed, problems surface which then need dealing with. The consequences that impact a course of action, rather than the need to make standalone choices, increase the decision dilemma (Staw, 1981). Where contract management had taken place, poor supplier performance had been identified that had led to a significantly increased workload for the procurement team thus creating a reticence to engage in this activity in the future for fear of exaggerating resource pressures. This clearly misses the point and creates a vicious cycle of avoidance rather than problem elimination.

Participants did not seem to equate contract management with new value creation, nor with the ex-post value capture of agreed outputs. This is despite examples where contract management had uncovered poor supplier performance that increased operational costs and highlighted that pre-agreed value contributions were not being realised, which could then be addressed. Significant here, is that under the current procurement and finance regime only financial savings are recorded, and only at the point of contract award. This lack of life cycle consideration effectively reduced the motivation to manage contracts at all.

RQ3: What are the levels of procurement maturity to manage contracts in an NHS Trust?
When purchasing for care (van Raaij et al., 2013), there is a triad of stakeholders made up of procurement, end users (e.g. clinicians) and suppliers. The introduction of CIP targets imposed on Trust departments has led to an improvement in relationships between procurement and end users, as the interdependence between them has rebalanced. Procurement recognises the importance of good internal relationships and has invested time into strengthening links with end users and elevating its reputation as a support function. Although all stakeholders saw better relationships as a positive progression, procurement were still very much seen as supporting, rather than leading, even on areas of commercial importance. Where there are pockets of contract management on the major spend areas, procurement take a central role, although the sphere of influence tends to be delineated to the contractual boundaries, rather than a broader approach to drive policy initiatives or consider, and respond to, wider market consequences.

Internal relationships are seen as improving and healthy in the Trust, although relationships with suppliers were still problematic in many areas. Evidence of the poor relationship between procurement and suppliers is the frequency with which NHS suppliers circumvent procurement and go straight to end users to sell products or demonstrate innovations, despite policies to protect against this. Given the importance attached to gatekeeping relationships, it is interesting that no reporting to monitor these policy breaches take place, which in itself sends signals to suppliers of the lack of consequence.

There is a high level of distrust of suppliers evident in the data. It is therefore surprising that contract management is not given more of a priority when allocating resources. Contract management can be viewed as a control mechanism between buyers and suppliers, which is arguably a necessity in relationships with little trust (van der Valk et al., 2016). Participants refer to examples where suppliers have performed poorly against contracts but without contract management processes, it is difficult to establish how extensive this is, and even harder to enforce solutions. By focusing resources on pre-award contract management activities, procurement are identifying the ex-ante risks in contracts but then passing the accountability on to the supplier. This assumes suppliers will comply, despite evidence to the contrary. The examples provided of supplier non-performance against agreed contract criteria further add to the emotional element of the dilemma for procurement as it provides

contradictory evidence to their position that a good contract is sufficient. Our observations highlighted that rather than engage with, reflect on and discus the consequences and options that the dilemma created, all behaviours we would see in robust governance, procurement instead disengaged with the issue and amplified their defence of lack of contract management.

Despite the pressure to move to value-based procurement in the NHS (Meehan et al., 2017), participants stated that even if procurement were provided with additional resources, there is currently a lack of government-approved, quantifiable measures that could be used to measure supplier performance throughout the contract period. For example, if a supplier's product reduces length of stay or number of visits to a hospital, how much does this save the NHS? Without these measures, procurement are unable to quantify the long term value of choosing supplier x over supplier y. Participants used this rationale to challenge that contract management is less strategically important for ensuring value is realised as beyond quantitative delivery metrics, value within a contract is not calibrated. The dominant view was that 'demonstrating' value through contract management is not recognised, and not within their remit.

Conclusions and managerial implications

Our findings support previous studies that contract management was not a priority for NHS procurement (Meehan et al., 2017), despite the drive for long term savings (Carter, 2016). Cost reduction in NHS procurement is their top-down, highly visible and much-pressured target. Crucially however, there is limited, if any, evidence of actual cost reduction from contract negotiations in terms of budget changes and overall spend profile. Rather, an anticipated financial saving is recorded at this stage, regardless of the length of the contract, and it is deemed to have been achieved, despite no monitoring of spend against the contract.

We introduce a novel approach of decision dilemma theory to contract management to expose some central assumptions around procurement maturity. Procurement maturity as presented in the literature centres on the level of internal integration and contribution to organisational value or competitive advantage (Foerstl et al., 2013). Procurement in this case has good integration through CIP activities although their ability to create and capture value is limited, thereby adding to the dilemma. There is evidence that they can, and do, engage in contract management in large contracts, and take a central role in some of these. Maturity here, we argue is not necessarily only about their ability to 'do' contract management, it is around the ability to deal with the consequences of contract management. Operationally, the consequences could mean resolving complex and litigious issues of non-compliance and securing value capture. Strategically it might refer more to governance issues around market impacts, power inequities, health outcomes, and influencing social, health and economic policies. Maturity in this sense demands the resolution of resource-based decision dilemmas and appropriate governance across and within stakeholder relationships to provide accountability around the choices made.

Through this study we identify limited resource as an important dimension in decision dilemma theories. This is important contribution and extension to dilemma theories and it has a broader resonance for procurement maturity research and public procurement policy environments. Resource limitations and pressures create mutually exclusive alternatives with challenges and choices that are difficult to reconcile, which are hallmarks of a dilemma (Ozkaramanli et al., 2016). Without resource constraints, procurement could employ additional staff to increase contract management capacity. However, without this option, as is the case in many public organisations, the dilemma is heightened and ethical dualities

exposed.

From a governance perspective, complexity and the need to grapple with and reconcile diverse values (Chen, 2009) is taken as a core condition of the environment (Schillemans and van Twist, 2016). Contracts, particularly in economically and socially important industries like healthcare, are enormously consequential, beyond the bounded goods and services purchased. Healthcare procurement, particularly on the scale of the NHS, impacts markets, power dynamics, health outcomes, taxes, opportunity costs, and innovation. Public organisations in particular therefore have ethical obligations to ensure public contracts are effectively governed so that value agreed is captured, deliverables are actioned, and that the spirit of the contract is mutually beneficial, equitable and responsible. Governance in public procurement should however go beyond the operational boundaries of the contract and should consider the potential, the risks, the challenges, and the dilemmas of steering to deliver wider societal and health outcomes. The point here is not that this more strategic governance approach will provide the 'answers' to the dilemmas identified, in many instances it will create increasingly complex dilemmas and knock-on effects. The issue is that governance actively engages this critical debates about what organisations 'ought' to do, whether diverse values can be reconciled (Chen, 2009), and openly confronts complexity as a core condition (Schillemans and van Twist, 2016). Opening potentially difficult stakeholder dialogues and exploring dilemmas of short and long term decisions can provide valuable space for considered decision-making and provide accountability for actions (Meehan, Touboulic and Walker, 2016). Failure to actively acknowledge the dilemmas, or provide support to consider the choices and consequences risks a reliance on shifting accountability and risk back through the supply chain (Brown and Potoski, 2003), that further damage supply relationships and behaviours (Benjamin et al., 2015)

A final contribution of this research is exposing how procurement deal with the conflicting legitimacies of short and long term actions in a resource constrained environment. A critical conclusion from our research is counter-intuitive. Although dilemmas create cognitive dissonance and emotional tension for procurement staff, we argue that rather than eliminating dilemmas, we should encourage more dilemmas, with the caveat that these are supported by robust inter-organisational, and intra-organisational governance arrangements. Our premise is based on the potential for dilemmas to force reflection on the consequences of our actions and decisions. Time considerations feature heavily in decision dilemmas as the temporally based choices polarise acting against thinking. In a dilemma people are faced between acting now versus reflecting on future impacts of current behaviours. Dilemmas can behave as a 'slowing down' mechanism and can often force people to stop and think about their choices as they try to reconcile these polarities. Studies from psychology show that people look at their past experience to deal with dilemmas (Vera, Crossan, Rerup and Werner, 2014). An issue here for NHS procurement, is that a lack of experience in contract management coupled with the outward lack of consequence of not doing these activities dilutes the pressure for taking longer-term contract management responsibility. Over time, patterns of behaviour – in this case neglecting contract management and the associated long-term impacts - become entrenched and the dilemma loses its power to induce stop and think behaviours. Without the dilemma behaviours, procurement inevitably focuses on short-term gains reinforcing, normalising and legitimising actions, and further concealing longer-term losses. As procurement conceptually decouples their actions from consequences, it is unlikely that we will see a movement away from their let and forget approach to post-award contract management.

Abstract
One of the most difficult challenges facing companies today is how to control and implement sustainability not only with direct first-tier suppliers but also how to extend or diffuse sustainability across entire supply networks. A growing body of research is dedicated to this challenge but the role of purchasing in sustainable supply network development remains under-researched. This paper provides a systematic literature review of the role of purchasing in the diffusion of sustainability in supply networks. We identified and analyzed 55 papers published in 11 peer-reviewed journals in the field of purchasing and supply management (PSM). Based on the review, the paper classifies strategies and practices for diffusing sustainability in supply networks, identifying the role of purchasing in the diffusion of sustainability in supply networks.

Keywords: Supply networks, sustainability, purchasing, diffusion

Introduction:
A growing amount of research on sustainability concerns purchasing and supply chain management, such as ethical sourcing (Preuss, 2009; Roberts, 2003), corporate social responsibility in the supply chain (Faisal, 2010; Maloni and Brown, 2006), socially responsible buying (Maignan et al., 2002; Park and Stoel, 2005) and green supply chains (Kainuma and Tawara, 2006; Mollenkopf et al., 2010). While significant progress has been made in these areas, it is important to make further advances and consolidate systemic issues that exist at the interface of sustainability, purchasing and supply (Linton et al., 2007; Miemczyk et al., 2012).

There is consensus in research that companies cannot tackle sustainability on their own as they rely extensively on their supply networks for the development, production and delivery of goods and services to customers (Andersen and Skjoett-Larsen, 2009; Krause et al., 2009). Addressing sustainability risk and implementing sustainability initiatives require network-wide changes involving coordinated action by actors across supply networks (Meqdadi et al., 2017). Companies are reportedly using different approaches - or strategies - in this endavour including, for example, supplier monitoring and development. However, the role of purchasing in this process remains an under-researched concept, despite being described as a key competence in the diffusion of sustainability in supply networks. In this

paper we report on a systematic literature review to develop a framework of possible strategies and specific practices within these for diffusing sustainability in supply networks (i.e. audits, surveying suppliers, requiring suppliers to comply with standards, supplier collaboration etc.) and to explicate the role of purchasing in these strategies and practices.

In this paper we seek to identify the state of the art of current research on diffusing sustainability in supply networks and on the particular challenges this poses for the field of purchasing and supply management (PSM). Therefore, the specific objectives of the paper: 1) to identify and classify strategies and practices for the diffusion of sustainability in supply networks and to explore the role of purchasing in this process, 2) to identify research gaps and needs for further development.

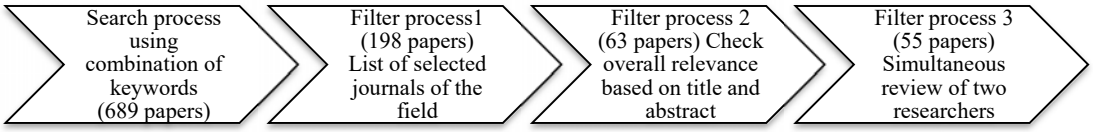
Methodology:

We have adopted a structured approach to the literature search and analysis. Following Tranfield et al. (2003), the key steps in a systematic review include the planning phase, the actually undertaking of the review, and reporting and dissemination. The aim of this method is to identify the current state of academic research and its key scientific contributions with regard to a defined research question. The review adopts a replicable, transparent and scientific process and follows certain steps that need to be clearly defined and described (e.g. Tranfield et al. 2003). This literature review systematically analyzes existing literature, examining publications on sustainable supply chains published in English, peer-reviewed journals, listed in the Scopus database. The literature review has been conducted in business, management and accounting journals. The keywords that were used for searching in article title, abstract and keywords fields were categorized into four groups:

- supply chain/supply network;
- sustainable/environment/social/CSR/responsible/green;
- extend/diffuse/spread/integrate;
- procurement/sourcing/purchasing.

Different combinations of these four groups of keywords have been used to search for literature published in the past 25 years; this first stage resulted in 690 papers. We then selected relevant research papers from a list of 32 journals generated on the basis of three major reviews of the field: general reviews of purchasing and supply management (Zsidisin et al., 2007; Spina et al., 2013) and sustainable PSM (Miemczyk et al., 2012); this filtering process reduced the list to 198 papers that were published in 20 journals. The titles of the papers within this initial sample together with the abstracts were then checked manually. Those papers with a title and abstract that was beyond the scope of this review were removed; papers that, were purely technical, as well as those concerning the consumer/marketing end of the supply chain, and did not cover social, environmental and sustainable issues were excluded. This reduced the list to 63 potentially relevant papers. Two researchers simultaneously reviewed these papers and ended up with 55 relevant papers (Figure 1) from 11 influential journals (Table 1) of the field that form the basis of our systematic literature review.

Figure 1 Systematic literature review process



The following table shows the journals in which we identified relevant research papers and

the number of relevant papers in every journal:

Table 1 Journals and number of papers identified for the final inclusion stage

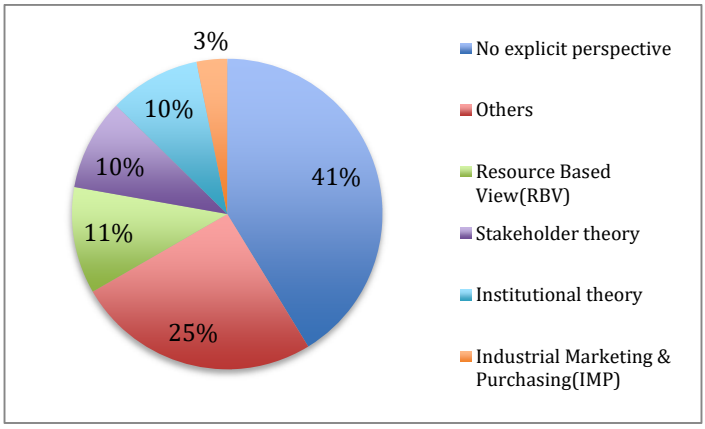
• *Journal of Cleaner Production*	14
• *Journal of Business Ethics*	9
• *Supply Chain Management: An International Journal*	8
• *Journal of Purchasing & Supply Management*	8
• *International Journal of Production Economics*	5
• *Journal of Operations Management*	3
• *Journal of Supply Chain Management*	3
• *International Journal of Operation & Production Management*	2
• *Industrial Marketing Management*	1
• *International Journal of Production Research*	1
• *Decision Sciences*	1

Data analysis and coding:
We built an Excel database that reflects the research framework and contains data regarding all 55 papers. This step was the starting point in conducting the analysis presented in the next section. Two researchers simultaneously and independently processed and coded majority of the papers, followed by regular meetings of three researchers to evaluate and finalize the codes. We commenced the analysis of the papers by examining theoretical background, dimensions of sustainability, methodology and level of analysis. Following this step, we analyzed and classified strategies and practices with a particular focus on the role of PSM.

Findings:
In the following section, we provide a general overview of the results of the analysis as a basis for understanding the research approaches that have been applied in the field.

Theoretical background
As a starting point, we analyzed the use of theoretical perspectives applied in extant research. As Figure 2 shows, 41% of articles are not grounded in any theories. The Resource-Based View (RBV) followed by an equal portion of papers based on Stakeholder Theory and Institutional Theory, are the most adopted theoretical perspectives, followed by Industrial Marketing and Purchasing (IMP) theory. For example, Arnold (2017) looks at how companies combine co-creation and relationship management approaches with respect to sustainability through a stakeholder perspective. Using RBV theory, Liu *et al*. (2016) seek to explain associations between supply chain capabilities and key elements of environmental management strategies. Based on institutional theory, Hoejmose *et al*. (2014) argue that the decision to implement green purchasing and supply chain practices and the choice between them is contingent upon institutional pressures (mimetic, normative and coercive). Adopting an IMP interaction approach, Meqdadi *et al*. (2017) seek to understand sustainability spread (or diffusion) as a change process that affects different supply network actors and the impact of power and trust on the spreading process. Other theories, such as transaction cost economics (TCE), resource dependence theory (RDT), are categorized here as 'others' as relatively few studies have applied these.

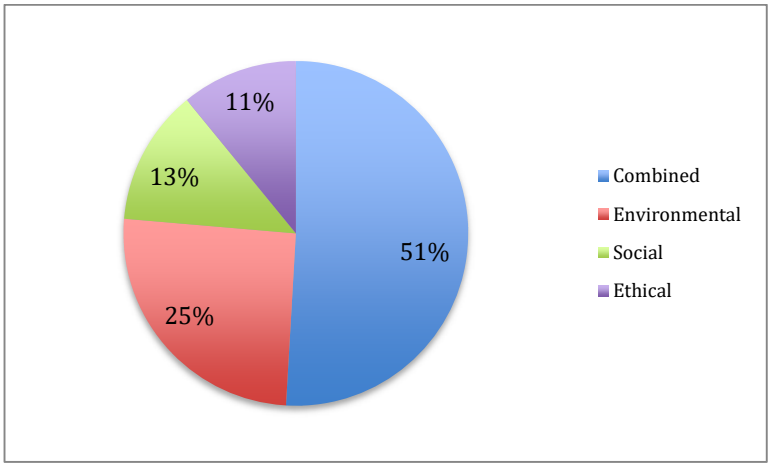
Figure 2 Proportion of papers based on theoretical background



Dimensions of sustainability

Sustainable PSM has been defined as " […] the consideration of environmental, social, ethical and economic issues in the management of the organization's external resources in such a way that the supply of all goods, services, capabilities and knowledge that are necessary for running, maintaining and managing the organization's primary and support activities provide value not only to the organization but also to society and the economy" (Miemczyk et al., 2012, 489). Thus, sustainable PSM takes in the three dimensions of environmental, social and economic sustainability but also separates out the ethical dimension. Often, research focuses purely on one or two of these dimensions: as Figure 3 reveals research with a focus on a combination of environmental and social aspects dominates the content of papers under study (43%), with the remaining papers focusing on environmental aspects only followed by ethical issues and social aspects only.

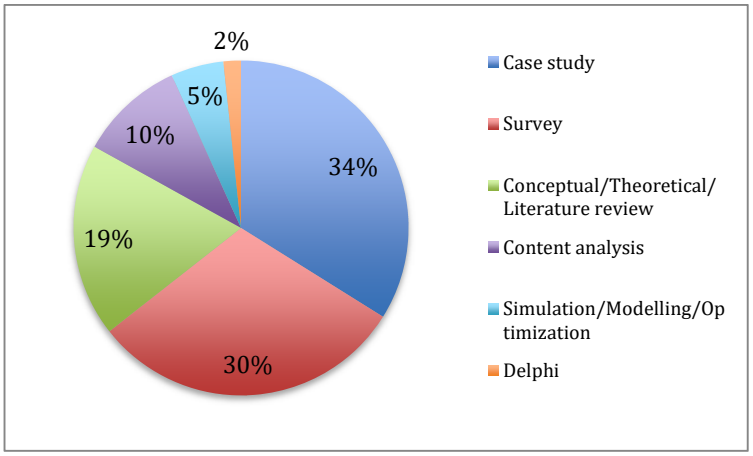
Figure 3 Proportion of papers across the different dimensions of sustainability



Research method and level of analysis

Figure 4 shows that the three most frequent methods are case studies (with 34% of papers), followed by surveys (30%) and conceptual studies including systematic literature reviews (19%). As identified by Spina *et al.* (2013), these three methods consistently proved to be the most popular in PSM literature. In terms of content analysis the contents under study were mostly published reports (CSR/sustainability reports) of the firms.

Figure 4 Proportion of papers based on the method of research

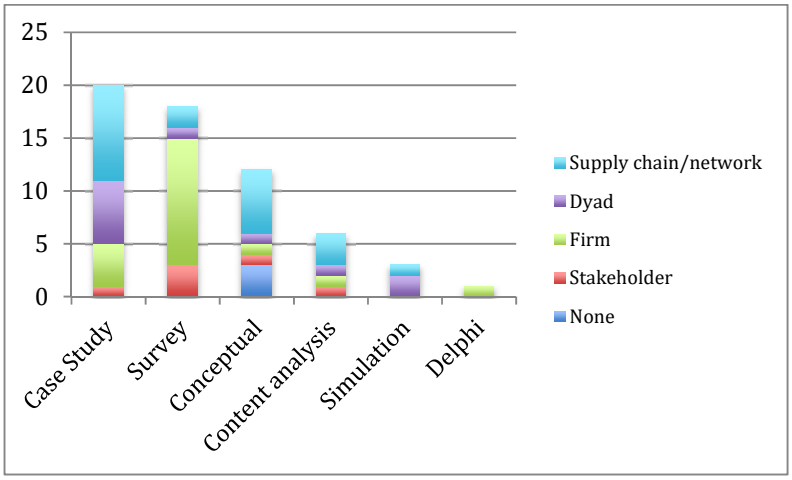


Furthermore, we analyze how studies have used different methods to examine different levels of analysis methods. We have identified four levels of analysis: firm level which concerns internal functions of the firm; dyad level which concerns internal functions of the focal firm and processes in interaction with immediate (first tier) suppliers; supply chain/network level of analysis which are processes beyond dyadic level also extending to multi-level involvement; stakeholder level of analysis which not only includes multiple levels of the supply chain/network, but also extends to other stakeholders (e.g. NGOs and public authorities). This analysis is important because diffusion of sustainability within supply networks can be done at different levels but different methods may be more or less able to fully uncover issues involved in this process. Analyzing methodological approaches, we are therefore able to get a clearer picture of which methods are used to research different levels of analysis. Figure 5 shows the relations between levels of analysis and applied methodologies, the proportions shown in the figure are based on each paper's claimed scope.

It is clear from the literature review that studies examining sustainability at the network level are rare. In reality, few studies adopt this wider view, and the terms "network" and "supply chain" are often used synonymously (Miemczyk et al., 2012). In defining the level of analysis we have therefore considered these two concepts together. The analysis shows that case studies are the most widely used method for supply chain/network level of analysis. The three in-depth case studies by Wilhelm *et al.* (2016) is one example of how case studies are used to reveal rich insights into supply chain sustainability, highlighting the importance of multi-tier supply chain involvement for achieving sustainability compliance along the supply chain.

Investigations and analyses of interdependencies among different actors are not typically included in dyadic or multi-tier focused analyses of sustainable PSM issues. This may explain the relative sparsity of survey-based studies that focus on supply chain/network issues with the exceptions of a few studies at the supply chain/network and dyadic level, which were based on survey methodology (Carter, 2000; Pérez and Gómez, 2015).

Figure 5 Different levels of analysis and applied methodologies



Overview of strategies and practices used in diffusion of sustainability in supply networks

The starting point for our framework development was working on purchasing strategies and practices (see Table 1). The structure of the table was inspired by Akhavan and Beckmann (2017) paper, which distinguishes between overall strategies and specific practices within these. Our framework provides a more comprehensive list of sustainable supply network strategies divided into six categories: (1) internal integration and governance; (2) sourcing (3) supplier monitoring (4) supplier development (5) stakeholder management (6) joint projects and co-creation. Based on our systematic review we are able to identify and categorize specific practices that have been investigated in the research that has considered PSM issues in sustainable supply network research.

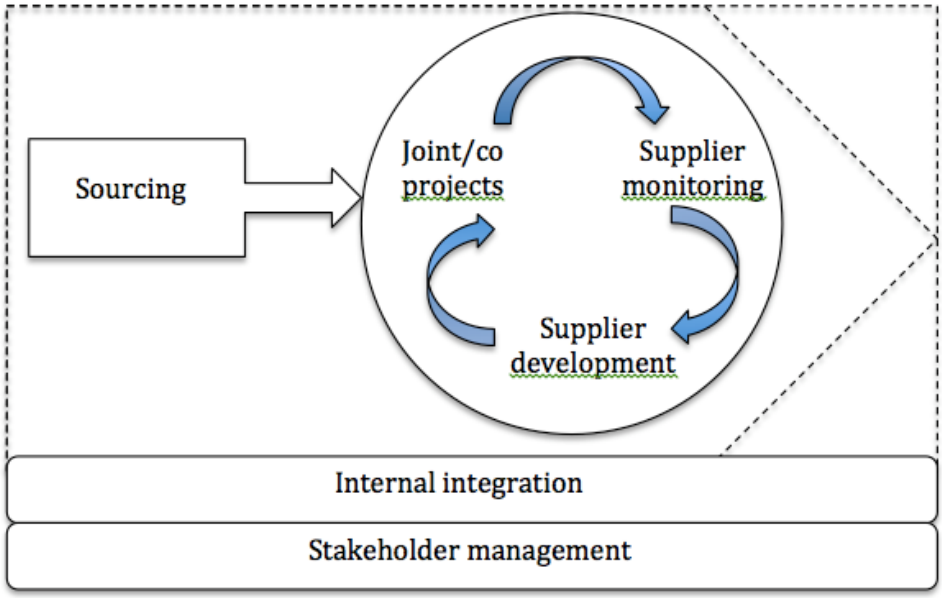
Table 1 Strategies and practices for the diffusion of sustainability in supply network

Internal integration and governance	• Internal training (Fritz et al., 2017; Teixeira et al., 2016; Bala et al., 2008) • Top management commitment (Akhavan and Beckmann, 2017; Knight et al., 2017; Griffis et al., 2014) • Employees ethical orientation (Griffis et al., 2014) • Defining, aligning and integration of sustainability goals (Liu et al., 2016; Akhavan and Beckmann, 2017; Knight et al., 2017; Large et al., 2013; Morali and Searc, 2013) • Data exchange (Fritz et al., 2017) • Assessment and application of green knowledge (Teixeira et al., 2016) • Permanent improvement of working conditions/enhancement of qualified employment (Large et al., 2013)
Sourcing	• Identification of the supplier requirements (Koplin et al., 2007) • Responsible buying strategy (Akhavan and Beckmann, 2017) • Sustainable sourcing strategies (Akhavan and Beckmann, 2017; Knight et al., 2017) • Responsible supplier selection (Thornton et al., 2013; Griffis et al., 2014) • Guidelines/codes of conduct/certifications/ standards/ ethical sourcing code (Teixeira et al., 2016; Van Bommel, 2011; Wilhelm et al., 2016; Morali and Searc, 2013; Preuss, 2009)

Supplier monitoring	• Supplier performance measurement (Sharma et al., 2017; Morali and Searcy, 2013) • Supplier audits (Wilhelm et al., 2016; Beske et al., 2014; Akhavan and Beckmann, 2017; Reuter et al., 2010) • Use of questionnaires and follow-up (Reuter et al., 2010) • Reporting (Morali and Searcy, 2013) • Supplier risk management (Van Bommel, 2011; Koplin et al., 2007; Schaltegger and Burritt, 2014; Beske et al., 2014; Cousins et al., 2004) • The role of power & trust in monitoring (Meqdadi et al., 2017)
Supplier development	• Supplier training (Akhavan and Beckmann, 2017; Hoejmose et al., 2014; Handfield et al., 1997) • Collaboration (Sharma et al., 2017; Fritz et al., 2017; Teixeira et al., 2016; Bala et al., 2008; Crespin-Mazet and Dontenwill, 2012; Morali and Searcy, 2013) • Incentives & rewards – Sanctions/filtering (Koplin et al., 2007; Akhavan and Beckmann, 2017) • The role of power & trust in development (Meqdadi et al., 2017)
External stakeholder management/interaction	• Relationship management/ stakeholder management (Arnold, 2017; Beske et al., 2014) • Co-creation (Arnold, 2017) • Governance/ policies (Morali and Searcy, 2013) • Collaboration with NGOs/non-business actors (Akhavan and Beckmann, 2017; Crespin-Mazet and Dontenwill, 2012)
Joint development projects	• Product design/green packaging/ eco design/ green design (Stindt, 2017; Teixeira et al., 2016; Liu et al., 2016) • Recycling/ down-cycling/ closed loop supply chains/ reverse logistics (Schaltegger and Burritt, 2014; Halldórsson and Svanberg, 2013) • Co-creation (Arnold, 2017)

In addition to the classification of strategies and practices shown in Table 1, we structure these into a process framework inspired by Johnsen *et al.* (2014) that depicts the processes involved in strategic sourcing, including the processes of selecting and approving new suppliers and the continuous cycle of monitoring, managing and improving these. Designed around the six categories of strategies that have been examined in extant research, Figure 6 provides a framework for how these relate to each other in terms of different ways in which companies can diffuse sustainability within supply networks in a structured fashion.

Figure 6. Framework for the diffusion process of sustainability in supply network



The role of the purchasing function

The next step in our review was to explicate the role of PSM in the diffusion of sustainability in supply networks. Or findings show that although procurement/purchasing managers have often been interviewed or surveyed, only a limited number of papers actually focus on the role of the purchasing function. For example, Teixeira *et al*. (2016) focuses on green purchasing, inclusion of environmental criteria in supplier selection and purchasing, but without a real consideration of the purchasing function. In Van Bommel's (2011) paper, purchasing is mentioned in the literature review but not incorporated or considered in the framework developed despite the focus on supply networks. Eltantawy *et al.* (2009) focus on supply management's ethical responsibility, reputation and performance impacts, however not with a focus on specific sustainability roles or competences. Other papers focus on specific contexts such as Large *et al.* (2013) who focus on the procurement of logistics services and sustainable development.

However, our analysis shows that there are very few studies that have specifically focused on the role of PSM in the diffusion of sustainability in supply networks. The focus of the paper by Koplin *et al.* (2007) is on incorporating sustainability into PSM, by integrating standards into supply policy and supply management; they state that the purchasing or sourcing function inside focal companies is the key actor to reach for, evaluate and monitor suppliers. Focusing on socially responsible supplier selection and supplier management (Ehrgott et al., 2011) firms are required to move beyond mere inspection of the offer terms they receive from emerging economy suppliers and to more intensively understand the business situation in the respective supply regions, which requires a cross-functional perspective and involvement.

Discussion and conclusion:

This paper set out to identify and classify strategies and practices for the diffusion of sustainability in supply networks and to explore the role of purchasing in this process, and to identify research gaps and needs for further development. Based on a systematic literature review we have examined studies across multiple levels of analysis and integrated multiple

fields of knowledge to show how research on sustainability in purchasing and supply is structured. In our selection of papers analyzed for the review, we ended up with a sample of 55 journal papers

We began the analysis of the field by examining the theories and methods used. Spina et al.'s (2013) comprehensive systematic literature review of PSM demonstrated that a relatively limited number of papers in the field made explicit reference to the use of theoretical perspectives, suggesting that the majority of papers in PSM are not grounded in consolidated theories. Focusing on sustainable (rather than general) PSM, Johnsen et al. (2017) recently showed that the sustainable PSM research in fact increasingly builds on theory to aid analysis of empirical results and to build new theory. They also demonstrate a growing trend whereby authors in the field make explicit statements about their use of theory, which is supported by others although as Chicksand et al. (2012) and Johnsen et al. (2017) both point out it is problematic to define what constitutes theory and that 'theory' is often used very loosely. Our results, based on a sample of sustainable PSM literature, would appear to support these recent results, as our analysis indicates that the majority of the papers do have explicit theoretical perspectives. Nevertheless, we found that 41% have no explicit theoretical perspectives, which is a higher proportion than Johnsen et al. (2017). Confirming the results of Johnsen et al. (2017), we also find RBV, stakeholder and institutional theories to be dominant whereas TCE – in contrast with its popularity in general PSM research (Spina et al., 2013) – is hardly ever adopted.

The use of theoretical perspectives ties in with the level of analysis and research methods applied. The topic of our systematic literature review is diffusion of sustainability within supply networks so about chains and networks. Our analysis shows that whereas PSM in the past dealt mostly with first tier suppliers, more recently there is a perceived need to look beyond the immediate suppliers relationships to understand and gain visibility over the extended multi-tier supply chain and this is reflected in research (Wilhelm et al., 2016). Some authors have argued that sustainability needs to be understood from an even higher level of analysis (Johnsen et al. 2017); this level is typically referred to as network or stakeholder analysis. The advantage, but also the challenge of adopting this level of analysis, is that the stakeholders in sustainable development are many and varied. The achievement of sustainability involves multiple inter-connected actors who are likely to have different ambitions and objectives, and the friction among these network actors may be critical (Araujo and Harrison, 2002). Our review shows that the majority of papers focus on firm or dyadic level of analysis, followed by the supply chain/network level and few stakeholder analyses to date. In general, the scarcity of empirical research at the network level highlights many opportunities for research, despite the methodological challenges. Case studies may be required to capture the complexities of supply chains and networks and on the basis of our analysis of research methods and theories we observe the recent use of in-depth rich case studies for exactly this purpose.

In this paper, we have focused specifically on the role of PSM in diffusing sustainability into supply networks. We argue that in order to be able to diffuse sustainability in supply networks, research needs to study the role and importance of PSM and its cross-functional interaction with and involvement of different functions. Our analysis shows a clear gap in current research on these questions creating a need to investigate how different functions are involved both from the managerial/implementation and research point of view.

A major contribution of this paper is the highlighting of gaps in the way that sustainability in purchasing and supply activities has been researched. In relation to specific purchasing strategies and practices, we found that the majority of research focuses on the selection and evaluation process of suppliers. However, few papers actually address other purchasing strategies, such as supplier development. Even fewer deal with issues relating to

sustainability implementation through co-creation and collaboration with other actors and stakeholders engagement. There is a need to understand issues related to strategies and practices, especially across the extended supply network where the risks involved may be considerable. Furthermore, on the network level, researchers are not asking how stakeholders are involved in organizational processes of decision making, i.e. in setting clear objectives or evaluating suppliers. Also, as companies are increasingly using third parties such as Sedex or EcoVadis to help identify "at risk" suppliers (Miemczyk et al., 2012) researchers need to examine the interaction with such new supply chain or network actors.

Future avenues of research:

One possible future direction of research is related to the fact that majority of research focuses on one or few of the six clusters that we have presented in our framework in other words researchers do not appear to be taking the whole diffusion of sustainability as a process into consideration rather than silos way of thinking towards this diffusion process. Following our proposed framework, future research could address the question of WHAT should be done in order to be able to diffuse sustainability in the supply chain/network. From the very first stage of sourcing to supplier monitoring, development and joint projects, the purchasing function would seem to be a key actor so research with focus on the role of purchasing could address the question of WHO can take the lead towards the diffusion of sustainability in supply chain/network.

Other avenues of future research center around 1) further in-depth case studies required to capture the complexities of supply network level of analysis and stakeholder issues, 2) cross-functional perspective and involvement of different functions required in order to investigate the level of involvement of every individual function but also in terms of interaction of different functions in the diffusion of sustainability, 3) broadening the coverage of purchasing strategies and practices required to diffuse sustainability throughout all stages of the process in order to be able to implement sustainability in the supply network, 4) taking a closer look at the role of purchasing function as the main actor in setting and implementing sustainable strategies and practices.

Keywords: complex healthcare procurement, temporal complexity

Abstract:
Delivering better value healthcare has been a key political aspiration of UK governments over the past 20 years. However the escalating £671m deficit that was reported for the UK National Healthcare System (NHS) for 2015 is an astounding paradox signaling a failing of government policy. The government responses to the NHS spiraling deficit, is one of increasing procurement control- both in terms of contractual control and governance mechanisms, with a clear £1 billion savings targeted at procurement improvement (Carter, 2015). This paper argues that short-termism approaches focused on healthcare productivity and reductionist cost efficiency-savings in purchasing environments such as the NHS, do not foster contemporary notions of collaborative innovation and value-based approaches. To support this we have studied over the last two and a half years, procurement practices across a cluster of 36 procurement departments and four Healthcare Trusts in the UK's NHS and across a variety of large and small-medium size NHS suppliers. In this paper however we are specifically reporting on a case study involving one Healthcare Trust where a different approach in managing purchasing was introduced to address issues of temporal complexity. This paper proposes that challenges around value-based procurement in the NHS are mainly complexity issues and using the theoretical assumptions of complexity theory we focus at the particular impact of temporal complexity and the responses to this as we contribute to collaborative health service ecosystem practices.

Introduction

The NHS as a viable care system forms a unanimous area of heightened concern amongst all socio-demographic groups in the UK (18-34 years old; 35-55 years old and 55+) with a staggering 61%-68% identifying the NHS as the most import issue facing modern Britain (IPSOS-MORI_5-15 May 2017, 2017). With ever increasing demands, spiraling deficits and the Brexit uncertainty on resource availability, the NHS ability to deliver care to the UK population is more than ever questioned. The founding aims of the NHS which are to provide equitable, comprehensive, high quality healthcare for free when patients use it—have not altered since its launch 69 years ago yet its ability to respond within turbulent times is not sustainable (Iacobucci, 2017).

The government response to the severe funding pressures on the NHS has been a funding slow-down from 2010/11, which prompted the relentless push for procurement to achieve price reductions. The drive for procurement to achieve target cuts (Hood 1991) without taking into account the institutional characteristics of the NHS, has fueled the perception that healthcare procurement professionals are mainly driven to cut costs and enforce process compliance. The financial control constraints therefore imposed from 2010/11 appear to have taken some time to impact on patient care (TheKingsFund, 2017) and many of the cuts that have been made are accumulating problems for the future. Unfortunately, this reductionist focus does not foster contemporary perceptions of collaborative innovation and service provision which has consequently led to an inability to operationalize value-based approaches into workable procurement processes (Meehan, Menzies and Michaelides, 2016).
Different perceptions of value within the complex health procurement ecosystem make value difficult to be measured with the currently available metrics across product and patient pathways.
The NHS as an organization demonstrates both structural complexity across its multiple trusts, departments and services as well as behavioral complexity, evidenced through the multitude of stakeholders with conflicting practices and logic. Indeed, the behavioral deficiency and non-existence of an overall decision maker makes it more difficult to optimize the impact of value-based procurement.

In addition the short-term structured budgets and fluctuating annual saving targets introduce the time element of temporal complexity that has a profound impact on the whole procurement lifecycle and collaborative ties with suppliers as they detract from ownership of cost and value considerations. It is this particular perspective of temporal complexity that this research seeks to address.

Governments have systematically failed to address the NHS as a complex social setting and their responses to the NHS diverse and competing institutional demands have been imposing *control* and *contractual governance* to regulate spiraling costs and collaborative interactions in multi-player arrangements (Roehrich and Lewis, 2014). It is a fair conclusion that these government responses of tight institutional control to healthcare procurement complexity has been unsuccessful as the NHS deficit is still growing as well as public concern escalating (IPSOS-MORI_5-15 May 2017, 2017). Public health purchasing strategies for managing product portfolio complexity and facilitating innovation is mostly focused on traditional process-based contexts of contractual, compliance-centred mechanisms (Meehan, Menzies and Michaelides, 2016). This says little about how purchasing strategies can be structured to facilitate collaborative innovation with suppliers. The notion of value across patient pathways and the inter-relationships of cost and clinical and commercial value across product and patient pathways remain challenging and complex.
So, suppliers navigate the complexity of healthcare structures by forging relationships directly with clinicians and users, frequently by-passing the procurement department. Which in turn perpetuates a *symbolic compliance* from actual practice as stakeholders by-pass the health procurement specialists – who are seen as the organizational control agents - thus undermining the exchange of knowledge as social capital forms the cornerstone of value-based thinking. So it follows that the expert knowledge that can be provided by procurement specialists (raging from commercial risk assessment and management, cost reporting and managing, contract compliance and regulatory standards assurance to embedding learning across contracts and trusts) is minimally realized within the NHS organisation. The behavioral complexity suggests that pockets of good practice are person-centric, and result from individual good relationships internally and externally, rather than being indicative of a culture focused on driving value,

improvement, learning and knowledge sharing.

In particular this paper reports on responses to procurement complexity within the specific context of temporal complexity in a case study.
We therefore address the following research question:

RQ1: What are the driving forces that create temporal complexity in procuring product portfolios?

Perspectives from complex adaptive systems theory (CAS) provide a lens to understand the overall effect that individual contractual arrangements across a cluster of 36 NHS procurement departments within four health trusts can have upon the public healthcare structure itself. Towards this, procurement activities were studied through focus groups and interviews with procurement staff, clinicians, health professionals and suppliers. Then a focused study targeting one of the above clusters was selected to identify the temporal complexity perceptions and it is these findings we will be reporting here. In the next section a brief review of the elements of a CAS system within the healthcare procurement are presented and also temporal complexity within public procurement systems is introduced.
Following this the methodological considerations and design for the deductive qualitative approach are discussed and the empirical case setting is described. The findings are then discussed in the light of the contextual background of temporal complexity in public procurement in the NHS.

Public Procurement as Complex Adaptive Systems and Temporal Complexity

In the last two decades an increasing number of researchers and professionals have started to use complexity science to better understand organizations. According to complexity theory, a complex system (CS) is a setting demonstrating a large number of interacting elements thus making it difficult to surmise that the properties of the entire system is based on the properties of its constituent elements (Simon,1962). This is mainly due to the way these elements interact interdependently and the strength of their interactions that changes with time (Ethiraj and Levinthal, 2004).
Complex adaptive systems (CAS), a branch of complexity theory, is useful to model complexity within a system. According to Anderson (1999) the difference between a complex system (CS) and a complex adaptive system (CAS) is that in CS entities (constituent elements) follow fixed rules whereas in CAS entities adapt. This ability to adapt is of particular interest as it infers that complex adaptive systems learn by creating new decision rules, structures and behaviours (McCarthy et al , 2006).
Sweeny (2002) articulates the benefits of using complexity theory as a study lens for the NHS as a complex system by suggesting that "complexity has the huge appeal of offering fresh potential for understanding systems, whether these 'systems' are patients, consultations, public health, organisations such as Primary Care Trusts (PCTs), or the whole National Health System (NHS)". Some recent research studies have specifically approached healthcare procurement using complexity as a theoretical approach to study contractual governance in managing complex procurement (Roehrich and Lewis, 2014) and purchasing structural and decisional complexity (Sanderson et al, 2015).
Complexity theory is the ideal lens to study procurement within healthcare because there are multi-level interactions and negotiations between stakeholders which are grounded in social

practice. Elements of CAS include self-organisation, emergence, multiple interconnections and systemic co-evolution with feedback loops (McCarthy et al. ,2006).
Self-organisation is evidenced in CAS as multiple stakeholders, agents interact and connect new behavior model patterns appear, and networks self-organise. These interactions cannot be completely understood or imposed from outside of the system (Anderson, 1999). Within the NHS procurement context patterns of behaviors across the procurement clusters and the Health Trusts show self-organising tendencies as they decouple symbolic compliance to actual practices (Bromley & Powell, 2012, p. 23).
Emergence is evidenced in a CAS setting with multiple changes happening as stakeholders/ agents enter, exit or transform within the organisation. Within the NHS procurement context individuals change and adjust during transformational times.
Another key characteristic of CAS are the multiple interconnections formed by multiple agents interacting, acting and making decisions that may affect related individuals and systems (Mitleton-Kelly, 2003). Within the complex healthcare procurement context multiple NHS agents coexist and interact widely within the structure and learn from each other within the organization and across the supply chain and patient pathway. Finally co-evolution and feedback loops are evidenced in CAS where striving for fitness drives adaptation between the states of equilibrium with varying output feedback loops. Within the healthcare procurement context where there are multiple and competing rules and practices, the inflexible procurement processes stifle co-evolutionary adaptation and innovation whilst collaborative, open interaction may enable innovation and encourage value-based approaches.

The elements of CAS mentioned above, such as self-organisation; emergence; multiple interactions and systemic adaptation with feedback loops (McCarthy et al. ,2006), are illustrated below (Figure 1). Figure 1 depicts in a visual way the interdependencies of these elements from the micro-perspective of the individual agent to the macro organizational level of a complex system across time. Indeed it is the temporal complexity that features high and is the focus of interest in this study.

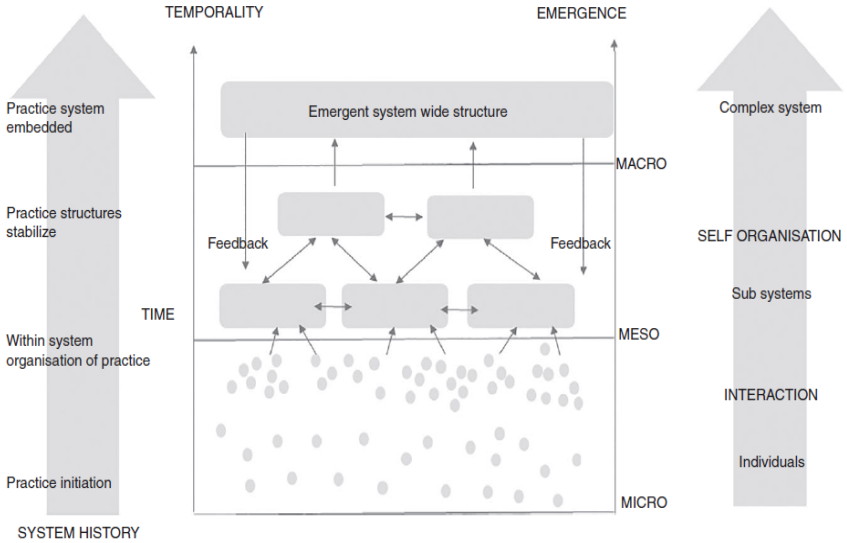

Figure 1. CAS model elements, *Source:* Chandler, et al (2016; p16)

In this paper we have adopted temporal complexity from Hassard (1996) who suggest that organisations need to understand and attempt to manage the impact of operational uncertainties when timing their activities. In operations management (OM) research time is often seen as one-dimensional, with much effort going into squeezing time to develop new products, improve

services, move resources, ship products and improve productivity by exploiting clock-time (Klassen and Halmohammad, 2017). So time exploitation (where less is more) in OM has a strong focus on process improvement, through compression of time but also through reduction of disruption which have led to complex scheduling and coordinating diverse activities (Klassen and Halmohammad, 2017). In the context of purchasing, time is also clearly defined as a key purchasing performance indicator, along with Cost; Quality; Flexibility; Innovation and Sustainability (Caniato et al., 2012).

In purchasing activities in the NHS, temporal complexities and uncertainties would include: the constant changes and dynamic nature of national health organisations (Paina and Peters, 2012); reconfiguration of healthcare procurement (Bals et al, 2018) with the introduction of new regulations, policies, frameworks, targets challenges; multiple interactions and power variances among clinical professionals, medical suppliers and purchasing professionals; conflicting priorities among various stakeholders; fluctuating procurement processes and lack of transparency in decision-making (Juha and Pentii, 2008).

Research Methodology- Empirical setting

Recent research studies have used complexity as a theoretical lens to study healthcare procurement from different perspectives such as: contractual governance in managing complex procurement (Roehrich and Lewis, 2014) and supply chain purchasing structural and decisional complexity (Sanderson et al, 2015).
This longitudinal study unravelled in two phases. In the first phase we examined interactions between healthcare agents involved in procurement across a cluster of 36 NHS procurement departments, four UK NHS trusts, and sought to identify how temporal complexity influences the structural characteristics of the healthcare environment. A longitudinal deductive, qualitative approach was used to study the purchasing environment and practices in the NHS. The research questions were drawn from gaps in existing literature and a number of interviews conducted using a interview protocol that was developed to assist us answering the research questions. In the first phase of our research study data collection involved interviewing, observation and focus groups consisting of purchasing managers within four hospital trusts, healthcare suppliers (multinationals and SMEs) who design and manufacture clinical products, clinicians who participate in the innovation cycle of products design (orthopaedic) from a user-perspective and clinical support staff. The analysis proceeded in several steps and lasted two and half years.
The practitioner feedback ensured that our qualitative study was firmly embedded in the procurement reality of the NHS so we could understand agent interactions, their interdependencies and the motivations behind these.

Following the first phase of our longitudinal analysis of four hospital trusts and 36 procurement departments we confirmed that indeed healthcare procurement exhibits the emergence, dynamicity, and interdependencies of a complex adaptive system. The findings of the first phase have been reported previously (Michaelides, Meehan and Menzies, 2016). We then sought to initiate the second phase, involving a specific case study to look at the temporal complexity aspects of procurement and to look at different value-based responses in managing purchasing to address issues of temporal complexity. Guided by Eisenhardt 1989, Yin, 1994, Gephart 2004 we selected a case study methodology as more appropriate to gain an in-depth understanding of the dynamics present in this particular NHS health trust setting and to

specifically study the key elements and their interactions. (Eisenhardt 1989, Yin, 1994, Gephart 2004).

The case presented here is based in one large health trust in the Northwest of the UK with the Procurement Department and a very large Audiology Center that sees approximately 2500 new patients a year. This particular Audiology Center was selected due to large volume of patients, the large variety of hearing-aid products procured but most importantly due to the temporal profile of "life-long" patients with most visiting at least twice a year for new supplies and maintenance of their hearing-aids. Which means that the clinical staff spend more time on old patients rather than new and this was highlighted as a key challenge.

The themes we sought to understand across the NHS Trust involved in the case study were:

- Temporal realities, key challenges and operating constraints and interdependencies in public healthcare procurement and competitive issues.
- Local perceptions of the key problems and trade-offs associated with temporal complexity

The fieldwork activities conducted in this study are summarised in Table 1.

Table 1: Chronology of the case study longitudinal fieldwork activities

Data activity instance	**Date**	**Activity Setting**	**Activity Focus**	**Affiliation**
Focus group	May 2016	NW Medium sized Hospital Trust : Large Audiology Department	Identification of temporal complexity perspectives across clinical, procurement and suppliers introduction of value-based procurement measures	Regional NHS Procurement Leader -1, Trust Procurement Manager -1, Audiology clinical head -1, Audiology department clinical staff -4, supplier -1, University researchers -1
Observation and service mapping	June 2016	NW Medium sized Hospital Trust : Large Audiology Department	Service blueprinting and value-based scenarios	Universityresearchers-2, Procurement Leader -1, Trust Procurement Manager -1, Audiology Department clinical staff -3, Audiology administrative support-2
Focus group	July 2016	NW Medium sized Hospital Trust : Large Audiology Department	Temporal Complexity responses: - through service blueprinting identify processes where temporal complexity manifests itself and run value-based scenarios	Regional NHS Procurement Leader -1, Trust Procurement Manager -1, Audiology Department clinical head -1, supplier -1, University researcher-1

Focus Group	September 2017	3 NW UK Trusts and cluster of procurement departments	Consolidate case findings and validate these across 3 more Health trusts	Regional NHS Procurement Leads -2, Trust Procurement Manager-1, Audiology Department staff -12, University researcher -1

The findings from the three focus groups and the observation activities involving a total of 39 NHS procurement, clinical staff as well as suppliers including regional NHS trusts procurement leaders and 2 procurement officers are reported here.

Case findings- Discussion

In the first focus group we sought to understand and identify the temporal complexity perspectives of healthcare provision and procurement and that drove our qualitative analysis protocol. During this first focus group it became obvious that within temporal realities of work there were objective and subjective dimensions of temporal complexity. The subjective dimensions were mainly around how staff perceive and experience time complexity in their care provision and their processes whilst objective dimensions were around cost targets. Once these temporal dimensions were identified the focus group participants were then asked to propose measures they would use to cope with these temporal complexities and increase value to patients in the form of "wouldn't it be great to…". The participant responses were scrutinised by panel of members including the regional procurement leaders, clinicians and topic audiology specialists.

The qualitative findings are summarized in Table 2.

Following the first focus group we sought to observe in action the temporal realities, key challenges and operating constraints in the case Hospital Trust and the large Audiology center. The observation period spanned across 2 weeks and service blueprinting was employed as this is a highly effective technique to map processes for service innovation through a customer experience design as well as running scenarios in value improving service(Bitner, Ostrom and Morgan, 2008).

Table 2: Temporal realities of the Audiology case study (focus group 1)

Staff affiliation	Staff experience of temporal complexity	Exemplary evidence	Value responses: Wouldn't it be great if ….
Clinical staff	- Most time spent on non-value maintenance work. For example currently the department schedules 13000 re-tubing appointments annually. - No time to run patient classes, demanded by patients, to demonstrate straightforward hearing-aids maintenance such as re-tubing. - The process of referrals by the GP is laborious and time-consuming thus delaying many appointments.	**"***my team would prefer to carry out more high-value work, and this could be achieved through giving more responsibility to the patients to re-fit their own tubes"*	• Offering the Receiver-in-Canal (RIC) hearing aids (a more expensive product) o Audiology would like to be able to offer literature, podcasts and a free kit (including tubing threader etc) for suitable patients to undertake their own hearing aid maintenance. This would lead to a reduction in appointments. This would have a slow and long-term impact. • Working in the Community o Direct referrals to save GP time. This would have a quick impact and is easy to implement.
Procurement	- Most time spent on compliance pre-contract tasks - A plateau price has been reached in most price negotiations with suppliers- new innovations in pricing to be investigated. - Increased pressure on suppliers could lead to suppliers leaving the market, providing poor products, with less competition at a higher price. - No time to manage contracts post-award - Cost saving annual targets driving "short-termism"	- *"we want to implement new ways of working but we are limited in capacity to do so due to the demands of the job"* - *"the implementation of national contracts may not necessarily be a good idea"*	• Keeping the market dynamic and understanding supplier/trust priorities • With top management particularly the Finance Director buy-in, there may be potential for extra resource allocation, and prioritisation on value-creation tasks not only cost-reduction. • Trusts to collaborate at a cluster / regional level to share contract innovations
Suppliers	- Variation in engagement with procurement across health trusts. An example was given of different Trusts receiving 'special customer' prices, and the variance in prices paid by different Trusts. - Everyone is busy in procurement and are deflecting requests		• Time to build relationships with procurement staff and to share best practices across all Health Trusts

The two value-based response scenarios adopted from Table 2 were: procuring the higher cost product (RICS hearing aids versus ear mould hearing aids) to see the long term service cost impact and patient time impact. With a value-based procurement outlook, the higher cost product is a more cost effective option long term. The service blueprinting outputs are seen in Figure 2 and 3.

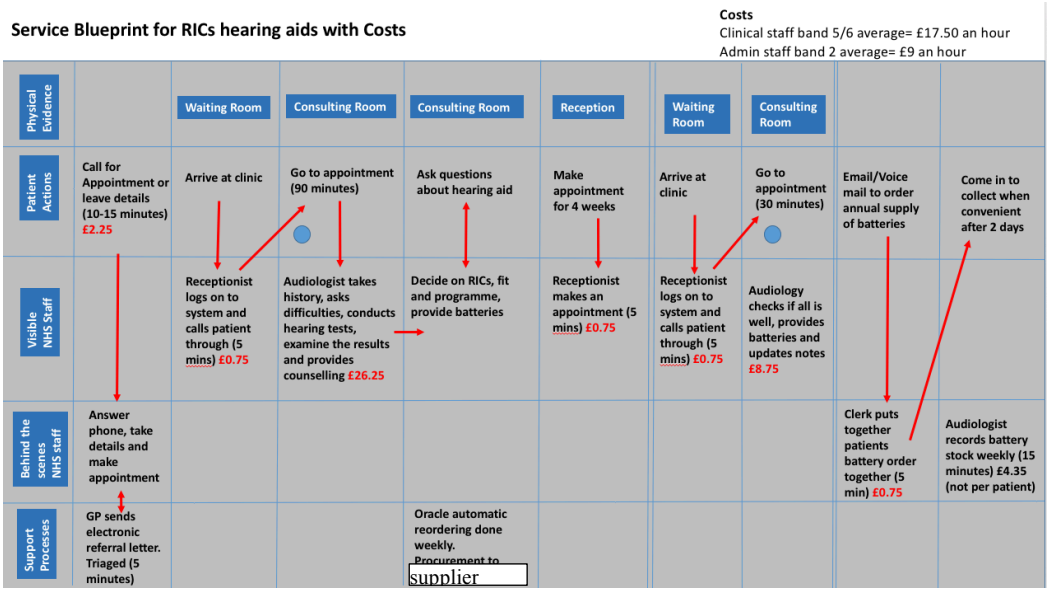

Figure 2: Service Blueprinting – high value product

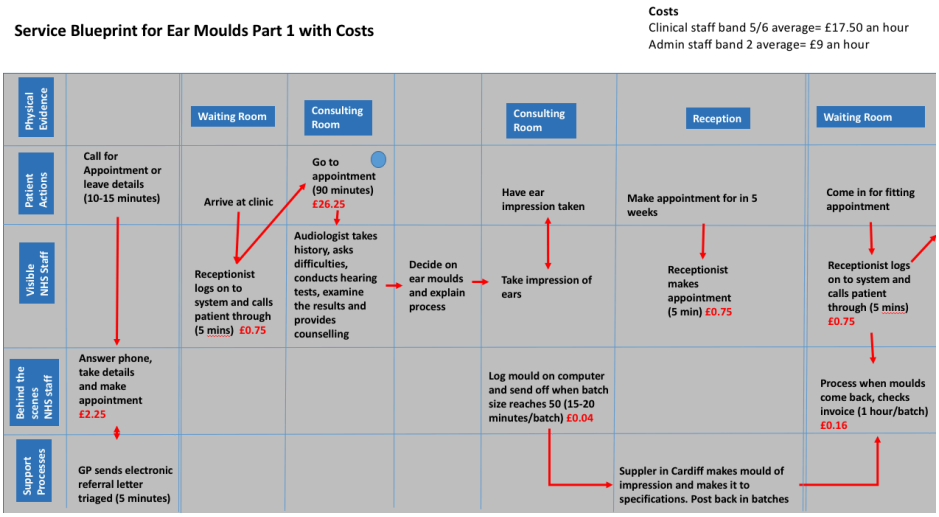

Figure 3: Service Blueprinting – low cost product

The service blueprinting demonstrated that spending an extra £3,760 on the more expensive product results in a saving of £44,255.20 in staff costs over three years. With a value-based procurement outlook, the higher cost product is a more time effective option long term as well. The service blueprinting demonstrated that procuring the higher value hearing aid saves the patient 6.5 hours over a three year period (roughly 4 clinic trips rather than 8) and saves 2.25 hours of clinical staff time and 2.2 hours of administrative staff time. Analytical findings are summarized in Tables 3 and 4.

Table 3: Audiology service blueprinting: Time impact of procuring cheaper product

The findings from the service blue printing were presented in the second focus group and participants were asked to identify an aspect of the audiology service that warrants change; to agree which process could be implemented and to demonstrate the benefits of working in

partnership with suppliers. It was clear that temporal complexity, manifesting as short-termism (Laverty, 1996), in healthcare procurement emphasizes immediate payoffs by selecting the cheaper product to meet the saving targets. This is also known as "managerial myopia" (Meulbroek et al., 1990) where the short-term payoff is favoured to the long-term benefits due to high uncertainty.

The third focus group was purposely organized to widen the scope of the study to include 2 more health trusts and a larger cluster of Audiology Centers/ Departments were invited. The findings on how the Audiology Center and Procurement in Health Trust 1 respond to the temporal complexity imposed by NHS annual saving targets and relentless cost-cuttings were presented and the participants were asked to review their existing processes in relation to operational efficiency, patient centred- outcomes and service expansion opportunities. Addressing the study research question, articulated in the Introduction section, it became evident in this latter focus group that the main driving forces that create temporal complexity in healthcare procurement of product portfolios are around achieving short-term savings.

It became obvious that time featured highly in the way that healthcare procurement was operationalized to cope with the pressures of cutting costs. Time responses through delays – with laborious procurement processes and long delays in scheduling patient appointments, impose a process – slowdown to healthcare services. Another response by health providers is by carefully selecting patients for care if they meet certain eligibility care criteria. These decisions usually utilize evidence about clinical effectiveness of treatments for people with particular characteristics. Another response has been deflection where hospitals have been encouraging patients that have private medical cover to use that for expedience. These responses to temporal complexity are not aligned with contemporary notions of collaborative innovative ways of providing healthcare.

Conclusion

This current study has responded to academic and policy calls for a better understanding of the challenges of healthcare procurement to adopt value-based approaches and specifically by using the theoretical assumptions of complex adaptive systems theory we focus at the particular impact of temporal complexity and the responses to this. We argued that systemic healthcare procurement approaches that emphasize immediate payoffs through selection of the cheaper product to meet saving targets have increased temporal complexity. We have also found that temporal complexity responses such as delays to treatments, introduction of tougher selection criteria of entitled patients and deflection are creating negative effects for a long-term care environment based on enhancing patient value and supplier collaboration. Our work explored Porter et al (2017) assertion that value improvement of healthcare is about enhancing patient outputs and not simple enactment of transactional healthcare compliance processes.

This paper builds on the literature on procurement complexity in public healthcare. We contribute to scholarly arguments that complexity appears as a useful lens to explore the emerging social complexity of procurement practices in public healthcare organizations. Our specific contribution is through establishing a new focus on the relationship between temporal complexity and responses to procurement complexity. The study introduces the concept of temporality to highlight the consequences resulting from healthcare policy decisions of investment cuts and the short-term payoffs of reduced annual NHS deficits. Recent policy decisions, for example include the Forward View that challenged the health service to achieve £22 billion in savings by 2020/21, which translates to an annual saving of 2–3% (NHS England, 2014). It is easy to deduce that the imperative of cost reductions does not consider the long-term sustainability of the NHS beyond minimizing the deficit. It is obvious that short-term

economic concessions are needed however embedding value aspects in procurement processes are key to building a long-term sustainable NHS service. Maintaining a long-term orientation of NHS service in collaborations with suppliers and stakeholders would according to our case findings help deal with these temporal complexities in procurement.

In this study we firstly sought to identify the temporal realities, key challenges and operating constraints and interdependencies in public healthcare procurement. Not surprisingly the lack of time to provide valued support and prevention services beyond the core care service was highlighted. Secondly, we wanted to reflect on the local perceptions of the key problems and trade-offs associated with temporal complexity within a large busy Audiology Department in the Northwest of the UK. The notion of value-based procurement was introduced to the clinical staff, suppliers and procurement stakeholders, who often have conflicting priorities. They were prompted to identify tangible outcomes and surprisingly they opted for procuring products that are more expensive but bring long term results. Which means that in practice the short-term approach of yielding immediate benefits was of no high importance. Our emerging insights are further extended in this ongoing research looking at more health clusters in the UK.

Drawing upon social exchange theory (SET), this paper investigates the role of buyer firm's leadership approaches toward supply chain performance. Moreover, this paper examines the mediating role of trust and power on the relationship between supply chain leadership and supply chain performance. By using a sample of 190 manufacturing companies, this paper employs a structural equation modelling technique for concluding that transformational and transactional leadership were significant contributors towards supply chain performance (suppliers' quality, cost, flexibility and reverse performance), while passive leadership negatively influenced suppliers' cost performance. This study also found that trust and power mediated the relationship between supply chain leadership and suppliers' cost performance.

Keywords – Supply Chain Leadership, Performance Measurement, Buyer-Supplier Relationship, Social Exchange Theory

Introduction

Strong commitment and excellent leadership are required to improve competitiveness and sustainability of supply chains (Gosling et al., 2017). In contrast to traditional leadership, SCL is concerned with the ability of an organization (for example, the buyer firm in a supply chain) to influence followers' (for example, suppliers) actions or behaviours (Defee et al., 2009; Gosling et al., 2017). SCL has been identified as the antecedent towards supply chain performance including organizational learning (Hult et al., 2000a), purchasing cycle time (Hult et al., 2000b), supply chain efficiency (Defee et al., 2010), supply chain learning (Gosling et al., 2017), sustainability (Blome et al., 2017) and supply chain agility (Dubey et al., 2018). Unfortunately, current SCL definitions lack consistency and uniformity. Nevertheless, most of the studies have focused on transformational leadership to define SCL without any consideration on transactional leadership. To date, less emphasis has been given to transactional leadership, and no comparison has been made between leadership approaches (transformational and transactional) and non-leadership approach (passive) to fully understand the role of buyer firms' leadership style. Moreover, there is a dearth of empirical studies devoted to the relationship between SCL and other antecedents toward supply chain performance (SCP), such as inter-organizational trust and power (Harland et al., 2007; Gosling et al., 2017). This study aims at filling these gaps providing an empirical investigation into the relationship between SCL and supply chain performance, also considering the mediating role of trust and power.

Background of the Study

The concept of SCL is derived from classical leadership theories. However, in contrast to the classical or traditional leadership theories (which focus on micro and inter-personal level), SCL

focusses on macro and inter-organizational levels. Usually, in the supply chain management context, a distinction is operated between *transactional* and *transformational* leadership styles. *Transactional leadership* in SCM context is referring to the ability of the buyer firm to influence supply chain members' actions and behaviours by enforcing rewards and punishments (Birasnav et al., 2015). Birasnav et al. (2015) further deduce that buyer firms who are committed toward contract compliance such as defect inspection and quality monitoring are practising transactional leadership on their suppliers. On the other hand, *transformational leadership* in SCM context is referring to the ability of a buyer firm to motivate and stimulate their supply chain members' actions and behaviours. By exhibiting transformational leadership, supply chain leaders can enhance communication and information sharing which is essential for supply chain collaboration (Birasnav, 2013). Moreover, Hult et al., (2000a) highlight that a buyer firm practising transformational leadership can execute its organizational learning to a higher level. Overstreet et al., (2013) claim that there is a positive relationship between transformational leadership approach exhibited by the buyer firm and their operational performance. Transformational leadership of the buyer firm expanded organizational innovativeness and led to a higher financial performance of the organization.

Theoretical Background: Social Exchange Theory

SET is grounded on the concept of interaction between one person and another which lead to interdependent transactions and contingency of actions. This theory was adopted from the perspective of reciprocity, which refers to the positive exchange behaviour of the actors and rewards. Theorists believe that a positive action exhibited by a person will be responded with another positive action from the other party (Tanskanen, 2015). In addition, individuals or groups are interacting for rewards or at least with the expectation to receive rewards from other parties. In SCM context, SET has been used extensively to understand supply chain relationships, particularly the buyer-supplier relationships. To date, several SCM studies have used SET in explaining supply chain relationships such as supplier's relationship orientation (Kingshott, 2006), supplier-buyer negotiation power (Narasimhan and Nair, 2005), and supply chain servitization (Bastl et al., 2012). The concept of SCL is related to the action of buyer organizations in influencing the action of supply chain members. Derived from SET lens, supply chain members' actions and behaviours are determined by rewards or punishments received from the buyer organizations. It is not necessarily extrinsic such as contract continuation or bonuses, but also can be intrinsic such as support and motivation.

The Role of Leadership in Supply Chain Context

Defee et al. (2010) deduce that SCL is an antecedent toward SCP by articulating vision for the future, communicating the vision and motivating supply chain members. To date, there has been a little agreement on SCL definitions and dimensions. A universally accepted definition of SCL is difficult to find, and differences of opinion exist in literature. However, there seems to be some agreement that SCL refers to "*a relational concept involving the supply chain leader and one or more supply chain follower organizations that interact in a dynamic, co-influencing process. The supply chain leader is characterized as the organization that demonstrates higher levels of the four elements of leadership in relation to other member organizations (i.e. the organization capable of greater influence, readily identifiable by its behaviours, creator of the vision, and that establishes a relationship with other supply chain organizations)*" (Defee et al. 2010, pp. 766).

SCL has been identified as a vital contributor towards organizational performance in many ways. Hult et al. (2000a) outline the importance of leadership in global purchasing. Buyer organizations' leadership style has directly influenced organizational learning and reduced cycle time (Hult et al., 2000a). SCL has also been identified as a contributor towards

supplier-buyer commitment. SCL is essential for coordination between business partners. SCL will enrich activities in the supply chain and improve contact with the external suppliers (Hult et al., 2000a). Moreover, Defee et al., (2010) state that the awareness of SCL has grown in importance over the past 20 years. Transformational SCL has been tested to have a significant positive influence on the communication between supply chain members. By having a greater communication across the supply chain, business partners will be able to disseminate information and articulate their vision to achieve supply chain efficiency (the utilization of organizational resources) and effectiveness (the accomplishment of organizational goals and objectives) (Defee et al., 2010). Moreover, there is an unambiguous relationship between leadership styles and organizational innovativeness). Transformational leadership allows organization to innovate and adapt to change, in which improve the organizational performance (Overstreet et al., 2013). On top of that, a supply chain leader has to be able to integrate organizational resources to address the rapid changes in business practices (Overstreet et al., 2013). In the same vein, Birasnav (2013) discusses the importance of SCL to improve product quality and customer service level across the supply chains. The role of SCL is considered as a fundamental to surge market share and return on investments which can boost firms' overall performance. In a recent study, (Birasnav et al., 2015) explore and compare between transformational and transactional leadership toward cycle time in the supply chain activities. The impact of transformational leadership on SCP, especially cycle time, has been found to be stronger than impact of transactional leadership.

Trust and Power in Supply Chain Context

The studies on "trust" have a long history within the discipline of management and psychology (Sako and Helper, 1998). However, in SCM context, the focus on trust is deficient. As psychologists are more concerned toward inter-personal trust, scholars in SCM are more concerned towards inter-organizational trust. Inter-organizational trust in SCM context can be defined as "*one's belief that one's supply chain partner will act in a consistent manner and do what he / she says will do*" (Spekman et al. 1998, pp. 56).

Inter-organizational trust has been revealed to have a significant influence on SCP. Inter-organizational trust enhances followers' commitment which leads to a higher performance and lower transaction costs (Kwon and Suh, 2004). Moreover, inter-organizational trust will promote cooperation and collaboration among supply chain members (Gualandris and Kalchschmidt, 2016). Collaboration between supply chain members is required to ensure that current practices are aligned with the pre-determined plan. Greater openness and transparency between supply chain members can be achieved with higher inter-organizational trust (Nyaga et al., 2010). Inter-organizational trust is vital to obtain mutual benefits and collaboration. Collaboration drives both parties (buyer organizations and suppliers) to achieve economic benefits as plans and practises are executed with mutual understanding and agreement (Nyaga et al., 2010). Commitment and satisfaction between supply chain members can only be attained by having collaboration from both parties.

Power has been defined as a multi-dimensional construct that is used to influence supply chain partners to adhere to the desired requests or actions from the other parties (Ireland and Webb, 2007). To date, most of the power research in supply chain devoted their attentions to the role of coercive and non-coercive power in influencing supply chain practices. Coercive power is mostly the act of getting agreement or improving the performance of the other parties by using punishments and sanctions, while non-coercive power is related to the act of influencing other parties behaviours by providing rewards (Brito and Miguel, 2017; Meqdadi et al., 2017). Even though most of the power literature explained and discussed those concepts in term of control, coercion and legitimacy, the reward form of power seems to contribute significantly to SCP (Meqdadi et al., 2017; Ireland and Webb, 2007). Recently, the role of trust

and power has also been observed in sustainable supply chain practices (Touboulic et al., 2014). Ireland and Webb (2007) discussed that even though trust and power seem to be opposing, it is actually complementary to each other. The ability of power to substitute trust (and vice versa) whenever trust fails to achieve pre-determined or desired outcomes explains the nature of complementary between both constructs. For example, a study of IKEA sustainability practises revealed that trust alone is insufficient and exhibiting power (coercive or non-coercive) may also significantly improve the outcomes (Meqdadi et al., 2017). In this study, coercive power (coercive and legitimate) was used.

Supply Chain Performance

Performance measurement refers to the procedure and process of quantifying actions and outcomes performed by a business unit (Neely et al., 1995). The traditional performance measurement systems are limited to quantitative financial outcomes such as profit margin, cash flow and revenue (Gunasekaran and Kobu, 2007). By using a financial benchmark, a significant positive outcome seems to be obtained whenever the financial outcomes are greater or improved, for example, profit margins increment. However, this conventional measure fails to measure and quantify intangible indicators. As the recent global economy is competitive, many activities and processes are not easily identified and measured by financial outcomes. Recent needs for sustainability are not solely based on financial performance but also environmental and social performance (Seuring and Müller, 2008). Thus, the needs to develop agile business processes and strategies have forced researchers to revisit the performance measurements and metrics.

A variety of measures found and categorized by the scholars lead to difficulty in defining and conceptualizing the performance metrics. In order to overcome the complexity, a few scholars have systematically reviewed the literature to find the best metrics for SCP measurement (Shepherd and Günter, 2006; Gunasekaran and Kobu, 2007). Shepherd and Günter (2006) found 132 measures for SCP metrics in the literature. Based on the review, 55 metrics are related to cost (cost saving, warehouse costs, disposal cost), 38 metrics to quality (rejection rate, defect percentage, accuracy), 25 metrics to time (lateness, cycle time, lead time) and 14 to flexibility (production flexibility, volume flexibility). This review is consistent with Gunasekaran and Kobu (2007), who also deduce that the performance metrics are mostly related to both financial (cost) and non-financial (time, quality and flexibility). It is justified that cost, time, quality and flexibility have been used extensively in measuring SCP. As such measures have been validated by the scholars, this study will use those metrics to quantify suppliers' performance with one additional dimension, reverse performance.

Conceptual Framework and Research Hypotheses

A research framework (Figure 1) and a set of hypotheses were developed for this study: (1) to examine the relationship between SCL and SCP; and (2) to examine the mediating role of inter-organizational trust and power on the relationship between SCL and SCP.

The Relationship between Supply Chain Leadership and Supply Chain Performance

Transformational leadership exhibited by the buyer organizations is promoting organizational learning within the supply chain (Hult et al, 2000b). Moreover, by exhibiting transformational leadership, an organization will be able to reduce their cycle time which allows them to enjoy minimum lead time or production downtime (Hult, Ferrell, et al., 2000a). Nevertheless, transformational leadership has been identified as an antecedent towards supply chain cost improvement (such as manufacturing cost), flexibility (innovation and ability to change), quality (product quality) and sustainability (green manufacturing, green supply chain) (Blome et al., 2017; Dubey et al., 2015; Sharif and Irani, 2012). Two dimensions in transactional

leadership also have been identified as antecedents in enhancing supply chain practises. In contrast with transformational leadership, transactional leadership is focusing on extrinsic rewards (such as long-term contract and investment) while transformational leadership is focusing on intrinsic needs of the supply chain members (such as motivation and commitment) (Blome et al., 2017; Birasnav et al., 2015). As the positive actions of an individual or groups are determined by the rewards or exchange means received over time, this study proposed that:

H1: Transformational leadership is positively related to SCP.
H2: Transactional leadership is positively related to SCP.
H3: Passive leadership has no significant relationship on SCP.

The Relationship between Supply Chain Leadership and, Trust and Power

The relationship between leadership and trust has been researched extensively in psychological and organizational behaviour fields. Transformational leadership has been identified as a strong predictor of employees' trust (Dirks and Ferrin, 2002). By exhibiting appropriate leadership approaches or styles, an organization will be able to enhance employees' trust and psychological well-being in which lead them to achieve job satisfaction and commitment. Even though there are limited studies on the relationship between SCL and trust, few scholars proposed that SCL can enhance trust between supply chain partners and lead to higher performance of the supply chain including reduction in cycle time and supply chain alliances (Birasnav et al., 2015). This phenomenon is also justified by the literature in which when a desirable action performed by a supply chain leader (motivation and intellectual stimulation), a supply chain member will respond with another positive action such as integrity and reliability of their actions, information or agreements. As mentioned previously, the concept of trust and power is co-exist and interdependent. Both trust and power shall exist in supply chain relationship as it provides relational exchange of supply chain partners. In this study, transformational leadership is seen as the contributor towards trust, while transactional leadership is more towards power-based relationship which are coercive and legitimate power. Hence, this study proposed the second set of hypotheses:

H4: Transformational is positively related to trust.
H5: Transactional leadership is positively related to power.
H6: Passive leadership has no significant relationship on trust and power.

The Relationship between Trust and Power, and Supply Chain Performance

Trust and power are recently being identified as the main mechanisms that can be used simultaneously to influence supply chain partners. However, most of conventional literature has separated trust and power-based supply chain relationships in which they argued that trust and power are unable to be executed together. Even though trust and power exist in different constructs and dimensions, it is actually interdependent rather than independent (Pulles et al., 2014; Yeung et al., 2009). Yeung et al., (2009) address that both trust and power improved internal and supplier integration. Trust and power have also led to a positive outcome on supplier resource allocation in which by exhibiting higher trust and power, a buyer firm will be able to convince (trust) or force (power) their suppliers to invest on the physical and innovation resources (Pulles et al., 2014). The authors further deduce that a buyer firm with a higher share in the supplier can use power to influence or force the suppliers. However, a buyer firm with a lower share should only use trust to influence their suppliers. Hence, this study proposed the third and fourth set of hypotheses:

H7: Trust is positively related to SCP.
H8: Power is positively related to SCP.
H9: Trust mediates the relationship between transformational leadership and SCP.
H10: Power mediates the relationship between transactional leadership and SCP.
H11: Power and trust do not mediate the relationship between passive leadership and SCP.

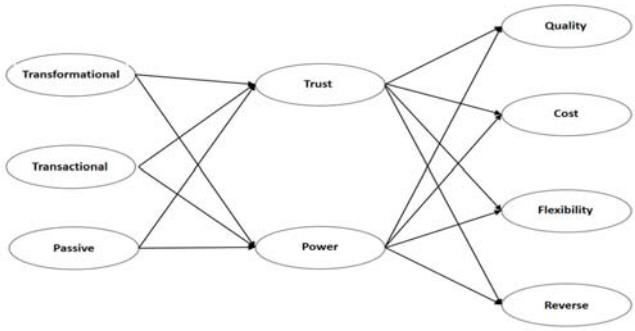

Figure 1: Conceptual Framework of the Study

Research Methodology

Construct Measurements

The main constructs in this research model are transformational, transactional and passive leadership as predictor variables; trust and power as mediators; and cost, quality, flexibility and reverse performance as the outcomes. The constructs were measured on a seven-point Likert-scale ranging from strongly disagree (or poor for performance) (1) to strongly agree (or excellent for performance) (7). The measures for transformational, transactional and passive leadership were adapted from Defee et al. (2010), Defee et al. (2009) and Avolio et al. (1999). The items in the questionnaire were designed to capture the leadership styles exhibited by the buyer firms toward their suppliers. Measures for trust were adapted from Liu et al. (2015), which designed to capture suppliers' trust towards their buyer firm. Measures for power were adapted from Nyaga et al. (2013). The questions for power were aimed to capture the exercise of reward, coercive and legal legitimate power by the buyer firms toward their suppliers. Finally, measures for suppliers' performance were adapted from multiple sources including Hazen et al. (2015), Olugu and Wong (2012), Kristal et al. (2010), Gunasekaran and Kobu (2007), Shepherd and Günter (2006). However, since the suppliers' performance might be interpreted differently in different industries, the items were modified based on the consultation with the panel of experts (academic and industry) during the pre-testing sessions. This study controlled for firms' size and their position in the supply chain (for example, tier-1 vs tier-2 suppliers). The unit of analysis was the senior level management in supplier firms (tier-1 onwards).

Survey Design and Sample Characteristics

The manufacturing companies surveyed for this study included top, middle and lower managers across various sectors including automotive, steel, oil and gas, fast moving consumer goods (FMCG), pharmaceutical, tobacco, rubber, chemicals, electronics and machinery. The survey sample was identified using Federation of Malaysian Manufacturer directory and the research team own industrial contacts. In total, 830 surveys questionnaire were distributed and 225 participants responded. However, the final responses were 190 as 35 responses were removed due to significant incomplete or missing data (23% or response rate). The respondents were working in 16 different sectors where the highest representatives were from automotive

(22.1%), electrical and electronics (16.8%), and, metal and machinery (15.3%). Furthermore, 57.4% of the companies responded for the survey were privately owned. Half of the respondents were in middle management position (53.2%). 35% of the respondents were the senior management while 11.1% were lower management. The highest representative of the sample for this study was the respondents who worked in the firm for more than 10 years (43.2%), followed by 2-5 years (31.6%), 6-10 years (20.5%) and less than 1 year (only 4.7%). The details of respondents' experience distribution are shown in Table 5.8. Finally, majority of the respondents (63.2%) were working in tier-1 firms while 23.7% in tier-2 and 13.2% in tier-3. However, 95.3% of the respondents stated that they were normally interacting with the focal firms.

Data Screening

The dataset used for this study was not suffering from extreme outlier and no response was removed, transformed or modified. Furthermore, the dataset did not contain extreme skewness and kurtosis based on the recommendation by Hair et al. (2014), which the value is within the range of -1 to +1. The multicollinerity test revealed that there was no multicollinearity between the independent variables as the tolerance value was more than .10 and the variance inflation factor (VIF) was less than 10.

Exploratory Factor Analysis

Prior to performing the EFA, it is necessary to measure the suitability of the data and its sampling adequacy. The Kaiser-Meyer-Olkin (KMO) test is useful to indicate whether the factor analysis is useful for the data (closer to 1.0 is better, with .6 is the minimum value for good factor analysis), while Bartlett's test of sphericity used to measure the significance p value which should be less than .001 (Pallant, 2016). KMO and Bartlett's Test was used to measure the suitability and it reveals that the sample was adequate (range from .888 and above) and the significant values were .000 ($p < .001$).

A total of 30 items were used to measure SCP, 21 items for trust and power, and 23 items for SCL. EFA using Principal Axis Factoring (PAF) extraction and Promax rotation matrix revealed that only 4 factors can be extracted based on eigenvalue more than 1 for SCP. Based on EFA, only four factors were retained for further analysis which are cost performance, quality performance, flexibility performance and reverse performance. EFA revealed that 4 factors can be extracted based on eigenvalue more than 1 for trust and power. The screeplot was also suggesting that the trust and power variables could be explained from four-factor structure. However, after further investigation on the pattern matrix, the fourth factor should not be retained as the items were cross-loaded with the first factor. The third factor consisted of 2 trust items and 1 power item, however, since there is no theoretical justification to explain those items in a single construct, all items were removed (Field, 2013). Hence, only two factors were retained to measure trust and power. Finally, EFA revealed that 3 factors can be extracted based on eigenvalue more than 1 for SCL. Those 3 factors are transformational leadership, transactional leadership, and passive leadership.

This study decided to use only top three items based on their factor loading to represent each factors. The practise of using items with the highest loadings (also known as surrogate items) is common as those items are having a greater influence on their respective factor (Dubey et al., 2015; Hair et al., 2014). Three items were chosen as it suits the rules for standard confirmatory factor analysis models which a factor should has at least three indicators (items) (Kline, 2016). Hence, 27 items were retained for subsequent examination using confirmatory factor analysis.

Confirmatory Factor Analysis

By using nine-factor model identified during the EFA (4 factors for performance, 2 factors for trust and power, and 3 factors for SCL), the initial measurement model was created. The measurement model was statistically adequate: Chi-square ($\chi 2$) = 459.633, degrees of freedom (df) = 288, chi-square goodness-of-fit ($\chi 2$/df) = 1.596, comparative fit index (CFI) = 0.959, Tucker-Lewis index (TLI) = 0.950, Bollen's incremental fit index (IFI) = 0.959, standardized root mean squared residual (SRMR) = 0.051, and root mean squared error of approximation (RMSEA) = 0.056.

Model Reliability and Validity

Cronbach's alpha and composite reliability (CR) were used to check the reliability of the model, while average variance extracted (AVE) was used to estimate convergent and discriminant validity. The lowest alpha for the variable was 0.810 (transformational leadership), which is higher than the recommended cut-off alpha value (0.7) (Pallant, 2016). It indicated that each items in the variable or construct were measuring the same attribute. Similarly, the lowest CR value was 0.804 (passive leadership), higher than the cut-off value of 0.70 (Hair et al., 2011). The square root of AVE showed that the variables were more related to its own measure instead of other dimensions (based on cut-off value of 0.50 recommended by Hair et al., (2014)). In a simpler word, it can be concluded that the items in the variables were measuring at least 76.4% of their own variable rather than any other (the lowest AVE value was 0.764 for passive leadership). The tests confirmed that the variables used in the model were not having any reliability as well as convergent and discriminant validity issues.

Common Method Bias and Measurement Model Invariance Test

By using an approach proposed by Podsakoff et al. (2003), a common method bias test using common latent factor (CLF) was carried out. The test revealed that there was no significant difference on the standardized regression weight before and after the common latent factor was added. Thus it can be concluded that no common method bias was reported for this study. The measurement model invariance test was conducted in order to identify the consistency of the factor structure on different groups. Two group were tested which are (i) Tier 1 Firms vs Tier 2 and Tier 3 Firms, and (ii) Small and Medium Enterprises (SMEs) vs Large Corporations. The test showed insignificant difference for the chi-squared between unconstrained and fully constrained models across the 4 multi-groups, indicating that the factor structure was consistent across all groups in the dataset. These findings confirmed that the dataset met the condition for configural invariance (same structure across groups) (Milfont and Fischer, 2010).

Findings and Discussions

The overall fit of the hypothesised structural model was adequate with the following fit indices: Chi-square ($\chi 2$) = 616.582, degrees of freedom (df) = 341, chi-square goodness-of-fit ($\chi 2$/df) = 1.808, comparative fit index (CFI) = 0.934, Tucker-Lewis index (TLI) = 0.922, Bollen's incremental fit index (IFI) = 0.935, standardized root mean squared residual (SRMR) = 0.08, and root mean squared error of approximation (RMSEA) = 0.065. All hypotheses were tested while controlling for firm's size and their supply chain position. The direct and mediation tests were conducted independently on the full model to ensure greater clarity and parsimony.

Direct Relationship Between Supply Chain Leadership and Supply Chain Performance

Table 1 shows that transformational and transactional-based SCL were equally contributing to SCP. Even though most of the literature in this domain argued that transformational leadership is the sole contributor towards SCP, this empirical study found that the role of transactional leadership is not supposed to be ignored by the scholars and practitioners. Both

transformational and transactional leadership are highly influential in improving suppliers' quality, cost, flexibility and reverse performance. Nevertheless, exhibiting passive leadership approach had no significant effect on suppliers' quality, flexibility and reverse, which means it had no influence in improving suppliers' performance in that respective dimensions. However, this study noted that by exhibiting passive leadership, suppliers' cost performance had worsened, which could contribute to increment of their products' cost and price.

Table 1: The Relationship between SCL and SCP

Independent	Path	Dependent	Standardized Path Coefficient
Transformational	→	Quality	0.425***
Transformational	→	Cost	0.452***
Transformational	→	Flexibility	0.316***
Transformational	→	Reverse	0.350***

Transactional	→	Cost	0.320***
Transactional	→	Flexibility	0.389***
Transactional	→	Reverse	0.231**
Passive	→	Quality	-0.103 NS
Passive	→	Cost	-0.312***
Passive	→	Flexibility	0.047 NS
Passive	→	Reverse	-0.135 NS

*p <.05, ** p <.005, *** p <.001, NS – Not Significant

Direct Relationship Between Supply Chain Leadership, Trust and Power

Table 2 shows that transformational was a significant contributor towards trust, while transactional leadership was a significant contributor towards power. Moreover, this study found that passive leadership had a negative relationship towards power. By practising transformational leadership, buyer firms will be able to enhance suppliers' trust. On the other hand, by practising transactional leadership, the exercise of power tends to be higher as the buyer firm are more likely to monitor and control suppliers' performance by looking into suppliers' obedience to pre-determined rules or procedures. In opposition to transformational and transactional leadership, passive leadership had no influence on suppliers' trust, however it negatively effects the power exercise by the buyer firms.

Table 2: The Relationship between SCL, Trust and Power

Independent	Path	Mediator	Standardized Path Coefficient
Transformational	→	Trust	0.615***
Transformational	→	Power	0.061 NS
Transactional	→	Trust	0.069 NS
Transactional	→	Power	0.514***
Passive	→	Trust	-0.024NS
Passive	→	Power	-0.205**

*p <.05, ** p <.005, *** p <.001, NS – Not Significant

Direct Relationship Between Trust, Power and Supply Chain Performance

Table 3 presents the final direct relationship analysis between the variables, the mediator and independent variables. This study found that trust had a significant positive relationship towards all dimensions of suppliers' performance (quality, cost, flexibility and reverse). This study also found that power had a significant positive relationship towards suppliers' cost and reverse performance, but not towards quality and flexibility performance.

Table 3: The Relationship between Trust, Power and Supply Chain Performance

Mediator	Path	Dependent	Standardized Path Coefficient
Trust	→	Quality	0.386***
Trust	→	Cost	0.471***
Trust	→	Flexibility	0.348***
Trust	→	Reverse	0.326***
Power	→	Quality	0.122 NS
Power	→	Cost	0.339***
Power	→	Flexibility	0.139NS
Power	→	Reverse	0.222***

*p <.05, ** p <.005, *** p <.001, NS – Not Significant

The Mediating Effects of Trust and Power

The second objectives of this study is to understand the underlying reasons for explaining the relationship between SCL and supplier's performance by testing the mediating role of trust and power. Even though the direct relationship between variables existed (i.e: transformational leadership to trust, trust to suppliers' performance), the structural model revealed that the relationship between SCL and suppliers' performance was not completely mediated by trust or power. The findings discovered that the role of trust and power were significant as the mediator on towards suppliers' cost performance. Trust partially mediated the relationship between transformational leadership and cost performance, while power partially mediated the relationship between transactional leadership and cost performance. Similarly, power partially mediated the relationship between passive leadership and cost performance. It can be concluded that the relationship between transformational leadership and cost performance was partially explained by trust. By exhibiting transformational leadership, buyer firms are able to enhance suppliers' trust on their firm, which at the end improve suppliers cost performance. As the buyer firm motivating, inspiring and stimulating suppliers' intellectual, the suppliers tend to believe that they buyer firms are transparent and honest with them. Due to that, they are willing to innovate and invest more to improve their operations, which lead mostly to the improvement of the cost such as manufacturing and inventory costs.

Similarly, power has been found as the mediator between transactional leadership and cost performance. The relationship between transactional leadership was partially mediated by power as the nature of transactional leaders are to apply reward and punishment scheme, as well as highly monitoring and auditing approaches. This will lead them to exercise high power, in order to ensure suppliers' obligation and obedience towards their requirements. By exercising high power, suppliers will carefully monitor their own performance, so that they will not violate the contract which can cause them subsequent penalty including business termination. In contrast, by exhibiting passive leadership, the buyer firm will not demonstrate their power, in which has a negative impact towards suppliers' cost performance. For instance, a passive leadership firm will not make any decision and suggestion for their suppliers' in terms of suppliers' production plan or operations. Using this approach, the buyer firm indirectly uses less power as they do not monitor their suppliers and do not concern about their suppliers' compliance, which can lead to poor cost management. Table 5 shows the bootstrap results for assessing the significance of indirect effects of the mediators. Table 6 presents the summary of the hypotheses testing.

Table 5: The Relationship between Trust, Power and Supply Chain Performance

Relationship	Direct Effect Without Mediator	Direct Effect With Mediator	Indirect Effect (95% Bias-corrected CI)	Bootstrap CI		Remarks

Table 6: Summary of Hypotheses Testing Results

Hypotheses	Result
H1: Transformational is positively related to SCP.	Accepted
H2: Transactional leadership is positively related to SCP.	Accepted
H3: Passive leadership has no significant relationship on SCP	Rejected
H4: Transformational is positively related to trust.	Accepted
H5: Transactional leadership is positively related to power.	Accepted
H6: Passive leadership has no significant relationship on trust and power.	Rejected
H7: Trust is positively related to SCP.	Accepted
H8: Power is positively related to SCP.	Accepted for Cost and Reverse
H9: Trust mediates the relationship between transformational leadership and SCP.	Accepted for Cost
H10: Power mediates the relationship between transactional leadership and SCP.	Accepted for Cost
H11: Power and trust do not mediate the relationship between passive leadership and SCP.	Rejected for Cost

Conclusion

Drawing upon social exchange theory, this study developed and tested a framework to examine the relationship between SCL and suppliers' performance. The findings offer guidance to the firms across the supply chain networks on the role of buyer firm's leadership approach and its influence towards suppliers' performance. This study also provides an avenue for both parties, buyer and supplier, to understand how the leadership of the buyer firms contributed to cost suppliers' performance via trust and power. Results of the study indicated that the direct relationship of SCL and suppliers' performance existed, which transformational and

transactional leadership approaches led to higher quality, cost, flexibility and reverse performance. The study also found a new result where passive leadership (non-leadership approach) deteriorated the cost performance of the suppliers. The 'full-range' leadership approach (consisting of elements of both transformational and transactional leadership) should be considered by practitioners for improving their buyer-supplier relationships. As the relationship with each supplier is unique, different leadership approaches might be needed and the concept of relying only into one type of leadership (either just transformational or transactional) and generalizing it to all buyer-supplier relationships are extremely perilous. Moreover, this study found that trust and power were significant mediators between SCL and suppliers' cost performance. The relationship between transformational leadership and suppliers' cost performance was partially explained by trust, while the relationship between transactional leadership and suppliers' cost performance was partially explained by power. It is apparent from this study that transformational leadership improved suppliers' trust on the buyer firm, while transactional leadership increased power exercised by the buyer firms. Both leadership approaches improved different mechanisms but led to a higher performance of suppliers' cost performance. It can be further explained by saying that transformational leadership used trust as the instruments to enhance suppliers' cost performance, whereas transactional leadership used power as the instruments to achieve the same goal. It is aligned with the result discovered for the passive leadership approach, in which it led to lack of power exercised by the buyer firm that negatively impacted suppliers' cost performance.

This study contributes directly to the leadership theory by expanding the classical intra-organizational leadership to inter-organizational leadership from the perspective of supply chain management environment. The result affirms that the role of buyer firms' leadership approach is significant towards suppliers' performance. Secondly, this study further validates social exchange theory by providing the empirical evidence of social exchange practises (leadership, trust and power) influence on suppliers' performance. The finding asserts that leadership, trust and power are three important antecedents towards suppliers' performance, especially towards cost performance. Finally, this study further adds to operations and supply chain management literature by proposing the 'full-range' leadership approach that should be implemented in order to improve suppliers' performance, where the passive leadership approach is definitely should be reduced. This study focussed on the leadership approach of the buyer firm towards suppliers' performance on a dyadic supplier-buyer relationship (based on immediate buyer-supplier). Accordingly, future studies could adopt a triadic approach to examine the buyer firms' leadership approach penetration beyond tier-1 suppliers.

Abstract
This study is motivated by a real-life problem as it aims to provide a user-friendly decision making tool used to select the best vendor from among the group towards their tenders submitted to implement a proposed radio frequency identification (RFID)-based passport tracking system. The DEMATEL algorithm is proposed to determine the importance weight of each criteria and the obtained weights are then to be integrated into the ELECTRE algorithm proposed to evaluate the performance of vendors. The efficiency of the proposed tool is to be evident from the real case study.

Keywords: Vendor selection; Traditional and Resilience; MCDM.

Submission category: working paper

Introduction

Vendor selection is a main key factor in implementing a robust business (Amid et al., 2006). This is based on the fact that enterprises depend more on suppliers to obtain a cost-effective high performance. Furthermore, purchasing activity is one of the main task for enterprises since its costs represent more than 50% of all enterprises 'internal costs (Mohammed et al. 2017; and Yazdani et al., 2016). Vendor selection can be defined as the activity of selecting the best vendor based on their tenders towards a number of criteria for obtaining a stabilized environment of competitiveness. Generally, it is a major concern and a challenge for decision makers since several uncontrollable and unpredictable factors are involved (Mohammed et al., 2018). Where an impropriate selection may compromise financial and operational status of the enterprise (Araz and Ozkarahan, 2007; and Faez et al., 2006). Thus, it is regarded as a complex, multi-criteria decision-making activity since different and conflicting criteria should be considered and assessed to assign consistent vendors.

In the context of criteria, decision makers are normally evaluating vendors based on their performance towards traditional criteria such as costs and quality neglecting resilience criteria (e.g., agility and flexibility) which is a paramount to sustain and improve their service. For instance, due to Japan's earthquake in 2011, Apple negatively affected in producing iPad 2 due to lack of flash memory and super-thin battery (BBC News, 18 Mar 2011). This event also interrupted the automotive sector and retail supply chains in the UK (Hall, 16 Apr 2010). Thus, enterprises ultimately have realized that their selecting method which encounters traditional criteria as the only criterion is inefficient and needs to be changed.

Several research studies have presented to solve Vendor selection problem. Amin et al. (2011) proposed a fuzzy SWOT method used to evaluate the vendor. Khaleie et. al. (2012) used ranking

process on the two indices, score function and accuracy function, to rank the alternatives. Haldar et al. (2014) developed a fuzzy multi-criteria decision making (MCDM) approach for supplier selection considering the importance degrees of specific attributes as linguistic variables formulated by triangular and trapezoidal fuzzy numbers. Torabi et al. (2015) proposed a fuzzy stochastic bi-objective optimization model to solve a SS/OA problem to improve the supply chain resilience under operational and disruption risks.

The literature review shows that there is a gap in this body of knowledge in terms of presenting a trasilient vendor selection approach that can help decision makers to encounter the traditional issues and unexpected disruptions, simultaneously. Within this boundary, this study presents a development of a hybrid decision making tool aiming to select the best tender presented from 7 vendors to implement a real RFID-based passport tracking system. First, a framework was developed for defining the trasilience criteria and sub-criteria (e.g. traditional pillar such as costs and delivery commitment and resilience criteria such as agility and flexibility). Second, DEMATEL was used to determine the importance weight for each trasilience criteria and sub-criteria. Third, ELECTRE was used to evaluate and rank vendors with respect to their trasilience performance.

Preliminaries

Quantifying criteria: decision-making trial and evaluation laboratory (DEMATEL)

DEMATEL is a multi-attribute decision making algorithm used to determine the weights of attributes and to evaluate the interaction relationship between different variables of a complicated system to establish direct and indirect causal relationships and influence levels among them. The implementation of DEMATEL includes the following steps (Tzeng et al., 2007):
Step 1: Generate the linguistic evolution decision matrix based on decision makers 'expert. In this research the linguistic evaluation and its correspondence quantitative scale is shown in Table 1.
Step 2: The linguistic evolution obtained from step 1 was converted using the quantitative scale shown in Table 1 to the correspondence scale to generate a pairwise comparison decision matrix among the three objectives.

$$A_{ij} = \begin{bmatrix} r_{11} & r_{12} & r_{1j} \\ r_{21} & r_{22} & r_{2j} \\ . & . & . \\ . & . & . \\ r_{i1} & r_{i2} & r_{ij} \end{bmatrix}$$

Where A_{ij} represents a pairwise decision matrix, in which the element a_{ij} denotes the level to which the ith attribute influence the jth attribute.
Step 3: The aggregated normalized decision matrix N was built based on decision matrix generated in step 2 using Eq.1.

$$N = A.K \quad (1)$$

Where

$$K = \frac{1}{\max\limits_{1<i<n}\left(\sum\limits_{j\in n} r_{ij}\right)}; i, j = 1,...,n \tag{2}$$

Step 4: Generate the total-relation matrix *T* using Eq. 3, in which I denotes the identity matrix. The matrix *T* reveals the total relationship between each pair of decision attribute.

$$T = N\left(I - N\right)^{-1} \tag{3}$$

Step 5: Sum rows and columns of matrix *T* using Eqs. 4 and 5. These two summations are resented by D and R vectors.

$$D_i = \left[\sum_{j\in n} t_{ij}\right]_{nx1}; i = 1,2,...,n \tag{4}$$

$$R_j = \left[\sum_{i\in n} t_{ij}\right]_{1xn}; j = 1,2,...,n \tag{5}$$
