IPSERA 2018 Conference

Purchasing and Supply Management
Fostering Innovation

CONFERENCE PROCEEDINGS

Foreword

The 27th Annual IPSERA (International Purchasing & Supply Education & Research Association) Conference is held in Athens, Greece from 25 - 28 March 2018. This volume contains all the papers that will be presented at the conference and is distributed electronically to the delegates. The proceedings are organised into three sections. Part A contains all the competitive papers, Part B contains all working and Part C all the practitioner papers. The papers are listed in alphabetical order (by first author's last name) in each part.

The theme for the conference is *'Purchasing & Supply Management: Fostering Innovation*. The choice of this theme reflects the growing importance of innovation for the purchasing and supply profession. The inevitable drive towards more sustainable development, the fast pace of business processes digitization of the fourth industrial revolution *(Industry 4.0)* and the introduction of enabling technologies such as blockchain are causing major disruptions in the way that supply chains are structured and managed. The current business environment necessitates perpetual supply chain innovation and creativity to stay ahead of competition.

We can observe a marked increase in the last 3-4 years in the number of papers presented at IPSERA conferences focusing on innovation, but this is the first time the conference theme has been dedicated to supply chain innovation. This year 18 papers specifically concern innovation, and a large number of papers that are classified under other themes also discuss themes related to supply chain innovation.

However, the conference also addresses a large number of other important topics within purchasing and supply management. Some of these other themes were this year proposed by scientific committee members, who have subsequently played a key role in managing the review process for papers submitted to their 'special stream', and they will act as chairs of these streams during the conference. The list of themes includes:

- Supply Chain Innovation (process innovation, sustainable innovation, NPD)
- Supply chain finance and financing
- Big Data & Analytics
- Sourcing and Contracting
- Public Procurement
- Supplier Relationships Management
- Demand Management and Forecasting
- Supply Chain Teaching Innovation
- Information systems and technology
- Supplier selection and evaluation
- Sustainability (social responsibility, purchasing ethics, circular economy)
- IoT and industry 4.0
- Purchasing Strategy and Organisation
- Supply Chain Risk management
- Supply Chain resilience and robustness
- Forecasting and Supply Chain Optimisation
- Healthcare Purchasing and Supply
- Supply Chain Theory Development
- Global supply chains
- Supply Chain Human Capital

In order to make the information and ideas presented at the conference promptly and widely available, participants in the conference were invited to submit written papers based on their presentation for inclusion in these refereed online conference proceedings. Each Competitive paper submitted for consideration was double blinded peer-reviewed according to the requirements. The extended abstracts of the Working and Practitioner papers were also peer reviewed by two reviewers. That is, papers were sent to two scholars who were asked to provide a scholarly judgement on the paper's suitability for publication.

176 papers were submitted to this year's conference. This presents a record for the history of IPSERA and signifies the increasingly important role of the purchasing profession. Following the review process, 148 papers have finally been accepted and distributed as follows:

- 54 Competitive Papers
- 90 Working Papers
- 3 Practitioner Papers

Competitive papers are often based on analysis of empirical data but may also be purely conceptual. In either case, these are generally at such a high level of quality that they are in principle ready for submission to an international scholarly journal; all competitive papers have undergone a double-blind review process and are maximum 15 pages in length. Working papers may also be empirical and/or conceptual but represent work-in-progress and are maximum 10 pages; in the case of working papers an extended abstract rather than the full paper has been double-blind reviewed. A selection of the best conference papers will be published in the Journal of Purchasing & Supply Management. Practitioner papers are written by people from (private or public) companies or organisations, although sometimes in collaboration with academics. These papers are maximum 7 pages and have also been double-blind reviewed although the focus of practitioner papers is less on the scientific rigour and more on practical perspectives and implications.

We would like to thank all the authors who responded promptly, willingly, and efficiently to their requests to referee papers, and to thank fellow members of the editorial board for their support. We are grateful to the scientific committee for ensuring the rigorous standards of all the papers.

We have been fortunate enough to work with a team of very talented and enthusiastic individuals that provided invaluable managerial assistance. The professionalism of Magda Laiou, Anna Bolosi and Alexandros Koressis, and our very competent and enthusiastic student volunteers made the organization of the conference a very smooth task.

We hope you enjoy reading the papers and attending the presentations at this year's IPSERA conference.

A Resource-based View on the Role of Global Sourcing for achieving Sustainable Development Goals

Anthony Alexander[1] and Joe Miemczyk[2]
[1]University of Sussex, School of Business, Management and Economics, Falmer, Brighton BN1 9RH, UK
[2]ESCP Europe Business School, 527, Finchley Road London, NW6, UK

Abstract
This paper provides a conceptual synthesis from reviewing literature across the sustainable development and supply chain management fields and then applying to examples from the 'grey' literature. The paper addresses capacity building in the international development literature and supplier development in the management literature to understand the implication for global sourcing in achieving sustainable development goals. Key theories in the literature are considered with linked concepts combining to form a conceptual framework. Two sets of examples from Brazil and West Africa are covered to pilot the nature of the framework leading to an outline research agenda.

Keywords: sustainable supply chain capacity building
Submission category: working paper

Introduction

Multi-national corporations involved in consumer goods manufacture frequently involve supply chains that source their raw materials from developing countries. Indeed, such trade links between developed world consumers and developing world producers are as old as international trade itself, particularly amplified in the colonial and industrial eras. Today, as awareness of global communities is enabled by modern media, consumers are coming to be made more acutely aware of the impacts such trade may have on the people and natural world where the raw materials of their purchases originate. Corporations are thus prompted to act, declaring a range of initiatives such as promising sustainable cocoa production to halt the habitat loss leading to the threatened extinction of primates (McClean, 2017), to the conflict minerals laws seeking to prevent child labour in metal extraction in mobile phones. The list of such connections is long, but so far, it is not clear to see how firms seeking to improve their global sourcing processes are able to simultaneously meet the need to maintain their profitability, whilst also meet the need to improve the social and environmental impacts linked to their supply chains. This developmental paper seeks to bring together theory in global sourcing and strategic capabilities concerned with sustainable development, with international development theory, concerned with improving communities.

Background Literature

Initial consideration of the conceptual landscape finds a relevant perspective in the resource based view (RBV) (Barney, 1991), further developed in the supply chain (SCM) context as the extended resource based view (ERBV) (Lewis, Brandon-Jones, Slack, & Howard, 2010), developed in the environmental context as the natural resource-based view (NRBV) (Hart,

1995), and more recently for social aspects as the social resource-based view (Tate & Bals, 2016). Relevant features of these conceptual approaches are the role of performance indicators, process control and governance.

This literature review therefore examines the role of social and environmental indicators across the international development (ID) (UNSC, 2017) and supply chain / global sourcing literatures, the conflicting roles of transparency, stakeholder influence, power imbalances (Touboulic, Chicksand, & Walker, 2014), network maps (Henneberg, Naudé, & Mouzas, 2010) and governance gaps (Ruggie, 2002). A theory for supplier capacity building for sustainable development may need to reconcile the nature of these factors. Synthesising these issues across two streams of literature - supplier development for sustainability as an aspect of supply chain management (SCM) and community capacity building as an aspect of international development (ID) helps build bridges between these two academic subjects and their related practitioner communities.

In SCM, supplier development is a well-recognized approach for improving the short and long-term capabilities and performance of suppliers (Hartley & Jones, 1997; Krause & Ellram, 1997; Krause, Handfield, & Scannell, 1998; Sánchez-Rodríguez, Hemsworth, & Martínez-Lorente, 2005). The goal of supplier development is to bring underperforming suppliers to a buyer's expected level of performance across quality, delivery, cost structure, new technology adoption, financial health, product design, and/or other important performance issues (Krause, Ragatz, & Hughley, 1999). Buying organizations need to invest in knowledge sharing activities to help suppliers internalize process and business level capabilities. With regard to sustainability, Vachon and Klassen (2008) called this environmental collaboration, to include training, on-site actions with suppliers' production processes and operations to improve their environmental impact, and mutual projects to develop innovations.

In the ID literature, a related concept to supplier development is capacity building. The United Nationals Development Programme (UNDP) defines capacity building as a 'long-term continual process of development that involves all stakeholders including ministries, local authorities, non-governmental organizations, professionals, community members, academics and other appropriate internal and external entities'. Others specify capacities ranging from intellectual, organisational, social, political, cultural, representational, material, technical, practical, or financial – and most likely a shifting combination of all of these (Eade, 2007). While capacity building is not always aimed at business organizations, there is a focus on transferring knowledge to local entities in order to improve process and practice, and focus on organisational learning (Jones, 2001). Yet a key difference with supplier development is the scope and inclusion of multiple stakeholders in the capacity building process and the transfer of knowledge across multiple organizational boundaries. Some criticism of this approach however highlights the one-way nature of knowledge transfer (Eade, 2007; Jones, 2001).

In the context of sustainable development, especially with regard developing market communities, supplier development and capacity building can be seen as related activities. In the case of Fair Trade coffee, the key benefits of a fair trade mechanism is the ability to help coffee producers develop their capabilities and perform better in the global coffee markets (Raynolds, 2004). A key feature is including local parties, such as financing institutions, in the improvement processes of local producers in order to create an external environment that can support the producer or supplier (Bäckstrand, 2006). However, Fair Trade itself has been criticised as 'private regulation', supplanting local institutions in the regulatory process. Hence, supplier development and capacity building can be seen as complementary and could provide more effective ways for local producer to meet sustainable development goals (Hajer et al., 2015). One concerns a focus on the supply chain and the desire of an international buying firm

(often a multi-national corporation, MNC) to improve performance of a supplier, and the other concerns a focus on a community or organisation in order to improve delivery of a social, environmental or economic development activity.

From the perspective of a buying firm seeking to improve the sustainability of its supply chain, it is unclear how to properly leverage the overlap between these two approaches. On the one hand, the strategic management theories around RBV state that firms are fundamentally concerned with competitive advantage, strengthened by developing appropriate capabilities in their global sourcing. On the other, they must simultaneously be attentive to the needs sustainable development encountered in the local context of the supplier organisations or related communities. This prompts a number of initial guiding questions addressing issues of competitive strategy whilst also meeting social and environmental challenges:

1. How does a combined extended, natural and social resource-based view develop our understanding of sustainable SCM and the role of MNC global sourcing policies?
2. Which sustainability challenges benefit from MNC strategic resources in supplier development / capacity building and how to manage and measure this impact?
3. How can this view reconcile levels of analysis from organisation, supply chain to a macro-scale of sector market-level changes and societal scale changes?

The first question concerns the strategic resource allocation decisions of buyers - often MNCs. At the level of theory, we are concerned with matching the RBV/ERBV/NRBV/SRBV approaches with SSCM and global sourcing to meet sustainable development or associated social, environmental and economic concerns. This is process of theory synthesis (Rousseau, Manning, & Denyer, 2008) involving the creation of a conceptual framework.

The second question concerns how sustainability challenges are defined. The current international policy landscape is orienting around the United Nations' Sustainable Development Goals (SDG), a series of agreed targets to improve social and environmental concerns. The SDG are a set of issues that national governments seek reportable metrics around. Businesses and investors are also using the SDG as a means to channel activity towards addressing sustainability, and in doing so prompt a need to verify the effectiveness of this activity. This is a central topic in the emerging field of impact investing.

The need for performance indicators, process control and governance is seen in the strategic management literature as an essential component of effective action, and this can clearly inform the impact investment community and its related interaction with the SDGs (Bebbington, Unerman, & O'Dwyer, 2014). Key performance indicators linking economic, social and environmental criteria within the supply chain, such as via supplier contracts, supported by a sufficient and reliable level of transparency of data, is required. Process control then refers to the ability to manage the performance of the supply chain on the basis of that information. Supplier development therefore proceeds on the basis of needing the goals for economic value to be generated by the buyer, also by the supplier, and also, simultaneously, for social and environmental outcomes (potentially modelled using the concept of 'public value', in contrast to pure economic value, such as by Bozeman (2002); Moore and Bennington (2011) to complement the specific targets of the SDG).

The element of governance is important in ensuring visibility, control, and corporate responsibility, over the upstream supplier, plus the nature of a suitable legal framework and level of national government responsibility. Various cases where commodity chains become non-transparent to buyers are common across many commodity types. Often when a product enters a market, its provenance is no longer knowable, and various attempts to prevent this 'laundering', through a black-box process of a market can be seen (for example, the 2012 US

Dodd-Frank Act clauses requiring buyers declare their awareness of their upstream supply chain and whether it includes minerals from designated 'conflict zones' (Narine, 2012)).

With an awareness of both a governance gap and an information gap, it may be thought that additional regulation and additional visibility, such as via auditing or better data architecture in a supply chain, these problems can be overcome. However, the objective outlined in the SDG policy framework may be at risk of assuming a structured performance measurement and management approach when in reality the deficit of information on required metrics and the underlying complexity of the context prevents easy accounting solutions for the impact in social and environmental terms of a given investment in supplier development (Alexander, Kumar, & Walker, 2018). Exploring and overcoming such limitations where possible may be is an important aspect of current and future research into SSCM and related topics.

The third question concerns levels of analysis or scales. Using the SDG as a normative set of criteria around which to define sustainability, the subdividing of these into a set of metrics prompts a further consideration of the architecture for performance measures, and how this extends from the local and specific scale of a given community or organisation deemed to be the supplier, and the related supply chain or supply network back to a given buyer. This vertical line or network can then be contrasted with a horizontal one, across a given spatial location, up to the scale of a sovereign nation, or across an economic sector of buyers, such as, say, palm oil. The role of cross-sector trade bodies seeks to aid maturity of this horizontal coordination.

Whilst a single MNC may wish to engage in supplier development (SCM) with a view to improving capacity of a given community (ID), and make a case for impact investing aligned with the SDG, a central issue of concern to both the impact investor and to the local government, will be to establish how significant that action is in achieving a macro-scale meeting of an SDG, how many such MNC actors might need to act together in order to make a substantial difference on these SDG, and hence whether the impact can really be legitimately claimed. An understanding of scale is therefore of central relevance .

This stage of the research concerns outlining of the conceptual framework. This is undertaken primarily by a literature review and subsequent thematic and conceptual synthesis, to then be extended by an initial elaboration of known case studies in the grey literature and primary research projects at an early stage of development. This paper continues by outlining the literature review undertaken thus far, a formulation of the initial conceptual framework, and an initial, basic application of this to case studies (in West Africa, concerning the cocoa supply chain, and in Brazil concerning the açai berry and brazil nut supply chain). Initial issues and challenges are then discussed, followed by an outline of next steps.

In summary, the strategic management theories of RBV and its extensions concern how the resources and capabilities a company has underpin its competitive advantage. Extending this into supply chain management and global sourcing strategies means developing supplier capabilities in order to support the buying firm's strategy. However, a significant limit to current theory is the role of multiple buyers with the same goals, hence questioning the traditional view of competitive advantage. Typical factors used are performance objectives such as product or service quality, speed or reliability of delivery, cost structure, etc. In environmentally-focused supplier development, this often involves training suppliers in new standards, improved process design (such as greater efficiency), collaboration on innovation in products or services to advance environmental (or social) performance, etc. (Vachon & Klassen, 2008). This involves various performance measures and related management processes, with the relative level of knowledge or transparency, the relative power of the

buyers, suppliers or other stakeholders, and the nature of governance and regulation, and related gaps. Meanwhile, from the perspective of international development (ID), capacity building is often also focused on organisations, including businesses, and also communities (which, in some cases, may be classed as micro-businesses, artisan businesses, or co-operatives) i.e. a different level and unit of analysis. Here, as the focus is often at a more aggregated level of a particular community, at various scales from the local up to the regional or even national, multiple stakeholders are assumed, and so multiple routes for organisational learning are considered. These various components are summarised in Figure 1, below. The goal of bringing these different elements together is in order to establish a potential 'theory of supplier capacity building for sustainable development'.

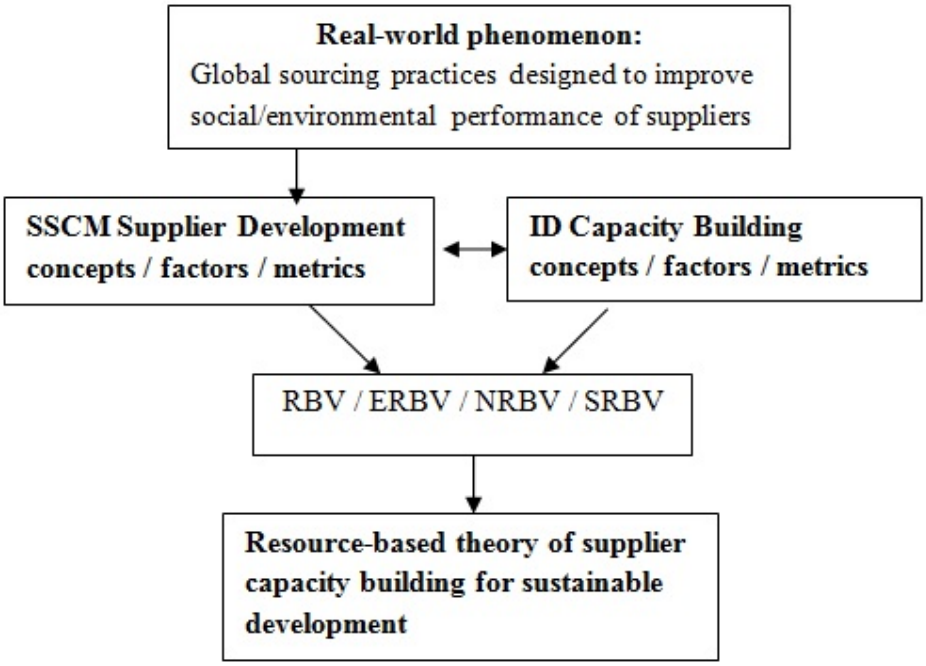

Figure 1: initial draft of conceptual framework based on background literature.

Methodology

Bringing these various themes together requires a focused and systematic literature review. This current paper provides an outline of this, with the bulk of the review itself to follow in a future paper. Here, the conceptual framework is mapped and initial findings discussed. The methodology for systematic reviews is that outlined by Briner and Denyer (2012); Denyer et al. (2008); Tranfield, Denyer, and Smart (2003), widely used in SCM research (Alexander, Walker, & Naim, 2014; Gimenez & Tachizawa, 2012; Miemczyk, Johnsen, & Macquet, 2012). The stages of this require a checking of key search terms, clear recording of the criteria used to conduct the search to enable replication and extension by other researchers, and a broad and interdisciplinary approach to ensure that insights to a topic from other disciplines are addressed and not lost in isolated academic silos. A similar analysis is being undertaken with academic, secondary sources, media/press reports and third sector reports in order to build case evidence.

Initial Analysis

Table 2, below offers a broad-brush synthesis of concepts from SSCM supplier development and ID capacity building to provide an initial typology against which to group the research found in the literature review (Table2). This clustering of concepts is a simplification process that provides an initial scan of the literature. Future analysis will take this process further, highlighting additional richness and detail that aids the usefulness and explanatory power of the review. For now, this initial synthesis finds two categories, operational issues and stakeholder issues. Broadly, these refer the performance management considerations led by the main buyer, and through which they seek to influence the supply chain, and the stakeholders include a wide range of parties and relationships that will influence the success of the firm's objectives.

SSCM **Typical factors in supplier development** (e.g. Vachon and Klassen, 2008)	**ID** **Typical factors in capacity building** (e.g. Eade, 2007)	**Combined SSCM and ID View on supplier development and capacity building** Combined list of concepts to form initial typology for literature review.
• Performance indicators (e.g. quality, delivery, cost structure, new technology adoption, financial health, product design, organisational learning, etc.) • Process control • SC Governance • Levels of transparency • Levels of stakeholder influence and power imbalances (incl. collaboration for innovation, network structure, governance gaps)	• Specific outcomes - local context - temporal and spatial scales - measuring & reporting on progress • Co-ordination of multiple buyers and suppliers to achieve progress at macro-scale. • Access to financial support • Access to technology and expertise • Multiple stakeholder dialogue • Multiple organisational learning (community level)	**Operational factors** • Performance objectives • Performance measurement • Process design & control **Relational factors** • Buyer-supplier relationships • Community cooperations • Sector cooperations **Financial factors** • Supplier investment support **Stakeholder factors** • Customer values • Governance and institutional voids

Table 1: Initial synthesis of SSCM and ID into two category typology

While stakeholder theory can be considered in relation to Freeman's work in the 1980s and subsequent iterations over the following 30 years, it can also be considered in terms of theories of network maps, social capital, power and influence, which can extend beyond the central disciplines of strategic management. As a concern of a typical MNC buyer, the link between their procurement policies and tangible contribution to a sustainable development goal suggests a need to anchor international development concepts into a strategic management frame.

Main concepts

The analysis of the literature to date shows that many SSCM papers are clearly identifiable as related to either operations management topics or to stakeholders. Operations concepts primarily include performance measurement (Yawar and Seuring, 2017) and supplier selection decision analysis. Stakeholder concepts cover inter-organisational relationships between buyers and suppliers (Kumar and Rahman, 2016), with NGOs (Rodriquez, et al. 2016), or with government (Edmonsdon et al. 2008; Lauridsen, 2004), or multiple parties (Yadlapalli et al., 2018; Liu et al. 2018). Some papers explore the barriers to effective sustainability-related supplier development (Busse et al. 2016) and others provide data suggesting that there is no economic benefit in such supplier development (Sancha et al. 2015). Overall, supplier development appears to be a growing topic of discussion in the SSCM literature, extending common theoretical approaches from supply chain, procurement and sourcing research in business and management scholarship.

The ID community by contrast takes a different approach, based on the specific evolution of that discipline and its areas of focus. Here, there is a larger number of papers across a wide range of journal titles. The approach taken is, however, very different to that of business and management scholarship. This is perhaps unsurprising in terms of the focus of the subject matter, but notably there is a difference in methodology and the use of theory. A significant majority of the papers are case studies. These largely describe a specific ID project and its context, offering some reflections and suggestions based on the findings. Notable clusters of topics are health, education, policing and climate policy. These papers are also largely a-theoretical. Few papers appear to draw foundations from organisational theory, though some papers are explicitly theoretical, drawing on evaluation theory and 'theory of change'. Some papers refer to stakeholders, but this is largely in relation to engagement between different groups, rather than the original strategic management meaning which supposes that there is a focal firm to whom stakeholders must be managed in order to achieve strategic objectives.

Notably, given the topic of this paper, there is almost no mention of the Sustainable Development Goals (SDG) in either sets of literature. This suggests firstly that there is a research gap on this topic. Secondly, that synthesis between the SSCM and ID perspectives on stakeholder engagement and performance measurement may be significant in informing the SDG agenda. Firstly, from an operations management and decision analysis point of view, the extensive number of indicators (performance measures) by which national governments will be held to account in their success or failure in meeting SDG contains some extremely familiar challenges over ambiguity, contradictions and trade-offs; resistance, gaming and unintended consequences; bounded rationality, incomplete data, and institutional bias. These areas are studied in business and management scholarship, but perhaps less so in the development literature that informs the SDGs. Future work will look at this in more detail.

The next section seeks to elaborate some of the broad concepts covered in Table 2 in relation to two case studies being investigated by the authors. These will offer the basis for a parallel consideration of conceptual model and real-world phenomenon in order to enable theory elaboration as the research project moves forward. Notably, the large number of metrics and indicators associated with the SDGs are tested in some specific contexts faced with obvious sustainability challenges. To date, these cover two cases concerned with meeting the sustainable livelihoods of forest-dwelling communities while countering the intractable problem of accelerating levels of deforestation.

Case study 1: Brazil

A specific community is being assisted in developing non-timber resources as a means to establish sustainable development and counter the short-term economic lure of logging. A number of crops are already being harvested for export. These include brazil nuts and açai berries. In this case, there is a clear territory, with a coherent community engaging with international buyers directly as well as through local markets. Supplier development initiatives are focused on providing small-scale local processing to increase the value of the commodities, including by improving transportability and quality control. Additional development actions concern mapping the territory to establish possible increases in yield of food products harvested from the wild (such as brazil nuts). A range of SDGs are being considered as performance metrics against the supplier development initiatives but there is as yet no link between the small scale, local level of activity, with the macro level.

Case study 2: Côte D'Ivoire

This case concerns the well known and much written about sustainable cocoa supply chain in in Cote D'Ivoire (which accounts for around 33% of global supply). In contrast to the previous example this supply chain is characterised by a complex network without a clearly defined single territory for the production and processing of cocoa beans. The role of trading companies and the commodity nature of the product means that gaining traceability is a particular challenge. However as in the case above the challenge to provide greater levels of value add and yield in the production locality and to support sustainable development goals is a key focus for a number of stakeholders in the locality as well as from global MNEs sourcing from the region. In particular the Côte d'Ivoire Sustainable Cocoa Initiative bringing together national governments (in CI and Europe, trade bodies and private companies), specifically to help build capacity/capability in the production of cocoa in a sustainable way. Similar to the case above the production is often within vulnerable forestry areas carried out by local farmers. The main supply chain stages are cocoa bean growing and grinding, before shipping to Europe or the US for use primarily in confectionary products. While the bean production is spread across many thousands of small holders (and some larger cooperatives), the grinding process is concentrated to major purchasers Cargill, SAF Cacao and ADM, some operating large capacity processing plants mainly in Abidjan and San Pedro. However the majority of exports (90%) are beans, with exports are divided between a few very large players mentioned before plus Nestle, Kraft, Ferrero for consumer products. Supplier development and capacity building issues centre round the adoption of sustainable cocoa production at the grower level and the inclusion of more value add in Cote D'Ivoire to support greater economic and social sustainability.

Conclusion

In the regional examples, from West Africa and Brazil, supply chains stretch between multinational corporation (MNC) purchasers and low income agricultural suppliers facing environmental impacts and social imperatives. Multiple levels are explored from market-scale impacts of an MNC to the local impacts of a borderline subsistence farmer, various structures are explored. Key nodes are intermediary wholesalers, or workers co-operatives, including in the processing of commodities (Marsden & Smith, 2005) highlighting structures of supplier development and link to provenance and transparency challenges. Supplier capacity building for sustainable development is dependent on these structures of the supply base in such countries. Identifying these forms is important where reports of barriers to sustainable development are prompted by over-dependency on natural resource exports (whether agricultural or mineral) and related exposure to commodity price volatility and outward migration of capital (noted by UNCTAD), hence a need to move up the value chain.

From a strategic management perspective, international development questions can be interpreted as design of the supply chain network and location of value add activities to fund and build capacity. Numerous anti-MNC campaigns by environmental and development NGOs have exposed a lack of delivery in the face of high sounding targets for progress (whether net zero deforestation, net zero carbon, sustainable palm oil, sustainable cocoa, etc.). Hence MNCs are struggling to realise objectives with current capabilities and are still exploring the most suitable strategy given global standards and local specificities (including political/institutional, financial, infrastructure, skills base and so on).

The conceptual framework that is emerging from the research suggests that the application of RBV to this topic highlights the role of governance, to control and monitor, of capability, to have the resources and abilities to deliver, in order to have a meaningful impact on performance. Yet this needs to reconcile the fair appropriation of value in the supply chain and the question of competitively valuable capabilities whereby capacity building is supported and facilitated by competing firms with common supply chain goals but competing market share objectives. By developing this further, a bridge may be developed between the macro-scale indicators of SDGs (and MNCs promoted targets to support these) and the micro-scale context of supply chains, affecting specific communities and habitats, at the national, regional and local scale.

ABSTRACT

This paper investigates the extent to which supply chain management is implemented in a South African provincial government and its role in accelerating inclusive growth and socio-economic development. Since 2004, supply chain management has gained significance, with regard to the procurement of goods and services by means of fair, competitive and cost-effective systems and processes. It is being used as an enabling mechanism for the South African government to implement policy towards inclusive growth, socio-economic development and transformation. The paper is exploratory and descriptive in nature and based on a survey conducted among supply chain practitioners in a provincial government. Based on the findings, the paper revealed that supply chain practitioners acknowledge the strategic role of supply chain management towards inclusive growth and socio-economic development. However, the maturity of supply chain management implementation is still in an infancy stage and it is not sufficiently used as a strategic. It is evident that the lack of proper implementation of supply chain management may be the root cause of inefficient inclusive and socio-economic development problems in the province. There is need to re-organise and re-align organisation structures in the province to elevate supply chain management practice. The paper recommends three pillars which are critical for accelerating inclusive growth and socio-economic development in the province.

Key words: Supply chain management, inclusive growth, socio-economic development, provincial government, South Africa.

1 INTRODUCTION

Supply chain management (SCM) is a transformation tool in the South African public sector. Since 2004, it has gained significance, with regard to the procurement of goods and services by means of fair, competitive and cost-effective systems and processes (Bent, 2014:14). It is being used as an enabling mechanism for the South African government to implement policy towards socio-economic development and transformation (National Treasury [NT], 2015: 1). The concept of SCM was adoption in the South African public sector management due to the lack of interpretation, accountability and implementation of the preferential procurement policy adopted after the first democratic election. With the adoption of SCM, a roll out implementation plan was established and a generic SCM policy developed (Bent, 2014:15). Since then, SCM has been transformed and the National and Provincial Treasuries embark on training to educate and capacitate SCM practitioners.

However, the potential of SCM is yet to fully achieve. The Auditor General's reports over the years indicated that SCM practices is characterised by fraud and corruption. There is pressure from citizens, service providers and the media on the potentials of SCM towards service delivery excellence (Business Day Report, 2011). The National Treasury (2015) review revealed that the strategic importance of SCM in the South African public sector is not well

understood and SCM is imperfect. There are constant allegations of corruption and inefficiency. Service delivery protests are evident on daily news Medias which are a sign that people feel that they are not receiving the quantity or quality of services they need. Other factors that prevent that affect efficient SCM implementation are: SCM not considered as a strategic function; lack of organisational structures and systems in place; lack of accountability; lack of clarity of roles and responsibility; lack of skills, knowledge and capacity; policies and regulations overlap; confusing and cumbersome; lack of supplier management relationships; strategic balance between major procurement objectives. Hence, the National Treasury have embarked on series of SCM developments in an effort to enhance SCM implementation in the country in line with the National Development Plan (NDP) 2030 vision. According xx, the pace of transformation has been slow and the government has set it sight on transformation and to re-dress unemployment, poverty and inequality. According to the NDP's vision 2030, long-term accelerated economic growth aimed to reduce unemployment and inequality and help create a more inclusive society.

While there has been numerous studies on SCM implementation in the South African public sector (Migiro and Ambe, 2008; Matthee, 2006; Van Zyl, 2006; Ambe and Badenhorst-Weiss, 2011), as well as inclusive growth (Ranieri and Ramos, 2013; Samantha, 2015), there are limited studies on the role of SCM to inclusive growth and socio-economic development especially in the South African context. This paper therefore intends to fill the void. Hence, the purpose of this paper is to:

- Investigate the extent to which supply chain management is implemented in accelerating inclusive growth and socio-economic development in a South African provincial government.

This paper is of utmost importance, as it gives an understanding of the state of SCM implementation in the province. It also contributes to increasing the body of knowledge in the field of SCM, especially on the role of SCM to inclusive growth and socio-economic development in the South African public sector context. The remaining section of the paper presents a theoretical review of SCM and it role to inclusive growth, the research methodology employed, the findings and discussion as well as a conclusion.

2 LITERATURE REVIEW

This section of the paper presents a theoretical review of SCM and inclusive growth. It begins with an overview of SCM in the South African public sector and in South Africa, followed by an overview of inclusive growth and the drivers of SCM to inclusive growth and socio-economic development.

2.1 Supply Chain management in the South African Public Sector

SCM is an important concept in today's business environment as it contributes significantly to the bottom line (Agus, 2011:269). SCM encompasses the planning and management of all the activities involved in sourcing and procurement, conversion, and all logistics management activities. Importantly, it also includes coordination and collaboration with channel partners, which can be suppliers, intermediaries, third-party service providers and customers. SCM can also be approached from different disciplines (Arlbjørn, Freytag and de Haas, 2011:277), namely logistics, purchasing, transportation, operations management, marketing and research (De Haas, 2011). Countries such as the UK, US and Canada have long employed SCM in the management of their procurement and logistics (Mwilu, 2011:3). In the South African public sector, SCM is an integral part of financial management and it is considered a strategic tool for

managing procurement practices. Since 2004, SCM in the South African public sector supply chain has undergone transformation through the introduction of procurement reforms. Hence, SCM is an important aspect of service delivery to governments.

For more than two decades, the South African public sector supply chain has undergone transformation through the introduction of procurement reforms. The procurement reforms began in 1995 and were directed at two broad focus areas, namely, the promotion of principles of good governance and the introduction of a preference system to address socio-economic objectives. The procurement reform processes were embedded in section 76(4) (C) of the Public Finance Management Act (PFMA) and the Preferential Procurement Policy Framework Act (Act 5 of 2000) (PPPFA) (SAMDI, 2005). In 2003 the South African Cabinet adopted a SCM policy to replace these outdated procurement and provisioning practices. The aim was to implement a SCM function across all spheres of government, which would be an integral part of financial management and would conform to international best practices (National Treasury [NT], 2005). The SCM policy framework aimed to promote uniformity and consistency in the application of SCM processes throughout government; facilitate the standardisation and uniform interpretation of government's preferential procurement legislation and policies; as well as complete the cycle of financial management reforms introduced by the PFMA by devolving full responsibility and accountability for SCM related functions, in addition to financial management functions, to accounting officers and authorities (Mkhize, 2004; NT, 2005).

The government over the years have made numerous enactment of procurement reforms and the introduction of SCM as a procurement and socio economic tool, numerous trends and developments have evolved. The National Treasury publishes policies, regulations, practices notes to guide SCM practitioners in government. In 2015, the National Treasury published the first review of the SCM policy, the first major assessment of the system of buying goods and services by the public sector since 2004. In 2011, the Preferential Procurement Regulations provided guidelines for the implementation of the 80/20 and 90/10 preference point systems. A revised preferential procurement policy regulations 2017 made provision for changes with the aim to accelerate inclusive growth and transformation such as tenders targeting specific groups, such as black women; increase of the threshold for 80/20 from 1million to 50 million and 90/10 above 1 million to above 50 million. Also, there is emphasis on procurement of locally manufactured goods and services as well as compulsory subcontracting of at least 30 per cent for tenders above R30 million where feasible, to advance designated groups. Also, in 2015, a revised Codes of Good Practice was enacted to change the way Broad Based Black Economic Empowerment (B-BBEE) scorecards developed in 2003 are calculated.

2.2 Drivers of supply chain management towards Inclusive Growth

Inclusive growth is of high relevance in today's global economy, offering an opportunity to mitigate inequalities and stimulate economic growth (Asian Development Outlook, 2012). Inclusive growth means making sure everyone is included in growth, regardless of the economic class, gender, sex, disability and religion (Ranieri and Ramos, 2013). It takes on a long-term perspective and focus on productive employment. Thus inclusive growth approach took a long-term perspective of development. Anand, Mishra, and Peiris (2013) asserted that the growth is said to be inclusive when it is sustainable in the long run and broad based across different sectors. Inclusive growth has become a central concern in developmental literature and policy decision making in many countries (Ranieri and Ramos, 2013). It has been used in countries such as the USA, Brazil, Viet Nam as well as in Ghana to boost growth, reduce unemployment and inequalities (Samantha, 2015). In South Africa, slow economic growth has

placed enormous pressure on the government finances resulting to the need for inclusive growth. Hence, the need for effective public procurement practices. According to National Treasury (2017), to realise the vision of the country, transformation is needed to open a path to inclusive economic growth and development. The National Development Plan's vision is that, in 2030, long-term accelerated economic growth has reduced unemployment and inequality and helped create a more inclusive society. This is in part due to diligent work in carrying out growth plans such as the New Growth Path, the Industrial Policy Action Plan and the National Infrastructure Plan.

SCM drivers are critical for enhancing the maturity of inclusive growth and socio-economic development initiatives. From a supply chain point of view, maturity can be defined as the level of adoption or realisation of modern collaborative and integrative practices (Bowersox, Closs, and Cooper, 2010). Randeree, Mahal and Narwani (2012:477) defined supply chain maturity as a staged structure of the extent to which a supply chain function has progressed by effectively adopting new processes and best practices. There are however, different dimensions to supply chain maturity as well as no unanimous definition exists (Schiele, 2007:276; Rudzki and Trent, 2011). In this paper, the following dimensions were considered strategic for enhancing the maturity of supply chain practices towards inclusive growth and socio-economic development in the South African public sector:

- **Understanding the strategic importance of supply chain management:**

SCM is one of the strategic mechanisms enabling government to implement policy. Traditionally, SCM has been misunderstood and undervalued. Its strategic importance has not been recognised, and it has been under-capacitated. According to the National Treasury (2015) review, the strategic importance of SCM is not well understood. SCM is explicitly in the public sector in South Africa to pursue socio-economic objectives. Understanding the strategic objective of SCM is therefore imperative (Boateng, 2015).

- **Strategic sourcing and commodity management**

Strategic sourcing is a collaborative, structured approach to analysing government's spending; using the information from this analysis to acquire commodities and services effectively; and as a result supporting government's service delivery objectives. It helps supply chain managers to plan, manage, and develop the supply base in line with these objectives; and creates an understanding of the categories of goods and services in government's spending portfolio, their intended use and the sources of supply (Boateng, 2015). This helps to identify the leverage points, develop appropriate sourcing strategies, reduce costs and increase the benefits and value of the service or commodity to government. The successful implementation of strategic sourcing may lead to an improved understanding of government spending patterns that will assist in optimising the budgeting and planning process and enable sourcing practitioners and decision makers to make better informed decisions (Reuter, 2017). The South African National Treasury in 2015 developed a strategic sourcing framework. The sourcing requires that government adopted a differentiated approach to procurement of the various commodity groups. Using the principles of strategic sourcing means distinguishing between the various categories of commodities and developing appropriate sourcing approaches for each. Categorised commodities presents a proven framework for transforming procurement operations to increase the value the department provides to its organisation. The framework categorises commodities in the country into strategic products, leverage products, routine products as well as bottleneck products (Mail & Gaurdian, 2015).

- **Procurement spend analysis and total cost of ownership (TCO)**

Spend analysis is one of the key tools that procurement organisations use to proactively identify opportunities to optimise their organisation's buying power. Government spends close to R600 billion annually on goods and services, and inefficiency should be a big concern in the procurement processes (Reuter, 2017). In line with the 2017 revised preferential procurement regulation, Departments and municipalities need to set procurement spending targets for SMEs, youths, women, disabled etc. The government has set itself the target of procuring 75% of goods and services from South African producers as part of its drive to create a new class of black industrialists and entrepreneurs (Ramaposa, 2014). With regards to total cost of ownership (TCO), Fawcett, Ellram and Ogden (2007:263) defined (TCO) as a philosophy for understanding all relevant supply chain related costs of doing business with a particular supplier for a particular good/service, or the cost of the process, or a particular supply chain design. TCO enables organisations to understand all specific cost drivers for goods and services and the resulting components that can be used to reduce overall cost. Understanding TCO broadens our baseline understanding of spend and identifies sourcing opportunities beyond purchase price. TCO identifies costs which are made up of two major components - direct and indirect. In the SCM policy, TCO is an important component of the demand management process referred to as TCO or Life Cycle Costing. Consideration for TCO is required in the development of the specification. This is particularly important for the procurement of assets, from need through planning to disposal.

- **Enterprise and supplier development**

Enterprise and supplier development (ESD) within the context of the South African BBBEE scorecard is defined as a program of developing SMMEs, called beneficiaries, by investing time, money, and capital in order to contribute to the development, sustainability, financial independence, and operational independence of those beneficiaries. According to the BBBEE Act, ESD is a combination of preferential procurement, enterprise and supplier development. Leveraging procurement to influence the development of the local supplier industry is key to realising Government's objectives relating to growth, employment creation and equality Morales-Nieto (2008). Pooe (2016:3) define ESD as the process of strengthening the integration of small firms with potential growth and expansion into the economic mainstream. ESD is a critical of the qualifying contributions which can reflect positively on an organisation's BEE Scorecard. ESD measures the extent to which organisations buy goods and services from suppliers with high BBBEE recognition levels. SMMEs contribute significantly to growing the economy; generally referred to as "drivers of economic growth" (Sithole, 2014). ESD alone contributes 40% of the entire BBBEE scorecard. Developing an ESD policy and objectives is imperative. Small Businesses represent 98% of the firms in South Africa, but only have a 9% survival rate over a 10-year period. For this reason, the major emphasis of ESD is the long term sustainability of these small businesses. According to Accenture (2012), the government is legally binding and have an obligation to develop suppliers and participate in ESD initiatives.

- **Supplier performance and contract management**

SCM performance exerts considerable influence on the actions of organisations as a result; most of these businesses realise that, to evolve an efficient and effective. Performance measures such as cost savings, quality, on-time delivery, and efficiency are not included in SCM scorecards (Accenture, 2012). For performance to be managed it needs to be measured first, an organisation must identify and implement a supply chain performance measurement system which bests suits the objectives of the organisation and such system must be aligned with the

organisational strategic goals. According to Ambe (2016), there are inefficiencies in contract performance, monitoring and evaluation mechanisms. Failure to monitor contract performance results in non-completion and or late completion of government projects". The are several reports of poor supplier performance and late delivery of projects in government. Supplier performance is usually done outside the SCM processes. SCM responsibility ends when a supplier is appointed (Accenture, 2010:3). The supply chain practitioner's key performance indicators are not linked to the overall business objectives; this is more prevalent in government where SCM is regarded as a procurement tool for accelerating transformation and inclusive growth, hence, the need to assess and properly manage contracts (Charan, Shankar & Baisya; 2008: 513).

- **Supply chain management implementation challenges**

SCM was introduced in the South African public sector was to introduce internationally accepted best procurement practice principles, while at the same time addressing Government's preferential procurement policy objectives (Office of Government of Commerce [OGC], 2005). It was aimed to address deficiencies in practices related to procurement, contract management, inventory and asset control and obsolescence planning (NT, 2003; Mkhize, 2004). Mnguni (2012:49) asserted that each government entity had to adopt SCM policy to suit its needs (NT, 2015:1). By virtue of the adoption of SCM practices in the South African public sector, national and provincial departments; local government (municipalities) as well as parastatals are expected to implement SCM efficiently and effectively to ensure good governance, preference and the socio-economic objectives of the country. Notwithstanding the adoption of SCM policies and practices across all spheres of government, its implementation remains a challenge, especially in local government. Universal challenges facing government SCM are suboptimal operational performance, weak corporate governance, poor performance of the board, corruption, political influence and poor service delivery (PWC, 2015:2). There are evidenced in daily reports of irregularities in newspapers, television, radio and social media. A report by the Auditor General of South Africa (AG) (AG, 2010- 2015) highlights challenges of non-compliance and irregular expenditure.

Following presentation and an overview of SCM as a driver to inclusive growth and socio-economic development and the challenges thereof, the next section of the paper presents the research methodology.

3 RESEARCH METHODOLOGY

This paper investigates the extent to which SCM is implemented in accelerating inclusive growth and socio-economic development in a South African provincial government. The paper is descriptive and exploratory in nature based on a survey conducted in a provincial government in South Africa. The provincial government embarked on SCM reforms in line with the National Treasury imperatives to ensure that, there are efficient use of its resources on the procurement of goods and services to drive socio-economic development and inclusivity of resources. The provincial government constitute twelve departments, five district municipalities and associated local municipalities as well as five provincial entities. A survey was conducted on senior supply chain managers in the province based on face to face interview (provincial department, municipalities as well as municipal entities). A purposive sampling technique was used and the focus was on senior supply chain managers (Head of supply chain) with expert knowledge on supply chain practices. Specific participants for interviews were thus selected according to their strategic positions and seniority in their organisations. The interview questions were semi-structured and measured using a five-point Likert response format with the end points (1) "strongly disagree" and (4) "strongly agree". A total of 55 (N = 55)

interviews were conducted from 20 provincial departments, 25 municipalities and 10 provincial entities. The data were analysed descriptively using the Statistical Package for Social Sciences (SPSS).

4. FINDINGS AND DISCUSSION

This section of the paper presents the results and discussion.

4.1 Presentation and Analysis of Findings

Five driver of SCM towards inclusive growth were empirically investigated. Presentation, analysis and interpretation of the results are discussed under different sub-headings such as the strategic importance of SCM, strategic sourcing, enterprise and supplier development, supplier performance management, commodity management, procurement spend analysis, total cost of ownership, challenges in the supply chain as well as the contribution of SCM to socio-economic development as indicated below:

- **Strategic importance of supply chain management**

Respondents were asked to indicate on a five-point Likert response format with end points 1 (strongly disagree) and 4 (strongly agree no extent), the extent to which they agree on the importance of their supply chain to inclusive growth and socio-economic development. The findings are presented in percentages as reflected in table 1.

Table 1: Perception of respondents on the strategic importance of supply chain management

Statements	SD	D	A	SA
SCM is seen as a back office role	17%	37%	30%	17%
SCM is a ticking box exercise	30%	52%	6%	12%
SCM helps to maximise limited resources in government	4%	15%	35%	46%
SCM is used to address inequalities of the past	2%	7%	40%	46%
SCM provide strategic direction in government	4%	9%	42%	45%
SCM is a regulatory instrument	6%	7%	44%	41%
SCM drives transformation to empower previously disadvantaged individuals	2%	9%	40%	49%
SCM contribute towards socio-economic development	0%	15%	30%	55%
SCM is contribute to SMMEs development	10%	27%	27%	37%

The results indicates that most of the respondents are of the view that SCM helps to maximise limited resources in government (81% agreement) and it is a transformation tool (79% agreement). It is important to note that most of the respondent do not believe SCM is ticking box exercise (82% disagreement). Interestingly, only 46% of the respondents see SCM as a back office role, hence, it is strategic towards the province socio-economic imperatives. Therefore, the practitioners do understand how strategic SCM is towards inclusive growth and contribute to socio-economic development [91% agreement]. All the respondents were of the view that SCM contributes to socio-economic development in the province. The respondents believe SCM drives transformation and restructuring to accommodate the previously disadvantage (89% agreement); and that SCM contribute towards job creation and the economy (85%). Furthermore, the respondents noted that regulatory regime change contribute to socio-economic development (89% agreement). However, only 62% of the respondents believe there is enough investment in the development of SMMEs (64% agreement). The finding alludes that SCM practitioners do understand how important SCM is towards inclusive growth and socio-economic development. However, implementation remains a challenge. The results

supports the fact that SCM is critical for the advancement of socio-economic development in the country.

- **Strategic sourcing and commodity management**

Respondents were asked to indicate on a five-point Likert response format with end points 1 (strongly disagree) and 4 (strongly agree no extent), the extent to which they agree on statement s regarding strategic sourcing and commodity management. The findings are presented in percentages as reflected in table 2.

Table 2: Perception of respondent with regards to strategic sourcing and commodity management

Statements	**SD**	**D**	**A**	**SA**
Strategic sourcing is aligned with organisation's annual procurement plan	16%	31%	29%	24%
Procurement plan are analysed for the purpose of developing sourcing strategies	13%	42%	25%	20%
Strategic sourcing process is concerned about quality	5%	18%	45%	31%
Strategic sourcing team conducts industry analysis	15%	35%	29%	22%
We have different categories of commodities	6%	24%	46%	24%
We conduct need assessment	7%	19%	48%	26%
We apply different procurement strategies for different commodities	9%	30%	41%	20%
We engage with key stakeholders during SCM processes	0%	23%	43%	34%
We perform market research before deciding on commodity strategy	11%	30%	28%	31%
We use simplified processes in the procurement of stationary and office equipment	6%	9%	59%	26%
We maximise commercial advantages when procuring travel and accommodation	6%	17%	56%	22%
We ensure continuous supply in the procurement of specialised commodities such as medical equipment	3%	38%	38%	21%
We form partnerships with our strategic suppliers	4%	63%	17%	15%

Table 2 reveals that strategic sourcing practices is to some extent aligned with the organisational annual procurement plan (53% agreement). However, the transactions on the procurement plans are not properly analysed for the purposes of developing sourcing strategies (55% disagreement). The respondents feels strongly that in the sourcing process, the concern is about quality than price (76%). Hence, the sourcing team do not always conduct industry analysis in the sourcing process (an average of 50% for agreement and disagreement). With regards to commodity management, the analysis of the data shows the perspectives with regards to commodity management. The respondents do agree that they have different categories of commodities in different departments (70% agreement); and they conduct needs assessment before procurement of goods and services (70% agreement). The respondents strongly disagreed with the statement that they form partnerships with suppliers in the procurement of strategic commodities.

- **Procurement spend analysis and total cost of ownership (TCO)**

Respondents were asked to indicate on a five-point Likert response format with end points 1 (strongly disagree) and 4 (strongly agree no extent), the extent to which they agree on

statements regarding procurement spend analysis and total cost of ownership. The findings are presented in percentages as reflected in table 3.

Table 3: Perceptions of the respondents with respect to procurement spend analysis and total cost of ownership

Statements	**SD**	**D**	**A**	**SA**
We perform procurement analytics annually	15%	36%	38%	11%
We know how much is spend on designated groups in our database	13%	36%	45%	11%
We keep statistics of spending on different categories of commodities	11%	28%	53%	8%
We have a quantified deviation register	6%	17%	49%	28%
We only consider price for the procurement of goods and services	15%	35%	29%	21%
We consider both direct and indirect costs when procuring goods and services	2%	23%	48%	27%
Our sourcing process takes into consideration TCO	4%	15%	46%	35%

With regards to procurement spend analysis, just above average (51%) of the respondents are in agreement that pprocurement analytics is perform annually. However, they are not sure of how much is spend on the various designated groups in their database (51% disagreement). Also, they do not have statistics of spending trends on the different categories of commodities that is procured (61% disagreement). Furthermore, the respondents did not have quantified deviation register (77% disagreement). This indicate that to a large extend procurement analytics is not well implemented to inform procurement best practices and compliance. For TCO, an average (50% agreement) of respondents indicated that only price is considered for the procurement of goods and services. A third (75% disagreement) of the respondents were of the view that they consider both direct and indirect costs when procuring goods and services. Furthermore, most of the respondents (81% disagreement) disagreed with the statement that their sourcing process takes into consideration total costs of ownership. Based on the results TCO is not well understood and implemented by institutions in the province.

- **Enterprise and supplier development**

Respondents were asked to indicate on a five-point Likert response format with end points 1 (strongly disagree) and 4 (strongly agree no extent), the extent to which they agree on statements regarding enterprise and supplier development. The findings are presented in percentages as reflected in table 4.

Table 4: Perceptions of the respondents on enterprise and supplier development

Statements	**SD**	**D**	**A**	**SA**
We have an ESD strategy in place	33%	39%	25%	2%
Our ESD strategy accommodates changing government regulations	35%	42%	19%	4%
Our ESD strategy has been translated into clear key performance indicators	34%	47%	17%	2%
Our ESD strategy is fully integrated with our sourcing and demand planning processes	32%	46%	18%	4%
Our ESD implementation plan is very clear	39%	39%	19%	4%

We have dedicated resources to implement our ESD strategy	39%	39%	15%	7%
Our ESD outputs are included in management performance contracts	41%	41%	15	4%
Our ESD process is close monitored and reported at Executive Management on a monthly basis	42%	42%	13%	4%
Our procurement plans has opportunities for SMMEs development	6%	21%	30%	43%

Based on the results, enterprise and supplier development initiative in the province is still in an infancy stage. Most of the respondents do not have an enterprise and supplier development strategy in place (72% disagreement) in their departments, municipalities and entities. The respondents do not have have an enterprise implementation plan (78% disagreement) and they do not not have a dedicated resources available for such initiatives (78% disagreement). However, they are opportunities in the procurement plans for SMMEs development (73% agreement). Therefore, the provincial government need to create sensitisation on the strategic importance of enterprise and supplier development towards job creation and upliftment of the living conditions in the province.

- **Supplier performance and contract management**

Respondents were asked to indicate on a five-point Likert response format with end points 1 (strongly disagree) and 4 (strongly agree no extent), the extent to which they agree on statements regarding Supplier performance and contract management. The findings are presented in percentages as reflected in table 5.

Table 5: Perceptions of the respondent about supplier performance management

Statements	**SD**	**D**	**A**	**SA**
Our contract management process is fully document	4%	28%	39%	30%
We utilise standard contract documents issued by National Treasury	0%	9%	58%	33%
We have structured service level agreement in place	2%	7%	60%	31%
We have formal review process in place for all contract	6%	28%	37%	30%
Our suppliers are held accountable for poor performance through contracts	5%	33%	33%	29%
We pay our suppliers within 30 days of invoice	4%	16%	53%	27%
We have periodic meetings with our strategic suppliers	2%	33%	38%	27%

Concerning table 5, the contract management process is to an extent documented (69% agreement). Standard bidding documents issued by the National Treasury are used for all transaction (91% agreement) while there are structured level agreements in place with their suppliers (91% agreement). However, just over half of the respondent felt that suppliers are held responsible for poor performance through contracts (62% agreement). It is interesting to note that suppliers invoices are settled within 30 days (80% agreement) and there are periodic meeting with suppliers (65% agreement). Therefore, the province have created a lot of sensitisation on the strategic importance of supplier performance which may have an effort for good contract management processes.

- **Supply chain management implementation challenges**

Respondents were asked to indicate on a five-point Likert response format with end points 1 (strongly disagree) and 4 (strongly agree no extent), the extent to which they agree on statements regarding SCM implementation challenges. The findings are presented in percentages as reflected in table 6.

Table 6: Perception of the respondents on supply chain challenges

Statements	**SD**	**D**	**A**	**SA**
Our SCM policies and regulations are fragmented	2%	33%	49%	16%
We do not have effective contract management systems	6%	37%	44%	13%
Our SCM objectives are not effectively communicated to staff	4%	36%	42%	19%
There is resistance to change in SCM systems by management	2%	25%	34%	40%
Our SCM planning is poor	2%	15%	34%	40%
We have cases of fraud and corruption reported	4%	17%	65%	13%
There is lack of skilled SCM workforce	0%	8%	72%	21%
There is unwillingness to share information due to lack of trust among SCM members	6%	26%	36%	32%
There is inadequate accountability and control mechanism	10%	31%	50%	10%
There is lack of top management support to the integrative SCM approach	13%	23%	36%	28%

From table 6, the findings revealed that there is fragmentation of supply chain policies and regulations (65% agreement). Just over half of the respondents believe there is poor implementation of contract management systems (57% agreement). Furthermore, 61% are of the view that the respondents feel that supply chain objectives are not effectively communicated. An interesting observation is that there is resistance to change in supply chain systems by top management/leadership (74% agreement). 93% of the respondent are of the view that there is poor procurement planning. The respondents noted that there is unwillingness to share information with to supply chain members due to lack of trust (68% agreement), inadequate accountability and control mechanism systems (60% agreement). In line with table 18, there is lack of top management support to the integrative SCM approach (64% agreement). This results confirms reports of the National Treasury (2015) reviews and also the baseline study conducted by the National Treasury (2016), on the state of implementation of SCM in the country.

4.2 Discussion of the Results

Following the results and analysis, it could be deduce that SCM drives transformation and restructuring to accommodate the previously disadvantage and that SCM contribute towards job creation and the economy. It is also critical for the advancement of socio-economic development in the country. SCM practitioners in province do acknowledge the strategic importance of SCM towards inclusive growth and socio-economic development. However, the implementation to a great extent is a challenge. Strategic sourcing is to some extent aligned with organisational annual procurement plan in the province. However, the sourcing team do not always conduct industry analysis in the sourcing processes as well as lack of strategic partnerships with suppliers in the procurement of strategic commodities. Procurement plans and targets are always not followed and respected. Thus, it has become a paper exercise. Enterprise and supplier development initiative in the province is still in an infancy stage. Most of the departments, municipalities and entities donot have an enterprise and supplier

development strategy in place as well as dedicated resources available for such initiatives. Nevertheless, there are opportunities in the procurement plans for SMMEs development. Furthermore, a lot of sensitisation on the strategic importance of supplier performance has been made as an effort for good contract management processes. In conclusion, some of the challenges identified hindering effective implementation are: fragmentation of supply chain policies and regulations; poor implementation of contract management systems; supply chain objectives are not effectively communicated; poor procurement planning; unwillingness to share information with to supply chain members due to lack of trust, inadequate accountability and control mechanism systems. An interesting observation is that there is resistance to change in supply chain systems by top management/leadership.

Inclusive growth requires the provincial government to break down structural impediments to new economic activities, deconcentrate industries dominated by few participants, and accelerate the inclusion of black designated groups into jobs and businesses. Three pillars of SCM that could accelerate inclusive growth and socio-economic development include:

- ✓ Improve SCM capacity development and professionalisation;
- ✓ Ensure ethics and good governance; and
- ✓ Enforce strategic procurement.

- **Ethics and Good Governance in Procurement**

Good, ethical governance is the key driver of a capable developmental state, and generates sustainable development without compromising the results. Significant capital and human resources have been deployed to enhance the NDP's objectives in the province. The following measures should be put in place to ensure ethics and good governance:

- Enforce laws and regulations to combat corruption
- Put system in place to detect and combat corruption
- Improving governance of public sector SCM through cooperation with stakeholders
- Improving governance of SCM through transparency
- Ensure *accountability by politicians and officials*, particularly the accounting officer and the SCM officials.
- *Promotion of ethical leadership across the provincial leadership.*
- Developing and prescribing a public disclosure framework to govern transparency within the SCM process.

- **Building Supply Chain Capacity and Professionalisation**

The shortage of skills remains one of the top constraints to effective SCM implementation. Following the findings, it is imperative to note that SCM operate at low levels of professionalism and competence, with assigned little organisational status and not seen as a value driver. A mind-set shift is needed so that SCM is located amongst government entities' highly strategic functions to transform and create value through its activities. Key activities to develop, empower competent and committed SCM employees should include:

- Promoting informal and formal workplace learning.
- Promoting workplace coaching and functional mentorship.
- Supporting the development and delivery of education and training programmes.

- **Strategic Procurement**

Procurement has important economic and political implications, and ensuring that the process is economical, efficient and crucial. However, it is often seen as a back office role within the public sector. It is not viewed as strategic by public sector decision makers. Its contribution is unfortunately seen as minimal and transactional. It is viewed purely as a 'number crunching

exercise as opposed to a value-added and strategic business development function, placing it at a rather low position within an organisation (Boateng, 2014). Procurement officials in the province should focus on long term supplier relationship, local economic development in favour of emerging local suppliers. Therefore, improving procurement practices in the province by removing obstacles and boosting the involvement of SMMEs is a key priority for inclusive growth and socio-economic transformation. The provincial government therefore need to identify efficient ways for procurement to realise value for money, create opportunities and promote beneficial change. Table 7 provides a guideline on how the provincial government can accelerate inclusive growth through strategic procurement.

Table 7: Accelerating inclusive growth through strategic procurement

Phases of SCM	**Description**
Demand management	Develop an effective procurement plans
	Develop specific target for different designated groups
	Clearly stipulate sourcing methodology to be used for each procurement.
	Categorise commodities and identify commodity managers/champions.
	Develop a "SMART" specification to cater for: • Local content • Designated groups • Sub-contracting • Enterprise and supplier development • Preference point systems applicable • Allocation & breakdown of BEE points } Drivers of inclusive growth
Acquisition (bid evaluation)	Enforce transformation criteria in the specification during evaluation
Contract and supplier performance	Evaluation of supplier performance in line with transformation criteria

CONCLUSION

Since 2004, SCM has gained significance in the South African public sector. It is being used as an enabling mechanism for the government to implement policy towards socio-economic development and transformation. The paper investigates the extent to which SCM is implemented in accelerating inclusive growth and socio-economic development in a South African provincial government. A survey was conducted among senior SCM managers from provincial government, municipalities as well as provincial entities.

Following analysis and discussion, the findings revealed that SCM practitioners in the province do understand the importance of SCM towards inclusive growth and socio-economic development. However, the maturity of SCM is still in an infancy stage and SCM is not sufficiently used as a strategic function. The report confirms to the views of the SCM (2015) review that SCM is imperfect. The province is challenge with skills, competencies and knowledge of SCM practitioners, non-compliance to policies and regulations, ethical conduct and political interference in achieving the full potential of SCM towards inclusive growth. Therefore, harnessing the potential of SCM requires a major physiological change and

embracing the strategic role within governments. There is also need to re-organise and re-align organisation structures to elevate SCM. The paper concludes with a recommendation on how SCM could be enhanced. Three pillars of SCM were identified as a blueprint to accelerate inclusive growth and socio-economic development in the provincial government: SCM capacity development and professionalisation; ethics and good governance; and strategic procurement.

The role of manufacturing automation as an enabler of reshoring

Alessandro Ancarani[1], Carmela Di Mauro[2], Francesco Mascali[3]
DICAR, Università di Catania, Viale Doria 6, Catania

Abstract
Building on a data set of over 800 reshoring initiatives in manufacturing, this paper explores the extent to which automation and additive manufacturing have acted as enablers of the relocation of production to high cost countries. The paper further delves into the linkages between offshore challenges, firms' competitive strategies and reshoring enabled by these technologies. Results suggest that the adoption of these technologies is tied to cost-oriented motivations underlying reshoring. Results also highlight distinct patterns for US and European manufacturing companies, in terms of perceived challenges offshore.

Keywords: Automation; Innovation; Reshoring.

Introduction

In recent years, there has been a rising interest in the reshoring of manufacturing (Fratocchi et al., 2014; Foerstl et al., 2016), intended as the relocation back to the country of origin or in its proximity of production processes previously moved to low cost countries.

Operational and strategic challenges that firms face in the offshore locations, causing actual performance to fall short of the expected target, have been pinpointed as being at the root of reshoring (Hartman et al., 2017). These challenges may arise out of an ex ante mistaken evaluation of the expected costs and benefits of offshore production (Bals et al., 2016; Gray et al., 2013; Kinkel and Maloca, 2009), or may reflect ex post changes that require a reassessment of locational advantages (Bals et al., 2016; Fratocchi et al., 2016). In this latter respect, several observers have attributed reshoring to the reduced labor cost differentials between high cost countries (HCCs) and low cost countries (LCCs), and to rising logistics costs (Kinkel, 2014; Simchi-Levi et al., 2012). Others have stressed issues such as unsatisfactory product quality offshore (Ancarani et al., 2015), and the growing need for production flexibility (Kinkel, 2014) and customer responsiveness (Moradlou et al., 2017). Several recent review articles have provided extensive discussions of the main offshore challenges that motivate reshoring (among others, Bals et al., 2016; Di Mauro et al., 2017; Foerstl et al., 2016; Fratocchi et al., 2016).

At the same time that some of the locational advantages of LCCs shrink, new opportunities arise in HCCs, encompassing the higher value attached by customers to "made in" products (Ancarani et al., 2015; Grappi et al., 2015), the lower cost of energy (Simchi-Levi et al., 2012; Tate, 2014), and governmental subsidies for reshoring (Joubioux and Vanpoucke, 2016; Tate, 2014).

Besides these changes in locational advantages, reshoring decisions have been influenced also by market and technological developments. Market factors include growing international competition, increasing market volatility, rising demand for highly customized products, and shortened product life cycles (Wiengarten et al., 2017). As part of the technological developments, automation and digital solutions are increasingly being embraced in manufacturing, driven by advancements and falling costs in digital technology (McAfee et al., 2012; Fitzgerald et al., 2014; Kotter, 2014; Schoenherr and Speier-Pero, 2015).

[1] Alessandro.Ancarani@unict.it
[2] cdimauro@unict.it
[3] fmascali@dica.unict.it

As a matter of fact, several scholars have pinpointed the availability of new technologies as the key enabling factor for reshoring, arguing that the return of traditionally labor intensive productions to HCCs to be economically sustainable only if coupled with the adoption of labor saving technologies. In fact, automation and digitalization improve product manufacturability, reduce time and waste in production processes, and eventually reduce the firms' reliance on labor (Arlbjørn, and Mikkelsen, 2014; Bals et al., 2016; Heikkila et al., 2017). However, current evidence on the extent to which the adoption of new technologies acts as enabler of the return of manufacturing to HCCs is scarce, and there is a similar dearth of conceptual elaboration on which value chains are most likely to be reshored exploiting the potential advantages technology creates. In order to fill this research void, the aim of the present study is threefold:

a) To develop a conceptual framework explaining the likelihood of adoption of advanced production technologies as part of reshoring;
b) To provide empirical evidence on the extent to which reshoring is associated with new technologies;
c) To explore whether reshoring taking advantage of new technologies responds to specific offshore challenges and firms' competitive strategies.

This analysis can shed light on macro aspects of reshoring, by identifying initiatives that we may expect in the near future in terms of sectors involved, firms' size, and country specificities. In this respect, this paper can contribute to inspire policies supporting the return of manufacturing to HCCs (Ketokivi et al., 2017; Spring et al., 2017). Micro level implications can be obtained by gaining understanding on the link between new technology adoption and specific competitive strategies. In this light, the results may inform the reshoring decisions of manufacturing companies.

The paper is organized into the following sections: Section 2 discusses theoretical underpinnings of reshoring initiatives, while Section 3 introduces the expected impacts of automation and additive manufacturing on reshoring. Section 4 elaborates on the types of reshoring strategies, and develops testable hypotheses. The empirical analysis is presented in Section 5. Section 6 provides a discussion of empirical results vis-a-vis our conceptual model, while Section 7 concludes with limitations and future research directions.

Theoretical background

Several theoretical approaches have been applied to the analysis of location decisions (international trade theories, international business, strategic management theories), each highlighting different core factors explaining location choice. Two important theories that can enhance our understanding of reshoring are Transaction Cost Economics (TCE) and Resource based view (RBV) (Foerstl et al., 2016; Fratocchi et al., 2016). In light of these theories, firms make location choices evaluating the efficiency of the control and coordination structures, and searching long-term competitive advantage (McIvor, 2013). Both theories have been applied to evaluate the conditions for disintegrating, mobilizing, or re-integrating specific value chain activities from a geographical point of view.

According to TCE, the rationale for offshoring production activities, especially those involving more manual routine tasks, stems from the fact that they require low monitoring and enforcing costs towards foreign subsidiaries and suppliers, and do not require coordination costs since they are independent from other company functions and stages of the value chain (Mudambi, 2008; Ketokivi et al., 2017). This makes location in LCCs attractive, because of the benefits of low labor costs and economies of scale.

RBV describes firms as bundles of resources that are heterogeneously distributed, with resource differences persisting over time. The selection of which sections of the manufacturing value chain to outsource/offshore should then be undertaken looking at how the decision

impacts upon the long-term capabilities of the organization, in order to avoid that over time key capabilities are relinquished (McIvor, 2013). In this perspective, the relocation of some activities can be considered part of the global disaggregation/aggregation of the value chain, as firms try to combine the comparative advantages of geographic locations with their own resources and competencies, with the goal to maximize their overall competitive advantage (Mudambi and Venzin, 2010). Firms retain control over the components or processes of the value chain through which they can create and appropriate the most value (Jensen et al., 2013), while outsourcing and/or offshoring less value adding activities (Mudambi, 2008).

In the so-called "smile curve" of the value chain (Mudambi, 2008) both TCE and RBV combine to explain the offshoring of manufacturing activities. Production activities are offshored because they are identified as standardized, modular and low value adding activities (Sturgeon, 2002), with respect to value-chain activities at the upstream (e.g., design and R&D) and downstream ends (e.g., marketing and after-sales services), which are more knowledge intensive and require non-replaceable skilled workers that command high wages and allow for market power. Therefore, manufacturing can be offshored to LCCs while upstream and downstream value chain activities are often retained in HCCs.

Reversing the above arguments can contribute to explain reshoring initiatives. A TCE-consistent explanation for the geographical re-concentration of the manufacturing value chain in HCCs implies an increase in coordination and control costs that firms face offshore with respect to the home country. These higher transaction costs may be caused by rising uncertainty, specificity of operations, or frequency of transactions within the value chain (Williamson, 1981). The greater degree of customization, differentiation, and product innovation currently required by many markets (Ashby, 2016; Bailey and De Propris, 2014; Bals et al., 2016) may all conjure to increase the specificity of production activities, therefore requiring a tighter control (through geographical proximity) and greater coordination within the value chain (e.g. between production and R&D). In terms of the shape of the value chain curve, customization, differentiation, and product innovation will translate into a higher value added content of production. This phenomenon, known as product upgrading (Humphrey and Schmitz, 2002), determines a "smirking" rather than a "smiling" value chain curve.

Conversely, in the perspective of RBV, reshoring may follow from the opportunity to exploit competencies geographically held in the home country, such as the competences residing in local industrial clusters (Di Mauro et al., 2017), greater labour skills that lead to higher product quality (Ancarani et al., 2015), or from the more effective protection of intellectual property rights in HCCs with respect to LCCs (Tate et al., 2014; Tate, 2014; Wiesmann et al., 2017).

The extension of RBV to dynamic environments that require fast adaptation of sources of competitive advantage (Dynamic capabilities theory, Teece et al., 1997), may also contribute to explain reshoring. Dynamic Capabilities identify the capacities to "sense" and "shape" opportunities and challenges, to grab opportunities, and to maintain competitiveness through enhancing, combining, protecting, and, when necessary, reconfiguring the firm's resources (Helfat and Peteraf, 2009; Pezeshkan et al., 2016; Teece, 2007). They encompass the capacity for improving quality and managing human resources, and the capacity for utilizing new technologies (Drnevich and Kriauciunas, 2011). In this light, reshoring may be viewed as the outcome of the learning process that builds on the firm's dynamic capabilities, and through which the firm identifies the opportunity to develop a more effective strategy by relocating production back to the home country, reshuffling the firm's resource base, and taking advantage of a geographically shorter value chain.

Advances in manufacturing technologies and reshoring

In recent years, growing international competition, increasing market volatility, demand for highly customized products and shortened product life cycles have created serious challenges

for manufacturing, making it necessary to simultaneously handle demands for cost-efficiency, flexibility, adaptability, and sustainability. In this direction, the rapid technological progress promises to open up a range of new business opportunities (Wollschlaeger et al., 2017), with new paradigms such as digitalization, internet of things (IoT), internet of services (IoS) and cyber-physical systems (CPS). The definition of "Industry 4.0" (Kagermann et al., 2013) identifies a systematic high-tech strategy, encompassing the integration of robotics, 3DP, big data analytics and IoT (Gress and Kalafsky 2015; Hofmann and Rüsch, 2017). These technologies promise to achieve a higher level of operational efficiency and productivity by providing IT-enabled mass customization of manufactured products, and to make the adaptation of the production chain automatic and flexible, by tracking parts and products, and facilitating communication among parts, products, and machines (Lu, 2017; Roblek et al., 2016).

Although robots and digital tools have already been inside companies for many years, what has changed recently is the acceleration of both the capabilities enabled by these tools, as well as the pace of adoption (Schoenherr and Speier-Pero, 2015), determined by the higher maturity of ICT and lower costs of hardware and software (Fraunhofer ISI, 2015). These technological innovations have the potential to create new sources of value for the business, resulting in a dynamic reconfiguration of the firm's resources (Galunic & Eisenhardt, 2001), therefore acting as and engendering appropriate dynamic capabilities.

Scholars have recently supported the idea that automation and, more generally, Industry 4.0 technologies, can be considered enablers of reshoring strategies. In fact, the conventional wisdom that HCCs do not need to manufacture and can simply act as a "hub" for high value added activities can be overturned by using the new generation of automated and digital technologies, which can be considered a great "equalizer" of location costs, as they allow to reduce products' unit cost by means of improved productivity and reduced scraps (Bals et al., 2016). This view is fully embraced by managers of reshoring firms. For example, Monster Moto President declared: *"We can't just blow up our cost structure, the only way to make it work in America is with robotics"*. Along the same lines, the vice president of the Confederation of Danish Industry: *"We can see the same trend in Europe that robots and automation are the driving forces of moving the production home, as they keep the payroll down," (Robotics Business Review, December 29, 2016).* (GeoCache, July 15, 2014).

Other benefits of adopting new technologies *while* relocating to HCCs may stem from the growing demand for customization and differentiation of products, which is making flexible production and shorter value chains advantageous (Simchi-Levi et al., 2012). Variety increases transport and logistics costs, as the production unit has to deliver each product in smaller batches, and to keep extra inventory to account for unforeseen variation in consumer demand across varieties (Zhou and Wan, 2017). In this perspective, technologies allowing for lower costs of flexible production will likely promote reshoring initiatives (Lu, 2017).

Finally, new technologies may drive reshoring also in those instances in which the geographical reintegration of the value chain is important for new product development, prototyping, etc. In these cases, the co-location of production and development may become a source of greater value creation at the manufacturing stage, by exploiting linkages economies (Ketokivi et al., 2017). In particular, technologies such as additive manufacturing may be called both at the development stage to aid prototyping and at the manufacturing stage to curb production costs, therefore becoming effective enablers of reshoring. The following example reports a paradigmatic case of a company benefitting from 3D printing in the development and production stages. Thinklabs, a company producing stethoscopes, outsourced production to China in 2003 but, by fall 2013, the company convinced itself that, with careful design, it could mass-produce stethoscope parts using 3D printing, therefore significantly increasing design and production flexibility.

To sum up, advanced and additive manufacturing technologies may provide strong incentives for reshoring when they contribute to reduce the benefits of extreme specialization and enhance flexibility, and when they are adopted within production-development coupled processes.

Model development

Building on the discussion of the previous two sections, in this section we propose a conceptual model that identifies three possible strategies underlying the reshoring of offshore production (Fig. 1). Following the manufacturing strategy literature (Parthasarthy and Sethi, 1993), we identify a pure quality-oriented strategy, a pure cost and efficiency driven strategy, and a flexibility-oriented strategy. The first two reshoring/strategy types are also related with the two main generic competitive strategies, oriented either to value/differentiation or to cost/efficiency (Wheelwright, 1978; Porter, 1980), while the third path is defined as a hybrid strategy as it aims at competing in the market based on product/volume mix and product innovation in a cost effective manner (Parthasarty and Sethi, 1993). We argue that the likelihood of adoption of advanced and additive technologies as part of the reshoring initiative differs according to the competitive strategy. The rationale is that strategy types are directly related to manufacturing competencies and that, especially under conditions of evolving manufacturing technology (such as Industry 4.0), a fit between manufacturing competences and the firm's competitive strategy is required in order for performance improvement to accrue (Parthasarthy and Sethi, 1993).

The starting point of the analysis is the assumption that the pre-reshoring value chain reflects a "smile curve" model (left hand side of Figure 1), whereby manufacturing was located offshore because it was considered low value adding, while R&D and marketing generally remained in HCCs (Mudambi, 2008).

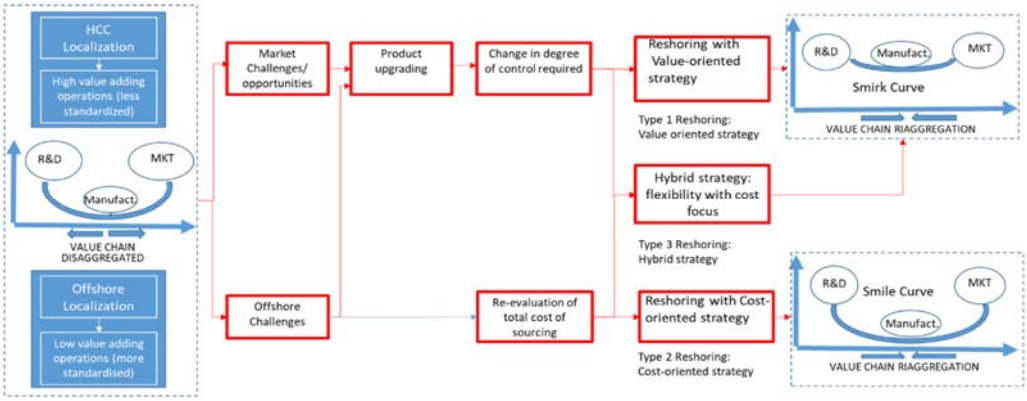

Figure 1 – Reshoring paths and predicted adoption of new manufacturing technologies

Type 1 – Smirking reshoring (Value/Differentiation strategy). It is relocation that concerns those value chains for which the company senses the opportunity for shifting for product upgrading, and from a cost-oriented competitive strategy to a quality/value-focused one (Bals et al., 2016; Di Mauro et al., 2017; Robinson and Hsieh, 2016). The product upgrading may follow from increasing competitive pressures in global markets and falling margins for standardized products, in response to which firms increase the knowledge content of their production activities, either by moving into more sophisticated product lines (Humphrey and Schmitz, 2002) and/or by moving into niches that have entry barriers and are protected to some extent from these pressures (Gereffi, 1999). As a result, value added becomes more equally distributed along the value chain, and the "smile curve" of value added flattens to become a "smirk" (Rehnberg and Ponte, 2017).

The creation of greater value at the production stage may also engender the need for cross-functional information exchange and collaboration. In this light, reshoring may represent the rational solution to the needs of the company to co-locate R&D, prototyping and production, in order to take advantage of linkages economies (Di Mauro et al., 2017; Ketokivi et al., 2017; Mudambi, 2008) and to reduce coordination and control costs. Finally, the firm may benefit from the shift from a global to a local/regional supply chain, because of customers', brand recognition through the "made in" effect (Ancarani et al., 2015; Grappi et al., 2015).

Building on previous empirical findings on the links between a differentiation strategy and automation of manufacturing (e.g. Zahra and Covin, 1993), we contend that the value-oriented reshoring strategy is not significantly associated with new technology adoption. The main reason is that firms for which product upgrading engenders a significant premium price may have weak incentives to seek efficiency and cost-containment through the new technologies. In addition, in line with RBV, in sectors such as clothing and the fashion industry, which are heavily involved in reshoring initiatives (Ancarani et al., 2015; Ashby, 2016), the value generated by highly specialized human capital by far exceeds the return that could be generated by capital investment in new technologies. Thus, it is hypothesized:

H1 – Reshoring led by a value-oriented strategy is not significantly associated with the adoption of automation and additive manufacturing technologies.

While capital investment and adoption of the latest technology may be independent of the firm's competitive strategy, automated processes and technologies such as additive manufacturing have the capability to significantly improve product development and producibility decisions (Garrido-Vega et al., 2015; Parthasarthy and Sethi, 1992). For instance, 3D printing supports customization and quick responsiveness to fast-changing consumer preferences and market conditions (Laplume et al., 2016). Therefore, additive manufacturing augments the benefits of the geographical reintegration of the value chain, being an essential requirement for fast prototyping (Garrido-Vega et al., 2015; Rehnberg and Ponte, 2017). Thus, when the reshored value-oriented production involves new product development, the adoption of advanced technologies such as 3D printing becomes likely, because of the complementarity between product and process innovation (Piening and Salge, 2015).

The above discussion leads to the following moderation hypothesis:

H2 – Reshoring led by a value-oriented strategy is positively associated with the adoption of automation and additive manufacturing technologies if it is coupled with new product development.

Type 2 – Smiling reshoring (cost-oriented strategy). In value chains with a cost leadership focus, firms relocate in HCCs as a response to changed conditions offshore that affect costs. Consistent with TCE, reshoring may follow from challenges such as the reduced gap in input costs between locations, increases in transport costs, and realization of the high costs of coordinating and monitoring distant operations and relationships (Manning, 2014).

For standardized and commoditized products, the cost/efficiency focus implies that the production stage of the value chain continues to be low value adding. Therefore, the shape of the value chain curve remains consistent with the "smiling curve" model. In this instances, labor saving technologies such as automation/robotization represent necessary pre-requisites for maintaining competitiveness following reshoring, since they act as equalizers of production costs between HCCs and LCCs (Dess and Davis, 1984; Zahra and Covin, 1993).

The above discussion leads to the formulation of this hypothesis:

H3 – Reshoring led by a cost/efficiency-focused strategy is positively associated with the adoption of automation and additive manufacturing technologies.

Type 3 – Smiling/smirking reshoring. Companies may also compete based on product variety and customization provided in a cost effective manner (Garrido-Vega et al., 2015; Parthasarthy and Sethi, 1993; Tracey et al., 1999; Tu et al., 2001). In particular, in mass customized markets differentiation and the emphasis on cost controls coexist, resulting in a "hybrid" or "dual" strategy (Kotha and Swamidass, 2000; Parthasarthy and Sethi, 1992, 1993). This strategy relies on production flexibility, and benefits from customer proximity that allows customization at point of delivery (Da Silveira et al., 2000). Therefore, for those firms whose markets are located in HCCs, reshoring can support a flexibility strategy through customer proximity, allowing companies to postpone final design and manufacturing decisions (Yang et al., 2004), and increasing the ability to be fully responsive to market demand.

In the past twenty years, advanced manufacturing techniques have made the cost-variety trade-off less stringent, as proven by the experience of companies in several sectors (Kotha and Swamidass, 2000; Fogliatto et al., 2012). In this direction, Salvador et al. (2009) proposed that among the tools available for making mass customization effective is the adoption of flexible automation. However, early analyses of the impact of automation argued that the willingness to pay a premium price for customized products largely depends on the higher performance quality of the product (Chakravarty and Kumar, 2002). In turn, this quality is assured by a dynamic network of relatively autonomous operating units, requiring multi-skilled employees who can develop new capabilities through learning processes. When firms try to implement mass customization relying on automation, the result is to weaken the skills of the workers and to reduce learning opportunities (Pine, 1993). Peng et al. (2011) empirically confirm this view, showing that manufacturing IT has an insignificant impact on the capability to successfully implement mass customization.

The above discussion leads to the following hypothesis:

H4 – Reshoring led by hybrid strategies is not significantly associated with the adoption of automation and additive manufacturing technologies.

There have been many studies linking flexibility with different types of innovation in the extant literature (Oke, 2007). It has been argued that while manufacturing plants can become flexible, without having to be innovative, flexibility is a necessary ingredient for innovation (Bolwijn and Kumpe, 1990). In the same direction, Slack et al. (2010) report that in order to satisfy customers' needs for new products, an operation must have a high degree of flexibility. Indeed, the flexibility of the machinery coupled with high labor skills enables new product ideas to be quickly developed to achieve product innovations (Oke, 2013).

Therefore, we hypothesize that:

H5 – Reshoring led by hybrid strategies is positively related with the adoption of automation and additive manufacturing technologies if it is coupled with product innovation.

In any of the three reshoring modes identified, the potential benefits linked to the adoption of new technologies for product innovation have been emphasized. Further, Millson et al. (1992) report that several well-known advanced manufacturing and design automation processes may be employed to accelerate product innovation. In particular, information technology can affect product development speed in a remarkable way (DeFosse and Barr, 1992). Menon et al. (2002) proved that the adoption of new manufacturing technologies speed-up product innovation and time-to-market. In accordance with the literature, we propose the following:

H6 – Reshoring led by the need for product innovation is positively related with the adoption of automation and additive manufacturing technologies.

Figure 2 summarizes the hypothesized model, in which reshoring leveraging on new technologies is depicted as a response to specific strategies of the company affecting the shape of its value chain. The adoption of new technologies is also affected by the product innovation necessary for the companies to be competitive in the market. Beside its direct influence, product innovation plays also a role as moderator of the impact of the strategies.

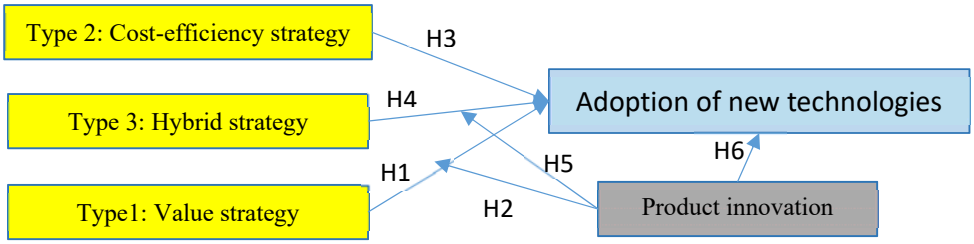

Figure 2 - Hypothesized model

Empirical analysis

Sample characteristics

In order to test our model, we created a database of 842 reshoring cases, obtained from secondary sources (press sources, press releases by the companies involved, companies' websites, and white papers from consulting companies). Secondary data have been used both in International Business and Operations Management research (Benedettini et al., 2015; Judd et al., 1991; Roth et al., 2008, Yang et al., 2006). Written records such as newspapers and magazines are considered useful when no other sources are available (Cowton, 1998, Franzosi, 1987, Mazzola and Perrone, 2013). This might be the case for reshoring, since the unit of analysis is often the product or component (rather than the firm), and therefore public secondary data are difficult – if not impossible – to obtain (Gray et al., 2013).

The database was created by merging information from the UniClub More Reshoring, a private database including data collected by a consortium of Italian universities and reporting reshoring moves of companies from all over the world from 2009 up to early 2016 (Fratocchi et al., 2016); from the Eurofound Monitor of Reshoring (https://reshoring.eurofound.europa.eu/), a public database reporting reshoring moves of European firms from 2014 to mid-2017; and from ReshoreNow.org, a public database of reshoring moves of US-based firms up to the end of 2016. The existing data bases were used to identify the cases of reshoring and the original sources of information. In order to build a homogeneous database, the research team re-examined the original sources and checked all the information required for the purpose of the present analysis. The available sources were evaluated by two members of the research team separately, and then compared in order to avoid misinterpretation of the text (Kolbe and Burnett, 1991). In case of different positions, a third researcher was involved, and the source was reviewed again until agreement was reached (Jacobson et al., 2012). In addition, when multiple sources were available, the information was compared and, in case of inconsistencies, the case was eliminated from the database. The unit of analysis was the single reshoring initiative, thus allowing for more than one initiative for each company, in case of reshoring of production from different host countries. The database provides information on firm's size, manufacturing sector, home country and offshore country, year of offshoring and reshoring, governance mode both offshore and inshore, and main motivations for reshoring. Whenever possible, companies' motivations for reshoring were inferred from the quotation of direct interviews with the companies' managers, as reported in the source. The coding of motivations applied for the purpose of the study was the one used by

the Eurofound Reshoring Monitor, which comprises 43 motivations inductively obtained from the literature on reshoring (https://reshoring.eurofound.europa.eu/methodology).

The sample includes small (24%), medium (23%), and large firms (53%). Most cases reflect a stability of governance modes offshore and inshore. In particular, insourcing both offshore and inshore represent 56% of cases, while outsourcing applies to 20% of the sample. The reshoring motivations most frequently cited by managers and deemed to be consistent with a value strategy are "Improve production quality" (22%), "Relevance of Made-in for customers" (18%), and "Protection of Intellectual Property Rights (IPRs)" (5%). Frequent reshoring motivations consistent with cost-focused strategies are "Increased logistics costs" (21%), "Change in total cost of sourcing" (20%), "Decreased gap in labor costs" (15%), "Cost of control of offshore subsidiaries/suppliers" (8%), and "Cost of delays and long delivery times" (19%). Reshoring motivations consistent with hybrid strategies include "Need for customer proximity" (19%) and "Production flexibility" (9%). Almost half of the reshoring moves are from China (49%). Production returns to USA (46%), Italy (15%), UK (10%), Germany (6%), France (6%), other European countries (Austria, Belgium, Denmark, Finland, Norway, Spain, etc.) (14%), and other countries in the world (3%). This makes the proportion of reshoring decisions in our sample balanced between USA and Europe.

Out of the total number of reshoring cases, 186 (22%) declare that innovation was involved in the relocation. Of these, 154 adopted process innovation, including 109 explicitly citing automation and additive manufacturing and 45 firms declaring other typologies of manufacturing process innovation (e.g. lean, six sigma). Support for the reliability of our sample stems from comparison with results of the survey carried out by the Boston Consulting Group in 2016 on manufacturing companies in Europe and the US. This survey shows that actual adoption of Industry 4.0 is still very low (19% in Germany and 16% in the US) and in line with the diffusion highlighted in our sample (13%).

Empirical modelling

In order to test the model described in Figure 2, we apply a binary logit model in which the dependent variable is the adoption of automation and additive manufacturing technologies by the manufacturing company following reshoring. In the measurement model described in Figure 3, we proxy manufacturing strategies by means of reshoring motivations. In turn, since motivations reflect perceived challenges and opportunities, we assume that strategic goals drive the perception of what constitutes a challenge offshore or an opportunity onshore, since challenges/opportunities are perceived as such only when they meet the firm's strategic goals and performance objectives, due to bounded rationality (Manning, 2014; Ocasio, 1997).

The adoption of value strategies (H1) is captured by the following motivations for reshoring: need to improve quality of production, "made in" effect, and need to better protect intellectual property rights. Cost-focused reshoring strategies (H3) are associated with the following challenges offshore: reduction of labor costs gap, increasing logistic costs, increased total costs of sourcing, complexity of coordination of offshore production, cost of delays in deliveries. Hybrid strategies (H4) are pinpointed by need for customer proximity, and need for greater production flexibility. The model also explores the association of new manufacturing technologies with new product development, as captured by a binary independent variable for product innovation (H6), and by its interactions with value-oriented motivations (H2) and with hybrid strategies motivations (H5).

Control variables include industry related variables (captured by dummy variables for three sectors typically involved in automation/robotization, namely automotive, electronics and mechanics), the degree of control (proxied by the governance mode following reshoring, whether insourcing or outsourcing), the offshore host country (China), the size of the reshoring firms (whether the firm is an SME), and the technological maturity reached (captured by the

normalized reshoring year). Finally, we control for other home-country-specific factors, such as the presence of external support for reshoring, either public (public incentives) or private (e.g. preferential contracts offered to reshoring suppliers by buyers for "made-in" products", as done by Walmart in the US).

In order to take into account potential differences between the industry structures in US and Europe (Ancarani et al., 2015), we estimated the logit model separately for firms whose headquarters are located in Europe (n = 429) and in the US (n = 388).

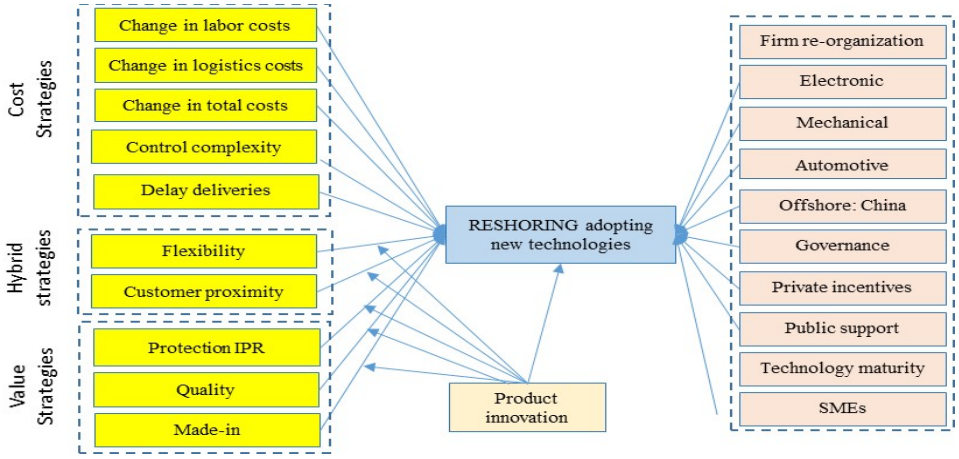

Figure 3 – Measurement model

Results

Table 1 reports results for each subsample (Europe and US). Model 1 includes level variables but no interactions with product innovation, while Model 2 includes interaction terms.

Consistent with hypothesis H1, none of the value-oriented motivations is significantly related with new technologies, both in the EU and in the US. Similarly, motivations related to a flexible strategy (i.e. production flexibility and customer proximity) are never significant, thus failing to support H4. Cost-related motivations are generally significant both in Europe and the US, albeit with differences in terms of specific significant variables. Therefore, results lend support to H3. Results from the European sample show that the complexity of controlling offshore activities, as well as costs stemming from delayed delivery are positive and significant. Increased logistic costs are significant but negatively related to the adoption of new technologies. In the US, control complexity and the increase in the total costs of sourcing are significantly related with the adoption of Industry 4,0. In Model 2, interactions terms with product innovation are statistically significant for the variable relating to quality of the offshore production in the European sample, and for customer proximity in the US sample. In order to assess the overall impact of quality and customer proximity we use the graphical moderation analysis introduced by Aitken and West (1991) (Figure 4). The left hand side of Figure 5 (a) lends support to H2, given that the adoption of Industry 4.0 when the firm adopts a quality oriented strategy is enhanced by product innovation in the EU sample. Conversely, in the US subsample when reshoring is motivated by the need to increase customer proximity, product innovation negatively moderates the adoption of Industry 4.0, therefore leading to reject H5. Product innovation is always significant and positively related to Industry 4.0, Therefore, H6 is confirmed. Turning to the control variables, the likelihood of new technology adoption following reshoring is never significantly associated with the industrial sector, with the offshore host country, or with the firm's size. No relation emerges with respect to public incentives, while private incentives from buyers are positively and significantly related to new technology adoption for the US. The European sample presents a significant but negative coefficient for

firm's global reorganization. Finally, technological maturity, as captured by the recency of reshoring, and the degree of control (insourcing of production) required positively and significantly affect the adoption of new technologies in the EU.

Discussion

This paper has developed a conceptual framework explaining the likelihood of adoption of new technologies as part of reshoring. Based on the tenet that manufacturing technologies must be aligned to the competitive strategy (Parthasathi and Sethi, 1992), we have elaborated on the expected association of new technology adoption by reshoring firms with cost-oriented strategies vs. value-driven strategies.

Our model posits that the majority of relocations to HCCs are purposeful and strategy-driven (Benito, 2015; Fratocchi et al., 2016). Although other scholars have attributed reshoring to mistaken offshore decisions (Bals et al., 2016; Kinkel and Maloca, 2009), only few companies reshore within a short time span (Ancarani et al., 2015), while more often, firms point to challenges arising in the offshore location due to changes in locational advantages (Manning, 2014) or to growth opportunities envisaged in the home markets (Di Mauro et al., 2017). Our model posits that for cost-oriented firms, automation and additive manufacturing technologies may represent a necessary ingredient of relocations to HCCs, because of the need to "equalize" production costs with LCCs' locations (Bals et al., 2016). On the other hand, rising demand for product differentiation has led many companies that had relocated production offshore to repatriate at least their high end segments (Ashby, 2016), or to upgrade their products (Humphrey and Schmitz, 2002) in order to generate higher value for the customer, leveraging either on the "Made in" label (Grappi et al., 2015), or on linkages economies within the value chain (Mudambi, 2008). Our model posits that for competitive strategies aiming at a premium price, technologies such robotization and additive manufacturing are not necessarily associated with reshoring, except in those cases in which reshoring is tied to product innovation. In this instance, new technologies may become an essential component of cost-effective prototyping and product development.

The other aims of the paper were to provide empirical evidence on the extent to which reshoring initiatives are associated with new technologies, and to test our conceptual model. Our sample, based on a heterogeneous set of firms with headquarters mainly in Europe and the US, shows that the diffusion of advanced and additive manufacturing among reshoring companies is still low (13%). Although we have already pinpointed that this figure is roughly in line with what has emerged from recent surveys on manufacturing companies (Boston Consulting Group, 2016), the adoption of these technologies does not appear to be crucial for reshoring yet. Consistent with RBV, dynamic capabilities need to be activated, as reshoring companies need to reshuffle their resource base in order to acquire skills related to the new technologies. However, data suggest that the adoption is on the rise and, especially for European companies,

adoption is higher for companies that have reshored recently. Of interest is also the finding that robotization and 3D printing are the only instances of Industry 4.0 technologies that are cited by the reshoring firms, while IoT and big data exploitation are never mentioned. This finding suggests that reshoring firms are drawn towards labor- and time-saving technologies, rather than towards the possibility of intra- and cross-firm integration.

Model testing lends support to the importance of the company's strategy, as proxied by motivations for reshoring (Manning, 2014; Ocasio, 1997). Both in Europe and in US, motivations linked to value strategies (Made in, Quality, Protection of IPR) are not significantly associated to new technology adoption. Given that about 40% of the reshoring cases report at least one value-oriented motivation, this result implies that there is a significant portion of reshoring for which labor-saving and flexibility advantages offered by these technologies are not – at least for the moment being, a necessary pre-requisite for repatriation. This value-oriented reshoring is partly driven by resource-based considerations, such as the search for supplier competences and labor skills in HCCs (McIvor, 2013) that do not engender the reconfiguration of the technological base. However, product upgrading, as signaled by the quality focus, is related with additive and advanced manufacturing adoption when it involves product innovation. This finding suggests that new technologies enables product-development coupling, by supporting timely prototyping and product design (Ketokivi et al., 2017).

Cost related motivations are significantly related to new technology adoption, consistent with the idea that these technologies support cost containment and productivity, therefore representing an effective equalizer between costs in HCCs and LCCs. This result suggests that, as knowledge and competences about these technologies become widespread, more cost-focused firms should embrace reshoring.

Mass customization, as signaled by the search for production flexibility and customer proximity, is not tied to reshoring. Contrary to our expectations, reshoring motivated by customer proximity does not promote the use of new technologies even when reshoring firms undertake product innovation. This finding may reflect the fact that relocation close to customers, i.e. the product-market coupling discussed by Ketokivi et al., 2017, may simply reflect the firm's need for better understanding the market and for benefitting from postponement, and may not require technology advancement, except in the form of digitalization of production and sales data. Hence, results indicate that product-development coupling enhances the need for the new manufacturing technologies, while production-market coupling does not.

While the conceptual model is confirmed, differences can be found between the two subsamples in terms of significant variables. In both samples, control complexity of offshore activities is significantly related to the adoption of new technologies. Costs stemming from the complexity of controlling offshore operations reflect both the mere geographical distance between the manufacturing offshore location and the other firm's activities (Handley and Benton, 2013), and the cultural distance between headquarters and LCC's production. According to TCE, control complexity will give rise to higher costs of monitoring and enforcement of plans/contracts and of coordination among units or buyer and supplier. In such a case, geographical re-concentration allows cutting these costs, while automation of production contributes to make total costs inshore level with those offshore.

For US firms, rising total costs of sourcing offshore are significantly related to reshoring through new technology adoption, suggesting that the closing gap between production costs in LCCs and HCC is further reduced through technologies enhancing productivity and quality control. New technology adoption is relevant for EU companies that reshored because of delivery delays problems. These companies had mostly offshored to Asia, and have adopted an insourcing governance mode following reshoring, possibly with the aim to combine cost cutting with tighter control of production and delivery times. Reshoring due to rising logistic costs is

negatively associated with the adoption of new technologies in Europe. This finding may indicate that reshoring per se solves the challenge of high logistic costs and does not require any additional investment in cost-saving technologies.

Contextual factors point to further differences between the two geographical areas. Of notice is the fact that automation for EU firms is associated with a reshoring insourcing mode, pointing to vertical integration as a strategy to overcome monitoring and control issues. In addition, the technological update is significantly associated with a global reorganization of production facilities, often exploiting untapped production capacity at home generated by the economic crisis. For the US, a significant role is played by corporate customers that have decided to increase their share of "made in America" suppliers (such as Walmart), pushing these suppliers to reconfigure their overall set of resources in order to remain competitive.

Conclusions and Limitations

Are advanced and additive manufacturing technologies going to support the return of manufacturing to high cost countries? And if so, which companies are more likely to use it as an enabler of their back-relocation? These questions, which are at the forefront of current academic and policy debate, have not received an empirically grounded answer so far. This paper has sought to provide at least a partial answer, by associating the adoption of new technologies not only to structural characteristics of reshoring companies (industry, size) but above all to firms' manufacturing strategies and challenges experienced offshore.

While results lend support to our conceptual model of the link between cost vs. value strategies and technology adoption, some limitations must be highlighted. First, the relatively low number of firms implementing advanced and additive manufacturing technologies has not allowed to study the linkages between reshoring models and specific components of the new paradigm (e.g. robotization vs. 3DP). Next, although careful textual search has been applied in order to extract information from our secondary sources, first hand data on firms' strategies, experienced challenges, and value chains should be used to complement and enrich our information.

As the adoption of new technologies progresses, future empirical research will be called to provide an in-depth assessment of whether the adoption of technologies related to Industry 4.0 will contribute to reshoring initiatives and to their success.

Environmental considerations when purchasing transport services: A Comparison between Swedish and French Shippers

Abstract

This paper explores transport purchasing among companies in Sweden and France. The purpose is to analyse shippers' transport purchasing behaviours, e.g the provider and mode selection criteria. Based on available data from a Swedish survey and a qualitative study conducted in France, this paper identifies similarities and differences between the shippers' perceptions and actions in these two geographical and cultural contexts. This research makes major academic contributions comparing transport solution selection criteria within European countries, collecting at the same time rich data bases on shipper's behaviours regarding their providers' environmental practices.

Keywords Transport purchasing behaviour; provider selection criteria

Working paper

Introduction

The Transport sector, which represents almost a quarter of Europe's greenhouse gas emissions (GHG), generates many debates, studies and discussions regarding how to decrease this impact. The problem has been addressed by a high-level group at the UN and the 23rd session of the Conference of the Parties (COP 23) included a "transport thematic day", highlighting the urgent need to reduce carbon emissions, which could be accomplished by a mix of policies and governmental measures. The majority of greenhouse gas emissions from transport is caused by CO2 emissions (Piecyk and McKinnon, 2010), and within Europe, in 2015, road transport accounted for over three-quarters (75.3%) of the total inland freight transport[1].

Initiatives to reduce the negative impact from transport can be observed in many countries, which primarily try to decrease CO2 emissions. Within Europe, France and Sweden are examples of quite proactive countries, while different in nature. France sets the objective to reduce the CO2 emissions from transport sector by 29% from 2015 to 2028[2] whereas Sweden has as an objective to reduce emissions from domestic transport by at least 70 per cent by 2030 compared with 2010[3]. According to Mahmoudi et al., (2017), Swedish freight initiatives have a great potential to lower road freight CO2 emissions. On its side, France has introduced various transport initiatives, for instance: carriers, who voluntarily adhere to a specific charter of commitments (*Charte Objectif CO2*) since 2008, can obtain compliance certification after 3 years if achieving a high environmental performance. In response to this measure, a new voluntary charter has been settled for shippers (*Charte FRET 21*). It has been under experiment by 10 pro-active shippers since May 2015 and should be open to 1000 other French companies until 2020 (Touratier-Muller and Jaussaud, 2017). In a different register, since October 2013 a mandatory scheme (decree n°2011-1336) obliges all French carriers to calculate and inform their customers about their CO2 impacts.

Although the European Union has prioritised the reduction of CO2 emissions from transport, practices and behaviours influencing this tendency, such as how freight transport is purchased

[1] Accessed on February 5th 2018: Freight transport statistics - modal split: http://ec.europa.eu/eurostat/statistics explained/ index.php /Freight_transport_statistics_-_modal_split

have been scarcely explored, and even less been compared between countries. Scrutinizing how shippers (i.e. transport purchasers who own the goods) select their transport providers (suppliers in charge of the transportation service) could provide insights which could facilitate development of appropriate environmental national or European freight transportation measures.

There are some national studies that have highlighted how sustainable development can better be taken into account during the transportation procurement process, for instance in Sweden (Rogerson et al., 2014), in Germany (Large et al., 2013) and in France (Touratier-Muller et al., 2017). However, to our knowledge, there is no literature analysing and comparing transport procurement practices between European countries. Such studies may generate knowledge and provide support when developing sustainable European policies. Consequently, as a first step, the purpose of this paper is to shed light on transportation purchasing process in two different European countries. The starting point will be Sweden and France, which both could be considered as progressive with respect to their ambitions to curb the negative consequences of transport emissions. In order to find comparable and interesting transport buyers in each country it was decided to focus only on transport buyers for which the environmental aspects of transport are of very high importance.
This research provides an overview of the features of transportation purchasing practices, and highlighting some specificities inherent to each country context. Our goal is not to test or generate theory but to use some industrial purchasing concepts of the IMP group (Cova and Salle (1992), to investigate the buying purchasing process in both countries.

This paper is organised as follows. A literature review provides the starting point for the work and the formulation of three research questions. The following section presents the methodology, and thereafter the main results are presented and discussed. A final section presents the conclusions and future research.

Literature review

Academic studies based on the road freight sector provides a broad spectrum of information. This literature review focused on two main areas: (1) shippers' incidence to adopt sustainable transportation, (2) shippers 'perspective when purchasing transportation services.

Patterns and characteristics incidence

While cultural values seem to shape certain processes within supply chains (Walker et al., 2008), the work of Thornton et al., (2013) reveal that socially responsible supplier selection is more encouraged and rewarded in developed countries. Other surveys conducted specifically in the transportation purchasing process in Sweden (Pålsson and Kovács, 2014) highlight the company cultural weight to retain environmental criteria. Although the culture of the shipper seems to play a key role, however, no work has been found scrutinizing these cultural differences according to country specificities.
Size of the company has no incidence according to Björklund (2011) whereas Lammgård (2012), Pålsson and Kovács, (2014) find a correlation showing that the bigger the company, the more proactive it is to integrate environmental issues. In line with these findings, Rogerson (2016) and Van den Berg and Wan De Langen (2016) underline that larger companies are more inclined to implement green transport practices than small companies. It could be explained by the willingness of large companies to pay for environmental improvements, whereas small companies' priorities are more focused on costs (Lammgård, 2012).
Industrial sectors also seem to exert a substantial influence, "*customers from the industry sector are considered to have fewer and lower green requirements than customers from the food*

industries" (Isaksson, 2012 : p.47). Industrial sectors involving direct consumer products seem to induce more detailed green demands than other services such as transportation. Product characteristics (Björklund, 2011) as well as material flow characteristics (Rogerson, 2012) also seem to exert an influence to green the transportation flows. These different findings lead to formulate the first research question:

RQ1. Are there any specific patterns among proactive shippers, willing to consider sustainability when purchasing transportation services?

Shippers' perspective when purchasing transportation services

The purchase of services that include logistic services as well as transport requisitions, are intangible by nature. As a consequence, the selection process is far different from the purchase of goods as it is underlined by Jackson et al., (1995). In order to explore shipper's perspective regarding the transportation purchasing process, the core elements of the ARA model, established by IMP researchers could be used (Cova and Salle, 1992; Håkansson and Snehota, 1995; Håkansson et al., 2009). This relies on three main network components which are: (1) the actors (involved in the business interaction), (2) the resources (physical, financial, human and technical assets) and (3) the activities. Each of these three elements play an important role in the analysis of the network. Furthermore, Håkansson's (1982) interaction model determines a fundamental framework to explain the specificity of Business to Business (BtoB) relationships. According to him, it is described by "*stability rather than change*", "*long-term relationship rather than short-term business transactions*" and by "*closeness rather than distance*" (p. 6). Furthermore, the relationships between buying and selling firms have the stability which derives from the length of the relationship.

This theoretical pillar attracts our attention for two reasons: not only does it allow to observe how companies, according to its resources and its sector activity interact with other companies (external interactions), but it also explores internal interactions among firms' functions.

Bardi (1973) seems to be one of the first authors that tries to identify the key factors determining the carrier selection. This author identifies five factors of influence: transit time reliability, transportation rates, total transit time, willingness to negotiate, and financial stability. More recent studies confirmed that service quality (Govindan et al., 2013; Rogerson, Andersson, and Johansson, 2014) and cost (Lammgård and Andersson, 2014; Rogerson, 2016) remain the two most important criteria when selecting a carrier. In this perspective, carrier's environmental performance is frequently cited but is still not a selection criterion (Large et al., 2013; Gonvindan et al., 2013). However, Björklund and Forslund (2013) noticed that companies that include environmental performance in transport contracts do not necessarily consider how to measure the environmental performance and how to handle non-compliance. In this perspective, Evangelista (2014) adds that the lack of a standard methodology for environmental performance measurement prevents companies from sharing the costs and benefits of environmental initiatives. As a consequence, in line with these findings, we could formulate the second and third research question:

RQ2. What are the selected criteria prioritized during the transportation tender process?
RQ3. How is the transportation purchasing organised?

Methodology

The purpose of this pre-study is to compare transport purchasing practices, especially concerning environmental aspects, and thereby it was deemed appropriate to use

environmentally concerned shippers in two progressive European countries. In France ten companies, being committed to a voluntary environmental program called FRET 21, were selected. In Sweden the companies stating the highest level of importance of environmental factors when selecting a transport solution were chosen (and this turned out to be 10 firms) out a random sample of (151) companies who had answered a very comprehensive survey about transport purchasing and environmental issues. This survey is part of the work of the Swedish Transport Procurement Panel (Andersson et al., 2016). The data from the two countries were collected at the same time but uncoordinated since these data collection efforts were part of previously designed projects which later were identified as partly similar and offering potentials for comparisons between countries. In both countries cases studies and qualitative data collection have been used but data used from the Swedish companies that were identified as most environmentally concerned is in this paper limited to survey data. The data from France is the result from a case-based methodology, providing rich descriptions and allowing examination of numerous factors and nuances (Boyer and Swink 2008). In total data about the transport purchasing has been collected from proactive shippers: 10 companies in Sweden and 10 companies in France.

Sample selection in France and Sweden

Companies in France			
Industrial Sector	**Size**	**Country of origin**	**Respondent**
Petrochemical	Large	American	Supply Chain Manager
Mass distribution	Large	French	Sustainable Supply Chain and Transportation Manager
Food industry	Large	American	Sustainable Supply Chain Manager
Food industry	Large	Italian	Transportation Purchasing Manager
Food industry	Large	French	Transportation Purchasing Manager
Food industry	Medium	French	Transportation Purchasing Manager
Chemical	Medium-	French	Transportation Purchasing Manager
Hygiene	Large	Swedish	Supply Chain Director
Building materials	Large	French	Supply Chain Director, and 2 Transportation Buyers
Automotive	Large	French	Environment Supply Chain Director

Table 1: List of the French shippers interviewed

Companies in Sweden			
Industrial sector	**Size**	**Country of origin**	**Respondent**
Manufacturing	Medium	Sweden	Warehouse manager
Paper product manufacturing	Large	Sweden	Transport manager
Mechanical industry	Large	Japan	Strategic purchaser
Wholesale	Medium	Sweden	Transport manager
Packaging material	Large	Sweden	Purchasing manager
Manufacturing	Medium	Sweden	Strategic purchaser
Wholesale equipment	Medium	Sweden	Logistics manager
Manufacturing of equipment	Large	USA	Purchasing manger
Food manufacturing	Medium	Sweden	Logistics manager
Chemicals	Large	Sweden	Transport coordinator

Table 2: List of the Swedish shippers

The 20 companies included in the pre-study provide a field study group showing geographical diversity, diversity in size and industrial sector. These characteristics are presented on a high level in table 1 and 2, and due to reasons of confidentiality, details and names of companies cannot be shown.

An interview guide was developed by the French researcher regarding various categories that include: (1) Motivations and resources to develop sustainable transportation procurement, (2)

Purchasing process and environmental sensitiveness, (3) CO2 information utilization as well as (4) Environmental collaborations between shippers and carriers. The Swedish survey instrument included similar questions divided into 34 main categories of with several sub-questions. These questions were answered in writing online, including both closed and open answer alternatives. All the respondents were selected based on their responsibilities to buy transportation services. Each interview with the French shippers was fully recorded, transcribed and codified by the researchers. This method of typing and organising handwritten field notes offers a great opportunity to obtain verbatim transcriptions (Patton, 2002).

Data analysis

The coding process consisted of reading, analysing and underlining key sentences from the French interviews. The Swedish data was coded when entered by the respondents in the online survey, however, there were also answers in the free text format. A cross case analysis offers a way to group together answers from different respondents to similar questions (Patton, 2002, p. 440). This process allowed researchers to centralise and synthesise key answers to our research questions. Researchers from Sweden and France put their data together and selected questions which were common in both studies. Similarities and differences in both countries were identified and analysed.

Findings and discussions

French and Swedish Shippers 'characteristics incidence' to integrate sustainability in their transportation purchasing process

Comparing table 1 and table 2, we can notice that, although shippers' countries of origin are diversified, the parent company coming from developed countries. This first results, in line with Pålsson and Kovács (2014) suggestion that cultural weight of developed countries seem to exert an influence to commit companies to integrate sustainability in their purchasing process. This observation ties up with the idea that socially responsible supplier selection might be more encouraged and rewarded in developed countries, as it had been suggested by Thornton et al., (2013). This cultural patterns can constitute the "Atmosphere", underlined by the ARA model, wich is translated as

Concerning the size, there is no link between proactivity and size, however, small companies were not included in the Swedish sample. There may be a difference compared with the result of Rogerson (2016) and Van den Berg and Wan De Langen (2016) results, highlighting that larger companies are more inclined to implement green transport practices than small companies. However, there is nothing in our result that contradicts this claim.

Moreover, as we can see in Table 2, industries sectors from proactive French and Swedish shippers are diversified: food industry, chemical industry, hygiene sector, building materials, petrochemicals, automotive, paper, mechanical mfg etc. Consequently there is no industrial sector in particular which seems to emerge more than another, which is also supported by an analysis of the entire Swedish random sample.

According to the IMP model, some characteristics impact the actor interactions such as social systems in particular countries that *"surround a particular industry or market*" (Håkansson, 1982 : p.29). Since the country of origins of the proactive companies come from developed countries, we could interpret that it constitutes a pattern to consider sustainability when purchasing transportation services whereas size of the company or industrial sector do not seem particularly relevant. These first findings, provide part of the answer to the research question 1, although larger-scale analysis would be needed to confirm these results.

Transportation criteria retained by 20 proactive shippers in France and Sweden

We explored and compare the transportation selection criteria among these 20 proactive companies in both countries (Table 3).

		French Shippers interviewed										Swedish Shippers responding									
		F1	*F2*	*F3*	*F4*	*F5*	*F6*	*F7*	*F8*	*F9*	*F10*	*S1*	*S2*	*S3*	*S4*	*S5*	*S6*	*S7*	*S8*	*S9*	*S10*

	Certification, ISO											●	●	●	●	●	●	●	●	●	●

Table 3: Some of the criteria used when selecting carrier/transport provider

From the French side the primary selection criterion is the price for half of the companies interviewed. Nevertheless, the other half of French shippers mentioned that the service quality (punctuality; reactivity, truck availability) and the safety of the vehicles (especially for transportation of dangerous materials) remain the primary criterion. Despite the fact that these 10 proactive French shippers are committed to a voluntary program to reduce their transportation impact, none of them stressed the environmental criteria in their decision process. Four of them took into account carriers' environmental performance, awarding points regarding their fleet of vehicles, their fuel consumption, their truck standards, truck consumption, or their engagement to sign a voluntary carriers charter of commitment (*Charte Volontaire CO2*) launched by the French government in 2008. They also add value on environmental proposals from carriers that use lighter trucks and to those who set up financial-benefit sharing, as well as fronthauling/ backhauling practices. Nonetheless, although environmental awareness is raising, these elements as well as certifications or ISO standards do not occupy a weight yet in the decision process.

From the Swedish side, all of the 10 proactive shippers had high marks on most of the provider selection criteria in table 3. However, none of the companies stress the previous experiences very much and three of them, 2,3 and 5 gave this criterion very low scores. In addition, one of them, S10 did not view price as important at all instead this company stated an array of service aspects, such as punctuality and reliability, as the most highly rated, and the environment was more important than cost. All of the other nine companies stated environment as the most or second most important provider selection criterion. There were no explicit questions about safety and it is not possible to make any statement about this.

All the paragraphs above regarding the selected criteria answers research question 2.

In both countries, awarding innovative initiatives are rather prioritized since a solution "at the same price, but less polluting" is favoured. In this way, Swedish shippers highlight their efforts to select the most environmentally friendly solution "if it works from a service point of view and is not too expensive."

Regarding findings by Björklund and Forslund (2013) and Evanglista (2014) who highlighted the lack of a standard methodology for environmental performance measurement performance, we notice that French government introduced various programs to assess carriers' environmental performance. The decree 2011-1336 which has to be respected by all French carriers could be a selection criterion for example. However, French shippers attitudes regarding decree 2011-1336 is insignificant. Surprisingly, French shippers value more when carriers are involved in voluntary programs. They do not give any weight at all regarding the fact that carriers obey or not to the law, respecting the decree 2011-1336.

Transportation purchasing organisation

In addition to transport selection criteria, the organisation of the transport purchasing will be scrutinized. In this perspective, comparisons are used to indicate which department inside the company participate to the choice of the transport provider. The contract length as well as the call for tenders or the purchasing of transport are also examined.

		French Shippers interviewed										Swedish Shippers

Table 4: Transportation purchasing organisation characteristics

Comparing results in both countries, it can observed that the purchasing department play a key role among the French proactive shippers whereas it is not prominent among the 10 environmentally focused Swedish shippers. However, this is not the answer to the same question, The Swedish companies responded to a question about which department (or other external organisation, as in case 5-7) that made the transport mode selection. In general the purchasing department is also involved in the transport purchasing in Sweden. The results highlight that the transportation tender process in France is rather handled by two departments (Purchasing and Supply Chain), whereas in Sweden several different departments (grouped into the category Supply Chain) supervise this task. However, the final decision in both countries is mainly made by units that can be categorised into to the supply chain department.

Regarding the ARA model, Håkansson and Snehota (1995) have highlighted how competencies, relationships as well as resources transform dyadic relationships and networks. From this ARA lens, we could then observe that the choice of the carrier in France require competencies and resources from two departments inside de company (the Purchasing and the Supply Chain departments)

Whereas all transportation contracts among the 10 Swedish shippers are signed for 2 or 3 years, a wide variety of responses is observed among French shippers. Six of them do not mention any length in the contracts at all or sign a "1 year contract". We could interpret these results as a search for a very low level of dependency. It could also be an operational strategy that fix and regulates the price for one whole year. The 4 French shippers remaining have contracts that last 2,3 or 5 years. But even if S5 had a contract for 2 years, S7 and S8 3 years all these shippers had a more than 10 year long relationship with their services providers handling the largest contract, and for S9 the relationship had been ongoing for 30 years

The IMP model, which explains the specificity of BtoB characteristics through long-term relationships (Håkansson's, 1982) do not seem to be reflected unanimously among these French shippers. Although they specify orally that they want to work on a long term relationship with their carriers, their organisational process highlight that they do not want to be confined into a contractual relationship. Analysing calls for tenders, we notice that contracts in France are mainly signed at a central level. In Sweden the ten companies focusing on environmental are buying a larger part of the total transport volume centrally 44% (to be compared with 23% for companies not focusing on environment) even if most of the volume in all cases is bought by the local unit 52% (72%). In two of the cases (S3 and S9) 100% of the transport volume was bought centrally.

The elements described above, focusing on the transportation purchasing organisation, respond to research question 3.

Conclusions

The need to achieve environmental sustainability within the transport is getting increasing attention and changes related to purchasing process is acknowledged as one way to contribute to cut CO2 emissions from transport. Although environmental sustainability is gaining recognition, strength and has an incentive impact during the tender process, it does not constitute a decisive criterion to select a carrier.

Both studies conducted in Sweden and France underline similar characteristics regarding the selection criteria. However the Swedish shippers put more emphasis on the carrier's ISO certification, in comparison to French Shippers. Although the French shippers are environmentally proactive, they do not evaluate if the carriers respect the legislation (decree 2011-1336) or any ISO norm. Instead they appreciate if carriers are committed to a voluntary program, such as the CO2 voluntary charter, even though it does not constitute a selection criterion. The proactive companies from both countries see price as an important selection criterion. However, environmental concerns are more influential to the carrier selection for the Swedish shippers than for the French shippers.

From a purchasing organizational perspective, our results highlight differences between the countries. The choice of the carrier in France is handled by the Purchasing and the Supply Chain departments, whereas the Purchasing department is not involved in the mode selection for the proactive Swedish shippers. Furthermore, the length of the transportation contracts highlights significant differences between the countries, with French shippers being more reluctant to sign contracts for more than 1 year. However, these results cannot be generalized. In order to do this other studies should be conducted in a coordinated way at a larger scale.

In both countries, awarding innovative initiatives are being appreciated since a solution "*at the same price, but less polluting"* is favoured. A Swedish shipper made the following comment on their efforts to select the most environmentally friendly solution: *"if it works from a service point of view and is not too expensive."*

There is a need to encourage changes in purchasing practices, which could be facilitated through environmental rules and adapted regulations. The French regulation, through the decree 2011-1336 did not have a real impact so far as it has been demonstrated in our results. A common European legislation using simple tools to measure carriers 'environmental performance could be relevant for all shippers. In addition to legislation, purchasing decisions may also be influenced by cost effects, customer demands and organizational factors. In this particular study, we have noticed both similarities and differences between France and Sweden but it is currently not clear if this is due to context or sampling of respondents.

As a consequence, a need for further research, in both countries as well as in other areas is most certainly needed to develop these initial results. Further research efforts are also needed to investigate the impacts of mandatory and voluntary initiatives to decrease road freight CO2 emissions as well as motivation factors to green the transportation procurement process. This is indeed relevant to better understand how the allocation of sustainable concerns can be taken into account by shippers in order to stimulate progressively supply chain partners to improve their environmental performance. This study confined to two countries presents some other limitations. The main one relates to the small amount of case companies investigated. In order to achieve an empirical generalization, it would be relevant to use same questions and methodology while increasing the number respondents. Furthermore, another limitation relates to the focus on large and medium-sized companies. It would be consistent to investigate shippers' behaviour among small companies.

PUBLIC PROCUREMENT AND SCHOOL FURNITURE IN BRAZIL

Leomir Ferreira de Araujo
Luiz Ricardo Cavalcante

ABSTRACT

In this paper, we analyze the public procurement as an public policy to improve the performance of the furniture industry in Brazil, which a sector dominated by suppliers (PAVITT, 1984). In particular, we analyze the impacts of the National Price Register (NPR) on the performance indicators of the Brazilian school furniture industry between 2009 and 2015. The analysis is based upon secondary data and semi-structured interviews with suppliers of NPR. We show that these NPR promoted: reduction of uncertainties; standardization of production; and gains of scale and, as a result, process innovations; acquisition of better machinery; and labor force qualification.

KEY-WORDS: Public procurement; low-technology industries.

1 INTRODUCTION

Public procurement has been widely recognized as an instrument for innovation and, more broadly, for industrial performance. Specially in European countries and in the United States, Public Procurement for Innovation (PPI), as it has been addressed in the international literature over the last twenty years, a relevant capacity of fostering the development of high-technology industries such as aircraft production, defense industry, public health (including the pharmaceutical industry), environmental ("green procurement") and energy (KALVET; LEMBER, 2011).

In Brazil, PPI has achieved some positive results in agencies related to energy, telecommunications, pharmaceutical and science and technology sectors (RAUEN, 2017, p. 23). However, public procurement is still little used in the National Innovation System (BONACELLI; FOSS, 2016). In fact, most purchases are related to traditional sectors. That may be a consequence of the reduced presence of high-technology industries in the Brazilian economy and of limitations imposed by the local legislation concerning public procurement. In the country, public procurement obligation is published at Brazilian Federal Constitution, which stablishes the means by which the public administration will secure the necessary contracts with third parties (article 37, item XXI). The General Procurement Law (Law nº 8.666/1993) states that public managers, when picking suppliers, must take into consideration not only the most advantageous proposal, but also the competition between potencial suppliers and the sustainable national development (Article 3 of Law nº 8.666/1993). However, in order to avoid opportunistic behavior, this Law creates obstacles to the adoption of public procurement models focused on innovation. As a result, public procurement in Brazil is more used in traditional sectors such as construction industry (contractors).

In the specific case of education, the National Fund for the Development of Education (FNDE, in its acronym in Portuguese) improved the public procurement instruments based on the so-called "Price Registration System" (PRS, article 15 of Law nº 8.666/1993). The aim of PRS is to elaborate specifications and market studies and to manage price registration (FGV, 2014). The PRS uses the National Price Register (NPR) to establish conditions for public procurement of school furniture in Brazil. Basically, NPR is a public procurement instrument

aimed at providing equipaments and furnitures to attend Brazilian schools . Created by the FNDE, it is structured on the basis of a shared management model which involves, besides the federal government, States and Municipalities. Each entity has a counterpart: submit requirements, appoint responsible agents and rendering of accounts of the values received from the FNDE, when applicable.

However, the impacts of these public procurement policies on the performance of the suppliers have not yet been studied. In fact, PPI is usually associated to high-technology industries such as the aircraft production and the defense industry, but there may be impacts also in low-technology sectors such as school furniture, for example. There is a reduced literature that analyzes the impacts of public procurement on the performance of more traditional segments. The hypothesis proposes NPR such as procurement policies works as coordination mechanism that promotes process innovation, permits the acquisition of better machinery creates incentives for labor force qualification and, as a result, has a positive effect on the performance of the Brazilian school furniture industry.

Thus, in this paper, we analyze the use of public procurement as an industrial policy tool to improve the performance of the school furniture industry in Brazil, which a sector dominated by suppliers (PAVITT, 1984). In particular, we analyze the impacts of NPR on the performance indicators of the Brazilian school furniture industry between 2009 and 2015. Besides this introduction, this paper is structured in four additional sections. In section 2, we summarize the literature on PPI and discuss the technological intensity and patterns of technical change of industrial sectors. In section 3, we describe the methodological procedures adopted in this paper. Results are discussed in section four and the main conclusions are highlighted in section 5.

2 LITERATURE REVIEW

According to Edquist and Hommen (1998), there are two possible designs for government procurement: simple government procurement (standardized products) and innovative procurement (production not yet available at the time of application).

As for the objectives and functions of public innovation purchases, the literature has motivated different possibilities:

- Market expansion (EDLER et al, 2014);
- Promotion of industrial innovation (BORRÁS; EDQUIST, 2013; EDLER et al, 2015);
- Economies of scale to establish the technology market and consolidate the market and technological specifications for standardization of productsof criteria (FRAUNHOFER, 2005); and
- Supplying of public services in the areas of sustainability or energy efficiency (DALPÉ, 1994; TAB, 2006; ASCHHOFF, B; SOFKA, W. 2009; BORRÁS; EDQUIST, 2013, page 22).

Kalvet et al (2013, p.4) provide a framework. For these authors, there are four functions for the use of acquisitions as a vehicle for innovation: *i)* industrial policy; *ii)* R&D policy; *iii)* to meet generic demands; and *iv)* market self-determination policy.

Edler et al. (2015) suggest that the implementation of public procurement policies may be segmented as follows: *i)* identification of a need or challenge; *ii)* transformation of demand into specifications; *iii)* submission of technical specifications to potential suppliers; *iv)*

execution of contracting processes; *v)* product development; *vi)* evaluation of bids; and *vii)* contracts (EDLER et al., 2015).

Some authors argue that this instrument deserves some degree of adaptation and "customization", according to the characteristics of the industrial sectors (BORRÁS, EDQUIST, 2013, p.77). Functional requirements are expected to be developed by the government, so long as production is left to industry (ROTHWELL; ZEGVELD, 1981; GEROSKI, 1990; EDLER; GEORGHIOU, 2007; ASCHHOFF; SOFKA, 2009).

In Valovirta's paper (2015, pp. 71-80), the main requeriments developed by the public innovation procurement policy in the industrial sector are the following: *i)* integration with organizational innovation goals; *ii)* identification of social challenges; *iii)* search for alternative solutions with the support of industry maturity; *iv)* interaction with potential suppliers; *v)* organization of performance tests on the best solutions of the suppliers; *vi)* promotion to the implementation of risk management; and *vii)* quality of the firms of each sector achieved.

On the other hand, the main barriers to the implementation of PPI found in the literature are:

- The low levels of R&D research and the lack of demand for certain innovative products (BORRÁS; EDQUIST, 2013; EDLER et al., 2015);
- The inherent risk aversion of the public sector (ROLFSTAM, 2013);
- The precarious risk management during the purchase process (EDLER et al, 2014, page 631);
- Bureaucratic procurement processes (OGC, 2004; HOUSE OF LORDS, 2011); and
- The information asymmetry (MEERVELD; NAUTA; WHYLES, 2015, pp. 112-113).

Among the risks mentioned above, the lack of experience in innovative purchases by public managers is the most frequent obstacle presented in the literature (EDLER et al, 2014; EDLERet al., 2015; VALOVIRTA, 2015). Besides, Vonortas (2015, pp. 175-176) refers to extensive judicialization, specification dangers, inclusion of industry in political decision-making, flexibilization of contracts.

With regard to the alternatives pointed out in the literature, it is clear that the interaction between the investments involved and the updating of the firms participating in the purchasing policies are fundamental to the success of the innovation processes, especially in relation to product specifications (ROTHWELL; ZEGVELD, 1981; GEROSKI, 1990; EDLER et al, 2014; VONORTAS, 2015; MEERVELD; NAUTA; WHYLES, 2015; BONACELLI; FOSS, 2016). Nevertheless, companies need guarantees of demand and flexibility in the procurement processes to achieve the state of the art for the benefit of society. (EDLER et al, 2015). Most analyses and case studies mentioned so far focus on the use of PPI in high technology industries. According to the Organization for Economic Co-operation and Development (OECD) classification of manufacturing industries based on R&D intensities, these industries involve, for example, aircraft and spacecraft and office, accounting and computing machinery, as shown in box 1.

Box 1: OECD classification of manufacturing industries based on R&D intensities

High-technology	Aircraft and spacecraft Pharmaceuticals Office, accounting and computing machinery Radio, TV and communications equipment Medical, precision and optical instruments
Medium-high-technology	Electrical machinery and apparatus, n.e.c. Motor vehicles, trailers and semi-trailers Chemicals excluding pharmaceuticals Railroad equipment and transport equipment, n.e.c. Machinery and equipment, n.e.c.
Medium-low-technology	Building and repairing of ships and boats Rubber and plastics products Coke, refined petroleum products and nuclear fuel Other non-metallic mineral products Basic metals and fabricated metal products
Low-technology	Manufacturing, n.e.c.; Recycling Wood, pulp, paper, paper products, printing and publishing Food products, beverages and tobacco Textiles, textile products, leather and footwear

Source: OECD (2011).

The use of Pavitt's (1984) taxonomy leads to a similar conclusion. In this case, the manufacturing industry is segmented in four blocks according to their sectoral patterns of technical change: *i)* supplier-dominated (technical change introduced by machinery and raw material suppliers; example include agriculture, housing, private services and traditional manufacture); *ii)* scale intensive (increasing division of labor, project engineering and production as technological support, tending towards incremental innovations, such as bulk materials like steel and glass and assembly like consumer durables and autos); *iii)* specialized suppliers (dynamic companies which focus on product innovations and are mainly associated with the diffusion of the technical progress, like machinery and instruments); and *iv)* science based (R&D intensive; cooperation of universities and research centers, include industries such as electronics and electrical and chemicals). Originally published in 1984, Pavitt's taxonomy was updated by Bell and Pavitt (1993) to include information intensive activities. It is quite clear that PPI usually targets specialized suppliers and science based firms.

On the other hand, it is quite clear that furniture industry is typical low-technology supplier dominated industry, as it fit the characteristics of the traditional manufacture. Technical change in these firms is strongly associated with innovations that take place in the supplier industries (both machinery and raw materials). Supplier dominated firms are generally smaller (than other scale intensive firms) and have weak in-house R&D and engineering capabilities. According to Pavitt (1984), these firms "appropriate less on the basis of a technological advantage, than of professional skills, aesthetic design, trademarks and advertising".

In fact, innovation in the furniture industry comes from suppliers of equipment, machinery and raw materials (quality of sheet size, for example), as reported in the Brazilian Innovation Survey (PINTEC) published by the Brazilian Institute of Geography and Statistics (IBGE).

The manufacture of furniture is a traditional industrial activity, which used inputs of natural origin. Firms are typically labor intensive and present low technological dynamism (BNDES, 2013). In this sense, the Brazilian furniture sector presents low productivity, due to aspects such as investments in physical capital and intangible assets. These characteristics are in line with the dynamics discussed in this section (BATTISTELLA; NEGRINI; WITTMANN, 2007, p. 135). Impacts of innovations are perceived, to a great extent, as the quality of the products and as the fulfillment of export criteria (FREITAS; SILVA; SOUSA, 2012). These authors also point out that barriers to innovating in the furniture industry are motivated by norms, laws and uncertainties of demand. However, to some extent, in some occasions, there are barriers to entry due to economies of scale (BARROSO; CORREA; LEMOS; ROSA, 2007).

As we shown in the remaining of this paper, public procurement – though not explicitly aimed at promoting innovation – can affect the performance indicators of the furniture industry because it affects a series of aspects related to productivity. These aspects involve *i)* reduction of market uncertainties; *ii)* standardization of production; and *iii)* gains of scale) which, in turn, lead to *i)* process innovations; *ii)* acquisition of better machinery; and *iii)* labor force qualification, which may justify a better performance of firms (as measured by labor productivity). As a result, we argue that simple government procurement focusing on standardized products (as described by Edquist and Hommen, 1998) can improve the performance of traditional low-technology and supplier dominated industries (such as the school furniture industry in Brazil).

3 METHODOLOGY

As stated in the introduction of this paper, we intend to analyze the impacts of the NPR on the performance indicators of the school furniture industry in Brazil between 2009 and 2015. In order to analyze these impacts of public policies on firm performance, it is recommended to compare data on the treatment group (i.e., the group of firms that had access to the policy instrument) and the control group (i.e., a group of similar firms except by the fact that these firms have not had access to the policy instrument).

In the specific case analyzed in this paper, we compared average indicators of labor productivity of the furniture industry with average indicators of the firms at NPR group in the period between 2009 and 2015. Labor productivity was measured as the ratio between industrial value added (IVA) and number of employees (NE). We collected data on these variables from IBGE (PIA), in the case of the control group, and from SIGARPWEB, in the case of the treatment.

However, the direct comparison of descriptive statistics of the treatment and of the control group does not face causality issues. In other words: even if indicators of firms at NPR are higher, we cannot be sure whether NPR is the cause of that. There might be a selection bias (i.e., the firms capable of supplying to the government and as such at NPR could be the firms with better indicators). Some statistical methods do cope with this difficulty. Propensity score matching (PSM) methods, for example, can deal with selection bias. However, these methods require microdata which were not available.

Thus, to cope with causality issues, we used i) documental analysis (analysis of laws, for example); and ii) semi-structured interviews with strategic and operational agents of suppliers and potential NPR suppliers. These interviews focused on representatives of NPR participating companies (15 in total) in all editions, from May 2017 to June 2017..

Basically, we assumed transmission channels between public procurement and promotion to performance of low technology sectors. In the case of NPR and the performance of the school furniture industry in Brazil, the transmission channels may work as follows:

- The NPR regulation patterns would stablish product standards and quality control requirements. This aspect is considered a requirement for the success of public procurement policies for innovation in Valorvita's theory (2015, pp. 71-80).

- The design of the public procurement policy would generate possible gains in scale and reduce uncertainties, according to the perception of potential participants, This phenomenon would occur due to the level of adhesionto the proposal by the federated entities, identification of the size of lots by region and level of information about the process.

- Complementarily, the time of the processes for the acquisition of products to the education would behave better than the national average that is of six months (BARBOSA; DEZOLT, 2016). These factors would influence the reality of the business environment provided to RPN suppliers in the context of public procurement in Brazil.

This framework of analysis along with data extracted from SIGARPWEB (product prices and demanded quantity, by edition was used to guide the interviews and as a set of hypothesis to be tested during the interviews. Thus, we analyzed the occurrence of possible gains in scale and reduction of uncertainties, according to the perception of the potential participants about transparency process, symmetry of information, reduced time to electronic trade.

4 RESULTS

Based upon the methodological procedures described in the previous section, in this section we analyze the impacts of the NPR on the performance indicators of the Brazilian school furniture industry between 2009 and 2015.

Table 1 shows data regarding the average of NPR suppliers (treatment group) and the Brazilian furniture industry (control group). In the case of the control group, we considered only the firms with 5 or more employees in order to eliminate smaller firms which would not be capable of being NPR suppliers. Data concerning NPR suppliers are available each two year, so that we considered 2009, 2011, 2013 and 2015. In order to compare labor productivity (LP), we collected data on the industrial value added (IVA) and on the number of employees (NE) for both groups in 2009 and in 2015.

Table 1: industrial value added, number of employees and labor productivity, NPR suppliers and Brazilian furniture industry, 2009 – 2015

	2009	2015	Variation (%)	Standard Deviation (2015)
NPR's IVA aver. (R$ 1000)	10820.38	62673.54	479.22	45095,72
NPR's NE aver.	85	160	88.24	90,46
NPR's LP (R$ 1000/employee)	127.30	391.71	207.71	146,52

Sector's IVA aver. (R$ 1000)	20182252	15895104	-21.24	n.a.
Sector's NE aver.	229.051	260.839	13.88	n.a.
Sector's LP (R$ 1000/employee)	88.11	60.94	-30.84	n.a.

Source: Brazilian Industrial Survey issued by the Brazilian Institute for Geography and Statistics (IBGE) / SIGARPWEB. Elaborated by the authors.

As shown in table 1, labor productivity of NPR suppliers is higher than the furniture industry average labor productivity. In fact, in 2009, the NPR's LP indicator (127.30) was 44,47% higher than Sector's LP registered (88.11). In 2015 the difference between NPR's LP indicator and Sector's LP grew to 542,80%. Besides, between 2009 and 2015, the growth rate of labor productivity of NPR suppliers was 207.71%, whereas the growth rate of the furniture industry labor productivity was 30.84%.

Although causal relationships may be questioned, the magnitude of the difference suggests that NPR firms outperform the industry average. However, considering the impossibility of performing the econometric causality tests, we turn back to the transmission channels described in section 3 to verify the hypothesis of this work.

The project elaborated by the Foundation for the Development of Education of the State of São Paulo (FDE-SP)is the innovative design differential, with standardized specification, ergonomics elements, according to the technical information sheets of the product (FNDE, 2016). By reserving this activity to non-governmental partnerships (National Institute of Metrology, Quality and Technology - INMETRO and Brazilian Association of Technical Standards - ABNT), the NPR contributed to reduce e uncertainty and pressure for R&D investment, for design of innovative processes. In addition, it has collaborated through innovation to the service of human satisfaction, as pointed out by the interviewees.

NFDE server perform a document analysis in order to verify the requirements conformity about products . From this, most of the interviewees registered approval for transparency and impersonality of the process.

The interviewees highlight the impact of risk management as a strong criterion in the manufacturing process. Thus, leading companies agree that success in public competition depends on quality control policies and partnerships to obtain imports of equipment at a fair price, to reduce the margins of error in production.In the context of the furniture sector, the hiring of engineers and the qualification of the employees was an expected result. In the same way, the acquisition of imported equipment was pointed out as the safest investment for business owners. Still, according to the companies interviewed, in most cases, the countries of origin of the machinery were Italy and Germany.

At the same time, NFDE funding to the cities concerned to reduce the aversion to innovation risk inherent in the public sector. This represented, between 2009 and 2015, between 40% and 70% of the contracting of school furniture in the NPR.

Thus, the definition of specification, standardization, investment in machinery, qualification of labor and specific financial transfers for the purchase of school furniture influenced the reduction of risk aversion from the perspective of the furniture industry.

In this sense, it is understood that the business environment for the sector was more attractive, since it induced the investment of the companies by the NPR.

By using portals and systems for the dissemination of public policy, positive effects have been produced for the transparency of processes. Otherwise, public hearings prior to the bidding of each product, as in the case of school furniture, led to the involvement of companies in the furniture sector in the construction of decisions on specifications, methodologies and batch size organization.

In the managerial view, NPR reduces bureaucracy and simplifies hiring procedures through price registration. It is worth noting that the transaction cost of NPR participants does not compromise competitiveness and productivity. Testing in laboratories only occurs after confirmation of victory in the process. As a result, potential suppliers engage in public policy in a pro-trade environment, in less time: from six months (national average) to less than ten days. This is supported by Bonacelli and Foss (2016), Meerveld et. al. (2015), Valovirta (2015) and Vonortas (2015). In addition, this perception converges with the interviewees' point of view.

In addition, it was discovered from the interviews that the technological growth and specialization of the school furniture segment have intensified since the first edition of NPR. With the transmission channels (as analyzed in the previous section), security was generated so that the market wanted to promote adaptation of the industrial park to the government project. In some cases, companies dedicated to the corporate furniture segment migrated to the production of school furniture, expanded factories and altered working hours (2 to 3 shifts).As a result, companies improved their performance through *i)* process innovations; *ii)* acquisition of better machinery; and *iii)* labor force qualification.

5 CONCLUDING REMARKS

In this paper, we analyzed the use of public procurement as an industrial policy tool to improve the performance of the school furniture industry in Brazil, which is a sector dominated by suppliers (PAVITT, 1984). In particular, we analyzed the impacts of the Brazilian Price Register carried out by the Brazilian Ministry of Education on the performance indicators of the Brazilian school furniture industry between 2009 and 2015. We argued that public procurement has been widely recognized as an instrument for innovation and, more broadly, for industrial performance, but most analyses and case studies on this subject focus on the use of PPI in high-technology sectors such as the aerospace industry. We also argued that simple government procurement focusing on standardized products (as described by Edquist and Hommen, 1998) can improve the performance of traditional low-technology and supplier dominated by industries (such as the school furniture industry in Brazil).

We compared average indicators of labor productivity of the furniture industry with average indicators of the firms at NPR group in the period between 2009 and 2015. To cope with causality issues, we used i) documental analysis; and ii) semi-structured interviews with strategic and operational agents of suppliers and potential NPR suppliers. These interviews focused on the link between NPR objectives and results and on a theoretical framework of analysis. Basically, we assumed the existence of a set of transmission channels between public procurement and performance of low technology sectors.

In short, we concluded that NPR suppliers achieved better results than furniture sector. The relevants lessons learned about public procurement innovation were: *i)* reduction of market uncertainties (as a result of a more stable public procurement policy); *ii)* product standardization; and *iii)* gains of scale and, as a result, can improve their performance through *i)* process innovations; *ii)* acquisition of better machinery; and *iii)* labor force qualification. These conclusions were based on the perception of managers and owners of firms of NPR suppliers interviewed during the elaboration of this paper.

Further studies can, however, i) use microdata to compare control and treatment groups; and ii) analyze formats and configurations of lots in order to verify their impacts on performance indicartors.

The creation of business deals for a sustainable supply chain: The case of rail transportation

Katarina Arbin, Johan Kask and Frans Prenkert
Örebro University, Sweden

Abstract
This paper aims at presenting how business deals are created leading to a more sustainable supply chain through the achievement of improved fill-rates and reduced empty transports. A longitudinal case study has been conducted following a European network of logistic actors over a two-year period of time (2015 – 2017) that has managed to reduce empty transports from the south part of France to Sweden. Literature about business deals in network structures is used to analyze the case. The paper contributes with knowledge about ways to improve load factors, sustainable transport solutions and the creation of business deals in logistic networks.

Keywords: Sustainable supply chain, transportation, deals

Introduction

According to the World Economic Forum 57 percent of all shipments by truck in EU have free cargo capacity on route to destination, and 24 percent of the around 6 million trucks in EU return empty after the goods have been delivered (Doherty and Hoyle, 2009). Also the logistical rail system is currently unbalanced. For example about 50% of all northbound railway cargo wagons travel empty from terminals in Europe to Sweden even though these wagons, in principle, could carry freight northbound (Trafikanalys, 2011).

Unutilized cargo capacity is not only economically costly for the transport providers and the transport buyers: Overall, traffic congestion costs Europe around 1 percent of annual GDP and by 2050 the EU must cut transport emissions of greenhouse gases by 60 percent compared with 1990 levels to limit global warming to an increase of just two degrees Celsius; and despite improvements in energy efficiency, the transport sector still depends on oil for 96 percent of its energy needs (EU Transport Policy).

Faced with these challenges and knowing that a large part of trucks, wagons and cargos are going back empty after delivered goods to final destination, this classical balancing problem requires an improved matching of goods flows and available transport capacities to be solved. Reduced empty transports will contribute directly to a reduction of congestion and fossil fuel dependency and to lower transport emissions affecting global warming in a less negative way. At the same time it may contribute to lowering the shipping costs for logistics service providers and goods owners alike. But how do we do this? How can the fill-rates in a transportation system be improved?

There is a current body of literature focusing on the reduction of empty transports (Basu et al., 2015; Dong and Dong-Ping Song, 2013; Islam et al., 2013; Islam, 2017; McKinnon and Ge, 2006; Xie et al., 2017; Yu and Cristiano, 2014). This literature is however relatively scattered and incoherent, and a large part of the literature is disconnected from other research findings in the area, not building on previous knowledge.

Looking at the literature, focus has mainly been on tools such as auctions for improving the matching (Basu et al., 2015), models of operations in order to find new more efficient strategies for repositioning of empty containers and for empty container inventory sharing (Xie et al.,

2017; Yu and Cristiano, 2014) and mathematical models to tackle the empty container repositioning (Dong and Dong-Ping Song, 2013).
This paper however focus on *how* business deals are created leading up to improved fill-rates and reduced empty transports, contributing to knowledge about business creation in logistic networks. This is in contrast to offering a possible theoretical model as a solution to the problem with empty transports as a large body of previous research has done (Basu et al., 2015; Dong and Dong-Ping Song, 2013; Xie et al., 2017; Yu and Cristiano, 2014). The paper also contributes by using an empirical case of rail wagons instead of cargos and trucks that is mainly the case in previous research (Basu et al., 2015; Dong and Dong-Ping Song, 2013; Islam et al., 2013; Islam, 2017; McKinnon and Ge, 2006; Yu and Cristiano, 2014). Thus facilitating a deeper understanding for reducing empty transports specifically in railway transportation systems.
Even though transportation of goods is an important part of the supply chain, previous literature on supply chain collaboration disregards transportation as an important part of the supply chain (Chan and Zhang, 2011; Feng and Yuan, 2007; Islam, 2017). This is supported by Quarshie et al. (2015) who shows that only five percent of the supply chain articles related to sustainability published in 2007-2013 is about transportation and logistics. Moreover, we share the concern of Islam (2017) arguing that the traditional assumptions and boundaries of supply chain management should be expanded in order to consider the role of transport providers in addressing the challenges that are common in freight transport management. The role of effective and efficient transport is an important part of the supply chain. As an effect of the disregards of transport in the supply chain literature, there is thus limited research focusing on how to overcome challenges that hinder supply chain goals such as reducing empty miles for carriers in order to reduce cost and contribute to increased sustainable transport solutions (Islam, 2017). There is a clear need for more knowledge in this area, both from a theoretical and practical perspective.
The purpose of this paper is to investigate the creation of business deals within a logistic network, its impacts on the organization of the physical flows and the sustainability in terms of improved load factors. Hence this study contributes with knowledge about ways to improve transportation load factors, sustainable transport solutions and the creation of business deals in logistics networks
The structure of the paper is as follows. First an introduction to and description of theory is given followed by a section on methodology. Thereafter the case is presented. The analysis follows and the paper ends with conclusions, contributions and managerial implications. Due to limited space (ten pages) we will not be able to present the analysis as detailed as we wanted, we therefore save the extended analysis to a second version of this paper.

A network approach to business deals
In this paper we proceed from a network approach (Håkansson, 1982; Håkansson & Snehota, 1995; Håkansson & Snehota, 2005). The network approach origins from empirical studies within industrial marketing and purchasing (IMP) and departs from the basic acknowledgement of the fundamental role of interaction processes and relationships for business activities (Håkansson, 1982; Håkansson & Snehota, 1995). In the network theory approach it is the relation between organizations that is key, not the business unit per se, thus emphasizing inter-dependence and interaction.
When comparing the network approach to other perspectives and theories such as the resource based view, the rational planning approach and transaction cost theory, what clearly distinguishes the network approach from these is the view on (company) independence (Håkansson, 1994; Johanson and Mattsson, 1994; Baraldi et al., 2007). Contrary to the network approach where companies have a restricted view of the surrounding network (i.e. firms have limited freedom to act independently, and their actions will be dependent upon the actions of

other firms within the network), a company in the rational planning approach, the resource-based view and in transaction cost theory, is instead able to act independently (Johanson and Mattsson, 1994; Baraldi et al., 2007). The company can carry out its own analysis of the environment in which it operates, develop and implement its own strategy based on its own resources, taking into account its own competences and shortcomings (Baraldi et al., 2007). With other words, the resource based view, the rational planning approach and transaction cost theory are all more firm centric compared to the network approach. In their world it is possible to plan and execute action without being affected by other companies' actions such as suppliers, customers and competitors.

In contrast, the network approach assume less independence. According to Håkansson and Snehota (2006) the propositions of the network approach can be summarized as follows: 1. Business organizations often operate in a context in which their behavior is conditioned by a limited number of counterparts, each of which is unique and engaged in pursuing its own goals. 2. In relation to these entities, an organization engages in continuous interactions that constitute a framework for exchange processes. Relationships make it possible to access and exploit the resources of other parties and to link the parties' activities together. The distinctive knowledge of an organization is thus created through relations with others. 3. Since the other parties involved in the interaction also operate under similar conditions, an organization's performance is conditioned by the totality of the network as a context, i.e. even by interdependencies among third parties. In other words, no business is an island and relationships and interactions are necessary for all meaningful economic activities to happen (Håkansson & Snehota, 1989; 1995; 2006 Håkansson and Olsen, 2015).

Within these network interactions of various kinds, deals and transactions also exists (of course), that are shaped by network relationships and interactions. In Håkansson and Olsen (2015) deals are described as an analytical construct at the intersection between social-material activities on the one hand, and monetary transfers on the other. A deal regulates parts of the exchange situation and defines and shapes parts of the relationship among involved actors, resources and activities (Håkansson & Olsen, 2015; Olsen & Håkansson, 2017). On the one hand there is a complex – and to a large degree informal – value creating interaction process about actual work, services, products and technologies, and one the other hand there are financial resources and monetary cash flows. In between, there are constraining formal deals that are based on these activities that define the exchange conditions between them (Olsen & Håkansson, 2017).

Looking at the making of deals in a network approach context, there are few studies that have addressed and investigated this so far (Håkansson & Olsen, 2015; Olsen & Håkansson, 2017). To us this is surprising since deals and how to make deals happen are vital to companies and their survival, more research is thus needed about deals in a business network approach context. When to analyze deals, Olsen & Håkansson (2017) claim that the analysis should be divided into two different analytical perspectives; the process perspective and the structural perspective. The process perspective involves the emergence of the deal through its history of becoming, and then follow its paths as it interacts and develops in relation to other influencing forces and events over time. The structural perspective involves how the deal relates to other deals on both sides of the dyadic relationship and how the dynamics of deal structures and additional deals both shape the conditions for, and influence the further development of, a given deal.

In this paper we use the definition by Håkansson & Olsen (2015) and the way of identifying and analyzing different components affecting a deal by Olsen and Håkansson (2017). We thus use the analytical framework suggested by Olsen and Håkansson (2017) when analyzing our empirical data in order to identify and analyze the different components leading up to, in our case, a deal leading to improved fill-rates and reduced empty transports.

Analyzing business deals in networks

When analyzing the deal, we use the framework from Olsen and Håkansson (2017) consisting of six points that warrants attention. While using this framework as a point of departure, this paper however enrich the analytical framework by of adding in more detail concerning what to analyze within the different points. In this way we add empirical detail and content to the points helping structure the analysis further. The framework by Olsen and Håkansson (2017) is as follows:

1. Who is involved in the deal?
   Through this question we want to analyze first, which actors such as suppliers, customers, collaborators, facilitators etc. are involved in the deal, secondly, what are their roles in the network and the deal, third, how are they connected to each other and fourthly, what kind of relationship do they have with each other? This relates to actors both as organizations and as individuals and we want to capture a variety of types of interactions. For example, if there are there personal relationships between individuals or have they communicated only through e-mail and over the phone, do they know each other from before, have they done business together previously etc.
2. Who is taking the initiative?
   Though this question we want to analyse who (actor and person) that took the initiative to show the origin of the deal.
3. What is the deal about? What are the specific challenges faced by the project? Through this question we want to analyse what the deal is about and challenges faced by the project/business set-up. Here we also include and analyse how challenges were possibly overcome.
4. What characterizes the money-handling process?
   Through this question we analyse characteristics of the money-handling process in the rail transport industry context, showing the money streams going between different actors. We also analyse the level of transparency, i.e., how transparent are the involved actors, and how is overall profit distributed between the players/actors.
5. Are there clear relationships to other deals?
   Through this question we analyse first, if there are relationships to other deals, and secondly, if so, to what other deals and in what way have these relationships influenced the focal deal in this paper.
6. Are there particular consequences for the involved actors with respect to future participation in the project?
   Here we modify the question somewhat and phrase it "Are there particular consequences for the involved actors with respect to future deals?" This instead of "…with respect to future participation in the project". This since we are interested in consequences for actors in future deals through being part of this deal, and how this has influenced the deal making in this case.

A Longitudinal Case of a European Logistics Network

A longitudinal case study was conducted following a European network of logistic actors over a two-year period of time (2015 – 2017) that has managed to reduce empty transports from the southern parts of France to Sweden. The logistic network has during a relatively short period of time managed to fill wagons in a return flow that used to travel empty from France back to the original destination in Sweden every month. Semi-structured interviews with key persons in the logistic network has been conducted together with observations at meetings and documentation studies. Also group interviews have been conducted. Altogether around 25 interviews were conducted with persons in 6 different companies with different roles, such as goods owners, terminal operators, logistics organizer, etc. On average the interviews lasted for two hours. The interviews were recorded and parts relating to the case were transcribed. After a first case description had been produced it was sent back to the persons interviewed for

respondent verification. Following this the case were complemented in order to ensure factual accuracy and relevance. While some actors may have slightly varying views on what is going on, in this way facts and figures were quality assured. Following revisions the case was again sent to the interviewees who approved it.
As a complement to interviews a number of site visits were conducted in which for example, a terminal operations and layout were experienced firsthand by the researchers, and where the flow of some specific good could be followed.
Finally, whenever secondary data in terms of company records, web-site data and information from industry journals and agencies could be found, this was incorporated in the case to provide depth and nuance.
In this way multiple qualitative data sources were used to build a case (Yin, 2009). The use of case methodology to investigate business network is a fairly established tradition (Halinen and Törnroos, 2005). It benefits the dynamic and contextual characteristic of business network phenomena and is thus a well suited to capture processes and structures (in terms of contextual conditions) such as the ones in our framework of business deals in networks. Our ambition is to use the case to provide interesting empirical descriptions paired with new theoretical insights as a way to develop theory (Vaughan, 1992; Eisenhardt, 1989).

Case Description: The Creation of a New Deal
The case describes the journey going from a low fill rate in a northbound return flow in a rail transportation system to a large increase in a relatively short period of time and how this happened. The case describes the process leading up to the deal, including actors involved, how they are organized, how dependent they are on each other in making this deal happen and main conditions and i.e. factors leading up to the positive result.
The main actors involved in the case are a European freight forwarder, a fourth-party logistics (4PL) provider based in Sweden, a Swedish paper and pulp producer, a freight rail terminal in the southern France, a freight train terminal in Sweden, a European provider of wagons and a company in Spain selling laundry detergents.
The case starts with a 4PL provider that has empty capacity in the wagons going from the southern of France up to Sweden that needs a deal with someone in order to fill the wagons. The context is railroad.

How the deal happened
Some years ago the account manager of the European freight forwarder had direct contact with a Swedish paper and pulp producer being the subcontractor responsible for terminal services in the southern France. Through the paper and pulp producer the freight forwarder also came in contact with the Swedish 4 PL provider. Through this contact the freight forwarder gained knowledge about the empty capacity in wagons going from the terminal in the southern of France up to Sweden and that transportation space could be bought to a relatively low cost.
As background information it should be mentioned that in Spain the train width is different compared to the train width in France which means that goods coming by train from Spain through France need to be reloaded in order to continue travelling north. The freight forwarder had made a business form this, offering their services to customers from the Spanish side wanting to ship goods north though France. The freight forwarder thus had previous experience of Spanish customers wanting to ship goods northbound through France. They also knew the region well, having knowledge about potential customers and how they currently shipped their goods.

"*There appeared an opportunity, corresponding well to existing conditions*."
Account Manager at the freight forwarder

The account manager of the freight forwarder knew since before about a plant in Spain close to the French border belonging to a large international company that produced laundry detergent. He had taken note of their tenders through the years, but they were always long and challenging to respond to. Autumn 2016 he got information that the plant had been sold to a Spanish company and that they were about to deliver laundry detergent to a customer in Sweden.

"*I got a tip from a carrier that something was going on towards Sweden and then a person close to my family that worked for the large international company told me that they had sold a plant close to Barcelona. At the same time I remembered an inquiry to Sweden that I thought was a bit strange. All those things together made me realize that there could be a new northbound flow*." Account Manager at the freight forwarder

The freight forwarder approached the plant directly and got in contact with the right persons presenting an offer, which resulted in a deal. In order to get the deal, several practical conditions involving other actors had to be in place.

a) That there was a northbound flow already in place from the southern France to Sweden. This was offered by the 4PL provider.
b) That there was enough space at the freight rail terminal in the southern France for loading activities. This was achieved through the rail terminal in southern France.
c) That there were enough and the right type of wagons (for transporting consumer goods as laundry detergent), and also a possibility to add wagons if needed. This was offered through a collaboration with the European provider of wagons.
d) That the rail terminal in Sweden had previous experience of handling consumer goods.

The deal resulted in an increase in fill rate, going from 48 to 91 percent in six months' time.

The freight forwarder is the actor selling the solution, a door-to-door concept to the end customer, by using subcontractors to enable the offer. The freight forwarder is thus overarching responsible for the freight from the plant in Spain to the terminal in Sweden, and responsible for coordinating subcontractors and surveillance. The end customer, the Spanish plant, pays the freight forwarder that in turn pays its suppliers/subcontractors.

The freight forwarder played a central role for the deal to happen. It was the freight forwarder that initiated, coordinated and made the deal happen. The local anchorage was important, as was knowledge about the region and contacts. The subcontractors played an important role in enabling the door-to-door offer. Without the rail terminals, the 4PL provider and the European wagon supplier, the solution had not been possible. And without the Swedish paper and pulp company the freight forwarder would not have known about the 4PL provider and its empty carriers going northbound from southern France.

Preliminary analysis

Due to space restriction this analysis is a tentative analysis analyzing the case only on an overarching level not going into detail under each point in the analytical framework. The first point by Olsen and Håkansson (2017) is illustrated in figure 1 and the rest is summarized and presented in table 1.

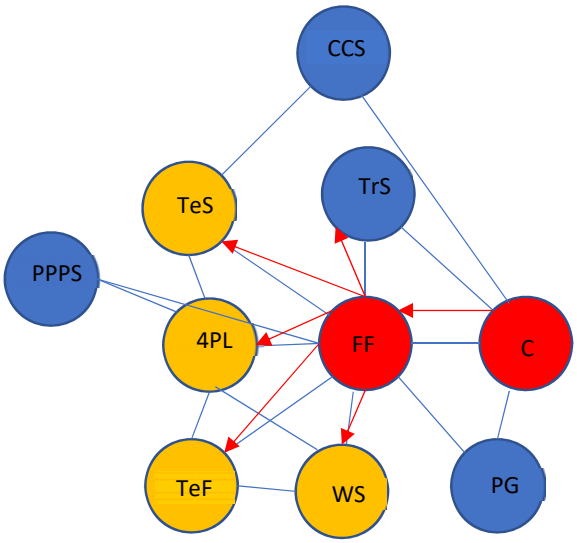

Figure 1. Who is involved in the logistic deal?
Red indicates directly involved, yellow indicates enabler and blue indirectly contributing to the deal.

Abbre-viation	Meaning
CCS	Customer to Spanish customer, located in Sweden. Customer Customer Sweden.
C	Customer, laundry detergent plant in Spain.
PG	Procter & Gamble employee informing freight forwarder person about potential deal.
TrS	Truck supplier, driving goods from outside Barcelona to Southern France.
FF	Freight Forwarder
WS	Wagon Supplier
TeS	Terminal Sweden
TeF	Terminal France
PPS	Paper and Pulp Producer in Sweden
4PL	Fourth-Party Logistics provider HQ in Sweden.

Point	
2. Who is taking the initiative?	Initiative to the deal is taken by the European freight forwarder, but the Swedish 4PL provider also have part in communicating free capacity to a relatively low cost due to return flow and pushing for a deal.
3. What is the deal about? What are the specific challenges faced?	The deal is about finding a win-win-win solution. From the 4PL provider perspective; filling the empty wagons going from southern France to Sweden. From the customer perspective; transporting goods in a secure and cost effective way from the border of Spain to Sweden. From the freight forwarder perspective; make a deal to make money. Challenges faced and overcome were: a) finding the right type of wagons for transporting laundry detergent and a flexibility in adding wagons if necessary, being able to promise that volume could be managed, b) availability to enough space at the terminal for unloading, loading and short term storage, c) offering a terminal in Sweden close to the customer's customer that had previous experience of managing consumer goods.
4. What characterizes the money handling process?	Money-handling process: the customer, the Spanish laundry detergent plant pays the freight forwarder that in turn pays its suppliers/subcontractors including the Swedish 4PL provider, the European wagon provider, the two terminals and its truck supplier (transport by truck from plant outside Barcelona to the terminal in southern France). For payment flows also see the red arrows in figure 1 above.
5. Are there clear relationships to other deals?	Regarding clear relationships to other deals, the main actors involved in facilitating the offer and i.e. the deal through the freight forwarder all knew each other from before, they were also involved in a parallel tender during this time resulting in a deal transporting goods from the Netherlands to Sweden. The freight forwarder knew about the customer (plant outside Barcelona) but no previous deal. Among the suppliers there were previous relationships to other deals, but not between the supplier network and the customer. None of the other actors except the freight forwarder in the supplier network knew about the customer's existence from before.
6. Are there particular consequences for the involved actors with respect to future deals?	Through participating in this deal, suppliers in the network (4PL provider, provider of wagons, terminals and the freight forwarder) get to know each other better, contributing to a stronger relationships. This will probably lead to more discussions how to collaborate and offer transport solutions through the freight forwarder. For the 4PL provider having a strong relationship with the freight forwarder and other European rail actors this enables business opportunities that the 4PL provider would otherwise not be aware of existed.

Table 1. Tentative analysis point two to six.

Conclusions, contribution and managerial implications

Conclusions

A conclusion is that none of the actors involved in enabling the deal could have offered the logistic solution by themselves. They are all dependent on each other in order to offer the logistic solution. None of the companies can be viewed as being independent, for all of them relationships to and interactions with other actors are necessary for the logistic offer to be possible. As the network approach argue, it is relationships that make it possible to access and exploit the resources of other parties and to link the parties' activities together. Without relationships and previous interactions with the 4PL provider, the supplier of wagons and the

terminals, the freight forwarder could not have offered the solution and i.e. realized the deal with the laundry detergent producer. Working together as a network is a prerequisite in order to make this kind of deal leading to reduction of empty transports through Europe and at the same time making money. The freight forwarder can however be viewed as the most important actor for the deal to happen, having knowledge about and contact in the region and i.e. contact with the customer. The freight forwarder acted professional and had the ability to get an offer together consisting of several actors and their services. Other actors were however needed in order to offer the solution.

Contributions

This paper has contributed to literature on deals in a network approach context through further enrich the analytical framework by Olsen and Håkansson (2017), this by adding in more detail concerning what to analyze within the different points. The paper has also contributed through using the analytical framework in another empirical setting, showing its relevance also in the rail transportation context. The paper also contributes with knowledge about the creation of deals in order to reduce empty transports in a railroad context, the importance of relationships and interactions resulting in creating and offering logistic solutions together with other actors.

Managerial implications

For a manager working in this empirical context it is a good idea to have an understanding of the importance of relations and interactions with other actors in the industry for finding new customers and improving fill rates. It is also good to be transparent about surplus resources and to some extent also regarding costs related to certain activities within the network of logistic actors. As a manager you need to have an understanding of where in the system there are surplus resources and make use of it. As a manager you also need to go outside your own organization and together with others find what is beneficial for both. In this case it was cooperation and "show the cards", being transparent with surplus resources and to a certain extent with costs, which gave the deal.

Summary
Purchasing and supply management influences practice through advancement of knowledge and theoretical principles and positions itself as an academic discipline. For the individual researcher, this calls for skills and experiences that can be associated with engaged scholarship. This paper explores tensions inherent in engaged scholarship, namely the quest to interact closely with professionals to ensure relevance and impact whilst at the same time live up to research quality criteria. The paper concludes that the individual researcher in a field such as PSM is easily left with guidelines that point in multiple directions as regards personal achievement and institutional merits.

Keywords: Engaged Scholarship, PSM, Professional Development of Researchers, Tensions.

Submission category: Working paper

Background
Scholarship in purchasing and supply management (PSM) intends to advance both theory and practice. As an applied academic discipline and a profession, the field has achieved a distinct status in industry by shaping and influencing how purchasing professionals operate through inter-organisational relationships in a wider context of supply networks. The field is developing as an academic discipline (Harland, Lamming, Walker, Phillips, Caldwell, Johnsen, Knight and Zheng, 2006; Johnsen, 2018; van Weele and van Raaij, 2014) and is still maturing (Wynstra, 2016) and getting a greater scholarship recognition (Zsidisin and Ancarani, 2016).

Another important feature in the development of PSM is the interaction between PSM scholars and professionals. Since PSM has increased in relevance for companies (Wynstra, 2016) and developed from a functional to strategic function (Johnsen, 2018; van Weele and van Raaij, 2014) it comes naturally that PSM scholars have become increasingly involved in interdisciplinary projects focused on research's relevance to practice (Knight, Tate, Matopoulos, Meehan and Salmi, 2016). That is, to become more engaged scholars that can balance rigor and relevance (van Weele and van Raaij, 2014) and use novel methods that are likely to improve understanding of known concept, or study new phenomena (Knight *et al.*, 2016). Van de Ven and Johnson (2006, p. 803) define engaged scholarship as "a collaborative form of inquiry in which academics and practitioners leverage their different perspectives and competencies to coproduce knowledge about a complex problem or phenomenon that exists under conditions of uncertainty found in the world." However, being the academic part of this collaborative form of inquiry comes with a price; not only do the researcher have to conduct rigorous research to coproduce knowledge about complex problems found in the world but should also be able to communicate and contribute to both academia and practice.

This paper builds upon the notion that the individual researcher experiences pressure from several directions, that deliver mixed messages about what tasks should be prioritized, what is being appreciated as output with relevant merits, and who the beneficiary of the outcome is. Also funders put requirements on business impact, utilisation and "technology readiness levels" as part of the research rather than part of the post-research dissemination (Wise, Berg, Landgren, Serger, Benner and Vico, 2016). The response to this development has been that an increased use of inductive and abductive reasoning as well as more participatory research methods that supports research relevance has become more acknowledged by e.g. academic journals (Knight *et al.*, 2016). On the other hand, whereas engaged scholarship may provide rich or novel insight for both academia and practice, it requires time, experiences and skills that are not always at hand for the individual researcher or may be in contrast with e.g. high pressure on a single dimension of research output, namely publications in highly ranked journals to attain promotion and tenure.

On the background of this, the purpose of this work-in-progress paper is to explore the tensions entailed in engaged scholarship as seen from the perspective of the individual researcher. The contribution of this paper is that we identify and describe various factors influencing the individual researcher. Then we identify and describe the tensions that arises when these influencers are contrary or conflicting and explain how they are inter-related.

Method/approach

This paper focuses on the relationship between engaged scholarship and PSM. Based upon the notion that PSM is an applied field that needs to develop further it's academic position, the tension that engaged scholarship entails will be conceptualised and explored. The study is at first hand based upon review of articles within PSM that are regarded of relevance to this, in particular on research methodology and theorizing in the field. Here, we also draw upon literatures on scholarship and collaborative research methodology. This is complemented by reviews of secondary evidence and archival data such as web-pages, reports and local instructions assessments of merits for promotion and when assessing research quality of academic institutions.

The approach taken is threefold: (1) *Literature* on theorizing and on research methods within participatory and collaborative research design is examined to conceptualise the "and" in rigor and relevance, and to provide background for concepts such as engaged scholarship in the analytical framework. (2) The *use of research methods* within PSM has been reviewed and analysed with respect to dimensions of engaged scholarship and scholarship in general (including application and integration). (3) *Tensions* that may arise between different influencing factors since the individual scholars do not only have to adhere to methodological principles but also operate in the context of institutional arrangements such as academic merits and reward systems have been identified. Accordingly, a *behavioural approach* (Bendoly, Donohue and Schultz, 2006) is taken to explore how the researcher as an individual relates to priorities set out by engaged scholarship and their institutional environment. By this, we suggest that the way by which engaged scholarship is operationalised is not only through the attributes of research method but also the conditions under which the individual researcher work, such as incentive systems, journal rankings and promotion criteria.

In order to strive for both rigor and relevance of our research we build upon the design science method (Hevner, March, Park and Ram, 2004) in order to understand, execute, and evaluate research focusing on the needs of an individual researcher in an academic setting within the PSM domain. The methodology applied is an exploratory multi-method approach initiated with a literature and document review resulting in a set of tensions. The next step in the design cycle will be to assess the framework using empirical data collected from PSM scholars at the 2018

IPSERA conference and analysed by using the principles of concept mapping (McLinden, 2017; Vaughn and McLinden, 2016).

Conceptual background

A call for more engaged scholarship – an external perspective

Given the nature of PSM as a field, we take a rather broad view on scholarship by following Boyer's (1990) distinction of scholarship that involves discovery, integration, application, and teaching, with our particular focus on the more engaged parts; integration and application. The interest in research approaches that can be associated with engaged scholarship seems to be increasing, both in the literature on qualitative methods and general management in general, but also in PSM in particular. Scholars in applied fields such as PSM have found it challenging to defend the scientific status of their research, both in terms of quality of publications, and in large when the field is compared with other academic disciplines, since the applied quality assessment criterions are not appropriate for engaged research.

First, much debate has taken place on how to balance academic rigour with practical relevance. There seems to be a general view that scholars must address both in their research (van Weele and van Raaij, 2014). This is not just a matter of writing about it in a journal article; rather, this relates very much to the research design and the conduct of research i.e. whether, or to what extent, rigor AND relevance being addressed. We find it useful to relate the dichotomy of rigor and relevance to scholarship in a wider perspective. Accordingly, our work is based upon Boyer's (1990) typology of scholarship that emphasises *integration* and *application* of knowledge.

Advancement through *integration* of perspectives across disciplines has had important impact on the development of PSM and its ability to deliver relevant results. This has resulted in the use of broader range of research methods (see e.g. Knight *et al.*, 2016) as well as borrowing "grand theories" from other fields such as management and economics (Carter, Kosmol and Kaufmann, 2017; Halldórsson, Hsuan and Kotzab, 2015). Relevance in this context does, though, not necessarily refer to practice or professionals, but rather relevance of PSM for other disciplines (see e.g. van Weele and van Raaij, 2014). One part of this development is the interaction of PSM with related areas such as supply chain management (Larson and Halldorsson, 2002) and industrial marketing (Johnsen, 2018), and by adopting theories from other disciplines such as transaction cost economics (TCE) and the resource-based view (RBV) (van Weele and van Raaij, 2014; Wynstra, 2016). Recent evidence also shows that this cross-fertilization is bidirectional; PSM does to an increasing extent contribute to journals in general management and economics (Wynstra, 2016).

Application of knowledge reflects in the way by which scholars interact with industry and professionals in research. The knowledge-creating relationship between the scholar and the professional is viewed from a *bidirectional perspective*; the knowledge is created at the intersection between scholars and professionals, i.e. research with rather than on practitioners. That is in line with the definition of "engaged scholarship" by e.g. Van de Ven and Johnson (2006), which has also been acknowledged in PSM (Walker, Harland, Knight, Uden and Forrest, 2008).

Second, another call for engaged scholarship comes from the emphasis on *theorizing*. Advancement in knowledge is not only stated in terms of "theory" or "testing theory" but also "theorising" (Swedberg, 2012); what the researcher does to produce a theory. This view brings particular attention to the *people dimension* of the researcher (or the scholar); the role of the researcher as individual in the act of theorizing in that it is "deeply personal in the sense that you can only theorize well by doing it yourself and drawing on your own experiences and

resources" (Swedberg, 2012, p. 2). A focus on theorizing pushes the boundaries of the current state of PSM research, which "has progressively evolved from a dominant exploratory focus to theory building and theory testing" (Wynstra, 2016, p. 218).

Third, new opportunities and challenges such as digitalisation may have disruptive consequences for the way in which managers operate, have led to greater *complexity*, which in turn requires more use of qualitative research methods to advance and disseminate knowledge (Guercini, 2014). Bringing PSM research closer to the particular context through balanced approach to rigor and relevance is not so much about dichotomy that is impossible to join, but rather about broadening a perspective of scholarship that bridges theory and practice through *theorizing*, acknowledgement of the researcher as individual, and the ability to solve *complex problems* through the use of qualitative research.

A call for more engaged scholarship – a PSM perspective

Scholars in PSM have reacted to the call for a broader perspective on research and scholarship. Considering the account of PSM by van Weele and van Raaij (2014), Wynstra (2016) and Johnsen (2018), the field has put more emphasis on scholarship of integration than on scholarship of application, by borrowing theories and concepts from other disciplines. PSM has acknowledged the importance of engaged research approaches (e.g. Walker *et al.*, 2008) and interaction with industry and professionals (Knight *et al.*, 2016). The research designs that dominate PSM are still surveys and conceptual approaches (Wynstra, 2016). Next to these in frequency of use are case studies, but the use of participatory and collaborative research approaches is "marginal in comparison" to these three predominant methods used (Wynstra, 2016). However, this does not say anything about the entire population of conducted research, only the sample that has been published. Earlier stream of research in PSM has assigned case studies, and in particular "casing", an important role in both advancing the development of the discipline in terms of theory development and by bringing operational closure between theory and data (Dubois and Araujo, 2007). And this quest for closure is still high on the agenda in PSM, where the points of reference cut across the research process, ranging from problematizing the particular study through use of methods and towards journal publications. First, Dubois and Salmi (2016) follow Alvesson and Sandberg (2011) by calling for *problematization* rather than gap-spotting to motivate research problems. To support this, they call for a more "diverse approach" to case studies than hitherto used in PSM. Second, Zsidisin and Ancarani (2016) observe that the core idea of JPSM is to *publish* research to advance *both* practice and theory. They also identify co-authorship between researchers and practitioners as further indicator of combination of rigor and relevance. Third, Knight *et al.* (2016) call for more *use of novel methods* in PSM research to promote learning and innovation. They continue to state two drivers of change; *concern* in terms of engaged PSM researchers and *curiosity* in terms of carrying out interesting research. Meehan, Touboulic and Walker (2016) claim that PSM needs an "engaged research" and pave the way for use of action research to influence organisations to engage in responsible PSM practice by challenging the "more dominant versions of PSM impacts". Common to these views is the quest for more proximity to, and engagement with, the profession of PSM in research, ranging from design, data collection and to interpretation of data and dissemination. This requires, however, the individual researcher to spend *more* time in the field, in an era where research quality of their institutions and individual merits during e.g. promotions are primarily assessed through non-engaged measures such as 'publications in highly-ranked journals'.

The call for advancement of research methods entails both strengthening current approaches and diversifying by seeking new ones. PSM seeks to *diversify* towards an increased use of more engaged research methods e.g. more diverse approach of case studies (e.g. Dubois and Salmi,

2016), use of novel methods (Knight *et al.* 2016) and action research (Meehan *et al.* 2016), but there are other pathways as well. van Weele and van Raaij (2014) put emphasis on *enhancement* of current methods and suggest that more replication studies and meta-analysis will both enhance rigor and benefit the field. Ellram and Tate (2016), on the other hand, suggest that secondary evidence may be useful to strengthen the use of multiple source of evidence. It is, however, particularly the diversification that paves the way for engaged scholarship.

The scholar as a part of research practice – influencers

This section suggests that the work of scholars in PSM is affected by influencers. Understanding the implications of these leads to a number of tensions that are derived from these. We refer here to 'influencers' as factors that shape the priority and work of the individual scholar, and act as point of reference for achievements across various dimensions. Based upon a review of literature and scrutiny of secondary evidence, two main categories of influencers are suggested. First, *institutional* influencers refer to the external environment of scholars and their academic disciplines that range from funding bodies and national schemes for assessment of research quality towards guidelines for assessment of achievement of individuals during recruitment and promotions. Together, these can be associated with accountability of research output in various forms and levels. The second category refers to *PSM as an academic discipline* and can be viewed as a more bottom-up, compared with the top-down nature of institutional influencers. Under here, academic journals, the nature of the subject area in terms of methods as well as concepts and collegiality are considered.

Methods are here given particular emphasis here as they define the space between research and practice, and it is often with reference to methods that the discussion on rigor and relevance takes place; we talk about advancement and development of our fields in terms of methods (e.g. JPSM special issue in 2016); and it is in this domain that the researcher as individual – with skills, tools and personal characters – can become engaged (and theorize, cf. Swedberg's 2012 account of this as being quite personal effort).

Institutional influencers

1. Funding criteria, which are diverse in scope. On one end, we have the large government funding agencies (e.g. VR and SSF in Sweden) in which subjects such as PSM may find it difficult to compete with more established disciplines from natural science and basic research. Here, strong focus is on the scientific status of the applicant, publications, and international experience. Other funding bodies focus more directly on innovation and industry competitiveness and are concerned with relevance and application of results through e.g. "Technology readiness level" and "Industrial leadership" (e.g. Horizon 2020, and KKS and Vinnova in Sweden). Here, scholars are expected to involve companies as project members to co-fund projects and co-create knowledge, to ensure that there is a commitment to both availability of empirical evidence and opportunity for intervention. A strong industry-consortium adds to the legitimacy of research applications, and being an engaged scholar is more or less a requirement.

2. National research assessment schemes that are common in e.g. UK and the Netherlands, and are emerging elsewhere on the agendas, e.g. in Scandinavia. Focus is on research output, and whether it is the intention or not, quality and number of journal publications as well as citations and international collaboration that can be conveniently depicted through bibliometrics have become increasingly important part of these assessments. Also included here is research environment (e.g. doctoral students, research funding) and research impact on practice, albeit practice for assessing this type of achievement is much less developed compared with the interest institutions and governments have in bibliometric data. As an engaged scholar this might mean that a considerable part of your work is not subject to assessment.

3. University promotion criteria and reward systems cut across all scholarly activity, and regard both internal and external working environment of scholars. Although these are very broad in scope, and some variance occurs amongst institutions, both nationally and internationally, one criteria tends to dominate decisions for promotions and rewards, namely achievement in research in terms of number of papers, number of citations, level of journals, and co-authorship internationally. Scholars are also expected to demonstrate excellence in teaching and ability to develop new techniques, courses, programs (at all levels), have experience in working with industry in different modes, and attract external funding. Furthermore, successful scholars should also contribute to services to the academic community as demonstrated by active involvement in academic associations, research councils, funding bodies and evaluation committees, both national and internationally; editorship or member of editorial review boards of scientific journals, review activities, experience as opponent at doctoral defenses/vivas (e.g. Ministry of Education and Research, 2014).

Influencers: PSM as an academic discipline

4a. PSM – methods: Sensitivity to the empirical context can be seen as part of theorization in PSM (see e.g. Halldorsson *et al.* 2015). Such proximity can be created through particular type of *research methods* but is also determined by the nature of the concepts and theories under scrutiny. The type of knowledge and the way by which scholars interact with industry/ professionals in their research can be understood in relation to the predominant *methods* in the field, in PSM being surveys, conceptual work and case studies (Wynstra, 2016). As influencer, method can point scholars into directions: using common research methods and build upon established practice and enable more replication studies. Or, to use current status of method usage to seek new boundaries through new or emerging methods and collaborative approaches that enable greater proximity to the empirical field, which have been called for, but are not yet common in published material.

4b. PSM – domain: *Concepts and theories* of the subject area may also set conditions for the work of scholars; when operationalised, a particular method may be called for that considers the particularities of these when investigated. A recent account of PSM in industrial marketing and management by Johnsen (2018) identifies four themes, all of which leave an impression of PSM as an intersectionist-concept (e.g. Larson and Halldorsson, 2002); PSM relates to marketing, new product development, and services. Further, networks as theme in PSM indicate that the perspective of a set of actors is also to adhered to. LaPlaca, Lindgreen and Vanhamme (2018) point out that when units such as dyads are studied, it is natural to collected evidence from both parties of that unit, i.e. the method must match the concept. Johnsen (2018) suggests that future research must pay more attention to both theory and management of networks, hence calling for even more sensitivity to the context and attributes of engaged scholarship such as the concept of arbitrage for "surpassing the dual hurdles of relevance and rigor in the conduct of fundamental research on complex problems in the world" (Van de Ven and Johnson, 2006).

5. Journal editorial policies and practice: Editorial *policies* outline a brief scope of a journal, and do frequently refer to improvement of industrial practice, practical relevance, managers, practitioners and professionals in their target group statements. Such statements were found in the statements of eight of nine journals relevant to PSM scholars that were reviewed for this research (JPSM; JSCM; IJOPM; IJPDLM; IJPE; JOM; OEMGA; POM; SCM:IJ). However, non-practitioner-oriented research still constitutes the majority of papers published in the area (Bäckstrand and Säfsten, 2017), regardless of what their stated audience or mission is. As regards editorial *practice*, LaPlaca *et al.* (2018) mention potential for citation as a factor that may increase chances of an accept of a manuscript. Further, based upon our personal experience, considering H-index of a researcher and likelihood for citation may also be factors

that cross minds of an editor, whether that is to attract a paper to a e.g. special issue or to judge the validity of the findings of a manuscript.

6. Academic citizenship and work-life balance: As an academic, other tasks than the ones stated under 'University promotion criteria' might be required from you. In a report from 2017 Gosling gives 12 examples of such engagement activities; Contributing to media coverage, Industry engagement, Leading research centres, Leading executive education programmes, Knowledge transfer partnerships, Working with associations, institutions and bodies, Writing guides, articles and books to support practitioners, Popular science speeches and articles, Linking research, teaching and practice, Winning awards, Hosting events, and Informing policy, public sector and government. As a 13th activity we can thus add "write department reports". These types of engagement are more often than not, carried out outside regular working hours, hence affecting the work-life balance (Burg and Macfarlane, 2017).

In summary, this list of influencers is quite diverse, and leaves an impression of ambidexterity or even multidexterity as regards scholars in PSM. These can both relate to a multitude of opportunities and the sense of being squeezed in the middle of conflicting and contrary influences. The following section addresses this further in terms of tensions.

Analysis – tensions

A tension refers to ambiguity and even conflicting messages from influencers to the scholar as an individual. This logic is summarised in Figure 1. One form is *divergence* in the consequences of the influencers, they simply contain conflicting directions. Another firm is *variety*; influencers provide multiple directions. Finally, *volume*; the scholar is expected to do more of the same, without a reflection upon what do reduce or remove.

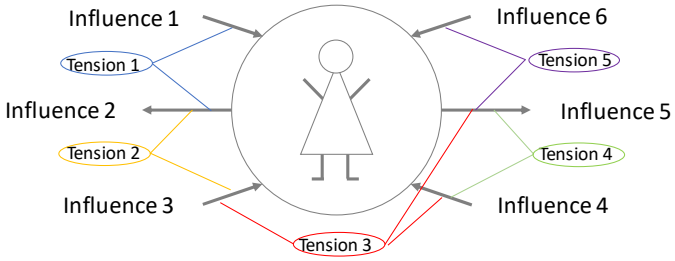

Figure 1. The Engaged scholar - Creative tension or squeezed in the middle?

The tensions reviewed below are derived from analysis of the influencers above, both in relation to each other, and ES. In this paper, priority is given to divergence of influencers.

T1 – Actionable and publishable? Usefulness of research is associated with actionable knowledge, which refers to a particular form that allows for an effective intervention and prescribes how to solve a problematic situation in practice (e.g. Van de Ven and Johnson, 2006). Although editorial policies of journals relevant to PSM explicitly identify practice or managers as audience, our review of managerial or practical implications in JPSM from 2015-2018 suggests that these primarily describe what can be done, but do seldom spell out the particular situation, or move beyond description towards prediction or solution. They stay at the 'may be' rather than 'will be' form. This may be due to the journal article format, conventions, or simply because we as scholars write implications for practice with other scholars, not managers, as intended readers. Interestingly, only one out of nine journals reviewed, namely JSCM, states clearly that practical oriented papers should be submitted to practitioner-journals.

T2 – Funders and use or research methods in PSM: This is a tension between what funders of applied research would expect (relevance, industrial competitiveness, innovation), and the

predominant methods use in PSM (survey, conceptual approaches, and case studies). One way of advancing the field is to make more use of same methods through e.g. *replication studies or meta-analysis*. Whilst this may support rigor (e.g. van Weele and van Raaij, 2014), the quest by funders to create business impact for increased competitiveness and results at an advanced technology readiness level, i.e. almost market ready solutions. Two questions emerge out of this. First, will funders provide resources to replication studies that may be more relevant for the rigor of PSM than the relevance to practitioners? Second, it is argued above that more relevant research needs more collaborative research approaches. The (rhetoric) question is what is whether current method portfolio in PSM will allow us to move beyond incremental changes, or whether we need more disruptive challenges that make collaborative and action-oriented methods more prevalent?

T3 – Do funders line up with calls on PSM subjects? As profession, PSM has grown in size and relevance, and gained a strategic position in many organisations. Interestingly, though, open calls for funding applications do seldom refer to PSM as the main focus. Rather, the subject can be a part of a call that e.g. refers to 'value chain' and 'suppliers', but calls tend otherwise to be sectoral, e.g. on transportation and healthcare. This may explain the intersectionist focus of PSM, i.e. to get funding, we seek theorization of PSM through topics announced by funders. This means that the development of the field as e.g. reviewed by Johnsen (2018) is not only a subject of the 'freedom' of the individual scholar but also influenced research funding bodies.

T4 – Collegial nature of PSM and ES vs. the "new public management" regime: Many characteristics of PSM such as focus on study of different actors in a supply network, and link with other functions such as marketing, services and new product development are collaborative in nature. Same regards the researcher-practitioner feature of ES. First, these stand in contrast with the new public management that is infused into academia through national research assessment schemes, and that in their operationalisation put emphasis on codified achievements such as bibliometrics rather than dealing with more intangible outcome such as business impact of research. Second, creating networks with industry, and studying supply networks can be time consuming, and may happen at the cost of spending more time on publishing papers in journals, which in turn reflects in achievement in terms of bibliometrics. Yet, academic citizenship and its association with collegiality is of immense importance for both young and senior scholars.

T5 – Happy idiots? The multiple nature of influencers requires good management and leadership skills to coach scholars through their career development in prioritising relevant activities at particular stages of their career. Funders pull towards practical relevance of research whereas rigor and journal publication have high status in reward systems and national assessment schemes. Adding good citizenship in academia to this, it and becomes an easy task to get lost in relevant tasks such as developing educational programs, spending time on attracting funding and managing large research projects, and working with industry, all of which are given lower priority than highly ranked journal articles when it comes to academic promotion or recruitment.

T6 – 24 minus 8 -- who gets the other 16 hours? Since the individual researcher is expected to contribute to the academic society, and even society at large, regardless if this in included in their job-description or not, this usually results in a work that takes place outside usual working hours. Academic "work" is easy to mix up with "life", and at an early stage of their career, many scholars experience difficulty in managing the work-life balance; requirements are immense, leadership is often note geared to deal with these and to create conditions that allows talents to grow and get promotion, and some big steps in the career development take place at a time when scholars are establishing families or re-locating for new universities. This affects

parents in general and female academics in specific since the society traditionally have higher expectations on mothers taking the main responsibility for the family and the household chores.

Final remarks

The scientific status of our subject area, ranging from SCM in general, towards logistics, PSM and operations, as well as practical relevance of research of these, is of growing concern for various stakeholders. A predominant point of reference has been the need for both rigor and relevance in research, which often takes place through discussions on what topics and research methods to pursue and moving towards more 'theorizing'. One way of responding to these increased or new expectations is through engaged scholarship. Even this pathway is strongly concerned with methodological matters, where knowledge (transfer, creation, and co-creation) and interaction between researchers and practitioners are in focus. However, less attention is paid to the individual researcher; what does all this mean, and what does it mean to be (or become) an 'engaged scholar'? The relevance of such focus on the individual is only enhanced by the understanding of theorizing as an important part of advancing the field; theorizing builds very much upon the personal experience and resources of the individual scholar.

By envisaging a PSM scholar as an 'engaged scholar' we have identified a set of *institutional* as well as discipline-based (PSM) *influencers.* These shape the conditions in which the various from of scholarship take place. Starting with the hope that the *tensions* that emerge out of this would result in 'creative tensions' we have ended up with a much more pessimistic and perhaps realistic view, namely that it is likely that we feel as 'stuck in the middle'.

Overall, there seems to be a discrepancy between requirements and opportunities, and the way by which these are rewarded. Current research methods in PSM are still biased towards quantitative methods such as survey studies and mathematical modelling. Participatory and collaborative are increasingly called for, but it is yet to be evident whether these have gained traction. However, scholars adhering to the more practitioner-oriented research, that ought to be for granted in an applied area such as PSM, are exposed to inconsistencies and misalignment between different requirements.

The paper identifies a range of inconsistencies and misalignments amongst requirements that are put on the individual researcher. These range from academic system (counting publications and assessment regimes that build on New Public Management that stand in stark contrast with e.g. academic citizenship and collegiality) through the requirements from the academic institution (teaching, networking, applying for funding, administration etc.) as well as the academic society (reviewer, editorials, organizations, conference arranger, grading committees etc. e.g. being an academic citizen) towards the society in large (increase competitiveness of national companies). In addition, the nature of PSM as an applied field, and the methodological range implied in engaged scholarship make this situation even more complicated for the individual researcher to act in.

Of course, we are not free of personal bias in this account. But we want to put this item on the agenda and have a dialogue with colleagues about how to become an engaged scholar.

Summary

The SCF ecosystem and market dynamics of SCF have so far not been widely studied. This paper focuses on conceptual development of a SCF ecosystem view by building biomimicry research, thereby extending SCF adoption research to the broader SCF ecosystem. This paper argues that increased connectivity and intensified information flows, enabled through information technology, is the innovation at the center of the evolution of the SCF ecosystem. However, the fragmentation within the current SCF ecosystem is likely to hinder such further co-evolution and transparent information flow, and as a result is likely to limit its broader adoption. The current state of SCF ecosystem fragmentation will be compared to key principles from natural ecosystems in order to derive propositions on how SCF ecosystem fragmentation might be addressed.

Keywords: Supply Chain Finance, Ecosystem, Market, Transaction Cost Economics, Biomimicry

Submission category: Working paper

Introduction

Previously rather largely ignored in the field of supply chain management (SCM), financial flows in supply chains are increasingly getting into the center of attention in research and practice (Gelsomino et al., 2016; Liebl et al., 2016; More and Basu, 2013; Pfohl and Gomm, 2009; Wandfluh et al., 2015). To the backdrop of the last financial crisis, companies needed to find liquidity solutions in a context characterized by restricted access to capital (Caniato et al., 2016; Gelsomino et al., 2016; Liebl et al., 2016). The solutions created in response to this situation spurred the growth of the area of supply chain finance (SCF) (Gelsomino et al., 2016; More and Basu, 2013).

Currently, technological changes are reshaping the overall business ecosystem of which SCF is part. Ecosystem dynamics have been described by Moore (1993: 76) as follows: "In a business ecosystem, companies co-evolve capabilities around a new innovation: they work cooperatively and competitively to support new products, satisfy customer needs, and eventually incorporate the next round of innovations." As information technology is enabling greater connectivity and information flow, it can be argued to be the innovation at the center of the SCF ecosystem. This improved connectivity and increased flow of information (e.g. through platforms), is decreasing information asymmetry between actors and therefore

challenging existing business models (Ng, 2014; Fairchild, 2005). As a result, since SCF solutions basically are formed by information and financial flows between multiple parties, following a business ecosystem view is regarded as helpful to understand the evolution of SCF.

The SCF ecosystem and market dynamics of SCF have so far not been widely studied, with exception of Iacono et al.'s (2015) simulation of a SCF market. The current SCF ecosystem has, however, been described as limited in reach and fragmented in its implementation (Gelsomino et al., 2016; Iacono et al., 2015; Nienhuis et al., 2013). Fragmentation in the SCF market is mainly reflected by a high number of competing closed provider-specific platforms as well as varying formats and definitions (Nienhuis et al., 2013; Martin and Hofmann, 2017; Fairchild 2005). Consequently, the need for providers to agree on standards and collaborate has been identified as one of the central pre-requisites to improve the current situation and allow the SCF market to grow further (Nienhuis et al., 2013; Martin and Hofmann, 2017; Forum, 2016).

This paper focuses on conceptual development of a SCF ecosystem view by following a biomimicry lens, building on research into forest ecosystems (e.g. Simard et al., 1997, 2012), thereby extending SCF adoption research to the broader SCF ecosystem and seeking to derive propositions on how the SCF ecosystem fragmentation could be reduced and co-evolution be fostered.

Biomimicry as a concept is known mostly from R&D applications, where products are developed that emulate natural examples/archetypes, such as the well-known sticking patches developed from imitating gecko feet (Sivakumar, Balasubramanya & Sundaresan, 2012). But reaching beyond products, biomimicry also looks for insights on managerial processes and organizational issues: "Biomimicry is an approach to innovation that seeks sustainable solutions to human challenges by emulating nature's time-tested patterns and strategies. The goal is to create products, processes, and policies—new ways of living—that are well-adapted to life on earth over the long haul" (Biomimicry Institute, 2017).

The idea is that natural ecosystems exhibit certain properties in their structure and evolutionary process that can be of inspiration to the emergent SCF ecosystem. Thus the overall research question is: *Which principles from natural ecosystems and their evolutionary processes can help overcome the current fragmentation of the SCF ecosystem?*

The paper is organized as follows: The current SCF ecosystem will first be described. Next, key principles from natural ecosystems and their evolution will be summarized from literature. Finally, these two will be contrasted and compared in order to derive preliminary propositions on how SCF ecosystem fragmentation might be addressed.

The current SCF ecosystem

Coming back to Moore (1993: 76), it becomes clear that there is not just one single ecosystem at any time, but instead "[…] in any larger business environment, several ecosystems may vie for survival and dominance […] In fact, it's competition among business ecosystems, not individual companies, that's largely fueling today's industrial transformation." Following that insight, the business ecosystem perspective is dynamic instead of static. From studying these dynamics, Moore (1993) has identified four stages of ecosystem evolution – i.e. (1) Birth, (2) Expansion, (3) Leadership, (4) Self-Renewal (as shown in Figure 1).

SCF Ecosystem

The Evolutionary Stages of a Business Ecosystem		
	Cooperative Challenges	**Competitive Challenges**
Birth	Work with customers and suppliers to define the new value proposition around a seed innovation.	Protect your ideas from others who might be working toward defining similar offers. Tie up critical lead customers, key suppliers, and important channels.
Expansion	Bring the new offer to a large market by working with suppliers and partners to scale up supply and to achieve maximum market coverage.	Defeat alternative implementations of similar ideas. Ensure that your approach is the market standard in its class through dominating key market segments.
Leadership	Provide a compelling vision for the future that encourages suppliers and customers to work together to continue improving the complete offer.	Maintain strong bargaining power in relation to other players in the ecosystem, including key customers and valued suppliers.
Self-Renewal	Work with innovators to bring new ideas to the existing ecosystem.	Maintain high barriers to entry to prevent innovators from building alternative ecosystems. Maintain high customer switching costs in order to buy time to incorporate new ideas into your own products and services.

Figure 1 – Evolutionary stages of a business ecosystem (Adapted from Moore (1993))

Following the above stage model, the SCF ecosystem can be argued to currently be between stages (2) Expansion and (3) Leadership. Moore (1993: 79) characterizes stage 2 by two conditions, which are also present in the current SCF ecosystem: "[…] (1) a business concept that a large number of customers will value; and (2) the potential to scale up the concept to reach this broad market." This is reflected in the growing number of offerings and providers entering the SCF market. In addition to banks, new SCF providers include platform providers with different capabilities, such as multi-bank platforms (Liebl et al., 2016; de Meijer and de Bruijn, 2014; Martin and Hofmann, 2017; Nienhuis et al., 2013).

In comparison, the characteristics of stage 3 are not yet fully shown by the SCF ecosystem. Stage 3 is described as follows: "First, the ecosystem must have strong enough growth and profitability to be considered worth fighting over. Second, the structure of the value-adding components and processes that are central to the business ecosystem must become reasonably stable. […] It's in Stage 3 that companies become preoccupied with standards, interfaces, 'the modular organization,' and customer supplier relations" Moore (1993: 80). The necessity for stable components underlines the current lack of standards in SCF as identified by Martin and Hofmann (2017) as well as Fairchild (2005). E.g. "One problem in this context is the lack of standards when financial services are communicated. For instance, approved payables financing is also known as SCF or supplier financing. It can be offered as an early-payment product or a true-sale product. Therefore, it becomes difficult for customers to understand products and compare different services" (Martin and Hofmann, 2017: 54). And concerning the customer-supplier relationships: "Finally, the variety of FSPs increases the diversity of practices and applied platforms due to a lack of standardization. For instance, one supplier may be part of several different supply networks and consequently, multiple platforms. Hence, FSPs often neglect the need of standards when deriving service specifications" (Martin and Hofmann, 2017: 54).

Nienhuis et al., 2013 argue that it is this lack of standards as well as the missing collaboration between providers, which leads to the current fragmented state of the SCF ecosystem. They go on to argue that overcoming this fragmentation is needed to further grow the SCF market, benefitting all actors in the SCF ecosystem. But this requires a paradigm shift in thinking of providers. It can be argued that one of the barriers is the perceived benefit of customer "lock-in" to the provider. These "lock-in" effects can be seen as beneficial from a provider perspective (e.g. arising from the use of a proprietary platform) as they help retain customers and provide a basis for longer-term cross selling (Iacono et al., 2015; Silvestro and

Lustrato, 2014; Hofmann and Zumsteg, 2015). However, from a corporate client perspective, the same scenario is negative as it limits options and potentially competition on financing costs when binding a company to a particular solution and funding provider (Martin and Hofmann, 2017; Liebl et al., 2016).

The lack of standards has also been identified as a major issue by practitioners. In 2016 the International Chamber of Commerce (ICC) and various industry associations produced a joined whitepaper proposing standard definitions for SCF terms and products. In that whitepaper, they state: "The value of a standard global terminology around SCF extends beyond pure financial transaction considerations, to the realm of automation, dematerialization and technology**.** […] Whilst perfect consistency is unlikely given the diversity of SCF techniques, standard nomenclature will greatly facilitate the design, development and deployment of the supporting technology and web-based services for the SCF market. A lack of standards will impede these processes" (Forum, 2016: 19). Coming back to the optimization of information and financial flows, automation and digitalization of supply chains was highlighted in its importance by Caniato et al. (2016: 541f.) who found in their case studies that: "Several managers highlighted how the implementation of the most complex SCF solutions requires a complete digitalisation of the trade process." Therefore, we can conclude that standardization together with higher degrees of automation are key conditions to getting the SCF ecosystem to the next stage of maturity according to Moore (1993).

Toward the aspect of participants in ecosystems, within the business setting Manikas (2016: 93) defines a software ecosystem "[as] the software and actor interaction in relation to a common technological infrastructure, that results in a set of contributions and influences directly or indirectly the ecosystem. […] The activity of each actor is motivated by value creation both towards the actor and the ecosystem. […]. Moreover, each actor has one or several roles in the ecosystem. One role that can influence the ecosystem to a great extend is the orchestrator. The orchestrator is the actor or set of actors that are typically responsible for governing the ecosystem and support (and possibly promote) the actor and software interaction to the extend required to meet the ecosystem needs and principles." This highlights the importance of having a certain number and variety of actors within ecosystems, already from a business perspective. As will be explored next, actors are also a central theme in biological ecosystem research.

Biomimicry – learning from natural ecosystems

Within mature natural ecosystems efficient and effective (re-)usage of resources (e.g. water, minerals etc.) is ensured by members of the system occupying one or multiple of four roles: producers, consumers, scavengers and decomposers (Liwarska-Bizukojc, Bizukojc, Marcinkowski, & Doniec, 2009; Geng & Côté, 2002). Within natural ecosystems, primary producers are, for exempla, plants, consumers are predator animals, scavengers are animals that search and feed on carcasses and decomposers are the fungi and bacteria.

The authors propose that these roles can also be applied to the SCF ecosystem, where actors occupy multiple roles along the two main resource cycles of information and funds. For example, suppliers are producers of information (invoice) and consumers of funds. By contrast, banks are consumers of information (for risk assessment) and producers of funds. Multi-bank platform providers can be seen as a form of scavengers and decomposers, who collect, transform and distribute information and funds amongst parties as needed.

Turning toward the distribution of each role in mature natural ecosystems the producers, scavengers and decomposers are the majority, the consumers the minority (Geng & Côté, 2002). While the analogy might not translate 1:1 to the SCF ecosystem, it can be noted that currently there is a lack of scavengers and decomposers helping to facilitate the smooth flow of information and funds amongst all producers and consumers.

One example of how natural ecosystems use decomposers to maintain information transparency as well as coordination of material flows are the mycorrhizal fungi networks within forests. The mycorrhizal (the term for "root-fungus") fungi networks "gather nutrients from farther away and trade them with the plant for sugar, eliminating the need for the plants to develop extensive root networks" (Rade, 2015). In fact, the fungi provide the infrastructure for a lively two-way exchange of nutrients and information between different species of trees: "Mycorrhizal fungal networks [i.e. root-fungus networks] occur where mycorrhizal fungal mycelia [like a web of threads] link the roots of multiple plants, including those of different species, sometimes facilitating interplant transfer of carbon, nutrients or water" (Simard, 2009: 95).

Preliminary results and discussion

In order to arrive at a healthy SCF ecosystem reflected in the transparent, efficient end unhindered flow of information and capital to create value for all involved parties, the central principles emerging from this explorative study are: 1) Standardization, 2) ecosystem actor diversity, 3) modularity and 4) orchestration. Figure 2 summarizes them in a sequential manner.

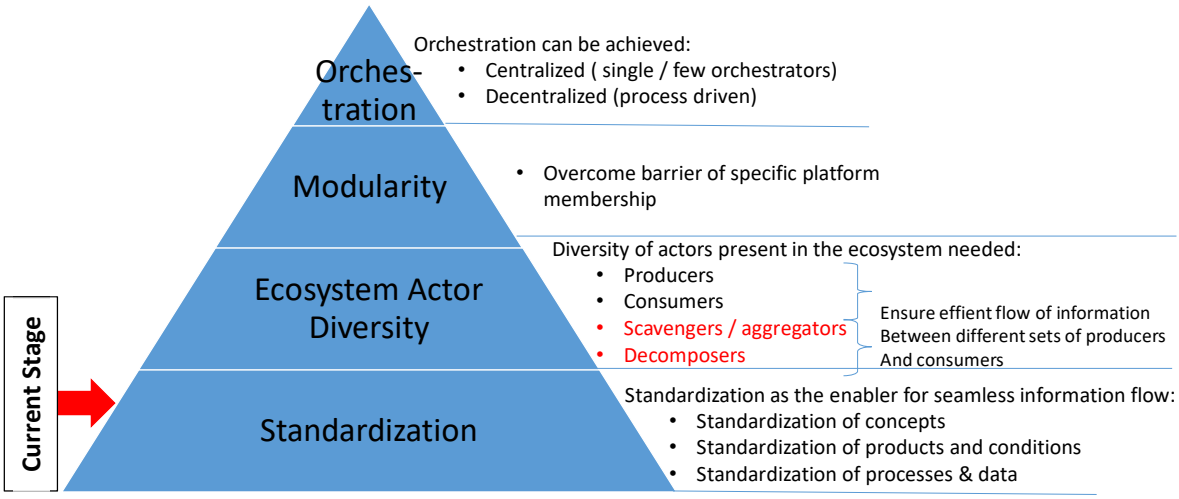

Figure 2- Pre-requisites for achieving ecosystem health & balance

As discussed earlier, standardization is a current challenge, while at the same time being the first precondition to further advance the SCF ecosystem. Standardization can be further differentiated into:

1) Standardization of concepts – agreed scope; definitions and terminology; value proposition etc.
2) Standardization of products and conditions – agreed parameters for a defined set of comparable offerings, which can be evaluated by customers
3) Standardization of processes and data – agreed parameters for a defined set of processes and data needed in order to provide the products.

As mentioned above, providers may not currently have incentives to invest resources into standardization if custom solutions are leading to a lock-in of customers, guaranteeing revenue vs. a vague promise of a larger market. Such a lack of transparency may hide the true impact of existing fragmentation and lock-in effects to customers (especially suppliers), not leading to them requesting a change in service. Moreover, complexities introduced by lack of standards in regulatory frameworks may further serve as inertia for providers to start collaborating on standards.

Thus, we propose:
Preliminary proposition 1: In order to evolve to stage 3, the SCF ecosystem needs further standardization across all three categories

Ecosystem actor diversity was highlighted from natural ecosystem research as a prerequisite of healthy ecosystems. With the vast majority of providers currently operating proprietary closed platforms, the current SCF ecosystem lacks such diversity.

Thus, we propose:
Preliminary proposition 2: In order to evolve to stage 3, the SCF ecosystem needs a higher diversity of actors

Leveraging the first two levels of Figure 2, modularity can be increased to better serve a broader customer base. Nienhuis et al., 2013 reflect the need for modularity by proposing a "4-corner model" of SCF where suppliers can freely choose providers and vice versa, thus overcoming the barrier of platform membership.

Thus, we propose:
Preliminary proposition 3: In order to evolve to stage 3, the SCF ecosystem needs more modular product offerings

Regarding orchestration, the central question emerging from this research is whether in future ecosystem orchestration will remain rather centralized, being performed by certain business, or – more similar to natural ecosystem – become decentralized. As Moore (1993:76) put in the context of business ecosystems: "Apple, IBM, Ford, Wal-Mart, and Merck have all been or still are the leaders of business ecosystems. While the center may shift over time, the role of the leader is valued by the rest of the community. Such leadership enables all ecosystem members to invest toward a shared future in which they anticipate profiting together." This resembles a centralized orchestration perspective. In nature there does not necessarily exist a single leader or a few particular leaders, instead it operates based on decentralized orchestration – as exemplified by the mycorrhizal fungi networks.

Thus, we propose:
Preliminary proposition 4: In order to evolve to stage 3, the SCF ecosystem needs improved (centralized or decentralized) orchestration

The next stage in this research will be to further substantiate and verify or falsify the preliminary propositions. With exploring the insights from natural ecosystems, we seek to contribute to research and practice bridging the currently fragmented SCF landscape towards a mature ecosystem.

Abstract
Competencies in Purchasing & Supply Management (PSM) are the individual-level foundations of PSM performance. This paper takes stock of previous research and presents empirical results on current and future PSM competencies based on case study research. It categorizes PSM competencies according to Tassabehji and Moorhouse (2008)Tassabehji and Moorhouse (2008), and identifies changes over the last 10 years in the requirements for modern PSM practitioners. The work adopts a Knowledge-Based View (KBV) and differentiates PSM competencies as either explicit or tacit. The results provide insights for higher education curricula development and provides stimuli for competency model development and training in practice.

Keywords: Purchasing and Supply Management; competencies; knowledge-based view

Acknowledgements: The empirical data in this paper comes from Project PERFECT (Purchasing Education and Research for European Competence Transfer), which has been set up and funded by the European Union to become the first worldwide region to establish an empirically validated pan-European PSM higher education curriculum. The project is embedded into the ERASMUS+ 2015 KA2 program (Cooperation for Innovation and the Exchange of Good Practices Strategic Partnerships for Higher Education) with the project number 2015-1-DE01-KA203-002174.

INTRODUCTION

Purchasing and Supply Management (PSM) plays a pivotal role in increasing overall organizational competitiveness. Considering that up to 60-80 % of their total costs, (Monczka et al., 2010; Van Weele, 2009) are external to the firm, i.e. being paid to suppliers, PSM's role in spanning organizational boundaries and managing these external networks has become increasingly important (Van Weele and Van Raaij, 2014).

While there exists a robust trajectory of research on skills, competencies and knowledge required in PSM (Cousins et al., 2006; Faes et al., 2001; Giunipero et al., 1999; Giunipero et al., 2005; Giunipero and Pearcy, 2000; Kern et al., 2011; Knight et al., 2014), a holistic assessment of the full competency base across a wide range of different PSM roles and different industrial settings is timely and it is this gap that this work seeks to address. In addition, although previous research has suggested the differentiation of tacit and explicit knowledge to be valuable in the PSM context (Giunipero et al., 1999), it has unfortunately not received enough attention to provide the basis for curricula or training design in higher education and/or practice, as well as for the selection of PSM personnel within organisations. This distinction is

discussed in more detail in the literature review, but in brief, tacit knowledge is that which is 'know-how', difficult to articulate and automatic and explicit knowledge, which is 'know-what' and describable in formal language in the form of manuals etc. (Smith, 2001). The importance of this distinction is relevant as it has implications for how organizations can most effectively harness, share and manage the knowledge of their employees in delivering increases in organizational performance.

There are recent developments that motivate to take stock of current and future competency requirements. Current challenges such as sourcing innovation (Schiele, 2010, 2012), handling potential supplier disruptions (Wieland et al., 2016), ensuring sustainability in the supplier network (Montabon et al., 2016; Schneider and Wallenburg, 2012; Wilding et al., 2012) and the implications of technology-based workplace changes in the wake of digitization are challenging previous assumptions about what will be sufficient competencies for the modern PSM professional. For example, with increasing automation, the question arises whether it is now enough to prepare students for a future career in PSM by merely conveying the textbook basics of purchase order processing or rather this education should include project-oriented learning on how to design processes and have them executed digitally with an advanced understanding of what IT can do for this field.

In the light of these developments and the need for generating further insights for research and practice alike, the research questions this study seeks to address are the following:

RQ1 – What current and future competencies/knowledge are necessary for PSM practitioners?

RQ 2 – How have the challenges of the modern PSM changed the competencies/knowledge required of PSM practitioners over the last ten years?

RQ3 – Which of these competencies/ knowledge are tacit/explicit?

Conceptual background

PSM Competencies

A PSM skills literature search resulted in an extensive list of skills and competencies found in 30 articles published from 1987 till 2017, shown in Table 1.

2007-2017	1997-2007	1987-1997
Baily et al. (2008)	Burt et al. (2003)	Anderson and Katz (1998)
Eltantawy et al. (2009)	Carr and Smeltzer (2000)	Carter and Narasimhan (1996)
Kern et al. (2011)	Cousins et al. (2006)	Cavinato (1987)
Knight et al. (2014)	Cousins and Spekman (2003)	Cruz and Murphy (1996)
Tassabehji and Moorhouse (2008)	Faes et al. (2001)	Dowd and Liedtka (1994)
Tatham et al. (2017)	Giunipero (2000)	Keough (1993)
Zawawi et al. (2014)	Giunipero et al. (2005)	Killen and Kamauff (1995)
	Giunipero and Handfield (2004)	Kolchin and Giunipero (1993)
	Giunipero and Pearcy (2000)	Murphy (1995)
	McKeefry (1998)	Pagell et al. (1996)
	Mulder et al. (2005)	
	Muller (2001)	
	Trent and Monczka (2003)	

Table 1: PSM skills literature 1987-2017

This work takes as its basis the work of Tassabehji and Moorhouse (2008). It has been chosen as the basis for the later comparative analysis in this study as it is the most elaborate categorised model and is in line with other research in the area, for example Tatham et al. (2017) and Killen and Kamauff (1995). Tassabehji and Moorhouse (2008) categorised procurement skills in 1) procurement specific skills and 2) generic management skills. This distinction is

also seen in the work of Killen and Kamauff (1995), Shou and Wang (2015) and Tatham et al. (2017).

Tassabehji and Moorhouse (2008) classify *Technical skills*, *Interpersonal skills*, *Internal and External enterprise skills* and *Strategic business skills* as described in Table 2, which cover both categories, procurement specific and generic management skills.

1	*Technical skills* (TS): Fundamental and basic administrative skills necessary for any procurement professional in the 21st century. They include product knowledge, computer literacy, total quality management and government legislation.
2	*Interpersonal skills* (IS): Necessary for interaction with people in teams and on an individual level including written and oral communication, conflict resolution, influencing and persuasion, group dynamics, leadership, problem solving and interpersonal and cultural awareness.
3	*Internal enterprise skills* (IE): These skills relate to the overall business and how the different functions interaction.
4	*External enterprise skills* (EE): These skills relate to the supply chain/network and its stakeholders.
5	*Strategic business skills* (SB): These skills relate to broader strategic issues and how procurement can impact on overall organisational value such as planning and managing strategic partnerships and alliances, risk management and adding value to the organisation.

Table 2: Introduction of a new taxonomy of procurement skills Tassabehji and Moorhouse (2008)

Theoretical background: Knowledge-based View

Knowledge within organisations has arguably become the most important source for competitive advantage, as organisations seek to harness the competencies and capabilities in a dynamic fashion and differentiate themselves from their competitors. Organisations are becoming increasingly focused on the creation, sharing and application of knowledge, as they have started to see the added value of assets other than capital, raw materials and labour, the effective management of which can lead to increases in organizational performance (Jasimuddin et al., 2005; Nonaka and Takeuchi, 1995; Smith, 2001). This shift in focus has "[...] stimulated a vast literature in the area of intellectual capital and intangible assets" (Elias and Scarbrough, 2004) and is key driver in the establishment of a Knowledge Based View (KBV) of organizations and the relevance of the field of Knowledge Management.

The KBV (Grant, 1996) is derived from the Resource Based View of the firm, which posits that a firm's competitive advantage is derived from the existence and management of tangible and intangible resources. If these resources are sufficiently differentiated by being valuable, rare, inimitable and non-substitutable, then these can be considered as core competencies and will result in varying levels and duration of competitive advantage will ensure (Hitt et al., 2013). An increasingly important intangible resource is knowledge (Grant, 1996) and in the field of supply chain management, this firm level view of resources has been expanded to also include external actors, such as suppliers (Dyer, 1996). Although in this study, the focus remains on firm level, the capability of managing and achieving value from suppliers is a key aspect of firm-based knowledge.

The third research question distinguishes between tacit and explicit aspects of knowledge, so it is necessary to briefly elaborate on the concepts of competency and knowledge as they are closely related and this work adopts the definition of 'competency' as "an underlying

characteristic of an employee (i.e., a motive, trait, skill, aspect of one's self-image, social role, or a body of knowledge) which results in superior performance" (Boyatzis, 1982) and that knowledge is "the understanding, awareness, or familiarity acquired through study, investigation, observation, or experience over the course of time. It is an individual's interpretation of information based on personal experiences, skills, and competencies" (Bollinger and Smith, 2001).

There are various approaches to managing, classifying and sharing knowledge, but many are based on a fundamental distinction between explicit 'know-what' and tacit 'know-how' (Nonaka and Takeuchi, 1995; Smith, 2002) and particularly the ease of transferability and aggregation of knowledge (Grant, 1996). Polanyi (1966) introduced the idea of tacit knowledge by stating: "we can know more than we can tell". Tacit knowledge is multidimensional, context-specific, and while it is often embedded within organizational routines (Kothari et al., 2012) and can only be observed through its application and acquired through practice, which means its transfer between people is slow, costly, and uncertain (Kogut and Zander, 1992).

The importance of tacit knowledge is high. There is proof that approximately 90 % of all knowledge in organizations is tacit (Smith, 2001). Conversely, explicit knowledge is that which can be articulated in formal language, like manuals, mathematical expressions, copyright and patents (Smith, 2001) and can be shared more easily between people (Grant, 1996). Explicit knowledge has even "the character of public goods" (Tamer Cavusgil et al., 2003). Jasimuddin et al. (2005) summarize: "Tacit knowledge is less vulnerable but less accessible by legitimate organisational users, whilst explicit knowledge is more accessible but also more vulnerable to illegitimate exploitation".

Although the distinction between tacit and explicit knowledge can be presented as being a clear cut dichotomy, there is evidence that knowledge exists in the continuum between both ends: between strict tacit and explicit knowledge (Jasimuddin et al., 2005; Nonaka & Von Krogh, 2009). The most common route to tacit knowledge lies in sharing experiences: "Without some form of shared experience, it is extremely difficult to project her- or himself into another individual's thinking process" (Nonaka & Takeuchi, 1995). However, tacit knowledge can also be codified and can shift to explicit knowledge (Nonaka & Takeuchi, 1995). This research classifies competencies according to the scheme established by Tassabehji and Moorehouse, taking into account whether they are tacit or explicit in nature (see Table 8).

In order to ensure that explicit and tacit knowledge is positioned in a relevant context, which provides something meaningful to practitioners and a robust contribution to the literature, the research model was developed from the relevant academic literature. The model shown in the Appendix served as the basis for the interview guide development in preparation of the data collection.

Methodology

Research Design

As discussed in the introduction, the overall purpose of this work is to provide an updated perspective on which PSM competencies are required now and in future and differentiate between which of these are tacit and explicit in nature. In the development of the research design, a qualitative data collection approach was deemed most suitable in order to allow for emergence of competencies outside of a predefined list based on previous research, i.e. directly using the Tassabehji and Moorhouse (2008) framework as pre-defined interview or survey areas of focus. In analysing the approaches for case study research for the topic at hand, the research team followed the decision tree of Ketokivi and Choi (2014) and concluded that the KBV would provide a suitable theoretical foundation for this research. Due to the exploratory nature of the research, the overriding goal was to deploy KBV in the context of PSM rather than testing any hypothesis based on it. Other theories considered initially were

Human Capital Theory (e.g. Osterman, 1987) and the Resource-based View (e.g. Barney, 1991; Wernerfelt, 1989).

Assurance of research quality criteria 1) credibility/internal validity, 2) transferability and generalizability/external validity, 3) dependability/reliability and 4) confirmability/objectivity was addressed by the use of a number of techniques (based on Lincoln and Guba, 1985; Riege, 2009; Salzberger and Sinkovics, 2006; Salzberger et al., 1999; Welch et al., 2002; Yin, 2013). For each major project phase, i.e. preparation, implementation, follow-up and dissemination, the specific measures to be applied were defined during March/April 2016, and then continuously reviewed and refined over the course of the data collection.

Case Study Research: Case Selection, Data Collection, and Analysis

Collecting qualitative data through the use of structured interviews, based on the research model (Appendix) ensured that a full and deep understanding of the phenomenon could be obtained. This is particularly important in tacit areas of knowledge, that are often more difficult to articulate and could therefore be developed through questioning. A selection strategy for the case companies was deployed to cover the following organizational characteristics and to allow for the widest possible perspective of different requirements. Industries with lower and higher external value added; also two major consultancies to hear their view on PSM's current and future knowledge requirements across their client base), geographical spread (to not overemphasize one particular national culture), and conventional (i.e. commercial) business models versus at least some social businesses (to challenge current PSM conventions). This led to a final selection of 12 overall cases, ranging at the higher end of the usual suggestion of having between 4-10 cases (Eisenhardt, 1989). Resulting details of the case company selection demographics are briefly outlined in Table 3. All companies had some international scope in their operations.

Within each case company the basic interviewee target sample included the Chief Procurement Officer (CPO) or a senior level PSM representative, a PSM employee responsible for strategic sourcing, as well as a PSM training/HR representative. In addition, some companies provided access to an even broader interviewee base, which followed our intention to cover the full procure-to-pay process (a process description was used to discuss potential interviewees before scheduling the interviews). Some of the smaller companies put forward a single interviewee, who, because of the role he/she had, was able to cover all PSM areas. In several cases it was possible to also obtain an interviewee at a supplier of the case company to obtain the buyer-supplier dyad perspective on required knowledge for a successful business relationship. In total, this yielded 12 case companies (including 4 buyer-supplier dyads, so 16 different companies in total) and 46 interviews.

All interviews were recorded and transcribed. The data analysis was done by four researchers, who jointly performed the coding in the qualitative data analysis software NVivo 11. At the beginning of the coding process, the researchers jointly coded the same interview to get accustomed to the approach and to become aware of any individual differences. An initial coding protocol was to use a pre-defined coding tree based on existing literature, but subsequent review suggested that an in vivo, or indigenous coding (Bazeley and Jackson, 2013) was more suitable to ensure that they were not overly fixated on certain categories of competencies . The coding team had regular discussion meetings and created a common reference document that captured an agreed consensus on how to approach certain nodes in a standardised manner. To ensure and increase the inter-coder reliability (i.e. how similar the coding between coders was) in NVivo 11, in the first discussion meeting a joint review of one commonly coded transcript was conducted. This also ensured consistency of the use of individual nodes in the coding process, for example through showing that an individual had coded 'willingness to work' under

'passion'. In addition, it helped to ensure a transparent and traceable qualitative data analysis approach (e.g. Bazeley, 2013). Once the initial joint review and discussions of the first interview coding was finalized, coding pairs were formed for all further coding activities. Thus, all interviews were coded by two researchers to ensure broad node coverage and to enhance the coding process reliability. Each coder continuously updated the common reference document and passed it on to the next coder, thus facilitating inter-coder consistency.

Case	Sector/Industry	Interviewees	Business Model	No. of Employees	Turnover in €*
AUTO1	Automotive	10 + 2 (supplier side)	Traditional	> 300 000[1]	>70 billion[1]
AUTO2	Automotive	1	Traditional	80 000 - 99 999	>10 Billion[1]

Findings and Discussion

Current and Future Competencies

PSM practitioners identified a total of 65 current competencies, which they felt were currently necessary for them to meet their organizational objectives. These were ranked by the number of instances that they were coded in the various interviews and the top 10 of the 65 current competencies are shown in Figure 1 on the left. "Negotiation" was coded with the highest number of instances. Besides, when grouping competencies into those that share similar characteristics, then the remaining competencies in this list reflect those that are related to communication and relationship ("Communication skills", "Interpersonal communication", "Stakeholder Relationship Management"), or to strategic and analytical ("strategic thinking", "analytical thinking", "strategic sourcing"), or to professional knowledge requirements ("Basic knowledge on PSM role & processes", "cross-functional knowledge"). Firstly, this shows that there is a clear mix of competencies that are required to be successful as a buyer or manager in PSM and also a link between some these competencies were stressed. Of particular relevance to those involved in an academic or training role, is that a PSM curriculum or training program needs to reflect all of these areas, which may need to be taught using different training methods. For example, classroom or web-based learning for professional knowledge and more social learning or non-traditional techniques for communication and relationship areas.

PSM practitioners mentioned a total of 56 competencies, which they felt would be necessary for them to meet their organizational objectives in the future. These were ranked by the number of instances that they were coded in the various interviews and the top 10 of the 56 future competencies were shown in Figure 1 on the right.

These competencies reflect areas of growing interest and concern for both PSM practitioners and the wider organizational context. There are a number of competencies that relate to the broader digitization agenda (e.g. "eProcurement Technology", "Automation", "Big Data Analytics" and "Computer Literacy") and the high ranking of "Sustainability" establish its increasing importance in the modern industrial context. However, interviewees expressed uncertainty on exactly what specific competencies would need to be developed in PSM practitioners and students to meet these requirements. Although the correlation with competencies that also were given a high priority in future PSM, such as "Holistic Supply Chain Thinking" or "Strategic Thinking", might give an indication as to how these areas can be further broken down into manageable areas. Four competencies were shared in both current and future views, i.e. "Analytical Skills", "Strategic Sourcing", "Strategic Thinking" and "Sustainability". It is therefore important that these form a coherent thread through any training or educational programs. The overall findings regarding frequencies of coding are shown in Table 4. The green color indicates commonality between current and future competencies.

Current Competencies	Future Competencies
Analytical skills	Analytical Skills
Basic knowledge on PSM role & processes	Automation
Communication skills	Big Data Analytics
Cross-functional abilities & knowledge	Computer Literacy
Interpersonal Communication	eProcurement Technology
Negotiation	Holistic supply chain thinking
Stakeholder Relationship Management	Process optimisation
Strategic sourcing	Strategic Sourcing
Strategic thinking	Strategic thinking
Sustainability	Sustainability

Table 4: Top 10 *current* and *future* competencies for PSM, in alphabetical order

Clustering Results

The coded competencies were grouped thematically. The cluster categories are based on Tassabehji and Moorhouse (2008), as introduced in the conceptual background.

Table 5 shows the mapping of the competencies to these clusters. Many of the nodes were very similar or the same as in the overview provided by Tassabehji and Moorhouse (2008), thus were easy to allocate; the others were clustered by the research team based on a careful review and agreed decision. The competencies marked in grey were only mentioned in the context of current competencies and the blue ones were mentioned only related to the future. The black ones were mentioned in both contexts. Newly added competencies are marked in bold and italics.

Technical Skills	Interpersonal Skills	Internal/ External Enterprise Skills	Strategic Business Skills
Automation (NEW)	Ability to Make Decisions	Change Management	Business Acumen
Basic knowledge on PSM role & processes	Analytical skills	Communication skills	***Critical thinking (NEW)***
Big Data Analytics (NEW)	Conflict Resolution	Cross-functional abilities & knowledge	Financial acumen
Computer Literacy	Creativity	Engineering	***Holistic Supply Chain Thinking (NEW)***
Contract Management	***Curiosity (NEW)***	Finance	PSM Best Practice Intelligence Scouting
Cost savings	***Deal with ambiguity (NEW)***	Logistics	Risk management
eProcurement Technology	Effective questioning techniques	Manufacturing/ Production	Strategic thinking
Innovation sourcing (NEW)	Humbleness	Marketing	***Sustainability (NEW)***
Innovative sourcing approaches (NEW)	***Integrity (NEW)***	Quality (QHSE)

Table 5: Competency Clusters (Grey: Only Current, Blue: Only Future, bold & italics: newly added based on case study research

In the overall clustering, the technical skills dominate, followed then by interpersonal skills, internal/external enterprise skills and strategic business skills as can be seen in Table 6.

1 : TassabehejiMoorhouse_1_*Technical skills*	1012
2 : TassabehejiMoorhouse_2_*Interpersonal skills*	739
3 : TassabehejiMoorhouse_3_*InternalExternal enterprise skills*	632
4 : TassabehejiMoorhouse_4_*Strategic business skills*	593

Table 6: Competencies Analysed by Clusters.

This order of how often one of the clusters was mentioned was relatively consistent across industries. In all of them the technical skills were the most often mentioned, only the other three clusters varied slightly. It is moreover interesting to note that interviewees from the supplier side slightly emphasized the strategic business skills more than the PSM professionals themselves.

Which of these competencies/knowledge areas are Tacit/Explicit?

The first part of this analysis takes the list of both *current* and *future* competencies/knowledge and uses the characteristics provided by Smith (2001) as a way of distinguishing them as being either explicit or tacit in nature. The Top 10 current and future competencies, which were referred to the most times in the interviews (number of instances), are shown in the table below along with whether they are explicit or tacit in nature.

Current Competency	Explicit/ Tacit	Future Competency	Explicit/ Tacit
Negotiation	T	Sustainability	T
Communication skills	T	eProcurement Technology	E
Interpersonal Communication	T	Automation	E
Sustainability	T	Holistic supply chain thinking	E
Analytical skills	E	Big Data Analytics	E
Strategic thinking	T	Strategic thinking	T
Strategic sourcing	E	Computer Literacy	E
Stakeholder Relationship Mgmt.	T	Analytical Skills	E
Basic knowledge PSM role & processes	E	Strategic Sourcing	E
Cross-functional abilities/knowledge	E	Process optimisation	E

Table 7: Top 10 Current and Future Competencies – Tacit and Explicit, ordered by number of codings.

When clustered according to Tassabehji and Moorhouse (2008), the picture shown in Table 8 emerges for current and future competences.

	Current Competencies_TACIT	Future Competencies_TACIT
1 : TassabehjiMoorhouse_1_*Technical skills*	318	71
2 : TassabehjiMoorhouse_2_*Interpersonal skills*	507	115
3 : TassabehjiMoorhouse_3_*InternalExternal enterprise skills*	436	100
4 : TassabehjiMoorhouse_4_*Strategic business skills*	329	186
	Current Competencies_EXPLICIT	Future Competencies_EXPLICIT
1 : TassabehjiMoorhouse_1_*Technical skills*	652	266
2 : TassabehjiMoorhouse_2_*Interpersonal skills*	196	76
3 : TassabehjiMoorhouse_3_*InternalExternal enterprise skills*	212	55
4 : TassabehjiMoorhouse_4_*Strategic business skills*	260	86

Table 8: Analysis of Competency Classifications

Of the top 10 *current* competencies, 6 were identified as tacit and 4 were explicit, therefore demonstrating the key role that tacit competencies play in ensuring that PSM professionals and the PSM function can meet their objectives. Further, although 6 out of the 10 Top 10 competencies were tacit, they form the top 4 ("Negotiation", "Communication Skills", "Interpersonal Communication" and "Sustainability") therefore further underlining their importance. Therefore, those involved in the education and recruitment of both new and existing PSM staff need to factor these tacit competencies into decision making in these areas of activity. Although explicit competencies can far more readily be imparted through formalized and didactic education methods (e.g. lectures), tacit areas often need to make use of different and non-traditional methods, for example, mentoring and practice-based learning. Whilst these methods may be more challenging for both educators and students alike, not adopting them may mean that these tacit competencies are underdeveloped.

In addition to the educational aspect of imparting tacit knowledge, it is also more difficult to share intra-organizationally than explicit knowledge, as it is less codifiable, being more difficult to articulate. As the tacit dimension is so important, knowledge sharing between individuals and within a function needs to reflect this and be prioritized accordingly. This means that aspects of socialisation (as per Nonaka & Takeuchi, 1996) such as mentoring and buddying need to be become integral parts of work practices to ensure that tacit knowledge can be articulated and shared in the most effective manner. Although Standard Operating Procedures (SOPs) and manuals undoubtedly serve a useful purpose in providing consistency of work

practices, they are not best suited to the full sharing of tacit knowledge. This means that such documentation should be seen as the start point of any training and education and not as the sole method of imparting knowledge.

The second part of the analysis follows the approach as above for current competencies, but now looks at whether the *future* competencies identified in the interviews are tacit or explicit in nature. When looking at *future* competencies, 2 were deemed tacit and 8 were explicit, although the top competency listed was tacit in nature ("Sustainability"). This shows a different balance than that found when current competencies were analysed and tacit competencies were deemed as being of overall more importance. This shift in emphasis between explicit and tacit aspects, can perhaps be explained by to the ease through which explicit knowledge can be articulated and those competencies that have yet to materialise may be more challenging to articulate. Nonetheless, as the majority of these future competencies are explicit in nature, there is an opportunity for explicit based training (both in-house and in education settings) to be developed and delivered in the present to ensure that PSM practitioners are best equipped to develop these future requirements. The demographics data has been used to generate a number of different insights, all of which cannot be covered in this working paper, but some of the key differences between groups are discussed here to provide these insights.

Firstly, when the differences in job role (Management, Operative and HR/Training Representative) are applied to *explicit* competencies, although a considerable degree of similarity was seen across the different job roles, the HR/Training Representative did not identify the "eProcurement" competency as being of importance, yet the Management and Operative role did. Therefore, as it is often the responsibility of the HR/Training Representatives to organize any in house training programmes, these need to ensure that "eProcurement" is adequately represented as this could lead to a potentially important gap. In addition, "Supplier Management" was not listed in the Management role, but was specifically in the Operative, which is not necessarily surprising, as it would be a more operational task to focus on direct dealings with suppliers. However, those in a Management role, whilst, of course, focusing on "Leadership" etc., should not overlook the key aspect of "Supplier Management" and ensure that they maintain dealings with suppliers, therefore getting a clear view of the to the supply market and current and future challenges that may arise.

When a similar view of *tacit* competencies across job roles is taken, there is a mismatch between "Languages", which was highly ranked by the Operative role, but not in the Management or HR/Training Representative lists. As those in Management roles would tend to be more experienced, they may have had chance to develop their "Languages" skills more fully and also, their more senior level may require them to deal with inter-organisational counterparts who have similar levels of "Languages" skills. This may not be the case for those in Operative roles, who tend to be less experienced and more likely to be dealing with the operational level of suppliers and therefore they may see "Languages" as a more immediate and regular challenge. This need highlights the importance of integrating schemes such as the ERASMUS Mobility Programme into HE curricula and also that organisations themselves should consider internships or exchange programmes with PSM parts of their organisation in different countries or supplier exchange programmes.

When looking at *current* and *future* tacit competencies by years of total work experience, "Conflict resolution" is seen as not being important for the "lower" years' work experience of 3 to 5 and 6 to 10 year groups, but is however ranked highly in the other higher year categories. This would therefore suggest that this is an importance competency later in a PSM career and could be integrated into Masters level HE curricula and/or more advanced in-house training programmes. Also of note, was that "Communication" was a key competency for all year groups apart from the 3 to 5 year bracket and, as this is a key (2nd ranked in Current Competencies), it may warrant a focus at all stages of education and training.

Conclusions, limitations and suggestions for future research

Our contribution to the academic literature is through the analysis of current and future individual competencies required for PSM, identifying differences and similarities from work done ten years ago and then differentiating these into tacit and explicit areas. Based on a combination of a systematic literature review and coverage of 16 case study firms, we updated the PSM competency landscape according to the classification by Tassabehji and Moorhouse (2008). Our research refers to the theoretical basis of the Knowledge-based View (KBV) that outlines the importance of individual competencies and knowledge for PSM and company performance. Guided by the 3 research questions ("1. What current competencies/knowledge are necessary for PSM practitioners?", "2. How have the challenges of the modern PSM changed the competencies/knowledge required of PSM practitioners over the last ten years?" and "3. Which of these competencies/ knowledge are tacit/explicit?"), a case study approach was followed, comprising interviews with 46 PSM practitioners representing either a managerial, operative or Training/HR role, in various companies across a broad range of industries located in different countries. The 65 current competencies and the 56 future knowledge areas identified by coding the interviews were classified into *explicit* knowledge in the meaning of 'know-what' and *tacit* knowledge capturing the 'know-how' (e.g. Grant, 1996; Nonaka and Takeuchi, 1995; Smith, 2002) Polanyi (1966).

To cluster the competencies, we used the categorization of Tassabehji and Moorehouse (2008). Based on this analysis, we suggest that a new category of competencies, i.e. meta-competences (Le Deist and Winterton, 2005), including such coded competences as "learning agility", "curiosity" and "self-reflection", is required. This may help to keep competencies up-to-date for the challenges of the modern PSM.

Overall, the results can be summarized as follows. The PSM professionals indicated that the current competency profile for PSM encompasses a range of knowledge areas. Besides "Negotiation", competencies regarding communication and relationship management (e.g. "Interpersonal communication"), strategy and analytics (e.g. "Strategic thinking") as well as professional knowledge requirements (e.g. "Basic knowledge on PSM role & processes) are perceived to be required for a successful buyer or manager in PSM. The majority of these knowledge areas are classified to be tacit.

When looking at future competencies, additional knowledge was identified to become important, especially in the area of "Sustainability" and "Digitization" (e.g. "eProcurement Technology", "Automation"). More future competencies are in the explicit knowledge area. The main limitation of this research lies in the restricted number of interviewees and companies. A broader empirical validation of the findings is suggested.

The findings of this research have various educational and managerial implications. First, academic PSM education as well as professional PSM qualification need to reflect the broad range of competencies that was identified. Taking into consideration the mix of explicit and tacit knowledge areas, different teaching methods should be applied. Methods like social learning or problem-based learning probably need to be more incorporated in PSM training programs. Companies should reflect the importance of tacit knowledge in their concept and their tools for intra- and inter-organisational knowledge transfer. Also, when it comes to educational training of professors and teachers, a pedagogy that encompasses a greater balance between tacit and explicit as well as meta-oriented competencies is required.

Second, academia as well a management needs to reflect "Sustainability" as well as "Digitisation" in their educational programs. Further research opportunities are seen in a breakdown of competencies and knowledge in these areas. Also, the finding that competencies related to digitisation are more explicit in nature invites further investigation.

Summary

This paper deals with summarising the trends and future requirements in Purchasing & Supply Management (PSM) related to digitalisation based on existing studies, papers and interviews. It outlines the consequences of digital transformation on purchasing departments and processes of organisations and requirements in order to keep or increase the importance of PSM in companies. Furthermore, the paper focuses on deriving the need for change management in PSM to cope with these challenges and gives an outlook on different change dimensions and their setup, always focussing on the roles of human beings and their preparation for future tasks and working environments.

Keywords: digital transformation, change management

Submission Category: Working paper

Introduction and Motivation

Business environments constantly underlie changes that organisations have to face and develop accordingly in order not to fall behind in times of Industry 4.0 and digitalisation, where fast adaption to new developments and reaction to this transformation is indispensable (Valenduc and Vendramin, 2017). Digitalisation, individualisation and increasing autonomy as basic principles of Industry 4.0 have extensive impact also on Purchasing and Supply Management (PSM) (Pellengahr, Schulte, Richard and Berg, 2016). Organisations and their activities, tasks and orientation are especially affected by lots of these developments.

Digitalisation stands for a combination of new technologies (Bounfour, 2016). It is the connection of processes and products as well as of the physical and virtual world (Demary, Engels, Röhl, Rusche, 2016). Transformation describes the decision to restructure a system in order to create competitive advantages and secure them sustainably. Business transformation is a holistic approach with the objective of developing new business models and empowering change processes (Schwenker and Hanßen, 2009). Digital transformation means new developments in the use of digital artefacts, systems and symbols within and around organizations. It is a continuously executed, technical and internet-based, disruptive transformation process. The competitive position of a company is sustained or extended by the use of modern technology. Digital transformation can affect all areas of a company: strategy, business models, processes, structures, culture. Besides the business environment, digital

transformation affects the whole society as well. (Bounfour, 2016; Schallmo and Rusnajk, 2017; Wallmüller, 2017)

The open outcome of the transformation is characteristic, as frame conditions can change very quickly and constantly during times of digital transformation. A framework adapted to the challenges of digitalisation is needed (Barghop, Deekeling and Schweer, 2017). In this study, the digital transformation stands for the impacts of technical developments on the business and working environment and all changes and new challenges arising with these. This paper focuses on how digital transformation affects Purchasing & Supply Management (PSM) and how companies need to take action in order to enable procurement staff to deal with the profound changes.

Profound changes and their effects on processes, organisations and people are the motivation for managing these developments and their consequences which means to initiate a structured change management approach. Change Management research started in the 1950s as a medium- to long-term process focusing internal changes with the goal of maximising effectiveness and efficiency of a transformation (Hartwich, 2011). Objectives, strategies as well as processes and structures of organisations are adapted to changing conditions (Kreutzer, Neugebauer and Pattloch, 2017). The process is supposed to be accompanied and accepted by the workforce (Cacaci, 2006; Rank and Scheinpflug, 2010). The change management process understanding in this paper underlies the fundamental research by Lewin, 1951, and Kotter, 1995.

When paying particular attention to the role of the human being in PSM related functions of an enterprise it comes to establishing appropriate human-centred change management in order to accompany the employees through the digital transformation. This paper points out possible implementation of change management, focussing on restructuring of processes, preparing and qualifying procurement staff and impact on the organisation of PSM function and departments as well as implications for the whole company and its roles in networks.

The research goal is to develop a framework that shows trends and possible future developments caused by digitalisation, how they lead to changed or new requirements for people in PSM (e.g. tasks, competences) and how companies can cope with the transformation using change management methods. This working papers' conceptual study forms a starting point for this greater endeavour. There is no literature available yet focusing directly on change management in PSM due to digital transformation. The paper derives recommended action in terms of building up digital and other related competences for the companies that face respective developments in the framework of structured change management and digital transformation procedures. The comparison of traditional change management phase models with the process of a digital transformation gives an indication of a set-up for configuring the procedure of the digital transformation in PSM accompanied with relevant change management approaches.

In the following sections, the methodological approach of this study is shortly characterised. Moreover, the results section summarises how the digital transformation effects PSM. A comparison of digital transformation, changes and challenges in PSM and applicable change management process steps is conducted.

Methodology

Firstly, the main impacts and related challenges for PSM caused by the digital transformation are summarised. Therefore, a number of up-to-date studies and articles are analysed which describe the trends and current developments in procurement. In addition, in the context of the EU project Purchasing Education and Research for European Competence Transfer (PERFECT) interviews with PSM practitioners were conducted (Project PERFECT, 2017). The core statements of the 41 interviews in the context of trends and digitalisation aspects discussed in the job environments and the arising challenges are evaluated.

The subsequent comparison of change management triggers with the situation of digital transformation in PSM and its effects mainly on the human factor leads to the need of a change management approach for exactly these challenges. It is argued why the implementation of tailored change management in PSM organisations makes sense in times of digitalisation. The phases of a digital transformation and change management are integrated with the trends in PSM as a concrete use case.

A business transformation process can be divided in four dimensions (Reineke and Bock, 2007):

1. Reframing: the process of changing the position of the company regarding its self-perception and own opportunities.
2. Restructuring: the process of restructuring the company in order to achieve a competitive performance level.
3. Revitalizing: the process of revitalisation in order to generate growth.
4. Renewing: renewing of the human part of transformation in order to increase motivation and enable the acquirement of new skills.

These dimensions are used to structure the digital transformation of PSM in this conceptual study. They partly resemble the change management phases by Lewin (unfreeze – move – defreeze). The change management concept to be developed bases on Lewin's and Kotter's process steps representing the most relevant and most frequently cited change management models. In future research, other models will be considered as well. Lewin developed the classic three phases model that is regarded as the fundamental model in literature. Kotter splits Lewin's three phases into more detailed steps of a change process, as visualised in **Figure 1**. Therefore, there is a connection between these two models. They are both linear approaches with process orientation. Kotter improves the involvement of employees and is less rigid in his steps. (Kotter, 1995; Lewin, 1951)

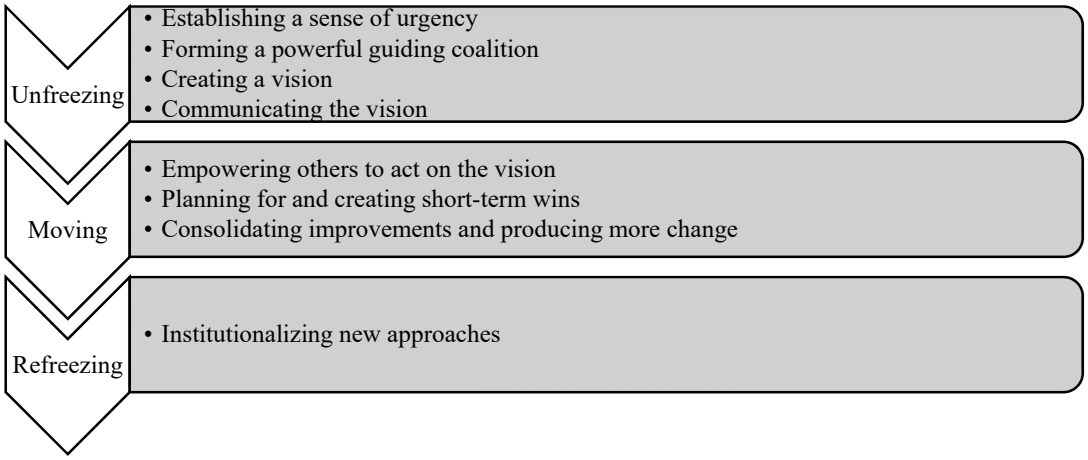

Figure 1: Integration of Change Management models by Lewin and Kotter (own illustration, adapted from Kotter, 1995; Lewin, 1951).

Results

Digital transformation in PSM

A number of up-to-date studies and articles describe the trends and current developments in procurement. They do all point out digitalisation as one of the main aspects influencing the future position of Purchasing & Supply Management (PSM) and the roles of purchasers (e.g. Kushner, 2015; Nowosel, Terrill and Timmermans, 2015; Pellengahr et al., 2016; PricewaterhouseCoopers, 2014). In addition, in the context of the EU project Purchasing Education and Research for European Competence Transfer (PERFECT) interviews with PSM practitioners were conducted. One of the main results of the interview analysis is that digitalisation and linked new requirements are one of the biggest challenges for modern procurement (Project PERFECT, 2017).

PSM is involved in digital transformation on different levels, each demanding different special adaptions within enterprises and PSM departments. On the one hand, digitalisation is represented by new categories. Firms purchase digital products, services, and hybrid components. Buyers must have reliable product knowledge about their new digital procurement portfolio, e.g. about quality and pricing. In order to acquire the demanded technical expertise, it is even more important to collaborate with other company functions. Purchasers have to be involved early in product development processes. New categories will have to be procured with new sourcing strategies while others might lose importance or even disappear from the purchasing portfolio. PSM confirms its strategic role by gaining additional knowledge and networking as an equal partner. (Arnolds, Heege, Röh and Tussing, 2016; Pellengahr, et al., 2016; PricewaterhouseCoopers, 2014; Schuh, Aghassi, Bremer and Graw, 2014)

On the other hand, digital transformation causes not only technological advances and new requirements but also organisational and process-related changes. The administrative purchase-to-pay process will mostly be automated, as digital technologies help facilitating. Further automation of transactional procurement (advanced eProcurement technology solutions)

decreases involvement of employees in purchase-to-pay and releases more personal resources for strategic tasks and relationship management (Kushner, 2015; Pellengahr et al., 2016; Scharlach, Schuh and Strohmer, 2014). Furthermore, digitalisation plays an important role for establishing systems and networks, connecting partners and integrating supply chains (Drake, 2012). Humans, machines, products, customers and other stakeholders are more and more connected and communicate with each other with the help of the Internet of things (IoT) and digital solutions. The traditional silo mentality has to be reduced further. Business processes become integrated in vertical direction as well as horizontal towards suppliers and customers; data is stored and processed in real-time by big and smart data methodologies (Botthof, 2014; Roth, 2016). Due to its many contacts and interfaces, procurement is the ideal function to adjust structures and processes to digitalisation and take over responsibility for Industry 4.0 implementations (Pellengahr et al., 2016).

Efficient processing of data evolving from digitalised processes is essential to make use of for market research, risk evaluation, supplier evaluation, demand analysis etc. to preserve competitiveness. Data serve as base for decision-making and have become a commodity themselves. (Kreutzer et al., 2017; Petry, 2016; Wallmüller, 2017; Weinreich, 2016)

The tasks of operational purchasing (purchase-to-pay P2P, order management) do not revolutionise, but they are rather automated and not carried out by PSM staff much longer. People working in procurement can focus more on strategic tasks. These are supported by digital solutions as well. (Petry, 2016; Wallmüller, 2017; Weinreich, 2016). Summarized it can be seen that PSM has to accomplish more strategic and interdisciplinary tasks with the help of modern technology (Schuh, Kromoser, Strohmer, Pérez and Triplat, 2011; Weigel and Rücker, 2015).

PSM organisation change due to the coordination of and intense collaboration with all internal and external partners (Bogaschewsky and Müller, 2008; Pellengahr et al., 2016; Weigel and Rücker, 2015). Buyers transform into interface managers, data analysts, innovation scouts and product developer. Besides explicit skills and knowledge in these new fields, soft skills such as communication with different stakeholders, persuasion, empathy, honesty, openness etc. are required to cope with the new roles.

The main statements of the PERFECT interviews regarding future skills and digitalisation aspects are briefly reproduced: The improvement of eProcurement solutions and implementation of new technical tools supporting standardisation and the automation of the P2P process is ongoing. Furthermore, operational as well as strategic tasks will be supported with robots and artificial intelligence more and more. Big data analytics are established to manage the flow of information, understand the market and support negotiation. IT skills are necessary to standardise systems, optimise and integrate processes for a better data exchange amongst the supply chain partners. Joint platforms are developed to support long-term strategic partnerships. Buyers and suppliers work closely with suppliers to foster innovation. People working in the PSM field need a holistic understanding of the business to understand the other function as their internal customers as well as external stakeholders. Leadership, problem solving, communication, analytical and strategic thinking, creative thinking and looking for new (digital) solutions belong to the broad set of capabilities. Interpersonal skills might become

more relevant because many other things have become automated. Still, different kinds of communication similar to social networks are increasing in the corporate world, as they can be faster and more efficient. Training is required for buyers as well as well-skilled students entering the workplace. Besides the digitalisation related skills and competences, PSM staff needs change management knowledge and competences in order to constantly being able to deal with transformation. (Project PERFECT, 2017)

The reasons for Change Management

The disruptive developments are triggers for the use of change management approaches. It reasonable to accompany the digital transformation in PSM with structured change management methods proactively. The implementation of tailored change management in PSM organisations makes sense in times of digitalisation. Feedback from customers and other stakeholders include the requirement for change management competences in PSM in order to enable the network to cope with the transformation. The environment changes fast and frequently, which needs action to remain competitive. For all aspects of digitalisation, employees need to be prepared and equipped in order to not be overstrained by its effects. For the companies' success, they should be enabled to react early to indications of possible future changes and influential developments. Digitalisation leads to growing education requirements and career opportunities. New and flexible profiles and ways of thinking will be needed in order to cope with these challenges. (Koch, Muschinski and Zeisel, 2017)

Changes in business context are often linked with anxiety of the staff about their personal employment situation. Transformation processes with their dimensions processes, leadership and qualification (Schwenker and Hanßen, 2009) as well as new forms of cooperation have to be structured systematically. In this context, use can be made of digitalisation for productivity and quality of work. To stay competitive, companies need to organise their environment with new technologies, adapt to changing organisation, processes and skill requirements and, therefore, include and qualify their purchasers at early stages.

There is explicit knowledge needed to deal with digitalisation, but certain competences and soft skills for the long-term orientation of digitised PSM are essential as well. This mixture of competences need to be included in trainings as part of a change management concept. Moreover, a transformation in a company can cause modifications in corporate objectives and values as an anticipation of and adaption to customer needs and transitioning environments is necessary (Kuntz and Gomes, 2012).

For a successful management of transformation, certain principles should be followed (Schwenker and Hanßen, 2009):

- Strategy based procedure
- Follow a holistic approach
- Strong governance of the transformation process
- Pragmatic application of differentiated and problem-based methods
- Broad Mobilisation of the organisation by change management.

The change management framework for digital transformation in PSM

In the following framework (see **Table 1**), the dimensions of transformation, the phases of change management, the aspects of digital transformation in PSM and skills requirement indications divided by strategic and operational PSM are listed in a matrix linking correlations. It gives a first overview maintaining general validity and without claim to comprehensiveness. Some transitions are fluent. It is a first draft of such a Change Management Framework for the Digital Transformation in PSM.

Change Management Framework for the Digital Transformation in Purchasing & Supply Management						
Transformation Principles (Schwenker and Hanßen, 2009) - Strategy based procedure - Follow a holistic approach - Strong governance of the transformation process - Pragmatic application of differentiated and problem-based methods - Broad Mobilisation of the organisation by change management.	**Business transformation dimensions** (Reineke and Bock, 2007)	**Change management phases**		**Challenges for PSM** (examples)		
		(Lewin, 1951)	(Kotter, 1995)	Supplier relationship: Scout and source innovation (examples)	From operational to strategic scope (examples)	...
	Reframing	Unfreeze	1 Establishing a sense of urgency 2 Forming a powerful guiding coalition 3 Creating a vision 4 Communicating the vision 5 Empowering others to act on the vision	- Status quo: analyse existing relations and innovation potential - Strengthen internal relations to clarify customer demand and product development processes - Market research for new innovative suppliers - Train staff in SRM, interpersonal communication, product knowledge - Establish long-term contracts with innovative suppliers, enlarge the network to n-tier suppliers and customers, share benefits - Constant market research updates	- Status quo: declining operational and growing strategic tasks - Clarify with staff a joint understanding of personal development opportunities - Develop a general vision on automated and strategic processes - Train the employees off and on the job (e.g. strategic thinking) - Highlight strategic improvements and benefits of the more strategic focus - Implement new tools and further trainings (e.g. big data analysis, integration of systems with stakeholders, communication)	...
	Restructuring	Move	6 Planning for and creating short-term wins			
	Revitalizing		7 Consolidating improvements and producing more change			
	Renewing		8 Institutionalizing new approaches			
		Refreeze				

Table 1: Draft of a Change Management Framework for the Digital Transformation in PSM (own illustration).

Conclusions and further research

This is a first draft of an integrated change management framework for the digital transformation in PSM. The characteristics of digitalisation of PSM will be worked out in more detail scientifically based and the models structure, applicability and completeness has to be tested in real life company cases. It is supposed to help companies and especially their PSM departments and related functions to restructure PSM organisation and processes and sustain change with the support of the staff.

Purchasing and Supply Management as an enterprise function has the opportunity to increase its importance by focussing on the newly upcoming tasks and paying attention to strategic approaches. Procurement can lead the way building up prospective competences to create understanding throughout the organisation and initiate innovative solutions coping with digitalisation when it accepts its pioneering role in the supply chains. (Pellengahr et al., 2016)

This research illustrates the first steps in developing a change management framework for PSM. Follow-up research can define learning, teaching and training methods for the identified competences in academia and practice and elaborate appropriate training courses as elements of a superior holistic change management concept.

The further goal is to develop a more detailed change management concept for PSM based on digitalisation impacts. Therefore, the analyses that are started for this working paper have to be conducted and evaluated in more detail. A structured complete literature review, more detailed analysis and comparisons, and a more detailed change management approach focusing on the dimension people and the challenges they face in their work environment, which digital skills and other skills related they need, how to train them and to enable them for the digital transformation are future research questions.

It needs to be investigated if and how it makes sense to apply change management methods selectively to one function like purchasing or if it needs to be embedded in the whole company, e.g. by breaking down a company-wide digital strategy to the functions. A number of levels of actions needs be defined as the sectors and digital transformation aspects to different degrees affect types of companies.

Abstract

In the context of the development of an innovative Purchasing & Supply Management (PSM) curriculum, existing study programmes in different European countries are scanned and analysed in matters of learning goals, content and provided competences with the help of an academically deduced template. It is found that only very few PSM specific study programmes do exist in Europe. Moreover, distinct gaps between what these programmes offer and what is actually demanded by industry regarding conveyed skills are discovered. An objective of a newly designed curriculum is to fill the gap accordingly and serve the current needs.

Keywords: PSM Education, Study Programmes

Background and Introduction

The purchasing and supply management (PSM) function in any organisation is a key contributor to a firm's performance (Drake, 2012). A significant portion of the total turnover of a modern industrial firm in Europe is directly transferred to suppliers (Schmid and Grosche, 2008; Van Weele, 2010). Moreover, the bulk of supplies is often no longer of domestic origin, but of European and international nature. The discipline is nowadays characterized by strategic roles, rapid change and, increasing complexity and is highly effected by trends like ongoing globalisation, technological advances and new purchasing portfolios, which require adjusted skill sets. (Giunipero, Handfield and Eltantawy, 2006; Giunipero and Pearcy, 2000; Knight, Tu and Preston, 2014; Pellengahr, Schulte, Richard and Berg, 2016; Van Weele and Van Raaij, 2014)

Firms struggle to find effective and efficient ways to cope with these circumstances (The PERFECT Consortium, 2016; Van Weele and Van Raaij, 2014), even though these allow PSM to remain as, and even increase its role in being a key contributor to performance and strategic

leadership (Pellengahr et al., 2016). Employers have difficulties in attracting suitable candidates for vacant positions, particularly at the entry level (Hays plc, 2015). Reports show that companies have rarely taken further steps to create or feed their future talent pipeline sufficiently (DHL Supply Chain, 2017).

The project Purchasing Education and Research for European Competence Transfer (PERFECT) was set up in 2015 and is funded by the European Union under the Erasmus+ program "Strategic Partnerships for Higher Education" for the term 2015 to 2018. The overall objective of the project is to develop an empirically validated, innovative and harmonised Purchasing and Supply Management (PSM) curriculum (The PERFECT Consortium, 2016). The development of a pan-European curriculum for PSM education, which is based on a combination of identified best practices and industry requirements, will ensure that students are provided with the necessary knowledge and that they learn to join a purchasing department of any size of organisation ready to engage in different aspects and roles of purchasing. The most desired impact of the project is an increase in the number of highly qualified students who are suitable for entering the workplace in such PSM related jobs. (Berger, Straub and Henke, 2017; The PERFECT Consortium, 2016)

In order to do this, it is necessary to establish the context of the European Higher Education Landscape of the PSM field and, therefore, one important activity of the project is a scan and analysis of existing European PSM Higher Education curricula (The PERFECT Consortium, 2016). In parallel, the PERFECT project captured the current skills and competencies that PSM practitioners require now and in the future to deal with the demands of jobs in the field through an in-depth literature review. This procedure aims to identify relevant PSM courses and the topics they deal with on the one hand. On the other hand, these findings are compared with the relevant skills and competencies to be provided in order to discover the gaps about which of the later are not adequately represented in the current education provision (cf. Birou, Lutz and Zsidisin, 2016).

The initial PSM Skills Model of project PERFECT (based on Schiele, 2007) with the top 10 skills identified as listed in **Table 1** is based on input from the literature review, job advertisements, practitioner skills models and studies on trends and future skills.

Negotiation skills	Cost analysis
Analytical skills	Leadership
Problem solving	Change management
Risk management	Supplier relationship management
Decision making	Strategic thinking

Table 1: Top 10 skills identified (The PERFECT Consortium, 2016).

The central problem is the mismatch between skills taught and skills needed in European PSM programmes. This paper highlights the methods and findings of the analyses of programmes in different European countries.

The scope lies on explicit purchasing and supply management (PSM) studies. PSM is understood as comprising the management of external inputs (materials, services, capabilities and

knowledge) that are required for building, running and maintaining the focal firm's processes, while simultaneously managing the external and internal stakeholder network with an extended upstream supply network understanding (The PERFECT Consortium, 2016), as visualised in **Figure 1**.

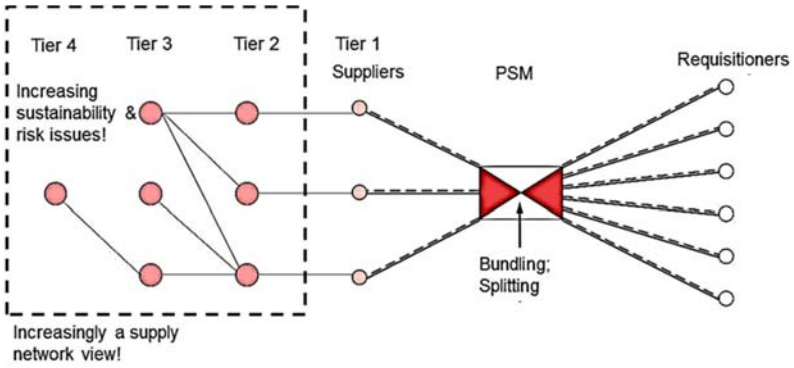

Figure 1: Purchasing & Supply Management scope (The PERFECT Consortium, 2016). Adapted from (Kummer et al., 2013).

Methodology for the Analysis of Existing Purchasing Study Programmes in Europe

The review process requires the identification and afterwards the analysis of relevant PSM courses/study programmes.

The education landscape is identified by Google searches and searches via specific course search engines listing existing study programmes in the respective countries. The search includes undergraduate/Bachelor and postgraduate/Master courses at universities and universities of applied sciences in the field of purchasing and supply management. Courses that are more general entitled with supply chain management, business or logistics programmes including purchasing modules are not considered due to the high amount and difficulty of ensuring completeness.

The analysis embraces courses from a variety of European countries with different level of detail. Following countries are included in this research: Germany, the Netherlands, United Kingdom, Finland, Switzerland and Austria plus a few single programmes from Denmark, France, Ireland and Italy. In the Netherlands, the research focus lies on single modules or courses as no full purchasing study programmes were found. No purchasing degrees were found in Austria neither. The detected variety of focused PSM courses is listed in **Table 2**. The final database includes 19 PSM study programmes (7 UG, 12 G) and 22 single courses in the Netherlands taught at 12 different universities and 13 universities of applied sciences.

Country	Institution	Programme
Germany	Technische Hochschule Ingolstadt (Master, extra-occupational)	Strategisches Beschaffungsmanagement (Strategic Purchasing Management)
Germany	BME–Akademie GmbH (Master, extra-occupational)	Strategisches Beschaffungsmanagement (Strategic Purchasing Management)
Germany	EURO-FH (Bachelor)	Einkauf und Logistikmanagement (Purchasing and Logistics Management)

Germany	Hochschule Heilbronn (Bachelor)	Management & Beschaffungswirtschaft (Management and Procurement)
Germany	OHM Professional School der TH Nürnberg in Kooperation mit der Hochschule Hof (Master, extra-occupational)	Einkauf und Logistik/SCM (Purchasing and Logistics/SCM)
Germany	Universität Würzburg (Master, extra-occupational)	Executive MBA mit dem Schwerpunkt (focus on) Purchasing & Supply Chain Management
Germany	AFUM Akademie für Unternehmensmanagement (Master)	Procurement Management
Germany	FHDW Bielefeld (Master, extra-occupational)	Einkauf und Logistikmanagement (Purchasing and Logistics Management)
Germany	FH Kiel (Bachelor)	Internationales Vertriebs- und Einkaufsingenieurwesen -Bachelor of Engineering (International Sales and Purchasing Engineering)
Germany	Hochschule Aschaffenburg (Bachelor)	Einkaufs- und Qualitätsmanagement (Purchasing and Quality Management)
Netherlands	University of Twente Technical University Eindhoven Maastricht University Erasmus University Rotterdam Tilburg University University of Groningen TIAS School for Business and Society	22 single courses with 5-15 ECTS from Bachelor and Master programmes
UK	CIPS	Chartered Institute of Procurement & Supply Levels 4, 5 and 6
UK	Aston University (Bachelor)	BSc Logistics with Purchasing Management
UK	Greenwich University (Bachelor)	Business Purchasing and Supply Chain Management
Finland	Aalto University	Diploma in Global Supply Management (DGS)
Austria	-	-
Switzerland	Fachhochschule Nordwestschweiz (Master)	Supply Management Excellence
Denmark	Copenhagen Business School (Master)	Minor in Strategic Procurement
Ireland	Irish Institute of Purchasing & Materials Management (Bachelor)	Procurement and Supply Management
Italy	Politecnico di Milano Graduate School of Business (Master)	Supply Chain and Purchasing Management
France	SKEMA Business School (Master)	Supply Chain Management & Purchasing

Table 2: analysed PSM higher education programmes

This descriptive analysis includes gathering information on the programme, name, level, duration, course contents and goals, education methods, evaluation criteria, and amount of ECTS, if detectable. Information from websites like course overviews and descriptions, module handbooks, and in some cases additional personal contact provided information about the content of the study programmes, courses and modules to be analysed in detail.

Having established what the current PSM education landscape looks like, a gap analysis between the Skills Maturity Model and the educational landscape is undertaken. Mentioned PSM Skills Model was developed during the initial work stages in project PERFECT (The PERFECT Consortium, 2016). It is based on the PSM Maturity Model by Schiele (Schiele, 2007), which became complemented with results of literature review, job advertisements and latest studies. It reflects the status of relevant PSM competences derived from mentioned various sources.

An excerpt of the skills model is displayed in **Table 3**. Each line has several sub-categories, which reflect the wide range of explicit and tacit PSM skills in more detail.

	Management Function	*Description*	*Percentages*	*EC observed*	*Observations*
Total			0,0	0,00	
PL	**Planning and Strategy**		0,0	0,00	
PL1	**Demand Planning**		0,0	0,00	
PL2	**Pooling Planning**		0,0	0,00

OT	**Other**		0,0	0,00	
OT1	**Other (purchasing)**		0,0	0,00	
OT1	**Other (non purchasing)**		0,0	0,00	

Table 3: Purchasing Education Content Mapping Model (without showing sub-categories)

The comparison and detection of gaps is conducted by allocating a percentage value of the content that is taught against the skill areas of the model. This is done for all single modules and courses forming a study programme. The number of ECTS for each course topic is considered. In addition, skills students may develop tacitly for instance from means such as participating in group debates or presentations were included to establish the full skill set that education providers are offering in their curriculum.

Sums are calculated to gain overviews of the distribution of taught skills in complete study programmes and in the European whole education landscape that is investigated.

Results

This analysis provides an initial indication of gaps between PSM skills required and what the PSM landscape is currently providing (Project PERFECT, 2018; The PERFECT Consortium, 2016).

The curriculum documents and available information of the analysed study programmes vary significantly. Furthermore, the standards of teaching vary widely, as PSM teaching does not have a harmonised tradition like other disciplines do. Still some generally admitted results are derived from the analysed material.

In summary, the PSM education landscape is characterised by the following:

- Short courses, only few full study programmes.
- Emphasis on post-graduate courses and some professional courses targeting individuals already working in the PSM field.
- Only few university and other higher education institutions offer PSM tracks.
- Most full programmes offered by universities of applied sciences.
- There is no harmonisation; each institution has its own focus.

A detailed analysis of course content using the method detailed above identified a number of key gaps, as well as strengths. The data shows that the PSM Education content analysed has a clear focus on the more processual aspects of PSM (Planning and Strategy), but is partly lacking in Structural Organisation, interdisciplinary understanding and particularly in Human Resources & Leadership aspects. Also the areas of sustainability and digitisation, which were confirmed as main future influence areas for procurement (Project PERFECT, 2017b), are underrepresented in existing curricula. Furthermore, the relevant aspects technology scouting, innovation sourcing, compliance and sustainability, change and human resource management (e.g. Pellengahr et al., 2016) are not sufficiently covered in existing programs.

Only few programmes are future-oriented and close to praxis. They contain business basics, but lack engineering and IT knowledge as well as active participation in the courses. Current studies show that in the future a broader scope of necessary skills then currently offered in higher education is required (e.g. DHL Supply Chain, 2017).

Compared with the findings of the PSM maturity based skill model top 10 skills identified (table 1), the mapped courses show that least attention is paid to soft skills development, either direct or indirect. The most explicitly taught soft skill is communication skills, being part of the top 10 in the PSM Maturity based skill model as well. In the future, greater focussing on identified skills, which include many soft/tacit/non-technical ones than covered in existing courses is needed.

The results go in line with Birou et al., 2016, who analysed PSM courses in the USA. This paper extends their research by the European dimension. The analysis shows that the relevant

aspects of PSM and the required competences are not fully reflected in academic education. A couple of universities offer single PSM courses, but the imbalance between consecutive and executive programs points out the mismatch between offer and demand of PSM education. The European PSM education landscape is characterised by a number of short, post-graduate or tailored professional courses. PSM is mostly only part of generic study programs such as Business or Supply Chain Management. This makes it necessary for companies to hire university graduates with other specializations and often spend years bringing them up to a skill level, which graduates in other disciplines already possess. (The PERFECT Consortium, 2016)

One of the key aims of the PSM profession undertaken over the last 20 years is to assert the importance of PSM within the organisational context and this analysis suggests that the current educational provision is not adequately preparing graduating students with the skills they need to further these goals and become more entrepreneurial business leaders. Whilst not underestimating the importance and necessity of technical PSM skills, the development of a pan-European PSM curriculum, as well as a skills assessment tool and a massive open online course (MOOC) on PSM fundamentals until summer 2018 in the framework of the project PERFECT needs to ensure that this broader skill set is adequately represented. There is a need for a PSM focused curriculum that will allow organisations to recruit graduate employees who are ready and prepared to cope with current and future requirements of PSM. Basic factors for the success of the project to ensure the novelty of the curriculum are the requirements that the curriculum (Project PERFECT, 2018):

- Meets the varied needs of different industrial sectors and organisations.
- Ensures that the PSM graduates are as prepared as possible for a variety of PSM roles.
- Can be flexibly used by a variety of Higher Education Institutions across Europe and form the basis of their own internal validation or accreditation requirements.
- Can be used by organisations as the basis of their own internal training programmes.
- Recognises the future requirements of the PSM field.
- Contributes to the enhanced perception of the PSM profession.
- Is based on contemporary approaches to and principles of teaching and learning and harnesses technological developments.
- Puts the student at the heart of the curriculum.

To close the gaps, a PSM curriculum consisting of different modules (listed in **Table 4**) is designed in the core work package of the project PERFECT. It describes the roadmap in developing an innovative and harmonised curriculum. The modular structure allows the adaption of either the whole programme for start-up PSM chairs or the selective choice of certain modules in order to fill up and strengthen existing programmes with PSM aspects. (Project PERFECT, 2018)

Category Management	Personal skills/Personal Development skills
Commercial Law	PSM Technology in a Digital Environment
Commercial Negotiation	Purchasing Finance
Cross-functional working	Purchasing Fundamentals
Customer Service	Quality Management in PSM
Entrepreneurial PSM	Risk Management in PSM

International Context of PSM	Advanced Category Management
Management & Leadership in a PSM context	Supply Chain Management
Operations Management	Sustainability Management
Organisational change	The Business Context
People skills/Interpersonal skills	Optional Language Modules as appropriate

Table 4: Modules of the new PSM curriculum

Conclusion, limitations and future research

This research misses a clear innovative contribution to academic PSM research as it is derived from an education project. Nevertheless, it gives an indication of the significance of PSM study programmes and hints on the development of new ones. This work contributes to the field of PSM education by identifying gaps in the contemporary education landscape that are seen as important for current and future PSM practice. The development of a harmonised and empirically validated European curriculum for the PSM discipline offers a significant opportunity to improve the described circumstances by closing the gap between new industry requirements caused by changes like digitalisation and existing study programs. Therefore, the results justify the endeavour of the EU project PERFECT to develop a new PSM curriculum.

Hardly any soft skills are taught in the analysed courses while this is considered as important by academic literature and studies focusing on trends in PSM. The current focus in PSM education lies on teaching explicit knowledge with traditional methods (via e.g. books, frontal lectures) instead of putting across tacit knowledge and competences. Institutions should facilitate their students in learning about necessary soft skills theoretically and about the application with direct and implicit teaching through interactive and practice oriented teaching and learning methods like for example, guest lectures, case studies, company projects, role-plays, teamwork, reflection sessions or mentoring. The Standards and guidelines for quality assurance in the European Higher Education Area (ESG) refer to such student-centred learning. They oblige institutes of higher education to encourage students to take an active role in creating the learning process (Standards and Guidelines for Quality Assurance in the European Higher Education Area, 2015). In context with the literature student-centred learning is the future teaching method that is preferable for teaching PSM at institutes for higher education. This would incorporate the need of teaching knowledge and soft-skills in order to fill the existing gap between the needs in practice and existing study programs in higher education.

A change is indispensable to meet employers' demands as well as to keep up the role and meaning of purchasing in the business context and even make use of the change of strategic enhancements of the function.

Apparently, the number of analysed countries is not representative for all European countries and does not include all cultural clusters (Hofstede, 1984; Kale, 1995); this may have created some bias. The necessity of further analysis, e.g. on additional countries and additional detailed comparison and adjustment with industry requirements undeniable. In further research, a widespread scan of all European PSM study programmes should be aspired. In addition, the skills,

which make a PSM professional successful, can slightly differ in different countries, as indicated by the results of a survey conducted in the project context (Project PERFECT, 2017a). As already discovered in previous research, there are gaps in PSM strategic influence factors such as purchasing skills, knowledge, professionalism, and status depending on focused companies; the sizes of discovered gaps differ, but the reasons are similar (Ogden, Rossetti and Hendrick, 2007). It is a reasonable attempt to solve this by a harmonised curriculum.

Furthermore, this study focuses on fully PSM centred study programmes only. Purchasing topics are often parts of other disciplines' courses such as supply chain management, logistics, and business in general (The PERFECT Consortium, 2016). A very in depth analyses of a huge number of courses would be necessary to discover all of these. Besides, it was only possible to look at snap-shots of current curricula; dynamics and past developments of the courses are not considered.

ACKNOWLEDGEMENT

Funding note: The project "Purchasing Education and Research for European Competence Transfer" (PERFECT) has been (partially) funded by the ERASMUS+ grant program of the European Union under grant no. 2015-1-DE01-KA203-002174.

What do suppliers perceive? The emergence of external social capital under conditions of environmental uncertainty

Tobias Bohnenkamp, Holger Schiele and Matthias De Visser
University of Twente, The Netherlands

Abstract

Given a fundamental change in supply chain organization buying firms increasingly have to deal with a smaller number of key suppliers that employ extended value adding responsibilities. Buying firms thus have to pay attention to establish relationships with these suppliers in order to prevent the risk of resource scarcity. While social capital theory has been considered for testing relationships, the effect of internal social capital on the emergence of external social capital is understudied. This especially holds when focusing on the perception that suppliers have about their customer organization's internal relations. Since already this perception could define whether a relationship is meant to last or not, gaining an understanding of this situation can be crucial for relationship management. Therefore, our study tests the effect of perceived internal social capital on the emergence of external social capital. Further, the influence of environmental conditions, including complexity, dynamism and munificence is considered. With this, our study contributes to the further development of social capital theory.

Keywords: Social capital, environmental complexity, environmental dynamism, environmental munificence

1. INTRODUCTION

Over the last decades, the value of inter-organizational relationship has gained increased recognition, being considered a fruitful source for achieving sustainable competitive advantages (Krause et al., 2007). Nowadays being able to bind parties together becomes especially crucial: On the one hand a fundamental change in supply chain organization has resulted in increasing responsibilities for suppliers (Schiele et al., 2015), on the other hand supply bases are more often consolidated in order to include a smaller number of key suppliers (Eggert and Ulaga, 2010). Consequently, since suppliers have constraints on resources they can devote to other parties (Schiele et al., 2015), having close, social relationships with them becomes top priority for buying firms. From the theoretical perspective, social capital theory has been considered for studying relationships between individuals and organizations (Ahuja, 2000; Tsai and Ghoshal, 1998). Building external relationships between buyer and supplier, however, only works if smooth running internal cross-functional relationships are in place (Zhao et al., 2011). As shown by Horn et al. (2014), the presence of internal social capital can be considered a prerequisite for

the emergence of external social capital. Though, while the authors surveyed a sample of purchasing managers, the supplier perspective was omitted. Interestingly, research on how suppliers perceive internal social capital present cross-functionally within the buying organization and, in turn, how this perception influences the emergence and development of external social capital within the relationship between the supplier and this specific buyer are, a priori, neglected in literature. Since suppliers never only deal with the purchasing function per se but are also in contact with other functions, such as Quality or R&D, we assume that suppliers are able to notice whether or not internal social capital exists. Arguably of course, this is only possible for suppliers that already had the first encounters with the buying firm. The neglect in literature on the relationship between perception and result, though, is unfortunate given that this understanding could improve future cooperation between buyer and supplier. As such, the interplay between perceived internal social capital and the development of external social capital could further enhance supply management as well as B2B marketing literature. Intending to close this gap, our study, through the pursuit of a quantitative approach, will aim to answer the following research question:

To what extent does perceived internal social capital influence building external social capital?

Social capital and, on a broader level, buyer-supplier relationships, however, are not to be seen as a self-contained system, but have to be considered in a wider context (Gelderman et al., 2016). An overarching factor that is understood to influence every buyer-supplier relationship to some degree is the environment or market that firms are operating in (Paulraj and Chen, 2007). Given the environmental pressure, firms have to rely on inter-organizational relationships to a smaller or greater extent (Matanda and Freeman, 2009). Commonly, academics distinguish between (1) environmental complexity (Starbuck, 1976; Bozarth et al., 2009), (2) environmental dynamism (Dess and Beard, 1984; Aldrich and Pfeffer, 1976) and (3) environmental munificence (Dess and Beard, 1984; Starbuck, 1976). What is missing, however, is the effect that the three attributes have on the development of social capital. Since the uncertainty of an environment firms are operating in can cause difficulties for achieving goals, thus requiring them to seek for closer relationships (Cousins and Spekman, 2003), it is fair to assume that this might also moderate the interplay of perception and result. In order to better understand this construct, the following research question is postulated:

To what extent do environmental complexity, environmental dynamism and environmental munificence influence building social capital?

By answering the two research questions, our paper will contribute in two directions:
(1) Firstly, our study will further extend the cohesive research on social capital in buyer-supplier relationships, specifically paying attention to the supplier point of view, and thus answering calls for more supplier-centric research (Carey et al., 2011). By considering the influence of perceptions suppliers have of their buyers internal relationships on the quality of their external relations between both parties, our study will provide indications to forming and sustaining inter-organizational relationships.
(2) In addition, our study will test for the effect the environment firms are operating in, including its complexity, dynamism and munificence, has on the development of social capital in inter-organization relationships. To our knowledge, research on social capital theory has not yet examined these possible influencing factors.

The paper will be organized as follows: Through conducting an extensive literature review, all variables will be introduced. Subsequently, the focus will lie on the research methodology, followed by a presentation of findings and limitations .

2. THEORETICAL CONSIDERATIONS

2.1 Social capital theory: Cognitive, structural and relational capital define the concept.

Social capital, being grounded on social relations, is understood as goodwill that is available to individuals as well as groups (Adler and Kwon, 2002). It can be referred to as resources, of actual or potential nature, that are available to different actors within a relationship and that comprises contextual factors underlying the resource exchange (Kankanhalli et al., 2005; Nahapiet and Ghoshal, 1998). As such, social capital considers social ties that are difficult to imitate and potentially able to generate a competitive advantage (Edelman et al., 2004). In academics the notion of social capital has been used as theoretical lens for studying relationships between individuals and organizations (Ahuja, 2000; Tsai and Ghoshal, 1998), or at more recent state in the field of supply management focusing on buyer and supplier interactions (Hartmann and Herb, 2014; Horn et al., 2014). Nahapiet and Ghoshal (1998) further divide social capital into three separate dimensions, distinguishing between (1) cognitive capital, (2) structural capital and (3) relational capital. While the majority of studies examine these dimensions as in parallel existing constructs, others also consider cognitive and structural capital as antecedents of relational capital (Carey et al., 2011; Horn et al., 2014; Preston et al., 2016).

Common values and visions shared by actors within a relationship are underlying the cognitive dimension (Tsai and Ghoshal, 1998). They also include common goals, norms and beliefs contributing to the understanding of the social system, as well as shared interpretations, such as language or signs (Uphoff and Wijayaratna, 2000; Tsai et al., 2008). A high level of cognitive capital therefore implicates that these attributes are shared by both relationship partners to a high extent. In this way, cognitive capital enables a consensus on strategic goals and processes that both parties might benefit from (Atuahene-Gima and Murray, 2007; Adler and Kwon, 2002).

Structural social capital refers to pattern of connections between parties as well as how they can be used and how frequent they occur (Burt, 1997; Villena et al., 2011). A high level of structural capital can therefore be found if both actors within a relation utilize multiple channel of interaction to facilitate the information and resource exchange (Koka and Prescott, 2002; Villena et al., 2011). The common usage of resources is enhanced through clarity, transparency on actions and processes fostered by a strong and consistent flow of information. This is stressed by empirical findings reporting the positive effect of structural capital on “information flow” and “information diversity” (Koka and Prescott, 2002).

Finally, the relational dimension of social capital, being based on the notion of Granovetter and Swedberg (1992) refers to embeddedness and to the relationships that actors have developed. It is considered closely connected to cognitive and structural capital, and further expressed through trust, friendship as well as mutual respect that partners have for each other (Kale et al., 2000) (Kale et al., 2000). Arguably, if parties in a relationship share common business goals and ideas as well as holding a dense net of interactions, relational capital might be more likely to develop (Tsai & Ghoshal, 1998). In the same way, a relationship based on trust requires frequent interaction and the means to do so. Interestingly, if trust and commitment are present, the information flow and intensity are increased (Hartmann and Herb, 2014).

The majority of studies focusing on social capital have been conducted from the buyer point of view, omitting the supplier perspective. Gaining understanding on not only the buyer but also the supplier side is however crucial for relationship management. Also, influencing external factors, such as the firm environment, that might affect the emergence and development of social capital within a relationship have not been discussed to a larger extent, being introduced subsequently.

2.2 The environmental context: Complexity, dynamism and munificence influence firm behavior.

Several studies have already shown that the environments firms are operating in can affect their choice of strategy as well as their performance (McArthur and Nystrom, 1991; Clark, 1971). The most commonly addressed attributes of the environment include (1) complexity, (2) dynamism and (3) munificence (Bozarth et al., 2009; Dess and Beard, 1984; Starbuck, 1976; McArthur and Nystrom, 1991). According to this consensus, these three factors are most important and allow characterizing the firm environment in the best possible way.

Compexity has been defined as the number and interconnectedness of elements in a system (Bourgeois, 1980; Bozarth et al., 2009). Environmental complexity refers to the heterogeneity a market displays as well as the dispersion of activities that organizations operating inside conduct (Starbuck, 1976; Choi and Krause, 2006). While simple environments are known for their homogeneity with few interactions between parties, complex environments depict a high degree of heterogeneous elements, requiring numerous interactions (Choi and Krause, 2006).

Dynamism on the other hand includes the change of elements and relationships over time (Aldrich, 1979, Bourgeois, 1980). As such, it also refers to the degree of predictability that these elements are changing (Dess and Beard, 1984). Environmental dynamism focuses on the degree to which a market is stable (or not) and to which extent the interconnectedness between firms cause turbulence (Mintzberg, 1979). While stable and slowly changing environments depict a low degree of dynamism, instability and fast changing circumstances are the main characteristic of highly dynamic environments (Calantone et al., 2003).

Finally, munificence focuses on the availability (or abundance) of resources that firms can nourish from. Environmental munificence therefore describes the capacity and opportunities firms have in a market as well as the extent to which it can support sustained growth (Randolph and Dess, 1984; Starbuck, 1976; Dess and Beard, 1984). As such, environmental munificence is also always related to the number of firms operating in the market, competing for these resources (Ward et al., 1995; Mintzberg, 1979).

After having introduced the theoretical constructs that our paper is based on, the next section will derive hypotheses that are to be tested.

2.3 Hypotheses

The study at hand considers by suppliers' perceived internal social capital present at their customer organizations as well as external social capital developing between suppliers and their customer as a result from this.

Firms that incorporate a high level of internal social capital are likely to foster a highly collaborative organizational environment (Leana and Pil, 2006; Sparrowe et al., 2001; Madhavaram and Hunt, 2017). They can be understood to practice extensive cooperation as well as communication on a functional level (Rosenzweig et al., 2003; Sherman et al., 2000). As such, employees from different functions work together in teams, exchange ideas regularly and provide their insights based on their diverse backgrounds. Utilizing a collaborative environment like this,

buyer and supplier have the nourishing basis to build up or develop external social capital together (Narasimhan and Kim, 2001). Through common meetings with different functions of his customer, the supplier could perceive this collaborative environment, the accumulation of internal social capital and acknowledge it as stimulating.
Employing the view of cognitive capital, internal cognitive capital would imply that departments, as well as employees working within these departments, share the same values and have a common understanding of what the goals of the their company are and how they can contribute together in the best possible way to achieve them (Tsai and Ghoshal, 1998; Uphoff and Wijayaratna, 2000). This unification in terms of goal alignment and values, departments would also exhibit to the outside world. As such, they are able to encourage the communication of these shared goals and values to other organizations (Thompson and Fine, 1999). Thus, for suppliers perceiving internal cognitive capital from their customers it would be less difficult to understand what the customer is aiming for and find common grounds to align their goals, since departments of the customer speak the same "language". Consequently, the suppliers would consider it valuable to develop external cognitive capital with their customer in order to reach their own goals more effectively. Following this, H1.1 has been formulated.

H1.1 The perception of internal cognitive capital is positively related to the development of external cognitive capital.

In terms of structural capital, internal structural capital would imply that departments within the organization would utilize multiple channels of interacting with each other (Nahapiet and Ghoshal, 1998; Villena et al., 2011). In other words, a high level of internal structural capital would entail intra-organizational communication through a variety of means, including not only the exchange of information via emails but also by personal and direct interaction in cross-functional meetings. Also, the frequencies of how the departments communicate as well as the hierarchical levels they use define internal structural capital (Burt, 1997; Villena et al., 2011). For suppliers it could be relatively easy to perceive whether internal structural capital is present at their customer's organization or not: Through visiting their customer or through having common project meetings, the suppliers could easily assess whether the information they receive from various parties is accurate and reliable (Chen et al., 2009; Villena et al., 2011) as well as, most importantly, aligned. Since information reliability provides the suppliers with planning security and prevents problems, the suppliers can be expected to develop external structural capital with their customer in order to access the customer's internal network and gain knowledge through it. Accordingly, H1.2 was formulated.

H1.2 The perception of internal structural capital is positively related to the development of external structural capital.

Finally, internal relational capital refers to trust and commitment that departments have for and share with each other (Lee and Cavusgil, 2006). A high degree of internal relational capital thus implies that departments trust each other to follow up on promises made and commit themselves to a common purpose for their firm. On the other hand, internal relational capital also prevents opportunistic behavior among departments and their employees (Kale et al., 2000; Villena et al., 2011) through leaking or withholding relevant information in order to e.g. decrease other parties' reputation and vice versa increase their own chances of promotion. Literature also argues that (internal) cognitive and structural capital are both positively related to the accumulation of

relational capital (Tsai and Ghoshal, 1998; Carey et al., 2011; Horn et al., 2014).
From the supplier point of view, the trust and commitment present within their customer's organization can be perceived from meetings with this customer, through the way departments dealing with the supplier interact with each other, how transparent they communicate as well as how aligned and familiar with each other they appear. The presence of internal relational capital could urge the supplier to also feel more secure about the information that is received as well as dedicated towards the common goal and project outcome. Having less to worry about being taken advantage of (Tsai and Ghoshal, 1998), the supplier could more openly share his resources and commonly improve both organizations performance (Lawson et al., 2008; Gelderman, 2016). Consequently, external relational capital would develop, being reflected in H1.3.

H1.3 The perception of internal relational capital is positively related to the development of external relational capital.

Next to the presumed relationship between perceived internal social capital and the development of external social capital, we also expect moderating factors to affect respectively stimulate this relationship. The moderating factor that we are paying attention to in this study is the firm environment. With literature having established how the firm environment can influence their strategic decisions (McArthur and Nymeth, 1991; Clark, 1971), firms are required to take precautionary actions for their own good. Through employing a strategic supply management role, firms can attempt to control environmental influences (Pfeffer and Nowak, 1976) and seek for predictably and stability (Bresser and Harl, 1986).
Operating in complex environments, firms are dealing with a high extent of competition, multiple ties and interconnections between firms as well as a lack of transparency preventing a full understanding of the market (Bozarth et al., 2009; Choi and Krause, 2006). Under these conditions of complexity, firms are well advised to seek for close relationships, relationships that guarantee them long term planning and orientation (Shin et al., 2000; Cousins and Spekman, 2003) in order to minimize and share potentials risks (Kotabe et al., 2003). As such, being the basis of every relationship (Ahuja, 2000; Tsai and Ghoshal, 1998) social capital could well be linked to environmental complexity.
In terms of cognitive capital under environmental complexity, suppliers perceiving internal cognitive capital from their customer would have a strong urge to bind with the customer and develop external cognitive capital: Since clarity on goals and targets as well as on values and work ethics prevents conflicts through developing a clear common understanding and allows for more effective planning (Terawatanavong et al., 2011), a must to survive in a complex environment, the supplier would consider a long-term relationship with their customer highly valuable. Further, in order to secure a long-lasting relationship with the customer, the supplier would try to align his goals with the goals of his business partner in order to prevent a contradiction on objectives. As such, the supplier would be led to develop external cognitive capital even stronger than without environmental complexity, resulting in H2.1.

H2.1 The presence of environmental complexity positively moderates the relationship between perceived internal cognitive capital and the development of external cognitive capital.

Through developing structural social capital with their customer, suppliers would be able to increase their external information flow (Koka and Prescott, 2002; Villena et al., 2011), and gain a clearer understanding about the market and thus about available resources and movements of

other firms as well as their business relationships and interactions. With this they would meet their information requirement and are able to commonly develop strategies for dealing with the environmental circumstances (Choi and Krause, 2006; Aldrich, 1979; Dess and Beard, 1984). Following this logic, suppliers perceiving the presence of internal structural capital are aware that their customer has the right structures and effective communication means to analyze their complex environment and deal with it accurately. As such, the supplier would be eager to also profit from these structures and further develop external structural capital, leading to H2.2.

H2.2 The presence of environmental complexity positively moderates the relationship between perceived internal structural capital and the development of external structural capital.

Finally, every relationship that wants to endure requires trust, commitment and reciprocity (Blonska et al., 2013). This is especially the case in environments which, by means of its complex nature, make ties and partnerships in order to sustain necessary. In this sense, relationships can well be considered resources (Lavie, 2006; Dyer and Singh, 1998) that support firms operating in complex environments (Choi and Krause, 2006; Aldrich, 1979; Dess and Beard, 1984). As has been pointed out, relational capital ensures that firms can trust and rely on the information they receive (Kale et al., 2000; Villena et al., 2011), an indispensable condition under environmental complexity. As such, suppliers perceiving internal relational capital from their customer might also be more likely to rely on the information they receive from this customer. Having obtained accurate information, the suppliers are more able to deal with their market in an attempt to reduce complexity. Consequently, the supplier would then also develop external relational capital with their customer in order to become part of a long-term oriented relationship (Cousins and Spekman, 2003; Shin, Collier and Wilson, 2000). Thus it is fair to postulate H2.3.

H2.3 The presence of environmental complexity positively moderates the relationship between perceived internal relational capital and the development of external relational capital.

Next to environmental complexity, the dynamics an environment underlies is a major influencing factor for firms (Aldrich, 1979, Bourgeois, 1980). In dynamic environments, characterized by low instability and fast change (Calatone et al., 2003), firms are more likely to engage in collective action and build closer relationships for stabilizing their environment (Salancik and Pfeffer, 1978; Zenger and Hesterly, 1997). As such having strong and in-depth relationships leads to increased coordination between firms counteracting the unpredictable nature of a dynamic environment (Paulraj and Chen, 2007). In this sense, the development of social capital can also be linked to environmental complexity.
In terms of cognitive capital, being internally aligned on goals, targets and values can be a means to create stability from the within in an otherwise unstable environment, through possessing a common understanding between internal parties (Tsai and Ghoshal, 1998; Uphoff and Wijayaratna, 2000). As such, when it comes to building relationships for stabilizing the market, the internal organizational environment could well be a point of departure (Narasimhan and Kim, 2001). Suppliers operating in a dynamic environment perceiving the presence of internal cognitive capital from their customer would obtain the picture that this customer is internally well established with functions being on the same line in an attempt to deal with external unpredictability (Dess and Beard, 1984). Similar to environmental complexity, the supplier would try to align and match his own goals with the goals of the customer to make a long-term relationship possible, thus attempting to develop external cognitive capital (H3.1).

H3.1 The presence of environmental dynamism positively moderates the relationship between perceived internal cognitive capital and the development of external cognitive capital.

As has been described in literature, collective actions between parties are a way to deal with dynamic and unstable environments (Pfeffer and Salancik, 1978; Zenger and Hesterly, 1997). Deploying structural social capital, developing strong communication mechanisms at high frequencies (Villena et al., 2011), is therefore a means to stabilize the environment. Suppliers that perceive that internal structures exist at their buying firm that allow for constant alignment and information exchange (Nahapiet and Ghoshal, 1998; Villena et al., 2011) might consider to also utilize and profit from this internal network in order to deal with the unpredictable environment they are operating in. As such, through developing external structural capital with the customer, supplier and customer could align their communication structures and insure themselves more carefully against changes in their environment. Following this, H3.2 was formulated.

H3.2 The presence of environmental dynamism positively moderates the relationship between perceived internal structural capital and the development of external structural capital.

Also, relational capital plays a role when it comes to stabilizing dynamic environments being closely connected to structural and cognitive capital (Carey et al. 2011), creating trust and commitment between relationship partners and preventing opportunistic behavior (Villena et al, 2011; Kale et al., 2000). All those attributes can be understood as requirements when executing collective actions by firms that have been said to positively affect the predictability of dynamic environments (Pfeffer and Salancik, 1978; Zenger and Hesterly, 1997). Similar to under environmentally complex conditions, suppliers that perceive the presence of relational capital at their customer know that departments are committed to their common purpose and do not engage in opportunistic actions (Villena et al., 2011). With this, also the reliability of information flowing through departments cross-functionally is ensured. Consequently, suppliers can be more certain that this customer is more suitable for collectively operating in and stabilizing their dynamic environment. As such, they also commit to developing an in-depth relationship and accumulate external relational capital with this customer, leading to hypothesis H3.3.

H3.3 The presence of environmental dynamism positively moderates the relationship between perceived internal relational capital and the development of external relational capital.

Finally, the last attribute characterizing the environment firms are operating in is environmental munificence (Starbuck, 1976; Dess and Beard, 1984; Randolph and Dess, 1984) referring to the extent of resources that are available to firms in their market and the amount of firms competing for them. In order to sustain in their market, firms that are dependent on acquiring external resources, a context that also links environment munificence to the resource dependency theory (Pfeffer and Salancik, 1978), seek to establish exchange relationships with other firms in an attempt to manage this dependency (Ulrich and Barney, 1984; Paulraj and Chen, 2007). Since social capital theory describes the underlying means for developing a relationship (Tsai and Ghoshal, 1998), a connection to environmental munificence can be found.
In terms of cognitive social capital, suppliers that possess all the resources to sustain and grow feel less attracted by a buying firm (Schiele et al., 2012) let alone by its internal alignment in terms of goals and values. While for suppliers operating in a resource scarce environment

perceived internal cognitive capital would paint the picture of a customer that is well equipped to deal with uncertain circumstances, and leading to the development of external cognitive capital, munificent suppliers would be less dependent on external relationships (Shou et al., 2013). Thus, these suppliers do not have the need to further develop external cognitive capital. Environmental munificence would therefore weaken the link between perceived internal cognitive capital and the development of external cognitive capital, leading to H4.1.

H4.1 The presence of environmental munificence negatively moderates the relationship between perceived internal cognitive capital and the development of external cognitive capital.

In order to evade resource scarcity, literature has indicated that firms should build up exchange relationships (Ulrich and Barney, 1984; Dyer and Singh, 1998). A way to deal with this is through developing structural ties that allow for effective communication (Villena et al., 2011). Suppliers operating in a resource scarce, non-munificent environment can therefore be expected to use every communication channel possible to secure their future growth (Starbuck, 1976). As such the perception of internal structural social capital present at their buying would signal that this customer has the communicative means in place that can be accessed to counteract environmental conditions. On the other hand, a supplier already operating in a munificent environment would only have to interact with their customer when necessary. The further development of external structural capital would therefore be less likely, despite the possible perception of internal structural capital, leading to H4.2.

H4.2 The presence of environmental munificence negatively moderates the relationship between perceived internal structural capital and the development of external structural capital.

Finally, since establishing relationships has been postulated of being a means to manage resource dependency (Ulrich and Barney, 1984; Paulraj and Chen, 2007), relational capital, through developing trust and commitment within a relationship, also plays a role when it comes to environmental munificence. Again, while suppliers operating in scarce environments would bind with their customers and develop external relational capital in order to sustain in the long-term, suppliers operating in a munificent environment might stick to a platonic business relationship since they are in no need to develop in depth relationships with their customer. Consequently, in munificent environments, the perception of internal relational capital would not per se lead to the development of external relational capital, which is depicted in H4.3.

H4.3 The presence of environmental munificence negatively moderates the relationship between perceived internal relational capital and the development of external relational capital.

3. RESEARCH METHODOLOGY

3.1 Data collection

With the goal of investigating the effect of perceived internal social capital on the emergence of external social capital, our research started off with a small-scale pre-study. In order to ensure that suppliers are indeed able to perceive the accumulation of internal social capital at their customer firm, a group of five experts from diverse departments, including R&D, Purchasing and Quality, of a multinational German automotive manufacturer located in China was interviewed:

The experts who were dealing with suppliers on a daily basis were given the questionnaire intended for the suppliers and had to comment on its feasibilty and ideally agree on it. The same procedure was repeated with two key-accountants selected from random suppliers. All experts confirmed the study applicability. Based on the positive outcome of the pre-study, a sample of 1386 suppliers was selected. The suppliers orginated from the portfolio of the German multinational. In order to minimize bias, suppliers from each commodity group dividing the purchasing department, including exterior, interior, metal, electric and powertrain, were equally selected. Eventually, 131 usable questionaires were received, equalling a response rate of 9%.

3.2 Measurements

The measurements used in this research were mostly adapted from previous studies. A conduction of in-depth interviews with experts from the German Multinational allowed for a subsequent further refinement. In terms of scaling, five-point Likert scales were used, ranging from 1=strongly disagree to 5=strongly agree. Perceived internal as well as external social capital were measured using the same items for ensuring comparability. Further, structural, cognitive and relational capital were broken down into three 2nd order constructs which could be measured individually, allowing for a finer grasp of the concept. Structural capital was then measured focusing on quantity and nature of interaction as well as means used for exchanging. Items from Villena et al. (2011) and Wang et al. (2013) were applied. The measurements for cognitive capital focused on whether goals and values are shared between parties, whether they overlap and whether corporate culture and management style match. Measures of Villena et al. (2011) and Yeung et al. (1991) were applied. Here the focus in particular lied on whether the corporate culture of both supplier and customer is comparable. Finally relational capital was meausred through a distinction into trust, commitment and reciprocity as outlined by Blonska et al. (2013). In terms of moderating factors, the measurement for environmental uncertainty was conducted by seperating between complexity, dynamism and munificence. Here, the items of Lau et al. (1999), Kaufmann (2012) and Li et al. (2013) were adapted for our purposes and applied.

3.3 Data analysis

To test the hypotheses, partial least squares structural equation modeling (PLS-SEM) was carried out (Fornell & Cha, 1994). In particular, the software SmartPLS (Ringle et al., 2005) was used to carry out a confirmatory factor analysis. The PLS approach has been characterized as useful for obtaining robust findings (Chin, 1998). Bootstrapping (Nevitt & Hancock, 2001) was applied to increase measurement accuracy to the used sample. The detailed path coefficients of our model can be found in Appendix I. Due to the reflective nature of our constructs, internal consistency and reliability were assessed using composite reliability (CR) (Fornell & Larcker, 1981; Wetzels et al., 2009) in combination with average variance extracted (AVE) and factor loadings (Edwards & Bagozzi, 2000). Individual item loadings were analyzed in order to assess indicator reliability: As it turned out, items of perceived as well as external social capital were strongly loading on each other, thus affecting each others explanatory power. This might have been due to the fact that same questions were posed for internal and external social capital as well as due to the high amount of indicators located to each construct. As a result, several items had to be removed, eventually leaving five items per construct. Further, one item with factor loading of 0.6 x was retained, all other loadings well exceed the threshold of 0.7 (Henseler et al., 2009). Focusing on convergent reliability, the analysis found that all items strongly correlate with the construct they

are related to. As such, all values exceed the threshold of 0.7 for CR, 0.5 for AVE and 0.7 for Cronbach's alpha (Edwards & Bagozzi, 2000; Fornell & Larcker, 1981). Further, the Fornell-Larcker criterion was used to test for discriminant validity. Also here, no concern was found (all see Appendix I). For assesing common method variance (CMV), the unmeasured latent methods factors test as described by Podsakoff et al. (2003) was conducted. A common method variance factor including all principal constructs indicators was introduced. As shown in table 3, the substantive variance averaged around 0.704 while the average method based variance was 0.020, resulting in a ratio of substantive to method based variance of 35:1. Following this result, CMV may not be regarded a concern

4. RESULTS AND CONCLUSION

Looking at the results the study at hand contributes, H1.1 (t = 12.626), H1.2 (t = 11.866) and H1.3 (t = 15.208) have been proven of having strong validity. As such, not only are suppliers well able to perceive the accumulation of internal social capital with their customer organization, but also this in turn leads them to build external social capital with their customer themselves. This postitive relationship between perceived internal and external social capital has not been found in literature so far and has an important implication for supplier management and B2B marketing: Buying firms are well adviced to consider how they appear in front of their suppliers, how they communicate and cooperate internally. Omitting this outside perspective might lead to a relationship between buyer and supplier with less trust, commitment and collaboration, which eventually could also result in decreased relationship output, e.g. success in common projects. Taking a look at H2, H3 and H4, the effect of environmental uncertainty of the relationship between perceived internal and external social capital, most of the hypotheses have found no support (see table 4): Only the relationship between perceived internal cognitive capital and external cognitive capital is moderated by environmental complexity (t = 1.747). In other words, under conditions of environemntal complexity, suppliers, who perceive that goals are aligned within their customer organization and values are shared, are more likely to also build cognitive capital with their customer, thus align their goals and values. For buying firms this implies that, whilst suppliers operate in complex markets, buying firms might find it easier to agree on goals with them and link values with their suppliers. Next to testing the hypotheses, and contrary to the logical assumption, also a positive direct relationship was found to exist between environmental munificence and external cognitive and relational capital. Apparently, suppliers who are sufficiently equipped and supported through the characteristics of the market they operate in, are more willing to commit to relationships with customers. One argument here could be that these suppliers are monopilists or oligopolists and simply more power and leverage on their customers so that they do not have to fear opportunistic behavior from their side. Future research should look into alternative antecedents or moderators refering to socal capital and also confirm our findings.

Moderation: Munificence → Relational SC (**H4.3**)	-	0.076	> 0.1, non-significant
Further significant paths			
Munificence → External cognitive SC	0.161	2.655	< 0.01, significant
Munificence → External relational SC	0.138	2.345	< 0.1, significant

Appendix II – Measures

Internal Structural Capital:

	During the project, departments at your customer firm…	
Infrastructure Actor Exchange	• Always conducted common activities / workshops. • Had common project reviews in place. • Used internal linking systems (shared fileserver etc.). • Had also purely social activities (common meals, after-work get togethers). • Made use of being located in close proximity to each other.	Own measure
Quantity of Interaction	• Frequently communicated with each other. • Frequently communicated at different levels (management, operative staff etc.). • Frequently communicated between different functions.	Villena (2011); CR: 0.87; AVE: 0.68
Nature of Communication	• Exchanged concessions throughout the project (e.g. granted more time etc.). • Solved / prevented problems commonly. • Easily found agreements jointly. • Constructively addressed topics that could entail conflicts.	Wang et al. (2013); alpha: 0.8

Internal Cognitive Capital:

	During the project, departments at your customer firm…	
Shared Norms & Values	• Interpreted situations in the same way / had the same approaches to business dealings. • Had a common understanding about what is allowed / not allowed. • Had the same vision of business in the relationship. • Viewed each other as partners.	Villena (2011); CR: 0.8; AVE: 0.5
Overlap of Objectives	• Were aware of each other's objectives / KPIs. • Were aligned on objectives / objectives matched. • Made the effort to align goals. • Had similar targets.	. Own measure

Internal Relational Capital:

	During the project, departments at your customer firm…	
Trust	• Considered own interests as well as the others. • Trusted in each other to keep the best interest in mind. • Counted on each other to follow through with promises..	Blonska (2013); CR: 0.87, AVE: 0.69
Commitment	• Found it pleasant to work with each other, which is why the relationship continued. • Wanted to remain in the relationship. • Were attracted by what the other party represented as a firm (image, brand, reference etc.).	Blonska (2013); CR: 0.86, AVE: 0.66
Reciprocity	• Considered the relationship as mutually beneficial. • Felt indebted because of what the other had done for each other. • Expected to also work on further projects in the future.	Blonska (2013); CR: 0.81; AVE: 0.69

External Structural Capital:

	During the project, you and your customer…	
Infrastructure Actor Exchange	• Always conducted common activities / workshops. • Had common project reviews in place. • Used internal linking systems (shared fileserver etc.). • Had also purely social activities (common meals, after-work get togethers). • Made use of being located in close proximity to each other.	Own measure
Quantity of Interaction	• Frequently communicated with each other. • Frequently communicated at different levels (management, operative staff etc.). • Frequently communicated between different functions.	Villena (2011); CR: 0.87; AVE: 0.68
Nature of Communication	• Exchanged concessions throughout the project (e.g. granted more time etc.). • Solved / prevented problems commonly. • Easily found agreements jointly. • Constructively addressed topics that could entail conflicts.	Wang et al. (2013); alpha: 0.8

External Cognitive Capital:

	During the project, you and your customer…	
Shared Norms & Values	• Interpreted situations in the same way / had the same approaches to business dealings. • Had a common understanding about what is allowed / not allowed. • Had the same vision of business in the relationship. • Viewed each other as partners.	Villena (2011); CR: 0.8; AVE: 0.5
Overlap of Objectives	• Were aware of each other's objectives / KPIs. • Were aligned on objectives / objectives matched. • Made the effort to align goals. • Had similar targets.	. Own measure

External Relational Capital:

	During the project, you and your customer…	
Trust	• Considered own interests as well as the others. • Trusted in each other to keep the best interest in mind. • Counted on each other to follow through with promises..	Blonska (2013); CR: 0.87, AVE: 0.69
Commitment	• Found it pleasant to work with each other, which is why the relationship continued. • Wanted to remain in the relationship. • Were attracted by what the other party represented as a firm (image, brand, reference etc.).	Blonska (2013); CR: 0.86, AVE: 0.66
Reciprocity	• Considered the relationship as mutually beneficial. • Felt indebted because of what the other had done for each other. • Expected to also work on further projects in the future.	Blonska (2013); CR: 0.81; AVE: 0.69

Environmental Uncertainty:

	In our market…	
Complexity	• It is difficult to compare firms / competitors. • The structures of firms / competitors are complex and difficult to understand. • It is complex and difficult to compare offers / products from different firms / competitors. • It is complex and difficult to compare the supply chains of different firms / competitors.	Lau (1999) alpha: 0.67
Dynamism	• A number of changes occur in the structure of firms / competitors over time. • A number of changes occur in the supply chains of firms / competitors over time. • It is very difficult to predict how the market will be in 2-3 years. • The barriers to enter are high / it is very difficult to enter the market.	Kaufmann (2012)
Munificence	• We are without external threat for survival and future development • We are with sufficient capital supply • We are with numerous profit opportunities • We can easily access the needed resources for operation and expansion	Li (2013); AVE: 0.55; alpha: 0.88

The effect of supplier satisfaction and the preferred customer status on successful project outcomes in China – A social capital perspective

Tobias Bohnenkamp, Holger Schiele and Matthias De Visser
University of Twente, The Netherlands

Abstract

Given a fundamental change in supply chain organization buying firms increasingly have to deal with a smaller number of key suppliers that employ extended value adding responsibilities. Buying firms thus have to pay attention to establish relationships with these suppliers in order to prevent the risk of resource scarcity. Satisfying suppliers and ideally becoming their preferred customer becomes top priority for buying firms in order to out-compete the competition. Before this becomes possible, however, firms are in need to establish relationships with their suppliers. Given its strong focus on social relations, having a foundation of well established relationships might be especially crucial for firms operating in China. In literature, social capital theory has been considered for studying relationships between buyer and supplier, however without quantitatively linking it to the concepts of supplier satisfaction and the preferred customer. This study therefore tries to establish this link. Further, through focusing on the Chinese market the study allows to test the effect of supplier satisfaction and the preferred customer in a low-cost country context, in particular on the success of projects with local Chinese suppliers.

Keywords: Social capital, supplier satisfaction, preferred customer status

1. INTRODUCTION

Reflecting upon the increased recognition that inter-organization ties have gained over the last decades in terms of contributing to the creation of value, buyer-supplier relationships have been considered more and more as a source of a sustainable competitive advantage (Krause et al., 2007). Forming and maintaining these relationships however is often seen challenging and considered rather complex (Johnston et al., 2004; Narasimhan and Nair, 2005). Yet, since companies increasingly outsource activities to their suppliers and thus grant them more responsibilities (Schiele et al., 2015) while their supply bases consolidate and include smaller numbers of key suppliers (Eggert and Ulaga, 2010), being able to successfully manage relationships becomes a necessary requirement. In fact, given that suppliers have constraints on capacities and resources they can devote to their customers (Huettinger et al., 2014), supplier scarcity becomes a risk for firms they have to mitigate (Bode et al., 2011). As such, creating satisfaction among the suppliers and in turn being considered their preferred customer can be a solution (Schiele et al., 2011; Schiele et al., 2012; Ellis et al., 2012).

Here, in order to answer the question of how supplier satisfaction can be achieved, Huettinger and colleagues (2014) identified 28 antecedents that firms should consider. One year later, Schiele et al. (2015) approached this from a more theoretical standpoint, proposing a link between supplier satisfaction and the presence of social capital. From the theoretical perspective, social capital theory has been considered for studying relationships between individuals and organizations (Ahuja, 2000; Tsai and Ghoshal, 1998). With social capital being present in an inter-organization relationship between buyer and supplier, the exchange of resources can be facilitated (Hughes and Perrons, 2011) and performance increased (Lawson et al., 2008; Whipple et al., 2015). Literature further suggests that social capital allows both buyers and suppliers to access and leverage resources tied within the relationship (Villena et al., 2011). Accordingly, the presence of social capital reduces the risk of conflicts and contrarily promotes cooperative behavior due to shared visions and trusting relations it emphasizes. Given this, social capital can surely be considered a piece of the puzzle for the necessary supplier satisfaction.
To this date, however research has not yet empirically tested a relationship between social capital and supplier satisfaction (Schiele et al., 2015). This is unfortunate, given that the strong reliance on capable though scarce suppliers would demand an even clearer understanding on how to satisfy them. Consequently, in order to fill this research gap, this study will aim to answer the following research question:

How does social capital present in a relationship influence supplier satisfaction?

Through doing so, this study will therefore try to quantitatively establish a link between social capital, supplier satisfaction and, with it, also the preferred customer status. A context, where this configuration based on social capital can be considered very important, is China, given its strong focus on social relations (Li et al., 2014). Since China has become the most important supplier market in the world, companies increase their efforts to integrate domestic suppliers into their sourcing activities for accessing the potential of the local supplier base and, predominantly for foreign companies located in China, to fulfil local content requirements (Lockström and Lei, 2013). Unfortunately, as indicated by empirical evidence, many foreign companies struggle when it comes to sourcing from domestic suppliers and building long-term relationships with them (Lockstroem et al., 2010; Kotabe and Murray, 2004; Pyke et al., 2000; Millington et al., 2005). Such a condition might also affect common projects between buyer and local suppliers, which are in many cases not only one-time activities. Following our prior stream of reasoning, project success might therefore depend on the firm's ability to accumulate social capital, achieve supplier satisfaction and eventually become preferred customer of the supplier. Especially understanding the relationship between preferred customer ship and successful project outcomes with local suppliers could be of strong interests for firms operating in China: Given the strong need to build a domestic supply base, or in other words to "localize", enforced through governmental requirements (Lockstrom et al., 2011; Nassimbeni and Sartor, 2007; Eberhardt et al., 2004), firms would have to strongly cooperate with their suppliers in order to catch up a loss in terms of quality or competitiveness. This could even go as far as collaborating with suppliers to implement local sub-tier suppliers into their supply chains for achieving certain local content rates. Through becoming preferred customer, firms could grant access to external resources (Schiele et al., 2012), that might even include a direct line to sub-tier suppliers. Thus, being preferred customer might have advantages, especially when dealing local Chinese suppliers. Literature however has not yet considered the preferred customer status in the Chinese context. Again, this gap in literature is unfortunate, given that in Chinese society with its strong reliance on Guanxi, a form of social

capital (Yang, 1994; Nie et al., 2011), being preferred customer could have a reverse effect: Suppliers might feel less challenged to deliver outstanding results due to the already established Guanxi with their customer (Nie et al., 2011). In other words, while a high accumulation of social capital could positively affect supplier satisfaction and the preferred customer status, the implication might not be the same for successful project outcomes in China. In order to shed light on this situation, the following research question is formulated:

> *How does the preferred customer status affect the outcome of projects with local Chinese suppliers?*

Through answering the two research questions, our study will contribute in two directions: (1) Through quantitatively testing the link between the presence of social capital and supplier satisfaction, our study will further extend social capital theory towards a framework of resource mobilization in buyer-supplier relationships. As such, through employing social capital as antecedent to supplier satisfaction, firms might find another means, grounded on theory, to build relationships with their suppliers going beyond the common business context, to eventually access external resources that are not available to competitors. Further, through surveying suppliers we will follow the call for more research on social capital from the supplier perspective (Gelderman et al., 2016).
(2) Focusing on the Chinese market, our study will extend research on supplier satisfaction and the preferred customer status to a new context. Here, especially the relationship between being preferred customer of a supplier and succeeding in common projects is of strong interest. Since the preferred customer status has not been tested in another cultural setting, its applicability might also differ which could lead to strong implications for firms operating in China. Thus, our study will fill another research gap.
The paper will be organized as follows: Through conducting an extensive literature review, all variables will be introduced. Subsequently, the focus will lie on the research methodology, findings will be presented and discussed, and eventually with concluding the paper, future research possibilities and limitations of our study will be presented.

2. THEORETICAL CONSIDERATIONS

2.1 Social capital theory: Cognitive, structural and relational capital define the concept

Social capital theory, having its roots in sociology, is grounded on social relations that underlie relationships between individuals and groups (Adler and Kwon, 2002). As such it refers to resources, of actual or potential nature that include contextual factors on which the resource exchange is based and that can be accessed by different actors within a relationship (Nahapiet and Ghoshal, 1998; Kankanhalli et al., 2005). Since those resources are not of physical nature but contained in the relations between parties, social capital accumulated in social ties is difficult to imitate and has the potential to create a competitive advantage (Edelman et al., 2004). In academics the notion of social capital has been used as theoretical lens for studying relationships between individuals and organizations (Ahuja, 2000; Tsai and Ghoshal, 1998), or at more recent state in the field of supply management focusing on buyer and supplier interactions (Hartmann and Herb, 2014; Horn et al., 2014). It is further distinguished into three dimensions including (1) cognitive capital, (2) structural capital and (3) relational capital (Nahapiet and Ghoshal, 1998). Whereas the majority of studies examine these dimensions as in parallel existing

constructs, others also consider cognitive and structural capital as antecedents of relational capital (Carey et al., 2011; Horn et al., 2014; Preston et al., 2016). A form of social capital that can strongly be found in the Chinese context is Guanxi (Yang, 1994). Having its roots as a cultural construct, Guanxi has been proven valuable within business relationships and consequently studied extensively over the last decade (Yang and Wang, 2011). Through incorporating social embeddedness (Ring and Van de Ven, 1994; Granovetter, 1985), Guanxi is built on inter-organizational trust that can resolve conflicts (Nicholson et al., 2001) (Carolyn et al., 2002) and allows firms to pursue long-term oriented goals (Dunning and Kim, 2007). Similar to the general understanding of the social capital concept, Guanxi is based on the assumption that common norms and social interactions enable firms to establish bonds and linkages that can influence their performance (Nie et al., 2011).

The cognitive dimension of social capital refers to common values and visions that relationship partners share (Tsai & Ghoshal, 1998). They also include common goals, norms and beliefs contributing to the understanding of the social system, as well as shared interpretations, such as language or signs (Uphoff and Wijayaratna, 2000; Tsai and Ghoshal, 1998). A high level of cognitive capital therefore implicates that these attributes are shared by both relationship partners to a high extent. In this way, cognitive capital enables a consensus on strategic goals and processes that both parties might benefit from (Adler and Kwon, 2002; Atuahene-Gima and Murray, 2007). In fact, as determined by Gelderman (2016), compared with the other two dimensions, shared cognitive capital exerts the biggest impact on the strategic performance of suppliers. Roden and Lawson (2014) on the other hand, while examining the configurations of the social capital dimensions, provide evidence that relationship adaptations might substitute for cognitive capital.

Within the social context of relationships, patterns of connections between parties exist. These patterns of connections are understood as structural capital which defines how they can be used and how frequent they occur (Burt, 1997; Villena et al., 2011), or, as Nahapiet and Ghoshal (1998) put it, “who you reach and how you reach them” (p. 244). A high level of structural capital can therefore be found if both actors within a relation utilize multiple channel of interaction to facilitate the information and resource exchange (Koka and Prescott, 2002; Villena et al., 2011; Zaheer and Bell, 2005). In other words, the common usage of resources is enhanced through clarity, transparency on actions and processes fostered by a strong and consistent flow of information. This is stressed by empirical findings reporting the positive effect of structural capital on “information flow” and “information diversity” (Koka and Prescott, 2002). Consequently, while structural capital, for example in terms of means to communicate, can benefit the relationship between actors, its complete absence has negative consequences (Villena et al., 2011).

Relational capital is expressed by trust, friendship and mutual respect between the partners (Kale et al., 2000; Carey et al., 2011) as well as reciprocity (Mathwick et al., 2007). The content is based on the works of Granovetter and Swedberg (1992) focusing on embeddedness and relationships people have developed with each other. Relational capital is built through exchanges between relationship partners (Blonska et al., 2013) and considered as being closely connected to the dimensions of structural and cognitive capital. Arguably, if parties in a relationship share common business goals and ideas as well as holding a dense net of interactions, relational capital might be more likely to develop (Tsai & Ghoshal, 1998). Since both parties are expected to regard each other as more trustworthy than those with whom they do not have any commonalities, the finding is comprehensible. In the same way, a relationship based on trust requires frequent interaction and the means to do so. Interestingly, if trust and commitment are present, the

information flow and intensity are increased (Hartmann and Herb, 2014).
The next section will now focus on the concept of supplier satisfaction as well as its relation to the preferred customer status.

2.2 Supplier satisfaction and the preferred customer status

Satisfaction within a relationship is understood as the perceived feeling of fulfillment when certain goals, targets or simply outcomes are achieved (Benton and Maloni, 2005; Essig and Amann, 2009). For several decades, literature has only considered satisfaction from the customer point of view (Dwyer et al., 1987; Walter et al., 2003) as crucial for business success, whereas the focus on satisfaction of suppliers has been neglected. Only by the beginning of the new century, research more and more began to comprehend the value that supplier satisfaction can contribute to firm competitiveness (Wong, 2000; Benton and Maloni, 2005; Schiele et al., 2012; Hüttinger et al., 2014; Pulles et al., 2016). By definition, supplier satisfaction emerges if the outcome from the relationship with the buying firm meets or exceeds the expectations of the supplier (Schiele et al., 2012). As such, it relates to a positive evaluation of the working relationship both parties have (Dwer et al., 1987; Huettinger et al., 2014). In other words, supplier satisfaction results from the perceived value in the relationship between the supplier and his customer (Pulles et al., 2016). Several studies have since paid attention to the antecedents of supplier satisfaction, i.e. the conditions that firms can provide to achieve a state of relationship that causes supplier to be satisfied: Whereas Benton and Maloni (2005) pay attention to mediated power sources that can promote supplier satisfaction, Leenders et al (2005) consider tools such as the establishment of long-term commitments or internal information sharing as means to facilitate supplier satisfaction. Others, such as Ghijsen et al. (2010) focus on direct and indirect strategies that buying firms can employ in order to increase the level of satisfaction among their suppliers. Huettinger et al. (2014), based on a literature review, go as far as outlining 28 antecedents that can affect supplier satisfaction. Though, no matter which suggestion to follow, once supplier satisfaction is achieved, buying firms have the opportunity to profit from a preferential resource allocation, being considered their suppliers preferred customer (Steinle and Schiele, 2008).
As put by Schiele et al., (2012), the preferred customer concept can be considered a mirror of the notion introduced by Trent (2005) who discussed the “preferred supplier”. The preferred customer concept is based on the idea that buying firms are able to influence their suppliers behavioral intentions in order to be awarded with a status allowing them to receive favorable treatment over other firms (Schiele et al., 2012). Examples of this favorable treatment could include first offering of new ideas and innovations, preferred resource allocation in case of capacity shortages or the delegation of the best personnel to common projects (Bew, 2007; Steinle and Schiele, 2008). In this sense the preferred customer status, from a strategic point of view, through combining external resources (Dyer and Singh, 1998), can provide firms with an advantage over competitors enabling them to achieve higher performance outcomes (Pulles et al., 2016). Blonska (2010), while studying the effect of supplier development investments on becoming preferred customer, also found a link between the presence of social capital and the preferred customer status, considering social capital a mediator.
The next section will now use the theoretical basis that was outlined before to build hypotheses concerning relationships between the introduced concepts.

2.3 Hypotheses

As introduced before, cognitive social capital can be closely related to the sharing of goals and values between parties in a relationship (Tsai and Ghoshal, 1998; Villena et al. 2011). As such, if the goals and values of both parties correspond to a high extent, a high level of cognitive capital is present. Consequently, buyer and supplier that share both attributes are able to develop an understanding of each other's processes, strategies and long-term targets (Adler and Kwon, 2002) that can be beneficial for the own as well as common planning activities. Further, the presence of cognitive capital might thus also go in line with a certain degree of similarity in terms of corporate culture. As shown by Parkhe (1993), such a similarity has a positive effect on business success of a buyer-supplier relationship. Next to this, the reduction of opportunistic behavior is then also seen as a key benefit (Ouchi, 1980; Villena et al., 2011). Also, as shown by Gelderman (2016), the presence of cognitive capital strongly impacts the strategic performance of suppliers. Following this reasoning, H1.1 has been formulated.
Structural capital on the other hand has been depicted as pattern of connections between firms (Villena et al., 2011). Utilizing these structural ties, such as the sharing of information, external resources can be accessed (Dyer and Singh, 1998) that might have the potential to create a competitive advantage. Since especially the exchange of the right information at the right time is considered important, dense social structures between parties have been argued of being highly beneficial for firms (Zaheer and Bell, 2005). Also, information accuracy and reliability can be achieved in this way (Chen et al., 2009; Villena et al., 2011). As such, structural social capital through providing the means of exchanging knowledge with the right people at the right time (Nahapiet and Ghoshal, 1998) enables intensifying cooperation and collaboration between buyer and supplier, which has been assumed to positively impact satisfaction among suppliers (Essig and Amann, 2009). Consequently and based on this reasoning, H1.2 has been formulated.
Finally, in terms of relational social capital, trust and commitment (Zhao and Cavusgil, 2006; Villena et al., 2011) as well as reciprocity (Blonska, 2013) have been argued to be the defining factors. Being closely connected to cognitive and structural social capital, relational capital is considered to prevent the risk of opportunistic actions as well as leakages of knowledge (Kale et al., 2000). As such, it can be considered likely to increase supplier satisfaction, since the supplier has to fear fewer risks. In their study in 2010, Nyaga et al. further discover that while collaborative activities positively affect supplier satisfaction, trust and commitment function as mediators. Consequently, since relational capital is grounded on both attributes, it is fair to argue that relational capital itself also positively influences the emergence of supplier satisfaction. Thus H1.3 has been formulated.

H1.1 The presence of cognitive social capital in the relationship between buyer and supplier positively influences the emergence of supplier satisfaction.

H1.2 The presence of structural social capital in the relationship between buyer and supplier positively influences the emergence of supplier satisfaction.

H1.3 The presence of relational social capital in the relationship between buyer and supplier positively influences the emergence of supplier satisfaction.

Once supplier satisfaction has been achieved, buyers might profit from preferential treatment of its supplier. In fact, (Hüttinger et al., 2012) Huettinger et al. (2012) empirically tested and proved that supplier satisfaction is positively related to becoming preferred customer. As has been described before, the preferred customer concept refers to the underlying assumption that suppliers are restricted by a limited amount of resources they can provide to their customers and that these customers may not be treated equally in terms of resource allocation (Mitsuhashi and Greve, 2009). Consequently, some customers receive favorable allocation while others have to rely on the remainder (Dyer and Hatch, 2006). Therefore, since obtaining better resources relative to competitors might result in a competitive advantage (Hult et al., 2006; Capron and Chatain, 2008), firms must pay attention to the moves of other firms in the supply base and aim to outcompete them for achieving preferential resource allocation themselves (Ellram et al., 2013; Steinle and Schiele, 2008; Schiele, 2012).
Firms that are able to be awarded the preferred customer status from their suppliers, have several advantages that might become valuable during common projects: The most obvious advantage of course is the preferential treatment in terms of resource allocation (Bew, 2007). This does not only refer to the suppliers themselves but also to the human capital, the personnel that is assigned to the preferred customer (Steinle and Schiele, 2008). Arguably, if more expertise and knowledge in form of "better" employees is accumulated, also common projects between buyer and supplier are more likely to succeed. Having the best employees assigned to a project could be especially crucial in China where foreign firms struggle with e.g. quality standards of local suppliers (Wilkinson et al., 2005; Lockstroem et al., 2010). High knowledgeability could increase the chance of success. Further, being preferred customer also comes with the benefit of unique cost saving opportunities (Bew, 2007). The suppliers might apply a more benevolent pricing behavior (Schiele et al., 2011). While this itself does not seem likely to affect project outcomes in a direct way, buyers might have to pay less, not only for the product itself, but also in form of invest intended for e.g. the suppliers tooling's necessary for production lines. Consequently, spending less money is more likely to lead to a positive business case which in turn could also influence whether a project is approved and successful, or not.
Arguably though, and as has been described before, when dealing with suppliers located in China the preferred customer status, due to its strong underlying connection to social exchanges and relations (Huettinger et al., 2014), might be established as a result of emerging Guanxi between buyer and supplier. Guanxi itself has been proofed to decrease supplier performance and increases the risk of opportunistic actions (Nie et al., 2011). This is in line with the research of Villena and colleagues (2011) focusing on the dark side of buyer-supplier relationships. They determined that identification-based trust resulting from (high levels of) accumulated social capital can entail the risk of opportunism. Their findings were later on confirmed by Wang et al. (2013). As such, through building the preferred customer status on a high accumulation of social capital in China, its possible positive effect might diminish. However, since a clear contribution of the preferred customer to firm value creation has been found (Huettinger et al., 2012), we formulate H2.2, despite being curious about whether it might hold. Also, in order to close our line of reasoning, we re-examine whether supplier satisfaction also affects becoming preferred customer with local Chinese suppliers, leading to H2.1.

H2.1 The presence of supplier satisfaction among local Chinese supplier positively influences the reception of the preferred customer status.

H2.2 The preferred customer status positively influences project outcomes with local Chinese suppliers.

The next section will now introduce the methods used in our study to test the hypotheses. As such, the background of data collection as well as the applied measurements are introduced.

3. RESEARCH METHODOLOGY

3.1 Data collection

The aim of the paper is to investigate the links between the social capital dimensions and supplier satisfaction as well as between the preferred customer status and outcomes of common projects between buyer and supplier in China. For this purpose, a sample of 1386 suppliers located in China was randomly selected. All of the suppliers are operating in the automotive industry and can be equally divided among the five automotive commodity groups including interior, exterior, metal, electric and powertrain. The automotive industry was chosen as the setting of our study for the major role it is playing in the world economy (Taylor and Taylor, 2009). Also, the automotive industry, due to its high requirements in terms of quality as well as intellectual property protection (Holweg et al., 2008), poses challenges for the establishment of relationships while simultaneously assigning relationships between buyer and supplier a crucial role (Lockstroem, 2010). Consequently, the setting fits nicely to our research goal.
The suppliers were then approached via email containing a link to a web portal. Here, they had the option to answer questions in the English or Chinese language. This was done to ensure that even non-English speaking local Chinese suppliers had the chance to participate. For guaranteeing that the implication of English and Chinese questions matched to the fullest and did not lose meaning in the translation process, two independent Chinese native speakers were involved: The first native speaker translated the English questions into Chinese, while the second native speaker translated them back into English. Afterwards, the original and back-translated English questions were compared, which resulted in minor adjustments of the Chinese translation. Eventually, 131 usable questionaires were received, equalling a response rate of 9%.

3.2 Measurements

The measurements used in this research were mostly adapted from previous studies. A conduction of in-depth interviews with experts from the German Multinational allowed for a subsequent further refinement. In terms of scaling, five-point Likert scales were used, ranging from 1=strongly disagree to 5=strongly agree. The measurement items as well as the values of Cronbach's alpha, composite reliability (CR), and average variance extracted (AVE) can be found in Appendix I. For measuring social capital, the concept was firstly broken down into its three dimension, cognitive capital, structural capital and relatonal capital. Subsequently they were broken down into three 2nd order constructs which could be measured individually, allowing for a finer grasp of the concept. Structural capital was then measured focusing on quantity and nature of interaction as well as means used for exchanging information. Items from Villena et al. (2011) and Wang et al. (2013) were applied. The measurements for cognitive capital focused on whether goals and values are shared between parties and whether they overlap. Measures of Villena et al. (2011) were applied. Finally relational capital was meausred through a distinction into trust,

commitment and reciprocity as outlined by Blonska et al. (2013). In order to measure supplier satisfaction, the items of Huettinger et al. (2014) were used. Here the focus especially lied on whether working with the business partner was pleasant and whether the decision to cooperate would be taken again. Focusing on the preferred customer concept, measures developed by Schiele et al. (2012) were utilized. Measures here were strongly focusing on the status that the customer has for the supplier, whether the supplier dedicated the best resources to its customer and whether the customer was treated with higher prioritiy than others. Finally, the measures for project success, thus whether the goals of the project were achieved and whether it was conducted in a timely manner, were taken from Horn et al. (2014).

3.3 Data analysis

For testing the hypotheses we carried out a partial least sqaures equation modelling, short PLS-SEM (Fornell & Cha, 1994). For this purpose, the software SmartPLS, which has been characterized as frutiful for obtaining robust findings (Chin, 1998), was utilized (Ringle et al., 2005), in partcular for carrying out the confirmatory factor analysis. In order to increase the measurement accuracy of the sample, bootstrapping was applied (Nevitt & Hancock, 2001). Appendix I includes the detailed path coefficients as well as the t-values. For assessing internal consistency and reliability of our constructs, compsite reliability (CR) as well as avergage variance extracted (AVE) and factor loadings were used (Fornell and Larcker, 1981; Wetzels et al, 2009; Edwards and Bagozzi, 2000). The assessment of the indicator reliabilty was conducted by analyizing individual item loadings: As it turned out, due to the high amount of indicators located to the social capital constructs, some items were loading on each other, thus affecting each others explanatory power, and had to be removed. Further, two items with factor loadings of 0.6x were retained, all other loadings well exceed the threshold of 0.7 (Henseler et al., 2009). In terms of convergent reliability, the analysis showed that all items strongly correlate with the construct they are related to. As such, all values exceed the threshold of 0.7 for CR, 0.5 for AVE and 0.7 for Cronbach's alpha (Edwards & Bagozzi, 2000; Fornell & Larcker, 1981). Additionally, in order to test for discriminant validity, the Fornell-Larcker criterion (Fornell and Larcker, 1981) was used: Since the squared roots of the AVE scores are all larger than cross-correlations scores, no concern was found. For assesing common method variance (CMV), the unmeasured latent methods factors test as described by Podsakoff et al. (2003) was conducted. As such, a common method variance factor including all principal constructs indicators was introduced. As shown in table 11, the substantive variance averaged around 0.661 while the average method based variance was 0.018, resulting in a ratio of substantive to method based variance of 37:1. Following this result, CMV may not be regarded a concern .

4. RESULTS AND CONCLUSION

The study at hand paid attention to social capital theory and its role as antecedent of supplier satisfaction. As such, we in particular considered the three dimensions of social capital, namely cognitive, structural and relational capital and the effect their have on the development of a relationship a supplier would consider satisfying. Hypotheses 1.1 to 1.3 therefore suggested that every dimension of social captial would positively influence the emergence of supplier statisfaction, as has been proposed by past research (e.g. Essig and Amann, 2009) . Our findings however reveal a different picture: Both, the relationship between cognitive and supplier satisfacton ($t = 1.158$) as well as between structural capital and supplier satisfaction ($t = 0.935$)

have found to be insignificant. Relational capital on the other hand can be depicted to strongly affect the emergence of supplier satisfaction (t = 4.529). This result might appear quite surprising however on a second thought it is also not too far-fetched: Suppliers might perceive structural as a means to communicate and interact with their customer. While this seems to be a necessity in order to keep the relationship alive and carry on with common projects, simply conversing on a regular basis and exchanging information might be a good start but would also proof meaningless without certain output. As such it must not be a surprise that the existence of structural capital per se does not lead to supplier satisfaction. A similar picture appears for cognitive capital: While sharing goals and values, and even aligning them might be an important necessity for suppliers to conduct common projects with their customers and commonly work into the right direction, it does not necessarily mean that these goals will also be reached. Since supplier satisfaction naturally emerges if the supplier also sees a benefit in the exchange relationship (Huettinger et al. 2014), sharing goals and values might simply not be sufficient. Relational capital on the other hand includes trust and commitment to the relationship as well as reciprocity that the relationship will also be continued in the future (Blonska et al., 2013). For supplier, this would imply that they have a perspective of not only proceeding with the current business but also having future business opportunities with their customer. Moreover, through having a relationship based on trust and commitment, suppliers might see less risk in the relationship of e.g. opportunistic actions. This would explain the strong positive relationship between relational capital and supplier satisfaction. While structural and cognitive capital have been proven ineffective when it comes to supplier satisfaction, we still found an indirect effect that after all underlines the importance of both dimension: In line with Carey et al. (2011), our study confirms the facilitating effect of cognitive (t = 9.337) and structural capital (t = 4.168) on the development of relational capital. Both types of social capital thus should not be neglected.

Next to testing the effect of social capital as an antecedent to supplier satisfaction, we also checked for the effect of supplier satisfaction on becoming preferred customer and in turn the effect of being preferred customer on projects success with local Chinese suppliers. While, in line with Huettinger et al. (2011), the relationship between supplier satisfaction and the preferred customer status could be confirmed (t = 7.850), also the effect of preferential customership on project success was found to be positive (t = 4.256). This has a strong implication for firms that would like to engage in a business relationship with a Chinese supplier respectively are already doing business with them: While, also being to a victim to the cultural influence, doing business in China and with Chinese suppliers might not always be easy and certainly not always fruitful, firms that are able to satisfy their suppliers and become their preferred customer, increase their likelihood of finalizing common projects successfully. Obviously, this however would firstly require an investment of time into the relationship. Since our study is dealing with Chinese suppliers, the finding should also be considered carefully: Guaxi, the Chinese firm of social capital, still plays a big role in all business relationships in China. While the preferred customer measurement has been proven successful in the Chinese context, it might though be closely related to Guanxi, the exchange of favors to reach a “preferential” outcome. It could thus be hard to distinguish whether a buying firm is truly the preferred customer of a supplier or whether he simply has a high degree of Guanxi with its supplier that has developed over time. Future research could further dig into the preferred customer status in a Chinese context and focus on the interconnection with Guanxi. Also, future research should attempt to recapitulate our findings in a more global surrounding.

Appendix II – Measures

Structural Capital:

	During the project, you and your customer…	
Infrastructure Actor Exchange	• Always conducted common activities / workshops. • Had common project reviews in place. • Used internal linking systems (shared fileserver etc.). • Had also purely social activities (common meals, after-work get togethers). • Made use of being located in close proximity to each other.	Own measure
Quantity of Interaction	• Frequently communicated with each other. • Frequently communicated at different levels (management, operative staff etc.). • Frequently communicated between different functions.	Villena (2011); CR: 0.87; AVE: 0.68
Nature of Communication	• Exchanged concessions throughout the project (e.g. granted more time etc.). • Solved / prevented problems commonly. • Easily found agreements jointly. • Constructively addressed topics that could entail conflicts.	Wang et al. (2013); alpha: 0.8

Cognitive Capital:

	During the project, you and your customer…	
Shared Norms & Values	• Interpreted situations in the same way / had the same approaches to business dealings. • Had a common understanding about what is allowed / not allowed. • Had the same vision of business in the relationship. • Viewed each other as partners.	Villena (2011); CR: 0.8; AVE: 0.5
Overlap of Objectives	• Were aware of each other's objectives / KPIs. • Were aligned on objectives / objectives matched. • Made the effort to align goals. • Had similar targets.	. Own measure

Relational Capital:

	During the project, you and your customer…	
Trust	• Considered own interests as well as the others. • Trusted in each other to keep the best interest in mind. • Counted on each other to follow through with promises..	Blonska (2013); CR: 0.87, AVE: 0.69
Commitment	• Found it pleasant to work with each other, which is why the relationship continued. • Wanted to remain in the relationship. • Were attracted by what the other party represented as a firm (image, brand, reference etc.).	Blonska (2013); CR: 0.86, AVE: 0.66
Reciprocity	• Considered the relationship as mutually beneficial. • Felt indebted because of what the other had done for each other. • Expected to also work on further projects in the future.	Blonska (2013); CR: 0.81; AVE: 0.69

Supplier Satisfaction, Preferred Customer and Project Success:

	From your perspective…	
Project Success	• One could be satisfied with how the project progressed. • The project goals were achieved. • The project was within schedule. • Overall, the project was done in an efficient way.	Horn et al. (2014); CR: 0.92 ; AVE: 0.6
	Concerning the project…	
Supplier Satisfaction	• Our firm was very satisfied with the overall relationship to this customer. • Generally, our firm was very pleased to have this customer as our business partner. • If we had to do it all over again, we would still choose to use this customer. • Our firm did not regret the decision to do business with this customer.	Huettinger (2014); CR: 0.94; AVE: 0.81
Preferred Customer	• We made sacrifices for our customer. • We were on our customers side. • We allocated our best resources to this customer. • We would have granted our customer prime access to our own suppliers. • We treated this customer with lower priorities than others. • In general, we offered a better service to this customer than to others.	Schiele et al. (2012); CR: 0.94 ; AVE: 0.77

The purpose of this paper is to analyze the effectiveness of Quantity Flexibility Contract (QFC) as Supply Chain (SC) coordination mechanism under market demand and spot market uncertainty, by measuring such effectiveness in terms of the profits gained by each actor under QFC with respect to the profits obtained under traditional contract. In so doing and by varying the contract terms and implementation conditions, we ensure that the QFC is chosen only when it ensure a win-win condition, namely it improves the profits of both parties. A simulation-based research has been carried out in order to address this issue. In particular, a real options-based model has been developed to model and quantify the benefits granted by flexibility incorporated into the QFC, for both SC actors. A plan of experiments consisting of different experimental settings was designed in order to investigate the effect that contract terms and implementation conditions have on the benefits of both actors and on the entire system. The proposed model's application and the experiments have been illustrated by considering a SC coordination problem handled by an example company operating as retailer in a European country through QFC.

1. Introduction

The aim of supply chain management (SCM) is to coordinate material, cash and information flows along the supply chain (SC) from an End-to-End (E2E) perspective, from materials suppliers to consumers (Christopher, 1992; Tsay et al., 1999). SC control may be either centralized or decentralized (Giannocaro and Pontrandolfo, 2004). Centralized control involves the presence of a single decision-maker in possession of all the information pertaining to the SC, managing it in its entirety and thus able to optimize the performance of the whole system (channel coordination). Decentralized control involves the presence of several decision makers (SC actors), each taking decisions in pursuit of their own probably conflicting goals (Schneeweiss, 2003).

Many modern supply chains operate under decentralized control for a variety of reasons. For example, outsourcing of various aspects of production is currently a popular business model in many industries (cf. Farlow et al. 1995, Iyer and Bergen 1997), which automatically distributes decision-making authority. However, decentralization is not without risks. While centralized control ensures the system's efficiency (channel coordination), in decentralized systems, locally rational behaviours increases the uncertainties and costs in the system (cf. Magee and Boodman 1967, Lovejoy 1998), resulting in the overall inefficiency of the SC (Tang and Kouvelis, 2014; and others). Both academic researchers and practitioners have focused on trying to find coordination mechanisms that can eliminate such inefficiency by driving local actors to behave in the interests of the global SC rather than their own.

Supply chain contracts are proposed and developed to assist supply chains to achieve better coordination and performance. These include quantity flexibility (QF) contracts (Tsay et al., 1999), backup agreements (Eppen and Iyer, 1997), buy back or return policies (Emmons and Gilbert, 1998), incentive mechanisms (Lee and Whang, 1999), revenue sharing (RS) contracts (Cachon and Lariviere, 2005), allocation rules (Cachon and Lariviere, 1999), and quantity discounts (Weng, 1995).

The purpose of this paper is to analyze the effectiveness of QFc as SC coordination mechanism under market demand and spot market uncertainty, by measuring such effectiveness in terms of the profits gained by each actor under QF contract with respect to the profits obtained under traditional contracts. In so doing and by varying the contract terms and implementation conditions we ensure

that the QF is chosen only when it ensure a win-win condition, namely it improves the profits of both parties.

The paper is organized as follows. Section 2 provides a brief review of the relevant literature, while Section 3 proposes the model of QFC for coordinating a two-stage SC. Section 4 illustrates the proposed model's application by considering a SC coordination problem handled by an example company operating as retailer in a European country through QFC. Some final remarks close the paper.

2. Literature review and paper positioning

2.1 Quantity Flexibility contract

Under a QF contract the supplier formally guarantees the buyer a specific safety cushion in excess of estimated requirements, thus providing some certain flexibility on the quantity of their products. The supplier allows the buyer to change the quantity ordered after observing the actual demand. In return, the buyer agrees to limit its order reductions, essentially a form of minimum purchase agreement. In this way, the buyer could deal with different kinds of market demand risks (Tsay and Lovejoy, 1999). By reviewing the literature on QFCs it is possible to identify four standpoints that differentiate the studies: 1) the scope, 2) the SC risks mitigated by QF contract; 3) the SC performance metrics used to assess the impact of QFC; 4) the parties of which the envisaged benefits of QFC are measured. Table 1 characterizes the previous studies on QF in terms of the four main standpoints and how these are connoted by the different studies.

Table 1. Characterization of QFC studies

	Scope	**SC risks mitigated by QFC**	**Metrics to measure the impact of QFC on SC**	**Parties of which benefits of QFC are measured**
Bassok and Anupindi (1997)	Contract design: identifying the optimal order policy for any pair of total minimum quantity commitment and discounted price	market demand uncertainty	SC economic performance	buyer
Tsay and Lovejoy (1999)	Contract design: Measuring the impact of the contract flexibility parameters on SC performance: inventory, variability of order and service provided at the market interface. Contract choice: Evaluating the buyer's "willingness to pay" for positive increments of flexibility	market demand uncertainty	SC Operational performance	Parts supplier, manufacturer, retailer
Brusset (2006)	Contract design: identifying the optimal contract parameters (penalty, time horizon, quantity, price) Contract choice: Identifying the conditions - time horizon, information cost about prices and providers, penalty - for choosing QF contract over spot-market and QF contract over minimum purchase commitment	market demand uncertainty	SC economic performance	Buyer, service provider
Sethi et al. (2004)	Contract design: identifying the optimal contract quantity that maximizes the buyer's profit	market demand and supply price uncertainties	SC economic performance	retailer
Mahajan (2010)	Contract design: identifying the optimal retail price that maximizes the parties' profit	market demand uncertainty	SC economic performance	Manufacturer, retailer
Shaodong et al. (2013)	Contract design: identifying the optimal retail price for the option stock that maximizes the parties' profit	market demand uncertainty	SC economic performance	supplier, retailer
Kim (2011)	Contract choice: Identifying the conditions – demand volatility and flexibility rate - for choosing QF	market demand uncertainty	SC Operational and economic performance	Buyer, supplier

The existing literature reveals a lack of studies that analyze the effectiveness of QFC as SC coordination mechanism under both market demand and supply price uncertainties. This in turn

means measuring the benefits of the QF contract through economic metrics (profit) for every SC actor in presence of market demand uncertainty and supply price fluctuation, and prove that under the contract every actor obtains a profit higher than he/she would do without the contract.
The existing studies discuss QF contracts as SC coordination mechanisms, while they provide little emphasis on their ability to give a protection against price and demand uncertainties. The literature lacks of studies that quantitatively assess the value of on QF contract as supply chain risk mitigation strategy. Thus, we observe a gap in the literature on supply chain risk management.
This research gap offers motivation for our work that expands upon previous research in the following crucial aspects:

1) We analyze the effectiveness of QFC by measuring the profits gained by each actor under QF contract with respect to the profits obtained under traditional contracts, thus ensuring that the QFC is chosen only when it ensure a win-win condition, namely it improves the profits of both parties.
2) We investigate how the contract terms impact on the supply chain economic performance thus providing guidelines to the contract design in order to ensured that higher profits are attained for both parties (win-win situation).
3) We examine a more realistic scenario for a QFC, where both market price and customer demand uncertainty are considered. In so doing we offer a novel contribution in the literature on supply chain risk management by presenting the benefits of QFCs in mitigating demand and supply risks.

2.2 Supply contract and real option valuation literature

Let us consider a standard wholesale contract between the upstream firm (manufacturer) and its downstream retailer: once the contract is established, the firm must supply the goods at the agreed price, regardless of the market conditions at each point in time. Furthermore, once the retailer has agreed to purchase the goods, he cannot reconsider the purchase, e.g., if the demand does not materialize or the price of the alternative supply market (spot market) is more favourable. With the QFC, on the other hand, the retailer has the right (without the obligation) to deviate from an initially committed quantity. For example, the retailer wants to change his previously committed purchasing quantity of a component because additional knowledge of demand and supply market price have become available. Operationalizing a contract of this type requires modelling the managerial flexibility of the retailer to deviate from the committed quantity within a pre-defined range, without paying any penalty, in case of demand fall, and with the insurance of fixed price, in case of demand rice; and to decide to reduce the purchased quantity up to the minimum quantity and buy from the alternative source (i.e., the spot supply market) in case of favorable spot market price, whenever such choice proves convenient. Traditional approaches, such as those based on Discounted Cash Flows (DCF) analysis (especially NPV), cannot be used to model this managerial flexibility. Consequently, they cannot be used to price the value of the investigated QFC. They implicitly assume that a strategy or project will be undertaken now and operated on continuously on a set time scale, until the end of its expected useful life, even though the future is uncertain. Therefore, they are “static” and underestimate the upside value of the investment (Kogut and Kulatilaka, 1994) by assuming management’s passive and inflexible commitment to a certain “operating strategy”. They are also “deterministic”, since they make implicit assumptions concerning a certain “expected scenario” of cash flows. In the real world, the actual cash flows will probably differ from what management originally expected because of uncertainty and competitive interactions. As new information is available and uncertainty about the market conditions and future cash flows is gradually resolved, management should revise the operating strategy it originally anticipated in order to achieve the initial desired goals (Boute et al., 2004). It is essential that flexibility be quantified, and any attempt to do so almost naturally leads to the concept of options (Trigeorgis, 1996). From this perspective, the QFC,

which provides the retailers with the flexibility to update its choices as the uncertainties of the market demand and supply price resolve where it is actually convenient, adopts an option mechanism.

This paper is closely related to the literature on the use of options in SCM (; Wang and Tsao, 2006; Cheng et al., 2003; Cachon and Lariviere, 2001; Wang and Liu, 2007; Costantino and Pellegrino, 2010; Carbonara et al., 2017). We are unaware of any research that specifically models QFC as an option contract, thus addressing the benefits for the supply chain when, under a QFC, retailers have the possibility, but not the obligation, to deviate from an initially committed quantity.

The above discussion offers a strong incentive for us to model the QFC as an option contract in the coordination of a two-stage SC faced with stochastic customer demand and supply price, including the flexibility of the retailer to deviate from the initially committed quantity, whenever it is actually convenient. This will allow a correct analysis of the general conditions under which the QFC is beneficial, i.e., able to bring about supply chain coordination and a win-win situation, as well as an understanding of the impact of contract terms.

Regarding option pricing, the methods traditionally proposed in the literature on real options are financially-based approaches to option pricing (Black and Scholes 1973; Merton, 1973; Boyle, 1977; Cox et. al., 1979; Longstaff and Schwartz, 2001; and others). However, they often turn out not to be workable in practice (de Neufville et al., 2006; Lander and Pinches, 1998).

Simulation-based research is preferred for complex and expanded problems with several factors and interactions, as it is in supply chain settings (Goldsby et al., 2006; Wan and Evers, 2011; Evers and Wan, 2012; Manuj and Mentzer, 2009; Manuj et al., 2014).

3. The ROV simulation model for QFC

In this section we consider a two-stage supply chain, where each node represents an independently managed organization. The first stage consists two nodes: a *manufacturer* that holds a relationship with a *retailer* through a QF contract, and the *spot market* which represents the alternative supply market for the retailer. The second stage consists of only one node, namely the *retailer*, serving an uncertain market demand. The analysis may be easily extended to more complex supply chains without undermining the foundation principles of the model.

We consider a multi-period problem where the retailer first plans procurement of products from the manufacturer for the next period based on the current demand forecast and then makes the actual purchases based on the updated information of the uncertain demand and the fluctuating price of the spot market.

3.1 Mathematical formulation

Let Q* be the fixed periodical quantity ordered by the retailer, at each order time t, up to the contract duration T. Contrarily to the traditional contract, the QFC allows the retailer to make the actual purchase, at each t, according to the updated information on the actual demand and spot market price. In each period t, the retailer can adjust the order quantity by increasing - up to a maximum quantity $Q^*(1+\alpha)$ - or decreasing - up to a minimum quantity $Q^*(1-\beta)$ - the purchased quantity without paying any penalty. For all the purchased quantities ranging in such interval, the retailer has to pay a price C_f to the manufacturer engaged in such QFC. The manufacturer is not the only source for the retailer, which may still decide to buy the needed quantity from the spot supply market at a price C_m. The flexibility provided by the QFC consists operatively in the right of the retailer to deviate from the committed quantity within the pre-defined range $[\, Q^*(1-\beta); Q^*(1+\alpha)]$, without paying any penalty, in case of demand fall, and with the guarantee of buying at a fixed price, in case of demand rice; and to decide to reduce the purchased quantity up to the minimum quantity $Q^*(1-\beta)$ and buy from the alternative source (i.e., the spot supply market) in case of favorable spot market price, whenever such choice proves convenient.

In terms of real options, this corresponds to a real (put) option hold by the retailer, where the saving obtained when the retailer does not buy from the manufacturer is the exercise price of the option. Hence, this put option will be exercised whether the price paid to buy from the spot supply market (i.e., the underlying asset of the option S_T) is lower that the exercise price.

The sunk cost of the flexibility, namely the transaction costs for implementing the contract, the higher costs for maintaining the contract, etc., is the cost of the option (option premium).
In order to operationalize and quantify the differential profits gained by the manufacturer and the retailer under the QFC compared to the traditional contract, the model adopts the following parameters:

t = 1, …, T	order time (week, month, quarter, according to the order characteristics), up to the total time horizon T, which depends on the length of the QFC
Q^*	the fixed periodical quantity ordered by the retailer, at each order time t, which can be revised when the retailer makes the actual purchase
α and β	flexibility parameters which determine the range within which the quantity purchased can vary with respect to the ordered quantity
P_v	final price of the product sold by the *retailer* to the final customer
C_f	fixed price paid by the retailer to the manufacturer for each unit purchased within the flexibility range $[Q^*(1-\beta); Q^*(1+\alpha)]$
C_T	price paid by the retailer to the manufacturer for each unit purchased under the traditional contract, which is generally the average actual price changed by the market when the contract is stipulated.
P_{pm}	penalty due to the manufacturer for each unit of product the retailer purchases less than the committed quantity Q^*, under the traditional contract. It also corresponds to the penalty paid to the manufacturer for each unit the retailer purchases less than the minimum quantity $Q^*(1-\beta)$ under the QFC.
C_p	the unit variable manufacturing cost of the manufacturer, under the traditional contract and the QFC. It includes: materials, energy and other variable costs.
C_c	fixed costs of the manufacturer, computed for the period related to the order time (week, month, quarter, according to the order characteristics). It is function of the production capacity and includes the investment costs in tangible (building, equipment, etc.) and intangible (patents, know-how, etc.) assets. Since the QFC requires a greater production capacity to deal with the flexibility of the supply contract than the traditional one, it generally results that $C_c^{TC} < C_c^{QFC}$.
D(t)	market demand at each t
δ_m	actual share of the demand supplied by the spot supply market when the retailer decides to purchase from this alternative source.
$C_m(t)$	market price that the retailer pays at each t when he/she buys from the spot supply market
$C_{st}(t)$	stockout costs due to the inability of the retailer to fulfil the customer requirement. For example, with no inventory of a certain item, a customer order will not be fulfilled.
i_t	periodical discount rate (calculated from the annual discount rate i)

We also made the following assumption:
- The availability of the spot market δ_m to provide the required quantity decreases when the market demand D(t) increases, according to an exponential probability distribution $f\big(D(t)\big) = \lambda e^{-\lambda \cdot D(t)}$, where λ measures the gradient of the function. We assume that an increase of the market demand may be considered a signal of growth of the entire sector's demand, this in turn will increase the total demand on the supply market. Hence, in the short period (as it is between two order time t, t+1), when it is not possible to increase the productivity capacity, the availability of the spot supply market to fulfil such a growing demand decreases.
- the stockout costs include all the costs charged by the retailer when she/he is unable to fulfil the customer order, such as lost sales, penalty, loss of customers, loss of image, etc. Although they are important costs in SCM practice, they are often neglected for their difficult objective estimation (Wu et al., 2008).

To investigate the effectiveness of the QFC to coordinate the two-stage supply chain (SC) in presence of uncertain market demand and spot market price, four basic scenarios may be identified:

- Scenario 1: the market demand is higher than the maximum quantity $Q^*(1+\alpha)$ that the retailer can order at fixed price under QFC.
- Scenario 2: the market demand ranges between Q* and the maximum quantity $Q^*(1+\alpha)$.

- Scenario 3: the market demand is between Q* and the minimum quantity $Q^*(1-\beta)$.
- Scenario 4: the market demand is lower than the minimum quantity $Q^*(1-\beta)$.

To quantify the differential profits of both actors, manufacturer and retailer, under the QFC compared to the traditional contract, we consider only Scenarios 2 and 3, since the other two Scenarios have the same characteristics of the traditional contract, without any differential profits provided by QFC. To put it differently, only in the Scenario 2 and 3 the QFC provides different profits for the two SC actors compared to the traditional contract, since it provides to the retailer the flexibility to revise the order quantity Q* and make the actual purchase, at each t, according to the updated information on the actual demand and the spot market price.

Also, we consider Scenario 2 and 3 separately since in the traditional contract the retailer's behavior in these two scenarios is different. In the first (Scenario 2) ($Q^* < D(t) < Q^*(1+\alpha)$), the retailer will purchase the quantity exceeding Q* from the spot supply market without any insurance of availability. Contrarily, in the latter (Scenario3) ($Q^*(1-\beta) < D(t) < Q^*$), the retailer has to pay a penalty for the shortfall.

In the following, the profits of the QFC compared with the traditional contract are modeled, for the manufacturer and the retailer, in both scenarios.

Scenario 2 - $\left(Q^* < D(t) < Q^*(1+\alpha)\right)$

In traditional contract the retailer will purchase the additional quantity $(D(t)-Q^*)\delta_m$ from the spot supply market at $C_m(t)$, based on the market availability, and will bear the stockout costs $C_{st}(t)$ for the residual quantity which is not delivered to the customer $(D(t)-Q^*)(1-\delta_m)$.

The retailer's profit in the traditional contract Π_R^{TC}, Scenario 2, is computed at each t by equation (1).

$$\Pi_R^{TC} = P_v Q^* + P_v(D(t)-Q^*)\delta_m - [C_T Q^* + C_m(t)(D(t)-Q^*)\delta_m + C_{st}(t)(D(t)-Q^*)(1-\delta_m)] \quad (1)$$

In QFC, the retailer may receive all the needed quantity (up to $Q^*(1+\alpha)$) from the manufacturer at C_f; he also has the possibility to reduce the quantity purchased under QFC up to $Q^*(1-\beta)$ and buy from the spot market at $C_m(t)$, whenever it is available and convenient.

In terms of real options, the retailer will decide to exercise the option if the saving when he does not buy from QFC (namely, the exercise price of the option, $C_f[D(t)-Q^*(1-\beta)]\delta_m$) is higher than the cost paid to purchase that quantity from the spot supply market (namely, the stock price of the option, $C_m(t)[D(t)-Q^*(1-\beta)]\delta_m$).

The retailer's decision to exercise the option will depend on the expected payoff of the option computed as in (2).

$$Option\ payoff = max\{C_f[D(t)-Q^*(1-\beta)]\delta_m - C_m(t)[D(t)-Q^*(1-\beta)]\delta_m; 0\} \quad (2)$$

Hence, according to (2), the retailer will decide whether to exercise the option ($O_{QFC} = 1$) and buy the quantity $[D(t)-Q^*(1-\beta)]\delta_m$ from the spot market at $C_m(t)$, and the remaining quantity $[D(t)-Q^*(1-\beta)](1-\delta_m)$ at C_f from the manufacturer under the QFC.

The retailer's differential profit gained under QFC compared to traditional contract at each t, $\Pi_R^{(QFC-TC)}(t)$, in Scenario 2, is computed by (3) or (4), depending on the exercise of the option ($O_{QFC} = 1$) or not ($O_{QFC} = 0$) respectively.

$$\Pi_R^{(QFC-TC)}(t) = \begin{cases} P_v[D(t)-Q^*(1-\beta)] - C_m(t)[D(t)-Q^*(1-\beta)]\delta_m - C_f[D(t)-Q^*(1-\beta)](1-\delta_m) + \\ \quad -\{P_v Q^*\beta + (P_v - C_m(t))[D(t)-Q^*]\delta_m - C_{st}(t)[D(t)-Q^*](1-\delta_m) - C_T Q^*\beta\} \end{cases} \quad if\ \ O_{QFC}=1 \quad (3)$$

$$\Pi_R^{(QFC-TC)}(t) = \begin{cases} P_v[D(t)-Q^*(1-\beta)] - C_f[D(t)-Q^*(1-\beta)] - \\ +\{P_v Q^*\beta + (P_v - C_m(t))[D(t)-Q^*]\delta_m - C_{st}(t)[D(t)-Q^*](1-\delta_m) - C_T Q^*\beta\} \end{cases} \quad if\ \ O_{QFC}=0 \quad (4)$$

The retailer's differential profit gained under QFC compared to traditional contract over the total time horizon T, which depends on the length of the QFC, is computed as the sum of the discounted profits gained at each t (with t = 1, …, T), as in (5).

$$\Pi_R^{(QFC-TC)} = \sum_{t=1}^{T} \frac{\Pi_R^{QFC}(t)}{(1+i_t)^t} \quad (5)$$

The manufacturer's profit in the traditional contract Π_M^{TC} at each t is computed by equation (6):

$$\Pi_M^{TC}(t) = C_T Q^* - C_p Q^* - C_c^{TC} \quad (6)$$

Where C_c^{TC} are the fixed costs borne by the manufacturer computed for the period related to the order time t.

The differential profit that the manufacturer gains under QFC compared to the traditional contract is affected by the retailer's decision to exercise the option and the availability of the spot market to provide the required quantity. When the retailer exercises the option, the manufacturer's differential profit decreases since the quantity sold to the retailer decreases to $(1-\delta_m)[D(t) - Q^*(1-\beta)]$. When the retailer does not exercise the option, the manufacturer gains a higher profit which is the difference between its revenues $\left(C_f[D(t) - Q^*(1-\beta)]\right)$ and its production costs $\left(C_p[D(t) - Q^*(1-\beta)] + C_c^{QFC}\right)$.

The differential profit of the manufacturer in Scenario 2 under QFC compared to the traditional contract $\Pi_M^{QFC}(t)$ is computed, at each t, by (7) or (8), depending on the exercise of the option by the retailer ($O_{QFC} = 1$) or not ($O_{QFC} = 0$) respectively.

$$\Pi_M^{(QFC-TC)}(t) = C_f[D(t) - Q^*(1-\beta)](1-\delta_m) - C_p[D(t) - Q^*(1-\beta)](1-\delta_m) - C_c^{QFC} - \left[(C_T - C_p)Q^*\beta - C_c^{TC}\right] \quad if \quad O_{QFC} = 1 \quad (7)$$

$$\Pi_M^{(QFC-TC)}(t) = (C_f - C_p)[D(t) - Q^*(1-\beta)] - C_c^{QFC} - \left[(C_T - C_p)Q^*\beta - C_c^{TC}\right] \quad if \quad O_{QFC} = 0 \quad (8)$$

The manufacturer's differential profit gained under QFC compared to traditional contract over the total time horizon T, which depends on the length of the QFC, is computed as the sum of the discounted profits gained at each t (with t = 1, …, T), as in (9).

$$\Pi_M^{(QFC-TC)} = \sum_{t=1}^{T} \frac{\Pi_M^{(QFC-TC)}(t)}{(1+i_t)^t} \quad (9)$$

Scenario 3 - $(Q^*(1-\beta) < D(t) < Q^*)$

In traditional contract the retailer will not have the flexibility of purchasing less than the committed quantity Q^*. In such case, in fact, the retailer has to pay the (unitary) penalty P_{pm} to the manufacturer for the shortfall. The retailer's profit in the traditional contract Π_R^{TC} in Scenario 3 is computed at each t as in (10).

$$\Pi_R^{TC}(t) = P_v D(t) - \left[C_T D(t) + P_{pm}(Q^* - D(t))\right] \quad (10)$$

Contrarily to traditional contract, in QFC the retailer may revise the purchased quantity without paying any penalty: he/she has the possibility to reduce the quantity purchased under QFC up to $Q^*(1-\beta)$ and buy from the spot market at $C_m(t)$, whenever it is available and convenient.

In terms of real options, the retailer will decide to exercise the option if the saving gained by not buying from the manufacturer under QFC (namely, the exercise price of the option, $C_f[D(t) - Q^*(1-\beta)]\delta_m$) is higher than the cost paid to purchase that quantity from the spot supply market (namely, the stock price of the option, $C_m(t)[D(t) - Q^*(1-\beta)]\delta_m$).

The retailer's decision to exercise the option will depend on the expected payoff of the option computed as in (11).

$$Option\ payoff = max\{C_f[D(t) - Q^*(1-\beta)]\delta_m - C_m(t)[D(t) - Q^*(1-\beta)]\delta_m; 0\} \quad (11)$$

Hence, according to (11), the retailer will decide whether to exercise the option ($O_{QFC} = 1$) and buy the quantity $[D(t) - Q^*(1-\beta)]\delta_m$ from the spot market at $C_m(t)$, and the remaining quantity $[D(t) - Q^*(1-\beta)](1-\delta_m)$ at C_f from the manufacturer under the QFC.

The retailer's differential profit gained under QFC compared to traditional contract $\Pi_R^{(QFC-TC)}(t)$, in Scenario 3, is computed at each t by (12) or (13), depending on the exercise of the option ($O_{QFC} = 1$) or not ($O_{QFC} = 0$) respectively.

$$\Pi_R^{(QFC-TC)}(t) = -C_m(t)[D(t) - Q^*(1-\beta)]\delta_m - C_f[D(t) - Q^*(1-\beta)](1-\delta_m) - \left\{-C_T[D(t) - Q^*(1-\beta)] - P_{pm}[Q^* - D(t)]\right\} \quad if \quad O_{QFC} = 1 \quad (12)$$

$$\Pi_R^{(QFC-TC)}(t) = -C_f[D(t) - Q^*(1-\beta)] - \{-C_T[D(t) - Q^*(1-\beta)] - P_{pm}[Q^* - D(t)]\} \quad if \quad O_{QFC} = 0 \quad (13)$$

The retailer's differential profit gained under QFC compared to traditional contract over the total time horizon T, which depends on the length of the QFC, is computed as the sum of the discounted profits gained at each t (with t = 1, …, T), as in (14).

$$\Pi_R^{(QFC-TC)} = \sum_{t=1}^{T} \frac{\Pi_R^{(QFC-TC)}(t)}{(1+i_t)^t} \quad (14)$$

The manufacturer's profit in the traditional contract Π_M^{TC} is computed, for the Scenario 3, by equation (15).

$$\Pi_M^{TC}(t) = C_T\big(D(t) - Q^*(1-\beta)\big) + P_{pm}\big(Q^* - D(t)\big) \quad (15)$$

The differential profit that the manufacturer gains under QFC compared to the traditional contract, in Scenario 3, is affected by the retailer's decision to exercise the option and the availability of the spot market to provide the required quantity. When the retailer exercises the option, the manufacturer's differential profit decreases since the quantity sold to the retailer decreases to $(1-\delta_m)[D(t) - Q^*(1-\beta)]$. When the retailer does not exercise the option, the manufacturer gains a higher differential profit which is the difference between its revenues $\big(C_f[D(t) - Q^*(1-\beta)]\big)$ and its production costs $\big(C_p[D(t) - Q^*(1-\beta)] + C_c^{QFC}\big)$.

The differential profit of the manufacturer in scenario 3 under QFC compared to the traditional contract $\Pi_M^{(QFC-TC)}(t)$ is computed, at each t, by (16) or (17), depending on the exercise of the option by the retailer ($O_{QFC} = 1$) or not ($O_{QFC} = 0$) respectively.

$$\Pi_M^{(QFC-TC)}(t) = C_f[D(t) - Q^*(1-\beta)](1-\delta_m) - C_p[D(t) - Q^*(1-\beta)](1-\delta_m) - C_c^{QFC} - \big[(C_T - C_p)[D(t) - Q^*(1-\beta)] + P_{pm}\big(Q^* - D(t)\big) - C_c^{TC}\big] \quad if \quad O_{QFC} = 1 \quad (16)$$

$$\Pi_M^{(QFC-TC)}(t) = C_f[D(t) - Q^*(1-\beta)] - C_c^{QFC} - \big[C_T[D(t) - Q^*(1-\beta)] + P_{pm}\big(Q^* - D(t)\big) - C_c^{TC}\big] \quad if \quad O_{QFC} = 0 \quad (17)$$

The manufacture's differential profit gained under QFC compared to traditional contract over the total time horizon T, which depends on the length of the QFC, in Scenario 3, is computed as the sum of the discounted profits gained at each t (with t = 1, …, T), as in (18).

$$\Pi_M^{(QFC-TC)} = \sum_{t=1}^{T} \frac{\Pi_M^{(QFC-TC)}(t)}{(1+i_t)^t} \quad (18)$$

4. Experiments and analysis

4.1. The base-line model

The proposed model's application has been illustrated by considering a SC coordination problem handled through QFC from an example company that is effectively similar to the real-world business unit of a company operating as retailer in a European country where one of the authors was involved in supply chain management for several years.

A time period T of 12 months with a time bucket of 1 month was considered for the analysis, while the discount rate was not considered since the time horizon was one year.

Table 2 summarized the characteristics of the QFC.

Table 2. Characteristics of QFC

T	12 months
Q^*	50 units
α	0.6
β	0.6
C_f	55 €/unit

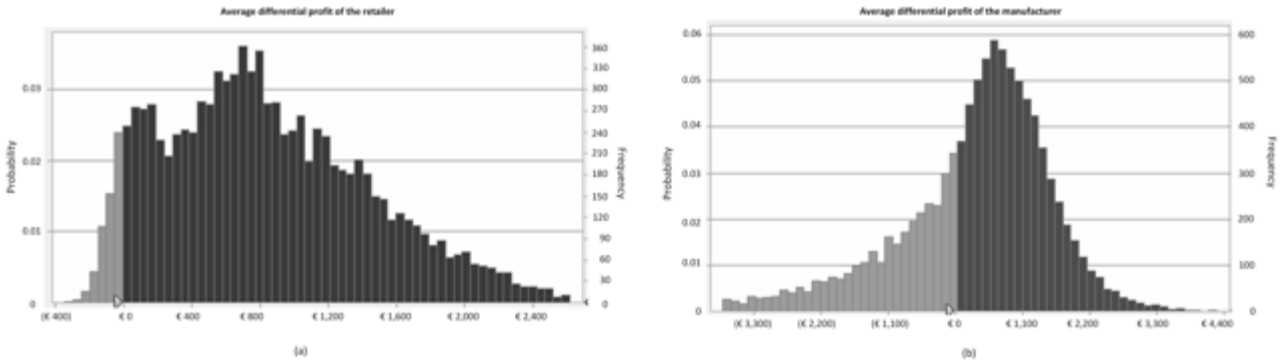
All the input data are reported in Table 3.

Table 3. Values of the input parameter of the base-line model

D_0	50 units
μ_D	0.80%
σ_Q	40%
Cm	Normal (μ=48 €/unit; σ= 1.44)
Pv	87 €/unit
Cst	Betapert(Optimistic = 34, Most likely = 35, Pessimistic = 36)
λ	0.06
CT	50 €/unit
Cf	55 €/unit
Ppm	4 €/unit
Cp	30 €/unit
C_c^{TC}	39 €
C_c^{QFC}	42 €
i	0.036

The simulation model is developed by using the @Crystal ball software. The Monte Carlo simulation approach was used for calculating the value of each strategy (10,000 computer runs).
Figure 1 shows the simulation results for the base-line model, namely the probability distributions of the differential profits of the retailer (Figure 1a) and manufacturer (Figure 1b) gained under QFC compared to traditional contract during the considered time period.

Figure 1. Simulation results for the base-line model



As shown by Figure 1a, the differential profit the retailer gains under QFC compared to traditional contract during the considered time period is positive with a probability of 0.94 (risk of loss 0.06), and shows an average value of about € 852. This means that in 94 cases out of 100 the QFC is more convenient than the traditional contract for the retailer. Besides looking at the probability of being positive, it is important to analyze the absolute value of the retailer's differential profit created by the QFC. It ranges between -€343 and €4,338. This suggests that although there can be cases where the QFC produces a loss compared to the traditional contract, the impact of such loss on the organization is low compared to the potential opportunity of creating profit (upper extreme of the distribution is much higher than the lower extreme: €4,338). Figure 1b shows that the QFC creates value also for the manufacturer, although with a lower probability of being positive, which is 0.67 (risk of loss 0.33). This means that the QFC is worthy for the manufacturer in 67 out 100 cases. This is due to the higher price charged by the manufacturer under QFC compared to traditional contract, in return for the flexibility for the retailer to revise the contract. For the manufacturer's differential profit, the range of variability is much higher than the one found for the retailer, since it ranges between -

€10.637 and €4,775. In this case, we find that the impact of loss is more significant for the manufacturer than for the retailer. The findings demonstrate the effectiveness of the QFC as a SC coordination mechanism under market demand and supply price uncertainty. This outcome confirms what qualitatively and empirically found by the existing literature about the effectiveness of QFC as SC coordination mechanism under market demand and extends it by quantitatively showing that QFC is an effective SC coordination mechanism under supply price uncertainty. We also find that the QFC adoption as SC coordination mechanism is not riskless since there is chance that it increases the costs in the system, resulting in the overall inefficiency of the SC and that the loss distribution between the two actors is unbalanced. As a consequent implication, beyond the specific values associated to the considered case, our study demonstrates the importance of properly assessing the value created by QFC compared to traditional contract.
All the simulation results were reviewed through a structured walk-through with a set of managers of both firms, which considered them as reasonable.

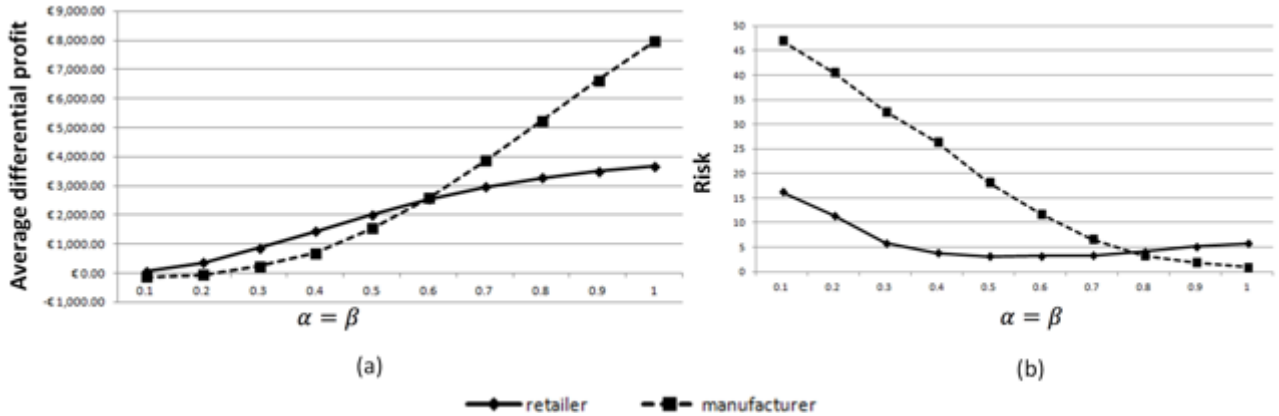
4.2. Simulation analysis

Once the base-line model was tested, we carried out a simulation analysis to investigate the effect that contract terms and implementation conditions have on the differential profits of both actors and on the entire system.
We designed a plan of experiments consisting of four experimental settings (in total 30 scenarios), which are briefly described in the following:

- The first experimental setting aims at investigating the effect of the flexibility parameters α and β (which determine the range within which the quantity purchased can vary with respect to the ordered quantity) on the differential profits of both actors and on the entire system. Operatively, we vary their value in the range [0.1, 1], by assigning them the same value ($\alpha = \beta$).
- The second experimental setting aims at investigating the effect of the availability of the spot supply market δ_m to provide the quantity required by the retailer on the differential profits of both actors and on the entire system. We vary λ in the range [0.02; 0.09].
- The third experimental setting is aimed at investigating the effect of the contract duration T on the differential profits of both actors and on the entire system, by varying T within the range [12; 48].
- The fourth experimental setting is aimed at investigating the effect of price paid by the retailer to the manufacturer under QFC on the differential profits of both actors and on the entire system. Operatively, we change the value of the parameter C_f (in the range [53; 60]). Such analysis allows us to study how the higher bargaining power of one actor over the other influences the differential profits of both actors. The assumption is that if the manufacturer has a high bargaining power over the retailer, he will force the retailer to pay for his products a higher price than the average one applied by the market (Cf >> Cm). On the contrary, if the manufacturer has a low contractual power, the retailer's purchase price will be slightly higher than the current spot market price.

The simulation results achieved by 10,000 runs for each experimental setting and the related managerial implications are discussed above.
The results of the first experimental setting (i.e., analysis of the effect of flexibility parameters change) are shown in Figure 2.

Figure 2. Results of the first experimental setting: effect of α and β on average differential profits and risk.

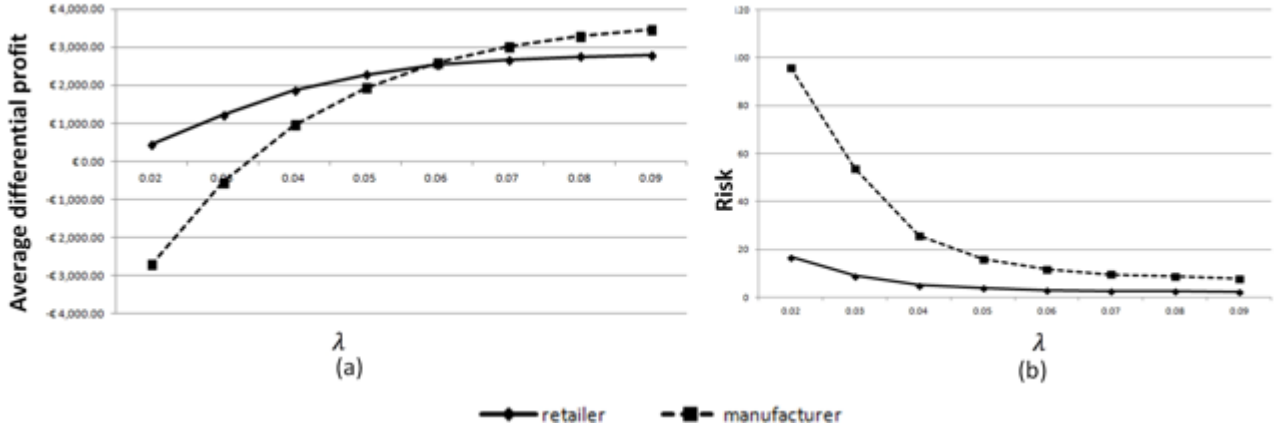


The figure 2a plots the manufacturer's and the retailer's differential profits gained under QFC compared to traditional contract over the total time horizon T for different values of the flexibility parameters α and β. Results show that when α and β increase, the manufacturer's differential profit is averagely higher than the retailer's one. In particular, when $\alpha = \beta = 0.6$, the average profits of the two actors are almost equal (around € 2,570). For values of α and β higher than 0.6, the differential profits increase for both actors, much more for the manufacturer than for the retailer; while for α and β lower than 0.6, the profits are lower but they are slightly higher for the retailer than for the manufacturer. As for the risk borne by the two parties (Figure 2b), the trend is opposite: the risk decreases when the flexibility parameters α and β increase. In particular, it is interesting to observe that the risk of the manufacturer is much more higher than the one of the retailer for low values of α and β, while the risk borne by the manufacturer and the retailer becomes equal for $\alpha = \beta = 0.8$.

This finding has two main implications. Firstly, while it seems that for flexibility parameters higher than 0.3 the QFC averagely provides higher profits for both actors compared to a traditional contract, it is very risky for the manufacturer to engage in such contract for values of α and β lower than 0.6-0.7. This supports the importance of quantifying the benefits associated with such contracts, and setting the contract parameters in order to ensure a win-win condition for both chain partners. Secondly, the profits of both actors increase when the flexibility granted by such contracts increases too, hence, confirming quantitatively the power of flexibility to coordinate supply chain.

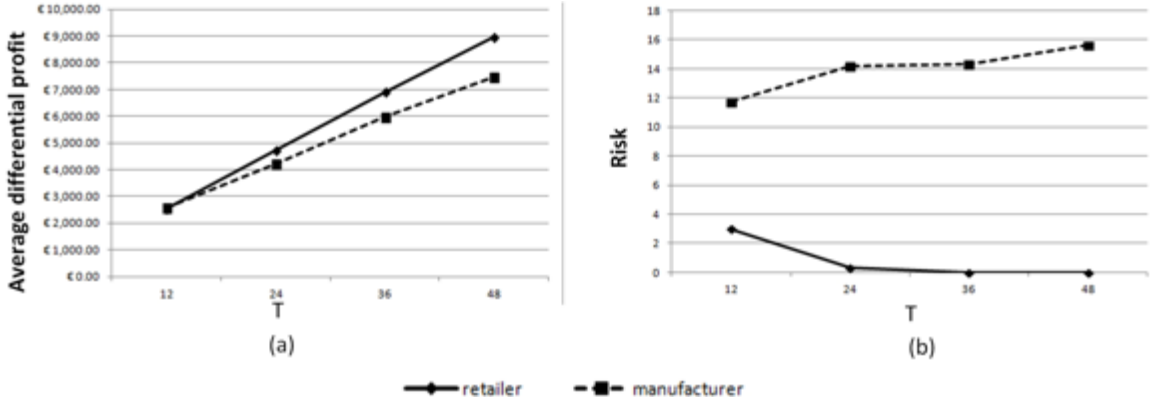
The results of the second experimental setting (i.e., analysis of the effect of the availability of the spot supply market to provide the quantity required by the retailer), shown in Figure 3, reveal that the QFC is more effective in coordinating the SC and creating win-win condition when the spot market is less available to supply the required quantity (i.e., higher value of λ). In fact, the retailer may obtain higher profits since he has the needed quantity that he would not obtain under the traditional contract due to the unavailability of the market, thus avoiding stock out costs, while the manufacturer may sell at higher price than the one that would have charged under the traditional contract.

Figure 3. Results of the second experimental setting: effect of λ on average differential profits and risk



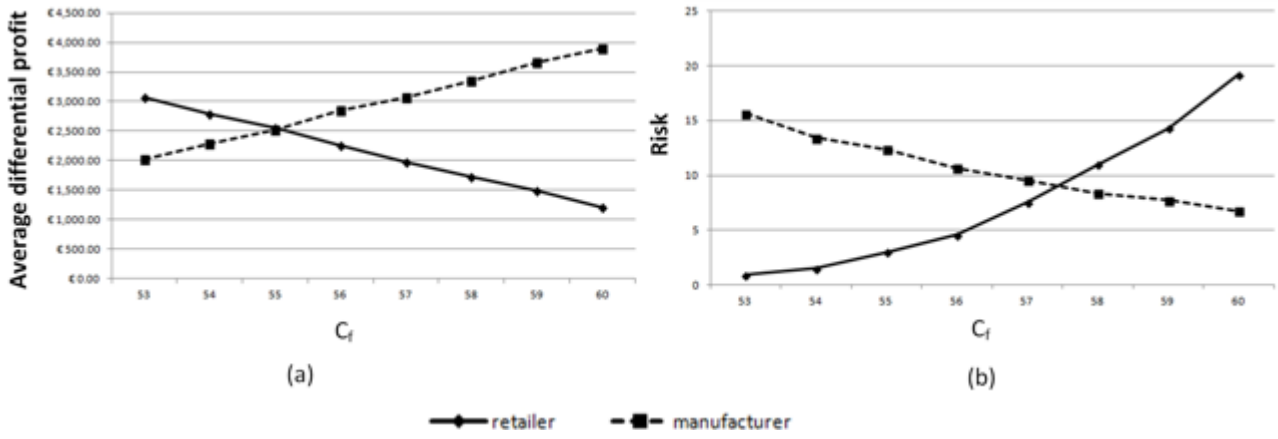
Also the risk bone by the two parties decreases when λ increases (Figure 3b): lower the availability of the spot market to provide the needed quantity, higher the probability of exploiting the contract and providing benefits to the chain partners. By inspection in Figure 3a and 3b, we can observe however that the QFC does not prove valuable in all the circumstances for both actors. In particular, when the availability of the spot market to fulfil the needed quantity increases, the retailer will exploit less the QFC since he will purchase from the spot market. Hence, the manufacturer reduces potentially its sales and revenues, hence its profit. The main managerial implication is that the QFC does not seem to be valuable in all the markets and contexts; it ceases to coordinate effectively the SC when the spot supply markets is widely available to fulfill the retailer requirements.
The results of the third experimental setting show that the profits of both actors increase linearly with the duration of the contract, keeping the same unbalanced risk distribution between the two actors. The main managerial implication is that the QFC increases its effectiveness as SC coordination mechanism when the buyer-supplier relationships become longer.

Figure 4. Results of the third experimental setting: effect of T on average differential profits and risk



Finally, the results of the fourth experimental setting show that a higher bargaining power of one actor over the other produces a resulting situation which is unbalanced towards the actor with high contractual power, either in terms of benefits or in terms of probability of loss (Figure 5).

Figure 5. Results of the fourth experimental setting: effect of C_f on average differential profits and risk



5. Conclusions

A simulation-based research has been carried out in order to analyze the effectiveness of QFC as SC coordination mechanism under market demand and spot market uncertainty, by measuring such effectiveness in terms of the profits gained by each actor under QF contract with respect to the profits obtained under traditional contracts. In so doing and by varying the contract terms and

implementation conditions we ensure that the QF is chosen only when it ensure a win-win condition, namely it improves the profits of both parties.

The experiments show the effect that contract terms and implementation conditions have on the benefits of both actors and on the entire system thus providing guidelines to the contract design in order to ensure that higher profits are attained for both parties (win-win situation).

Efficiency and Effectiveness of Knowledge Management Systems in Supply Firms

Abstract

This paper proposes a 3D fuzzy logic methodology to assess the efficiency and effectiveness of knowledge management systems (KMSs) adopted by suppliers and identifies a taxonomy bringing together the behaviour of suppliers when adopting KMSs. The proposed methodology was previously tested on an individual supplier and then implemented on a sample of 61 suppliers. The results highlight that there is an ample variety of behaviours related to the nature of knowledge and the KMSs used. Specifically, four typologies of behaviour are identified: the efficient and effective supplier, the inefficient supplier, the ineffective supplier, and the inefficient and ineffective supplier. The results show that only 18% of surveyed suppliers are efficient and effective for both KM-Tools and KM-Practices, the remaining 82% are inefficient or ineffective for KM-Tools and/or KM-Practices. Lastly, the paper shows how this methodology may be used by a supplier as a managerial tool to suggest appropriate changes in order to improve the efficient and effective use of KMSs supporting supply firms in the knowledge management process.

Keywords - Efficiency and effectiveness, IT-based systems, knowledge management system (KMS), organization practices, supplier

1. Introduction

A vast literature underlines that knowledge management (KM) has becoming increasingly crucial for a supplier's competitiveness. The growing interest of scholars and practitioners is proved by the positive trend for papers dealing with the topic of knowledge management. In fact, consulting the Scopus database, it emerges that between 1971 and 1985 there were only 32 papers on the topic of knowledge management, but between 1986 and 2000 the number of papers increased to 1,302 (a 3,969% rise compared with 1971-1985), and in the period 2001-2016 the number of papers reached 56,463 (with a growth ratio of about 4,237% with respect to 1986-2000).
Despite this an increasing literature analysing how knowledge management is becoming a key strategic factor in the new industrial environment (Hong et al., 2014), in the field of supply chain management the role of knowledge management seems still neglected. Whereas exists a consistent amount of research concerning knowledge management in large customer companies, the literature has devoted little attention to supply firms. In particular, while the literature proposes a variety of contributions underlining the critical success factors affecting KM (Desouza et al., 2003, Blome et al., 2014; Chang et al., 2012; Cheng and Fu, 2013; He et al., 2013; Kim et al., 2012; Loke et al., 2012; Mak and Ramaprasad, 2003; Zhang and Zhou, 2013), and the impact of KM on performance (Abid and Ali, 2014; Fugate et al., 2012; Gholami et al., 2013; Halley et al., 2010; Hult et al., 2004, 2006; Liu et al., 2012; Lu et al., 2014; Sambasivan et al., 2009), there is little empirical research on knowledge management systems (KMSs) used by suppliers to support knowledge management process. The few papers that deal with the topic of KMSs in supply chain do not offer a clear framework about the KMSs used. Moreover, the issue of the

efficiency and the effectiveness of knowledge management systems (KMSs) according to the nature of a firm's knowledge still appears to be largely neglected (Cerchione and Esposito, 2016). Nevertheless, this issue is extremely relevant for four main aspects (Bhatt, 2001; Holsapple, 2005). Firstly, the use of efficient and effective KMSs leads to a correct alignment between the nature of the supplier's knowledge and the KMSs used, which is itself a factor that could positively affect the KM process (and could conversely be a barrier to the KM process). Secondly, inefficiency means a misalignment between the nature of knowledge and KMSs that may generate problems relating to the underutilization of KMSs, which could in turn have a negative impact on a supplier's performance. Thirdly, any inefficiency and ineffectiveness will, in turn, affect the entire supply chain (Esposito and Passaro, 2009, Liu et al., 2014; Nagati and Rebolledo, 2013). Fourthly, over the last few years, information and communications technologies (ICTs) have changed the nature of KMSs, offering customers and suppliers new low-cost, easy to use knowledge management tools (Antonelli, et al., 2000; Garrigos-Simon et al., 2012; Matlay and Westhead, 2005).

In this context, this paper aims to address the issue of the efficiency and effectiveness of knowledge management systems in relation to the nature of a supplier's knowledge. Specifically, the paper proposes a fuzzy-logic based methodology to evaluate the level of efficiency and effectiveness of KMSs used by suppliers. The methodology is implemented by means of a survey involving 61 Italian suppliers operating in high-tech industries and/or complex industries.

The remainder of the paper is structured as follows. After this introduction, the methodology is set out in the second section. The third section illustrates the field analysis and the context of the investigation. The fourth section is dedicated to the implementation of the methodology and the discussion of the results obtained from the suppliers surveyed. Lastly, the conclusions and implications are discussed in the fifth section.

2. Methodology

A fuzzy logic-based methodology is proposed to evaluate the efficiency and effectiveness of knowledge management systems in relation to a supplier's knowledge. The proposed methodology is divided into three phases. The first phase consists in mapping supplier's knowledge according to the two perspectives of analysis proposed by Nonaka in 1994. The second phase consists in mapping the KMSs used by suppliers by means of a Delphi panel involving two senior IT consultants and two researchers. Finally, the indices of efficiency and effectiveness are defined in the third phase.

2.1 Mapping a supplier's knowledge

In accordance with Nonaka (1994), two knowledge dimensions have to be taken into consideration in order to map a supplier's knowledge: the degree of formalization (epistemological dimension) and the degree of sharing (ontological dimension).

The epistemological dimension regards the nature of knowledge. It ranges from tacit to explicit knowledge (Polanyi, 1966). Tacit knowledge is knowledge embedded in a human mind and entails a body of beliefs, perceptions, perspectives, and values. It is difficult to access without ongoing engagement with the knowledge holder. Explicit knowledge is articulated, codified, and communicated in symbolic form and/or natural language. Hence it may be accessed and used without the physical presence of the knowledge creator.

Conversely, the ontological dimension concerns the level of knowledge sharing (individual,

group, organization, openness only to partners, full openness).
There are two main reasons for selecting these dimensions to map a supplier's knowledge: it is by far the most commonly used by managers and scholars in the field of knowledge management, and it is familiar to supplier managers and therefore easy to use in field investigations.
Starting from these premises, each supplier was divided into five macro-areas: planning, production, organization, market, and strategic relationships so as to provide a map of a given supplier's knowledge on the basis of the ontological and epistemological dimensions. More specifically, two managers from each supplier were involved in identifying the degree of formalization and the degree of sharing of the supplier's knowledge for each of the five macro-areas. The fuzzy set theory (FST) based approach (Zadeh, 1965; Watanabe, 1979) was used to process the information gained during the meetings with the two managers. This approach makes it possible to integrate the rigour of logic with the natural language model and common-sense reasoning (Michellone and Zollo, 2000; Zimmermann, 2001).
In particular, the degree of formalization and the degree of sharing of each supplier's knowledge per macro-area were established as shown in the following five steps:

1. A *first term set* of five qualitative judgments was defined in order to identify the degree of formalization of the supplier's knowledge: VPF (very poorly formalized), PF (poorly formalized), MF (medium formalized), SF (significantly formalized), VSF (very significantly formalized).
2. A *second term set* of five qualitative judgments was defined to identify the degree of sharing of the supplier's knowledge: MI (mainly individual), IG (inside group), IO (inside organization), OP (open to partner), FO (fully open).
3. Two managers were involved in a focus group with two researchers to identify the degree of formalization (DF) and the degree of sharing (DS) of the supplier's knowledge for each of the five macro-areas;
4. Each qualitative value was codified into the correspondent fuzzy number (Figure 1a and Figure 1b).
5. These fuzzified values make it possible to create a fuzzy map of the knowledge categorized by the epistemological dimension (DF) and the ontological dimension (DS) for each macro-area. Specifically, each pair of qualitative values associated with the degree of formalization and the degree of sharing of a supplier's knowledge used in one of the five macro-areas is represented by a 3D fuzzy set that may be either a pyramid or a truncated square pyramid. The combination of the 3D fuzzy sets associated to the five macro-areas identifies the epistemological and ontological map of the supplier's knowledge.

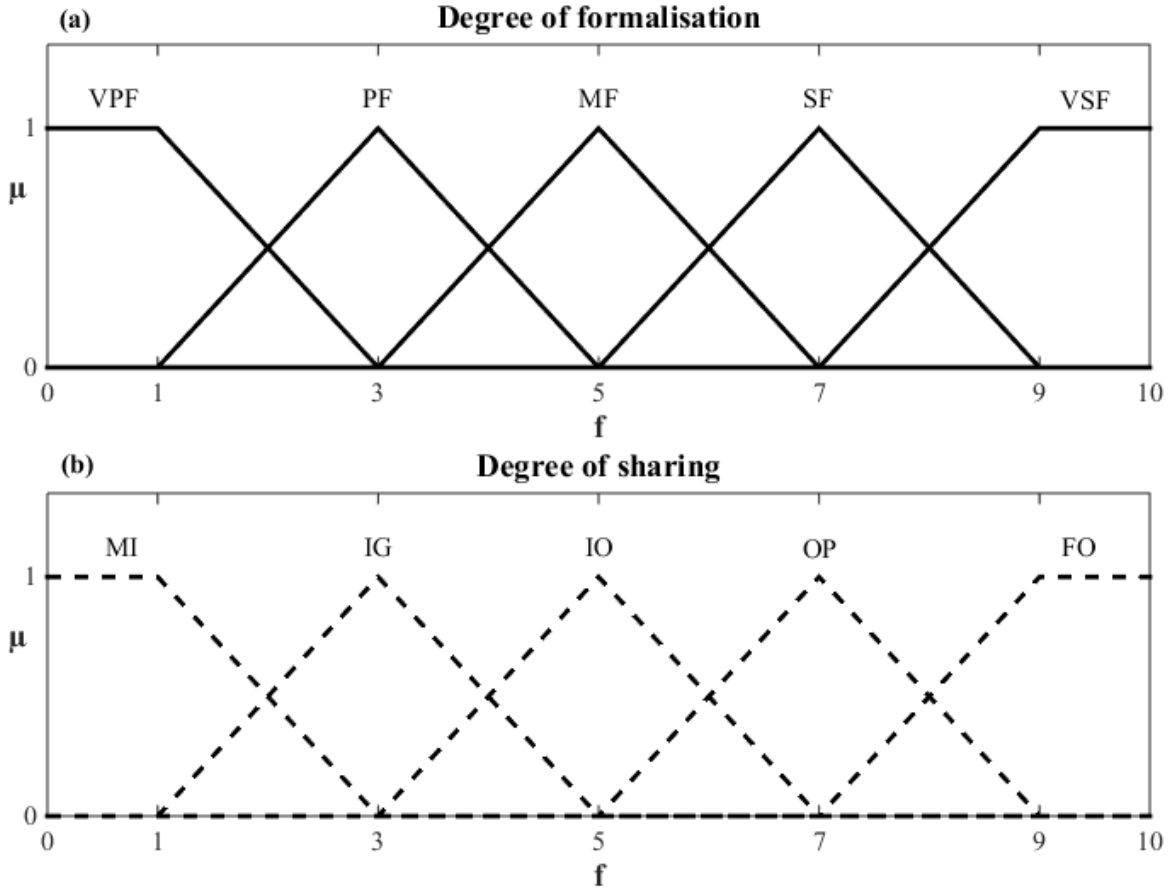

Figure 1. Fuzzy term sets for (a) the Degree of formalization (epistemological dimension) and (b) the Degree of sharing (ontological dimension)

2.2 Mapping Knowledge Management Systems

According to Cerchione and Esposito (2017), KMSs are divided into two groups for this research: Knowledge Management Tools (KM-Tools, defined as the specific IT-based systems supporting KM methods and techniques) and Knowledge Management Practices (KM-Practices, defined as methods and techniques to support the processes of knowledge creation, storage, transfer/sharing, and application).

A group comprising four experts, two senior IT consultants and two researchers, was involved to identify the epistemological and ontological dimensions of KM-Tools and KM-Practices. A Delphi panel was used to converge the answers provided by the expert group (Okoli and Pawlowski, 2004; Hsu and Sandford, 2007). During the meetings, the group of experts identified a couple of shared judgements about the degree of formalization and the degree of sharing of each individual KM-Tool and KM-Practice, applying the five-level scale used to assess the supplier's knowledge (Figure 1a and Figure 1b). The final list of KM-Tools and KM-Practices identified is reported in Table 1.

Each pair of fuzzy numbers, which represents the degree of formalization and the degree of sharing of the individual KM-Tool (or KM-Practice) used by the supplier, identifies a 3D fuzzy set that may be either a pyramid or a truncated square pyramid. The combination of these 3D fuzzy sets associated to the individual KM-Tool (or KM-Practice) identifies the epistemological

and ontological map of KM-Tools (or a map of KM-Practices) used by the supplier (Figure 2). The final list of KM-Tools and KM-Practices identified is reported in Table 1.

2.3 Efficiency and effectiveness indices

In this section, two couples of indices are proposed. The first pair of indices evaluates the degree of efficiency and the degree of effectiveness of KM-Tools in relation to the supplier's knowledge. The second measures the degrees of efficiency and effectiveness of KM-Practices in relation to the supplier's knowledge.

TOY (Efficiency of KM-Tools) = $\frac{K \cap T}{T}$; (1)

TOS (Effectiveness of KM-Tools) = $\frac{K \cap T}{K}$; (2)

PRY (Efficiency of KM-Practices) = $\frac{K \cap P}{P}$; (3)

PRS (Effectiveness of KM-Practices) = $\frac{K \cap P}{K}$; (4)

In these indices,

- **K** represents the supplier's knowledge, i.e. the union of five 3D fuzzy sets associated with the firm's knowledge in the five macro-areas of planning, production, organization, market, and strategic relationships;
- **T** regards the KM-Tools used by the supplier, i.e. the union of 3D fuzzy sets associated with the individual KM-Tools adopted by the supplier;
- **P** depicts the KM-Practices used by the supplier, i.e. the union of 3D fuzzy sets associated with the individual KM-Practices used by the supplier.

Each index ranges from zero to one depending on the level of intersection between the two variables used for the specific index. Table 2 summarizes all the five possible intersections for the proposed indices.

The TOY index measures the degree of efficient use of KM-Tools in relation to the supplier's knowledge in the epistemological and ontological dimensions. The hypothesis is that the higher the percentage of KM-Tools (T) intersecting with the supplier's knowledge (K), the higher the percentage of adopted KM-Tools suited to the characteristics of the supplier's knowledge, and the higher the level of efficiency. The TOY index is zero if the 3D fuzzy sets associated to T and K are disjointed (case B in Table 2). In this case, the supplier does not adopt KM-Tools suited to the characteristics of its knowledge. This means that the supplier uses inadequate KM-Tools in its knowledge management process, which implies dissipation of resources and serious problems of inefficiency (inefficient use of KM-Tools). By contrast, the TOY index is equal to one if T coincides with K (case E in Table 2). This means that there is a close correspondence between the KM-Tools used and the supplier's knowledge. Hence, all the KM-Tools are suited to the characteristics of the firm's knowledge (efficient use of KM-Tools). Even if T is a proper subset

of K (case C in Table 2), the index is equal to one. In this case, there is no strict correspondence between the KM-Tools and the supplier's knowledge because all the KM-Tools are appropriate to the supplier's knowledge, but not all the supplier's knowledge is covered by the KM-Tools.
The TOS index measures the degree of effectiveness of KM-Tools in relation to the supplier's knowledge in the epistemological and ontological dimensions. The hypothesis is that the higher the percentage of the supplier's knowledge (K) intersecting with KM-Tools (T), the higher the percentage of the supplier's knowledge covered by appropriate KM-Tools, and the higher the level of effectiveness. The TOS index is equal to zero if the 3D fuzzy sets associated with T and K are disjointed (case B of Table 2). In this case, no part of the supplier's knowledge (K) is covered by the KM-Tools (T) adopted. This means that beyond the issues of inefficiency already pointed out, there are also problems of ineffectiveness since the KM-Tools do not satisfy the supplier's needs in terms of knowledge management (ineffectiveness of KM-Tools). The TOS index is equal to 1 if K coincides with T (case E in Table 2) or if K is a proper subset of T (case D in Table 2). This means that all the supplier's knowledge is covered by the KM-Tools. Hence, the KM-Tools are able to satisfy the supplier's needs in terms of knowledge management (effectiveness of KM-Tools). Nevertheless, in case E there is a full intersection between K and T (both efficiency and effectiveness) whereas in case D, part of T is outside the intersection (effectiveness but no efficiency).
To summarize, case A (Table 2) shows a context in which a part of the KM-Tools is not aligned with the supplier's knowledge (low level of efficiency) and a part of the supplier's knowledge is not covered by the KM-Tools (low level of effectiveness). Case B represents a situation of complete inadequacy (inefficiency and ineffectiveness). Case C highlights a condition of efficiency, since all the KM-Tools are used in a proper way, but there is a lack of effectiveness because part of the supplier's knowledge is not covered by the KM-Tools. Case D represents a condition of effectiveness since all the supplier's knowledge is covered by proper KM-Tools, but there is a lack of efficiency since a part of the KM-Tools does not correspond with the supplier's knowledge. Lastly, case E shows a condition of full efficiency and effectiveness.
Similarly, the PRY and PRS indices respectively depict the level of efficient use of KM-Practices in relation to the supplier's knowledge and the index of effectiveness of KM-Practices in relation to the supplier's knowledge.
The following section provides an overview of the research context in which the field analysis was conducted.

Table 2. Alignment indices by 3D fuzzy term sets

	INDICES					
	K-T			K-P		
	3D TERM SETS	TOY	TOS	3D TERM SETS	PRY	PRS
A		[0, 1]	[0, 1]		[0, 1]	[0, 1]
B		0	0		0	0
C		1	[0, 1]		1	[0, 1]

D		[0, 1]	1		[0, 1]	1
E		1	1		1	1

3. Field analysis and context of investigation

Sixty-one suppliers were investigated to shed light on the level of alignment between a supplier's knowledge and its KMSs. The methodology for the analysis is based on semi-structured face-to-face interviews. This methodology has the following dual advantage (Qu and Dumay, 2011):

- It does not limit the interview to a set of predefined answers. This makes it possible to catch weak signals that might not otherwise emerge using predetermined questions, and
- The use of predetermined questions gives uniformity to the investigation.

The investigation was organized into the following six steps:

1) *Preparation of the draft semi-structured questionnaire*. In this phase, a draft version of the semi-structured questionnaire was prepared taking into account the basic objectives of the investigation.
2) *Establishment of a focus group*. In this phase, a focus group including researchers and senior IT consultants operating in the field of KM was established. It was set up in three different phases. Firstly, the topic investigated was presented in order to familiarize the focus group participants with it. Secondly, the draft semi-structured questionnaire was submitted to the panelists in order to receive their useful feedback and comments. Lastly, the panelists' remarks were discussed in a plenary session.
3) *Re-focusing the semi-structured questionnaire*. The semi-structured questionnaire was revised and finalized on the basis of the feedback received during the focus group discussion.
4) *Testing the semi-structured interview*. In this step, the final version of the semi-structured questionnaire was tested by means of pilot interviews with three suppliers.
5) *Final version of the questionnaire*. Suggestions emerging during pilot interviews with the three suppliers were included in the final version of the questionnaire.
6) *Field analysis implementation*. The semi-structured questionnaire was submitted during face-to-face interviews involving at least two managers with different skills and roles (e.g. a manager involved in the supply firm's strategic decision-making process and a manager involved in operations management). This made it possible to obtain both strategic and operational perspectives. The total number of respondents was 61 out of 78 supply firms with a response rate of 78.2%.

The field analysis was carried out on a sample of 61 suppliers located in the South of Italy. The sample includes medium (36%), small (49%) and micro suppliers as shown in Table 3.

Table 3. Breakdown of suppliers by employee bands

suppliers category	Number of suppliers	%
Micro (0-9)	9	15
Small (10-49)	30	49

Medium (50-249)	22	36
Total	61 Suppliers	

Table 4 shows that 61% of suppliers operate in high-tech and complex manufacturing industries, such as aerospace, the automotive industry, and engineering. 39% operate in the service industry, such as information and communications technology, research and development, and services.

Table 4. Supplier industries

Overall economic industry	Specific industry	Number of Supplies	%
Manufacturing	Aerospace	12	20
	Automotive	20	33
	Engineering	5	8
Service	Research and Development	7	11
	Information and Communications Technology	14	23
	Management Consulting	3	5
Total		61 Suppliers	

Moreover, suppliers have been selected for the following two main reasons:

- they are part of important supply systems operating in high-tech and complex manufacturing and service industries with a critical impact on the territorial development of an Italian region that is a long-established leader in producing complex components for the aerospace and automotive industries
- knowledge management plays an important role since all the suppliers operate in high-tech and complex industries, where knowledge is a critical factor.

The above characteristics make the chosen sample relevant for this study and make it possible to consider the suppliers in question an appropriate context for enquiry.
The following section presents the results of the field analysis.

4. Results

This section presents the main findings for the four indices of efficiency and effectiveness emerging from analysis of the 61 surveyed Suppliers. Nevertheless, to show how the proposed methodology works in practice, section 4.1 shows how it was implemented in the case of an individual supplier. The results of the survey will be discussed in section 4.2.

4.1 Implementation to an individual supplier

The supplier analysed is located in southern Italy with other plants located in Italy and USA. The supplier operates in the aircraft industry and its main activities regard the manufacturing and assembly of aircraft airframes as well as the design and production of aeronautical parts.
The three phases of the methodology are illustrated below.

First phase – Mapping the supplier's knowledge
For this supplier, the survey has evidenced that knowledge is, by and large, very significantly

formalized (VSF). Nevertheless, in the Planning and Organization macro-areas, knowledge is manly individual (MI), whereas in the Production, Market and Strategic relationships areas, knowledge is shared inside the organization (IG) (Table 5).

Table 5. Fuzzy numbers associated with suppliers' knowledge

Macro area	***Degree of formalization***	***Degree of sharing***
Planning	VSF = (7,9,10,10)	MI = (0,0,1,3)
Production	VSF = (7,9,10,10)	IG = (1,3,3,5)
Organisation	VSF = (7,9,10,10)	MI = (0,0,1,3)
Market	VSF = (7,9,10,10)	IG = (1,3,3,5)
Strategic relationships	PF = (1,3,3,5)	IG = (1,3,3,5)

Each pair of fuzzified values concerning the degree of formalization and the degree of knowledge sharing (Table 5) allows us to identify the 3D fuzzy map representative of the supplier's knowledge for each macro-area Figure 3.

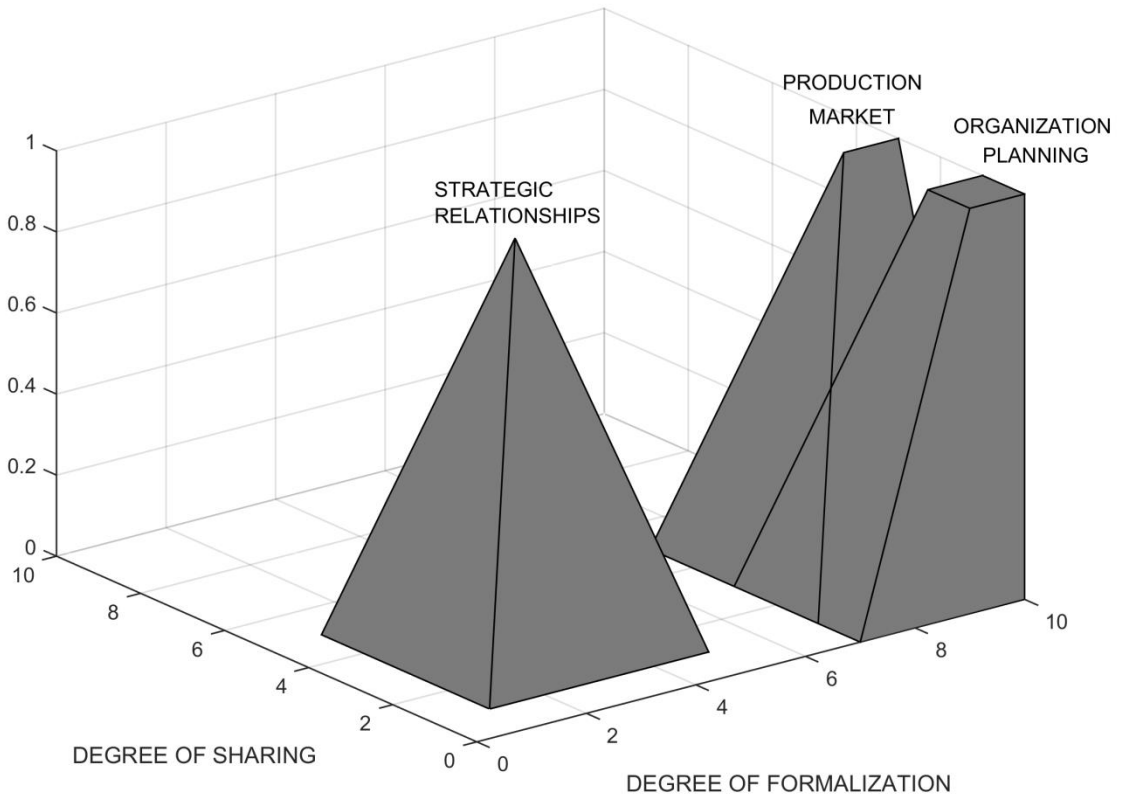

Figure 3. The supplier's knowledge

Second phase – Mapping KM-Tools and KM-Practices

Turning now to the KM-Tools, the supplier uses *E-mail*, which is a very poorly formalized and

fully open tool, so it is suited to mainly human-embedded knowledge management, an *ERP system*, which is a medium formalized tool useful for sharing knowledge inside the organization, and *Data Warehouse*, a significantly formalized tool suitable for sharing formalized knowledge within a specific group (Table 6).

Table 6. Fuzzy numbers associated with KM-Tools

KM-Tools	Fuzzy numbers	
	Degree of formalization	**Degree of sharing**
Data Warehouse	SF = (5,7,7,9)	IG = (1,3,3,5)
E-mail	VPF = (0,0,1,3)	FO = (7,9,10,10)
ERP System	MF = (3,5,5,7)	IO = (3,5,5,7)

Each pair of fuzzified values, which represents the degree of formalization and the degree of sharing of each KM-Tool, identifies the epistemological and ontological map of KM-Tools (Figure 4).

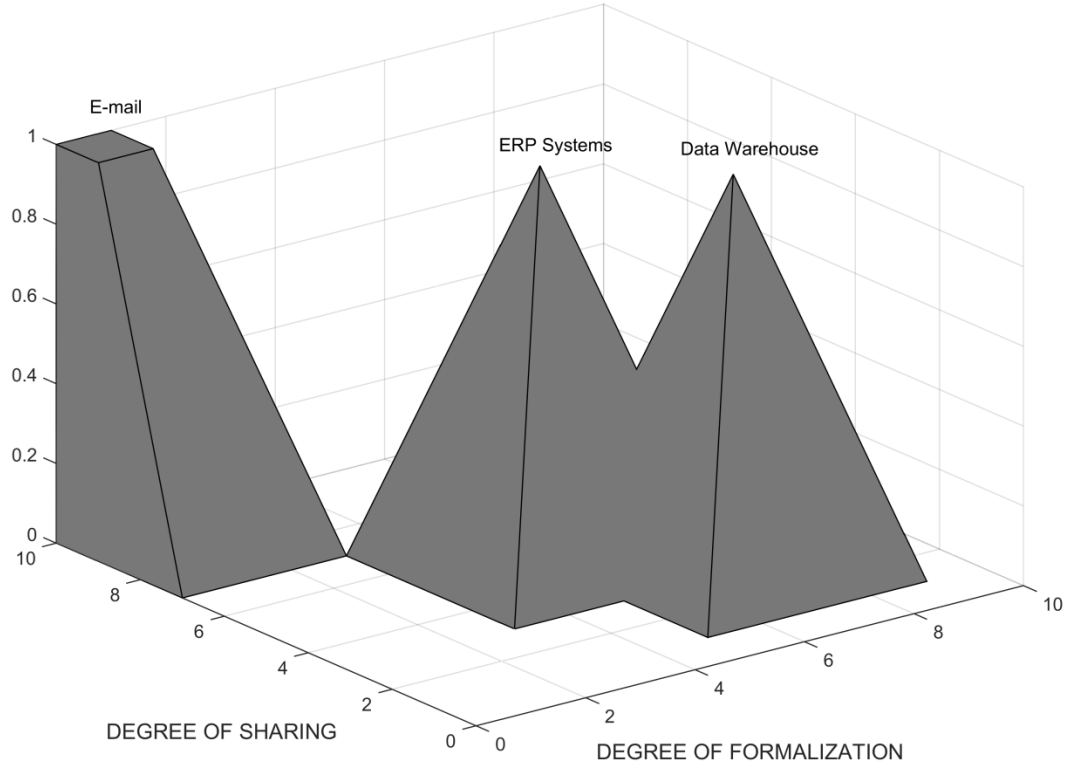

Figure 4. KM-Tools

Regarding KM-Practices, the survey has evidenced that the supplier uses (Table 7) *Learning by doing* and *Coaching/Mentoring*, which are very poorly formalized practices suited to human-embedded knowledge, *Brainstorming* and *Work groups*, very poorly formalized practices useful for knowledge sharing inside a group, *After action review*, a poorly formalized practice useful for knowledge sharing inside the organization, *Problem solving*, a medium formalized practice suited to knowledge sharing inside a group, *Process mapping* and *Knowledge mapping*, which are significantly formalized practices useful for knowledge sharing inside an organization, and the *Meeting/Task Force*, a very poorly formalized practice shared with partners.

Table 7. Fuzzy numbers associated with KM-Practices

KM-Practices	Fuzzy numbers	
	Degree of formalization	Degree of sharing
After Action Review	PF = (1,3,3,5)	IO = (3,5,5,7)
Brainstorming	VPF = (0,0,1,3)	IG = (1,3,3,5)
Coaching/Mentoring	VPF = (0,0,1,3)	MI = (0,0,1,3)
Knowledge Mapping	SF = (5,7,7,9)	IO = (3,5,5,7)
Learning by Doing	VPF = (0,0,1,3)	MI = (0,0,1,3)
Meeting/Task Force	VPF = (0,0,1,3)	OP = (5,7,7,9)
Problem Solving	MF = (3,5,5,7)	IG = (1,3,3,5)
Process Mapping	SF = (5,7,7,9)	IO = (3,5,5,7)
Work Groups	VPF = (0,0,1,3)	IG = (1,3,3,5)

As for KM-Tools, using the fuzzy values shown in Table 7 it is possible to identify the epistemological and ontological map of KM-Practices (Figure 5).

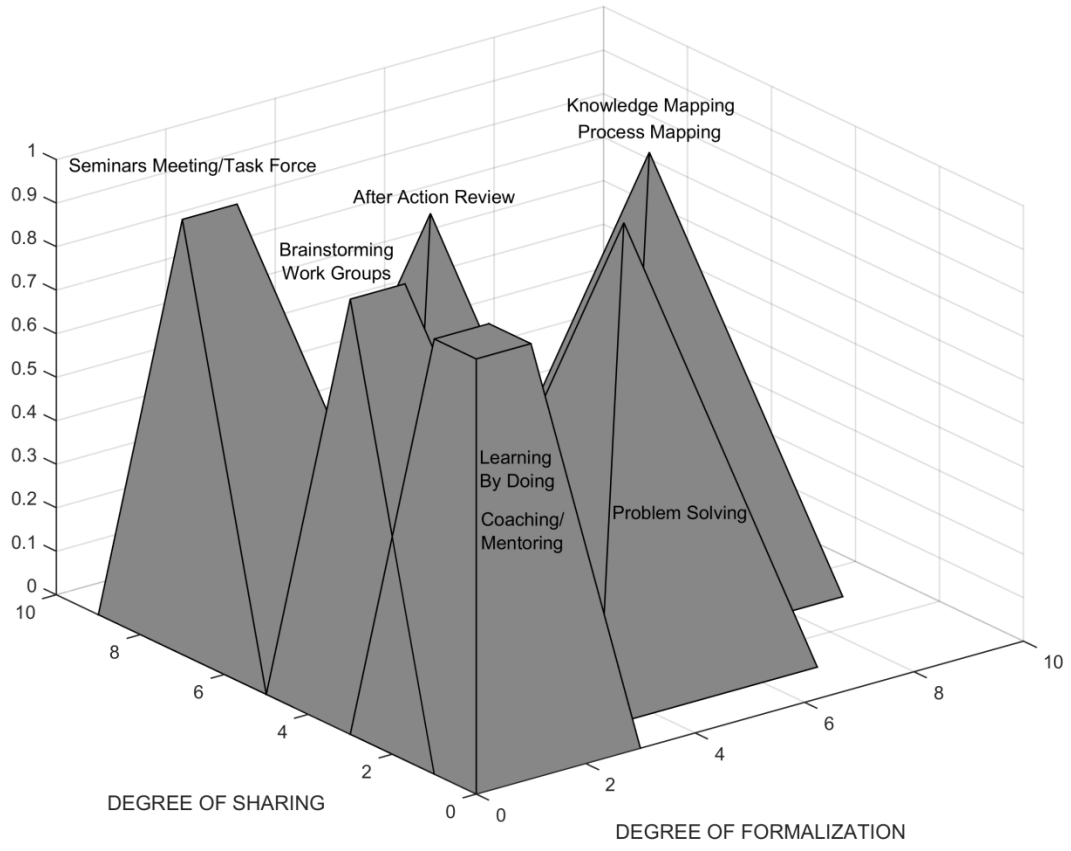

Figure 5. KM-Practices

Third phase – Building efficiency and effectiveness indices

In order to formulate efficiency and effectiveness indices it was necessary to calculate two 3D fuzzy intersections:

1- The intersection between knowledge (Figure 3) and KM-Tools (Figure 4) as illustrated in Figure 6
2- The intersection between knowledge (Figure 3) and KM-Practices (Figure 5) as illustrated in Figure 7

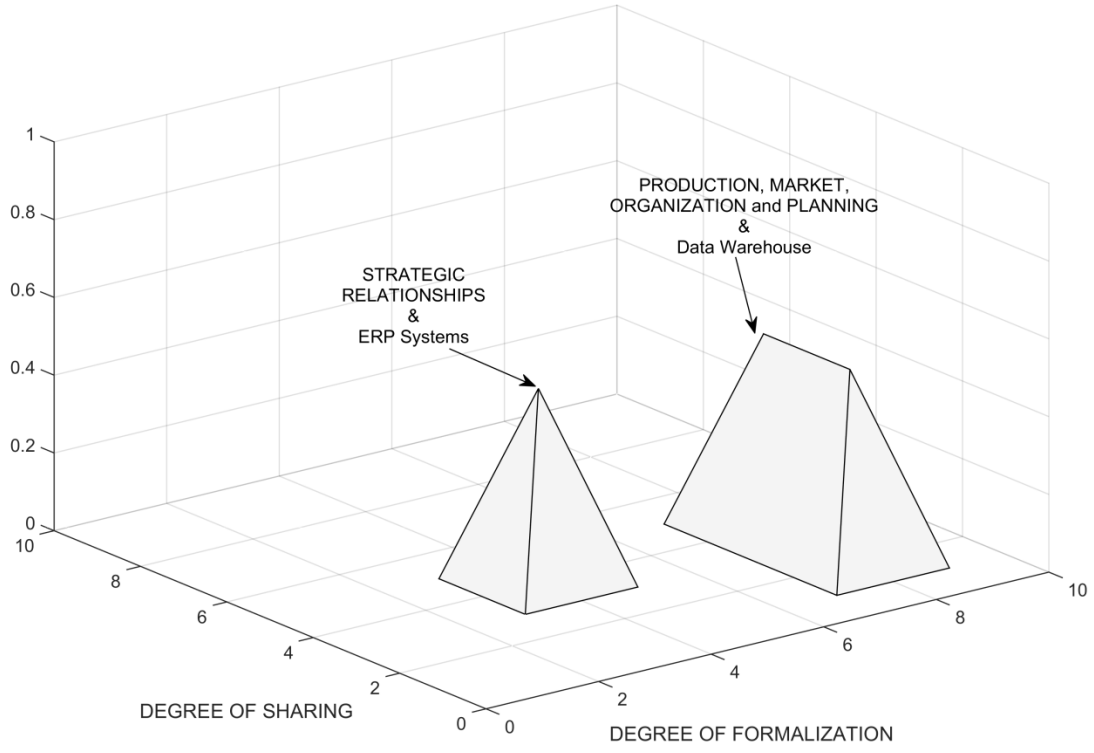

Figure 6. Intersection between Knowledge and KM-Tools

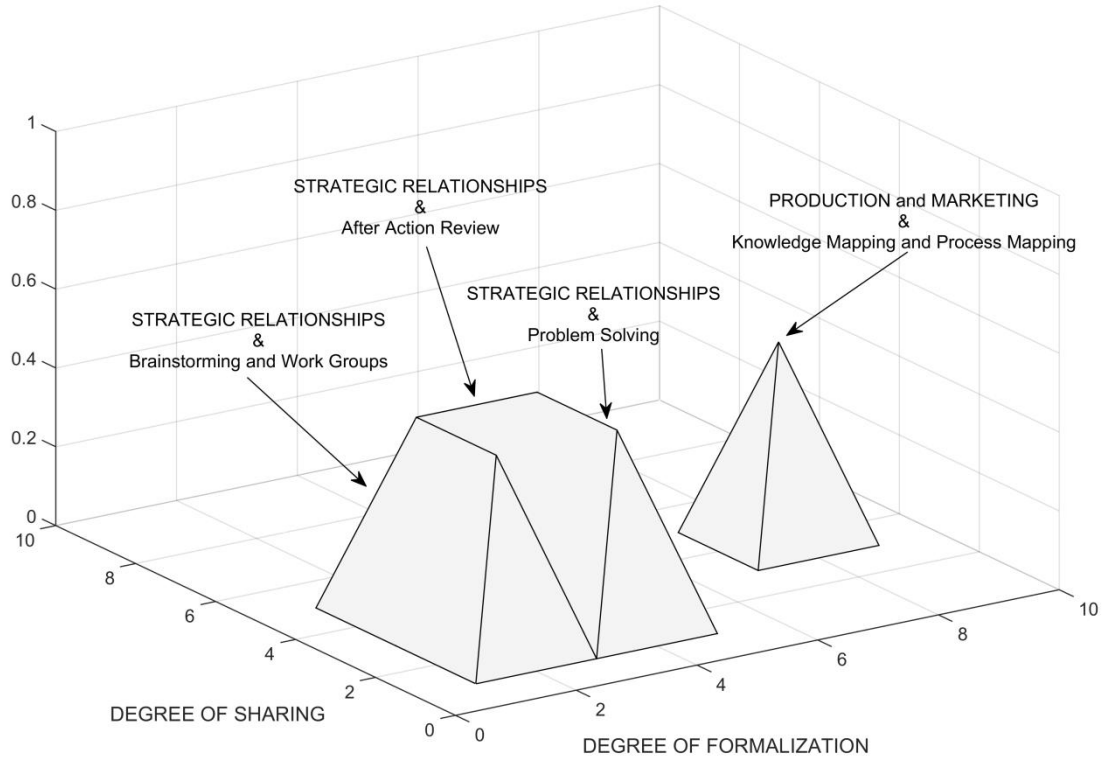

Figure 7. Intersection between Knowledge and KM-Practices

Finally, the four indices for the selected supplier are calculated using the formulas (1), (2), (3) and (4):
TOY = 0.16
TOS = 0.18
PRY = 0.17
PRS = 0.33

After showing how the methodology is applied to an individual supplier, the next step illustrates the results of the survey.

4.2 Survey results

This section provides the main findings for the 61 suppliers surveyed. The objective is to calculate the degree of efficiency and effectiveness of KM-Tools and KM-Practice (Table 8) and highlights differences and similarities among the surveyed suppliers.

Table 8. Efficiency and effectiveness indices for KM-Tools and KM-Practices

Supplier	INDICES			
	KM-Tools in relation to the supplier's knowledge		KM-Practices in relation to the supplier 's knowledge	
	TOY	TOS	PRY	PRS
A1	0.43	0.60	0.34	0.75

A51	0.26	0.41	0.24	0.37
A52	0.11	0.11	0.43	0.71
A53	0.19	0.40	0.19	0.49
A54	0.24	0.82	0.21	0.82
A55	0.23	0.64	0.12	0.40
A56	0.26	0.70	0.31	0.78

A57	0.26	0.46	0.31	0.56
A58	0.44	0.80	0.41	0.80
A59	0.13	0.13	0.40	0.87
A60	0.50	0.85	0.40	0.92
A61	0.19	0.53	0.19	0.61
Mean	**0.29**	**0.55**	**0.29**	**0.62**

Table 8 highlights that the efficiency index of KM-Tools compared with the supplier's knowledge ranges from 0.00 (suppliers A7, A23) to 0.70 (A21) with a mean of 0.29, whereas the effectiveness index ranges from 0.00 (A7, A23) to 1.00 (A30, A44) with a mean of 0.55. It is possible to identify four areas limited by the average values of the two indices (Figure 8).
In the top left quadrant there are suppliers that adopt KM-Tools with a low degree of efficiency, but a high degree of effectiveness. This is the *area of inefficiency* for KM-Tools.13 of the 61 suppliers are located in this area. The bottom left quadrant contains the suppliers that adopt inefficient and ineffective KM-Tools. This is the *area of inefficiency and ineffectiveness*. 20 out of 61 suppliers are located in this area. The suppliers that adopt KM-Tools with a high degree of efficiency, but a low degree of effectiveness, are in the bottom right quadrant. This is the *area of ineffectiveness* for KM-Tools. 7 out of the 61 suppliers are located in this area. Lastly, in the top right quadrant we find suppliers whose KM-Tools have a high degree of both efficiency and effectiveness. This is the *area of efficiency and effectiveness*. 21 out of the 61 suppliers are in this area.

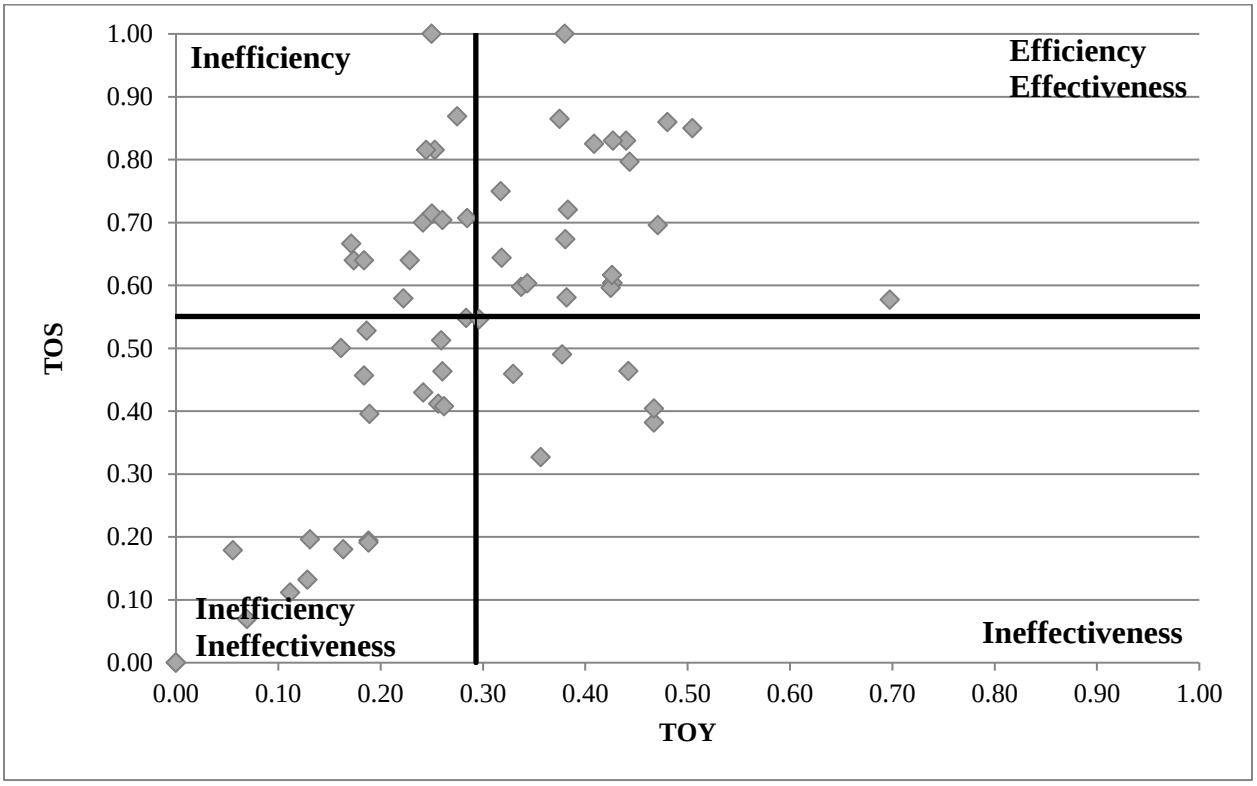

Figure 8. The relationship between TOY and TOS

To sum up, Figure 8 shows that only 36% of suppliers have efficient and effective KM-Tools in relation to their knowledge. The remainder of the suppliers have problems of inefficiency and/or ineffectiveness (64%).

Looking now at KM-Practices, Table 8 shows that the index of efficiency of KM-Practices in relation to a supplier's knowledge ranges from 0.05 (suppliers A26, A48) to 0.53 (A36) with a mean of 0.29, whereas the effectiveness index ranges from 0.18 (A48) to 1.00 (A04, A16) with a mean of 0.62. Also in this case it is possible to identify four areas on the basis of the average values of the two indices (Figure 9). The top left quadrant contains suppliers that adopt effective, but inefficient, KM-Practices. This is the *area of inefficiency* for KM-Practices. 8 out of the 61 suppliers are located in this area.
The bottom left quadrant contains suppliers with inefficient and ineffective KM-Practices. This is the *area of inefficiency and ineffectiveness*. 20 out of 61 suppliers are located in this area. The bottom right quadrant contains suppliers that adopt KM-Practices with a high degree of efficiency, but a low degree of effectiveness. This is the *area of ineffectiveness*. 8 out of 61 suppliers are located in this area.
Lastly, in the top right quadrant we find suppliers with both efficient and effective KM-Practices. This is the *area of efficiency and effectiveness*. 25 out of the 61 suppliers are located in this area.

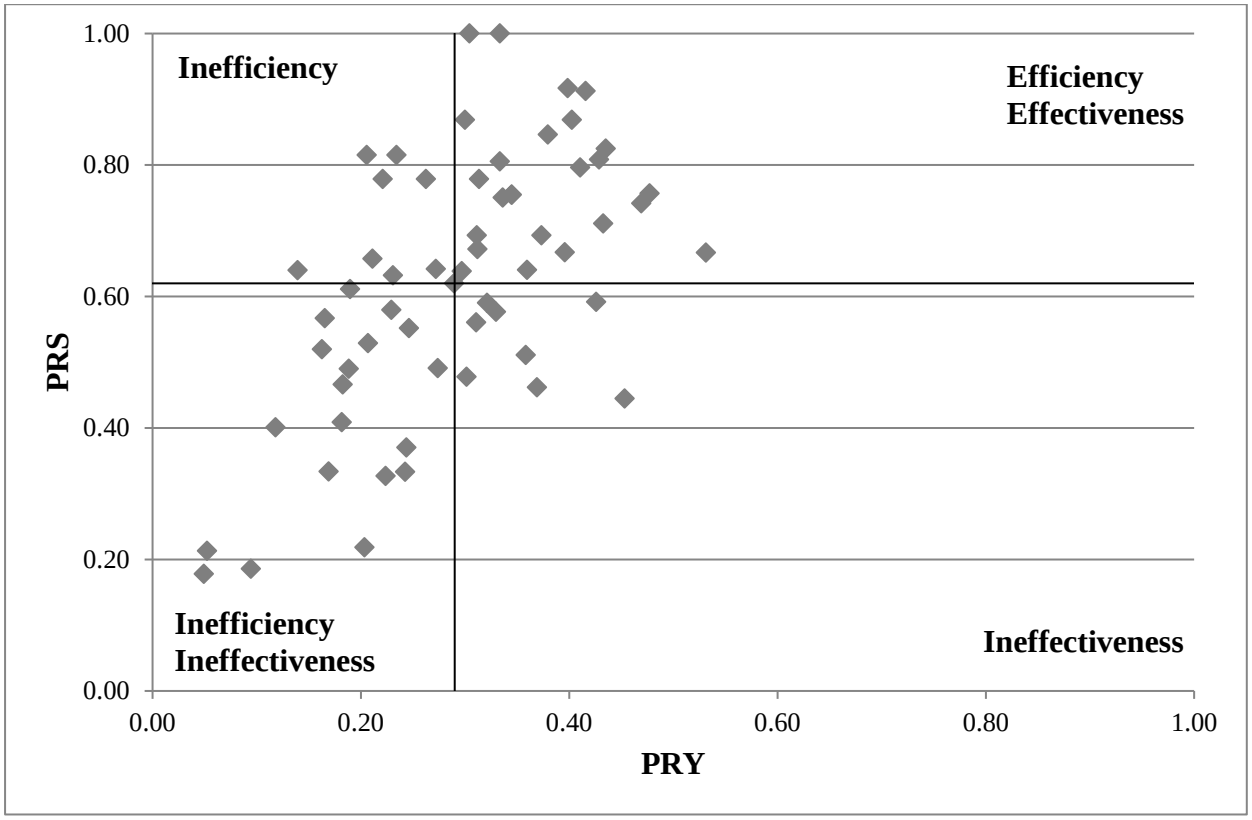

Figure 9. The relationship between PRY and PRS

Moreover, comparing the area of efficiency and effectiveness of KM-Tools (21 suppliers) and KM-Practices (25 suppliers) emerges that only 11 out of 61 suppliers are efficient and effective

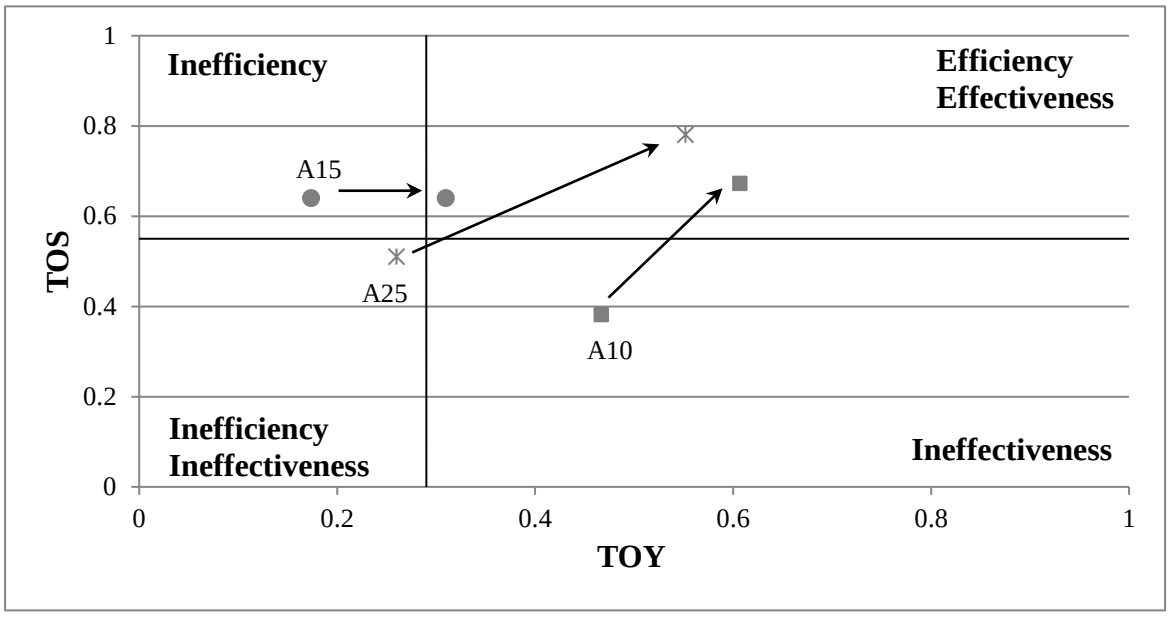
for both KM-Tools and KM-Practices.
Given this scenario, Figure 8 and Figure 9 reveal operative taxonomies which may be used to identify the specific strengths and weaknesses of an individual supplier and to suggest appropriate changes to improve the degree of efficiency and effectiveness of KMSs in relation to its knowledge (Figure 10a and Figure 10b).

As for KM-Tools, Figure 10a shows that supplier A15 is located in the *area of inefficiency* (top left area) and has a low percentage of KM-Tools intersecting with the supplier's knowledge, but a high percentage of knowledge covered by appropriate KM-Tools (TOY=0.17; TOS=0.64). This means that this supplier uses KM-Tools that are not aligned with the supplier's knowledge. This supplier could improve its position and shift towards the *area of efficiency and effectiveness* (top right area), thus increasing the degree of efficiency. This may be achieved by reducing the KM-Tools that do not cover the supplier's knowledge, e.g. *Cloud Computing, Peer-to-Peer Resource Sharing, Audio and Video conference* and *Content Management System* (TOY=0.31; TOS=0.64).

Supplier A10, situated in the *area of ineffectiveness* (bottom right area in Figure 10a) has a high percentage of KM-Tools intersecting with the supplier's knowledge, but a low percentage of its knowledge is covered by appropriate KM-Tools (TOY=0.47; TOS=0.38). This supplier should improve its position by shifting towards the *area of efficiency and effectiveness* (top right area), significantly increasing the level of effectiveness by adopting even just one KM-Tool (*Cloud Computing*) to cover one of the supplier's knowledge macro-areas (TOY=0.61; TOS=0.67).

Suppliers located in *the area of inefficiency and ineffectiveness* (low-left area in Figure 10a) have a low percentage of KM-Tools intersecting with their knowledge, and a low percentage of knowledge is covered by appropriate KM-Tools. These suppliers should improve their position by shifting towards the *area of efficiency and effectiveness* (top right area), thus increasing both efficiency and effectiveness levels.
For example, supplier A25 is located in the area with inefficient and ineffective KM-Tools (TOY=0.26, TOS=0.51), so to shift towards the *area of efficiency and effectiveness* it would be necessary to introduce and, at the same time, exclude certain KM-Tools. More specifically, the supplier may consider adopting the *Business Process Management System*, a KM-Tool aligned with the nature of its knowledge rather than *Peer-to-Peer Resource Sharing, Audio and Video Conference*, *Document Management System*, and *Content Management System*, which do not cover the supplier's knowledge (TOY=0.55, TOS=0.78).
As for KM-Practices, Figure 10b shows that supplier A39 is located in the area of inefficiency (top left area) (PRY=0.22; PRS=0.78). To improve its effectiveness, it has to consider that some of its KM-Practices (i.e. *Knowledge Filtering, Benchmarking, Knowledge Mapping,* and *Communities of Practices*) are not suitable to cover the nature of its knowledge. Excluding these practices will therefore improve this supplier's efficiency and effectiveness indices (PRY=0.40; PRS=0.78).
Supplier A43 (bottom right area in Figure 10b) is located in the area of ineffectiveness (PRY=0.36; PRS=0.51) and it should adopt additional KM-Practices (such as *Lesson Learned* and *Balance Scorecard*) based on the nature of its knowledge in order to improve its effectiveness (PRY=0.47; PRS=0.81).

(a)



(b)

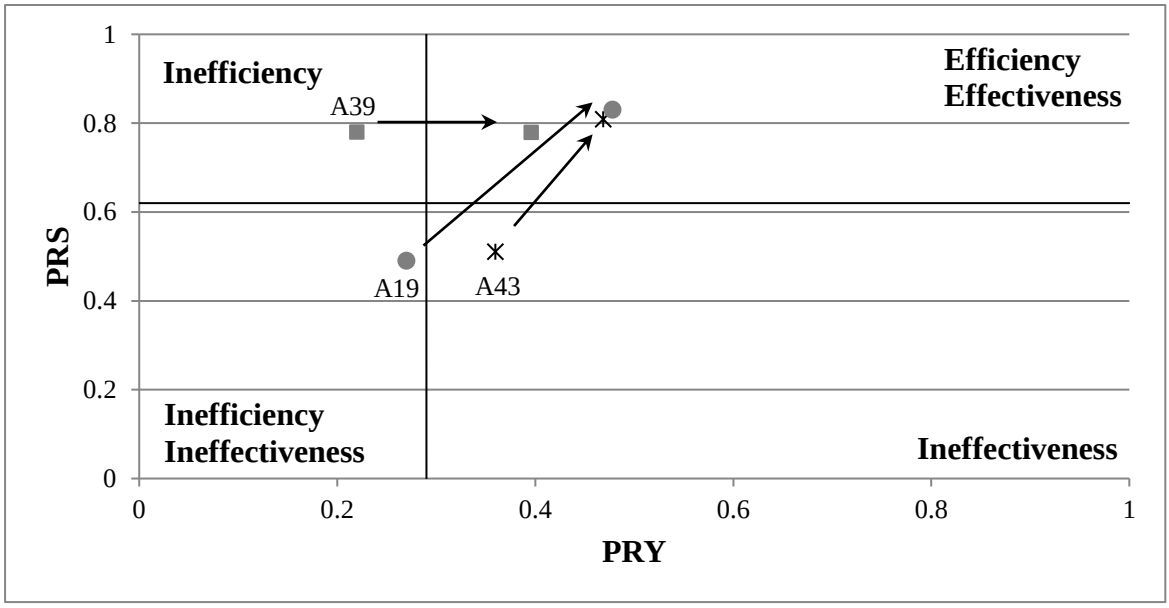


Figure 10. Taxonomy of the efficiency and effectiveness of KM-Tools in relation to a supplier's knowledge (a) and KM-Practices in relation to a supplier's knowledge (b)

The last condition to investigate is that of the suppliers located in the bottom left area in Figure 10b. These adopt inefficient and ineffective KM-Practices. By way of example, the supplier labelled A19 (PRY=0.27; PRS=0.49) should consider abandoning some of its KM-Practices (*Meeting/Task Force* and *Communities of Practice*) and implementing some different ones (*Best Practice, Lesson Learned* and *Balance Scorecard*), better able to cover its knowledge and lead to

improved efficiency and, at the same time, effectiveness (PRY=0.48; PRS=0.83).

5. Conclusions and implications

In this paper, a methodology based on 3D fuzzy logic has been proposed to answer our research question assessing the level of efficiency and effectiveness of KMSs in relation to the supplier's knowledge.
In this paper the knowledge management systems identified were divided into two groups: knowledge management practices (KM-Practices), namely methods and techniques to support the processes of knowledge management, and knowledge management tools (KM-Tools), i.e. the specific IT-based systems supporting KM methods and techniques.
Two pairs of indices are proposed in order to identify the level of efficiency and effectiveness of knowledge management systems in relation to a supplier's knowledge. The first pair of indices assesses the degree of efficiency and the degree of effectiveness of KM-Tools. The second measures the degrees of efficiency and effectiveness of KM-Practices.
Starting from these indices of efficiency and effectiveness, a taxonomy able to encompass the possible typologies of suppliers was established. Specifically, four typologies of suppliers were identified: efficient and effective suppliers, inefficient suppliers, ineffective suppliers, and inefficient and ineffective suppliers.
The proposed methodology was implemented in a field analysis based on semi-structured face-to-face interviews that involved a sample of sixty-one suppliers operating as suppliers in high-tech and/or complex industries.

Implications
Starting from these conclusions, it is possible to outline some managerial and policy implications. Firstly, the paper shows that only 18% of surveyed suppliers (11 out of 61) are completely in the area of efficiency and effectiveness for both KM-Tools and KM-Practices. 82% of surveyed suppliers are inefficient and/or ineffective for at least one of the two components of KMSs (KM-Tools or KM-Practices).
Secondly, the paper evidences that suppliers adopt a large variety of KM-Tools and KM-Practices to support the process of knowledge management. It seems to be of less concern that suppliers have scarce human and financial resources to invest in the area of knowledge management. This could be the result of the process of innovation in the field of information and communication technologies (ICTs) that are increasingly offering suppliers new low-cost opportunities (not requiring significant financial investments) and ease-of-use (needing no specific skills). But if the human and financial barriers that hinder suppliers in improving the process of KM are weakened, what then is the problem? The results of this paper suggest that the problem lies in the misalignment of the supplier's knowledge with the KMSs adopted. In the end, the problem does not lie in difficulties in investing in human and financial resources, but in the ability to invest in the specific KMSs better able to support the KM process.
From this point of view, the methodology proposed in this paper offers an operative tool that may be used by both suppliers and policy makers to support the decision-making aimed to suggest changes able to increase the efficiency and effectiveness of a supplier supporting its knowledge management process.
Finally, the proposed methodology provides an operational tool for both suppliers and policy makers.
Concerning the suppliers themselves, the proposed methodology may be used as a decision-

making tool to suggest suitable changes in the adoption of KM-Tools and KM-Practices in order to increase the level of alignment with knowledge and thus improve the process of knowledge management.
For policy makers, however, the methodology proposed here may be of help in identifying the weaknesses of the suppliers and identifying specific policies to support the competitiveness of supply systems by improving their management processes and the circulation of knowledge among suppliers.

The spread of environmental sustainability in logistics service providers: A cross-country investigation in Europe

Abstract

This paper provides an overview on emerging green practices and technological systems adopted by logistics service providers (LSPs). On the basis of a literature review on the topic, two research questions were identified and addressed through a literature review on the topic and a cross-country analysis conducted in a sample of 402 Italian LSPs, 304 British LSPs, and 295 German LSPs. The first research question regards a taxonomy of green practices and technological systems that could be adopted by LSPs. The second research question concerns the degree of adoption of green practices and technological systems.

Keywords - cross-country analysis; logistics service industry; sustainable supply chain

Introduction

In the last few years, there was an increasing number of papers dealing with the topic of environmental sustainability in logistics industry (Seuring and Müller, 2008; Vachon and Klassen, 2008) due to the growing number of environmental requirements established by the climate change agreements (Kyoto Protocol, 1998; Copenhagen Accord, 2009; Doha Amendment, 2012; Paris Agreement, 2015). Nevertheless, this literature focuses mainly on green initiatives adopted by large manufacturing firms (Dao et al., 2011; Park et al., 2010; Ranganathan et al., 2011; Wang et al., 2015; Whinkler, 2011), whereas in the field of logistics service providers (LSPs) there is not yet a structured framework (Centobelli et al., 2017; Maas et al., 2012; Zailani et al. 2011). This issue is crucial since the adoption of green initiatives by LSPs could play a pivotal role towards the achievement of environmental sustainability strategies affecting the entire supply chain. In addition, in the literature there is not a shared definition of green initiatives, but there is a variety of definitions that converges into two main definitions according to an organisational and a technological perspective: 1) green practices to achieve the green aims through organisational methods or techniques (Lieb and Lieb, 2010; Perotti et al., 2012; Pieters et al., 2012); 2) technological systems supporting the green practices (Iacob et al., 2013; Kang et al., 2013; Loebbecke and Powell, 1998).

The literature on the topic identifies specific green practices to support the adoption of environmental sustainability strategies and achieve the green aims (e.g. alternative fuels, alternative vehicles, alternative transportation modes) and proposes specific technological systems to support the green practices (e.g. GPS applications, warehouse management systems, environmental database systems, expert systems). Nevertheless, the literature does not offer an exhaustive framework of the whole set of green initiatives including comprehensively the emerging green practices and the emerging technological systems that could be adopted by LSPs. In addition, the literature deals with green initiatives adopted by LSPs, but not focuses on LSPs that adopt green initiatives. This means that from the literature does not emerge the perspective of individual LSPs. In other words, the literature does not show out the degree of adoption of green initiatives by the individual logistics service provider. Furthermore, it does not emerge if there is a relationship between the diffusion of green practices and the adoption of technological systems by LSPs. These topic areas are particularly important as logistics service providers are not entities without an own strategy to deal with the environmental sustainability.

This literature gaps are also heightened by the scarcity of empirical papers on the topic. Starting from these gaps our paper identifies two research questions (RQs) regarding: (1) the

proposal of a taxonomy of emerging green initiatives that could be adopted by LSPs and (2) the relationship between the degree of adoption of green practices and technological systems adopted by European LSPs. The proposed RQs are addressed through a cross-country analysis conducted in a sample of 402 Italian LSPs, 304 British LSPs, and 295 German LSPs.
The paper is structured in six sections. After the introduction, in the second section the framework is described. The methodology is analysed in the third section. In the fourth section the context of investigation is presented. The main findings of field analysis are illustrated in the fifth section. Finally, conclusions and implications are discussed in the sixth section.

Framework

Starting from the different definitions of green initiatives analysed in the introduction (Iacob et al., 2013; Kang et al., 2013; Lieb and Lieb, 2010; Maas et al., 2012; Perotti et al., 2012; Pieters et al., 2012), Centobelli et al. (2017) proposed a novel definition of green initiative and developed a framework aimed to integrate the concepts of green aims towards the achievement of environmental sustainability strategies, green practices, namely the set of specific organisational techniques and methods to achieve the green aims, and technological systems, defined as the IT-based systems supporting green practices. Therefore, a green initiative may be defined as a set of aims (managerial perspective), green practices (organisational perspective) and technological systems (technological perspective) supporting LSPs to achieve their environmental sustainability strategies (Figure 1).
Starting from the proposed conceptualization, a literature review on the adoption of green initiatives in freight transportation and logistics service industry was conducted to provide a taxonomy of LSP green practices (Table 1) and a taxonomy of LSP technological systems (Table 2) supporting an LSP green aim.

As for LSP green practices, two main categories of practices have been identified in the body of literature, i.e. single-firm practices and supply chain practices. Furthermore, according to the specific service provided, single-firm practices are divided into four sub-categories: transport practices (alternative fuels, alternative transportation modes, alternative vehicles, eco-driving, empty running, full vehicle loading, routing techniques to minimise travel distances), warehousing practices (alternative energy sources, energy-efficient warehousing), logistics service practices (materials recycling and packaging recycling), and management practices (certification ISO 14001, employee training, environmental performance measurement and monitoring).

With regard to LSP supply chain practices, i.e. the set of green practices requiring the involvement of partners, they are all categorised into management practices. This last category includes both sharing practices (i.e., spreading information on the carbon footprint, spreading information on greenhouse gas goals) and collaboration practices (i.e., coordinated logistics and transportation programs, coordinated certification programs and green goals, collaboration with customers, collaboration with other LSPs).

To support the above-mentioned green practices, the literature identifies two main categories of LSP technological systems that can be adopted: single-firm systems and supply chain systems. This taxonomy (Table 2) presents a similar classification (i.e. single-firm systems,

supply chain systems) and the same service categories as the taxonomy used for LSP green practices: transport systems (emission control systems, GPS applications), warehousing systems (real-time locating systems, warehouse management systems), logistics service systems (logistics management systems, material management systems), and management systems (environmental database systems, environmental management systems, enterprise resource planning - ERP, expert systems, learning management systems, order management systems). All the systems regarding the supply chain are categorised into management systems and, also in this case, supply chain systems include sharing technologies (i.e., content management systems, environmental apps, mash-up, syndication system, and videocasting) as well as collaboration technologies (i.e., cloud computing, collaborative system, customer relationship management systems, email, P2P resource sharing, social media, wiki).
These two taxonomies presented above allow us to provide an answer to the *RQ1*. They also offer an overview of the set of green practices and technological systems supporting LSPs in the process of adoption of environmental sustainability towards the achievement of their green aims. Based on these taxonomies identified on the basis of the literature review, the following two sections highlight the methodological steps and the investigative context of the research process in order to provide an answer to the *RQ2*.

Methodology

A web-based document analysis methodology has been used to investigate the degree of adoption of green practices and technological systems in a sample of European LSPs.
The web-based document analysis was carried out from May 2015 until July 2017. As the web is becoming a critical tool for the dissemination of ES strategies (Coope, 2004; Guziana, 2011) there is a growing amount of research based on communication of environmental issues on the web (Eyun-Jung and Childers, 2006; Chaudhri and Wang, 2007; Greer and Moreland, 2007; Guimarães-Costa and Pe, 2008; Sones et al., 2009; Tagesson et al., 2009). The research conducted among the LSPs is based on a systematic approach. A comprehensive review and content analysis was carried out using the information available on the websites of the firms analysed. In order to have a more comprehensive picture of each individual LSP investigated, information from additional sources (e.g. LSP environmental reporting, industry reports, industry magazines) were collected and analysed. The websites and the complementary sources were analysed for the presence of information related to the environment included in the above-mentioned taxonomy, such as adopting a specific green practice (e.g. environmental performance measurement and monitoring, routing techniques to minimise travel distances) or a specific technological system (e.g. environmental management systems, real-time locating systems, emission control systems).
The web-based document analysis has been conducted through the following six steps:

1) *Document search* (Labuschagne, 2003; Zhang and Wildemuth, 2005), in which LSP websites and other relevant sources (e.g. LSP environmental reporting, industry reports, industry magazines) are identified using key words in various search engines, websites and databases
2) *Document selection* (Labuschagne, 2003; Zhang and Wildemuth, 2005), in which the materials of interest are selected in parallel by two researchers and collected in a document management systems including a folder for each LSP
3) *Manual analysis* (Hsieh and Shannon, 2005; Bowen, 2009), in which the two researchers have conducted the conventional analysis described by Hsieh and Shannon (2005) to analyse in-depth the materials of interest selected. In this phase a database has been created to identify for each firm a preliminary list of individual aims, practices and technological systems adopted.

4) *Computer-assisted analysis* (Laender et al., 2002; Zhang and Wildemuth, 2005), in which each material of interest is further analysed using NVivo[1] software to code frequency of keywords represented by the individual items included in the taxonomies identified in section 3 by cross-examining information using query functions for web mining and knowledge discovery.
5) *Confirmation analysis* (Angers and Machtmes, 2005; Bowen, 2009), in which the triangulated findings are confirmed and/or supplemented by an interview carried out by telephone or videoconference to ensure the reliability of results.
6) *Triangulation of findings* (Patton, 1990; Eisner, 1991; Angers and Machtmes, 2005; Bowen, 2009), in which the results provided by manual analysis (step 3), computer-assisted analysis (step 4), and confirmation analysis (step 5) are validated through cross verification.

Context of investigation

Starting from the methodological premises illustrated above, the empirical analysis was carried out on a sample of 1275 LSPs belonging to three different European countries (Germany, Italy, United Kingdom). The selected LSPs meet the following four criteria (Zhu et al., 2007; Colicchia et al., 2013): 1) micro-, small-, medium- or large-sized firms, with their headquarters, or at least a branch, in Germany, Italy or United Kingdom; 2) firms that operate in different supply chains; 3) samples of firms that represent the population of LSPs operating the country investigated; and 4) firms that communicate their environmental sustainability strategies to their stakeholders on their websites or on environmental reports.

Germany

In Germany, the analysis was carried out on a sample of 295 out of 798 LSPs listed in *Bundesvereinigung Logistik (BVL). BVL*, founded in 1978, involves companies and individuals from the worlds of industry, commerce, services and science who are actively involved in the business of logistics and supply chain management.
The sample mainly comprises medium and large enterprises (SMEs) as shown in table 3. For this table, the latest definition of SMEs proposed by the EU Commission is used (European Commission, 2005). Table 3 also highlights that 45.4% of LSPs has a core business in transport, 28.5% in value added logistics services, 11.9% in distribution, and 14.2% in warehousing.

Table 3. Breakdown of the German LSPs investigated

CONTEXT OF INVESTIGATION		Number of LSPs	%
Employee band	Micro (0-9)	25	8.5
	Small (10-49)	73	24.7
	Medium (50-249)	92	31.2
	Large (>250)	105	35.6
Industry	Transport	134	45.4
	Logistics Services	84	28.5
	Distribution	35	11.9
	Warehousing	42	14.2

Italy

The analysis has been conducted in a sample of 402 LSPs listed in *Confederazione Generale Italiana dei Trasporti e della Logistica (Confetra)*, the largest Italian association of firms operating in the logistics service and freight transportation industry. *Confetra*, founded in

[1] http://www.qsrinternational.com/products_nvivo.aspx

1946, currently comprises 544 LSPs and carry out a number of activities to support the associated firms. The analysis was carried out on a sample of 402 out of 544 LSPs listed in *Confetra* achieving a response rate of 73.9%. The sample mainly comprises small and medium enterprises (SMEs) as shown in table 4. Turnover varies from 9 to 1,500 million euros.

Table 4. Breakdown of the Italian LSPs investigated

CONTEXT OF INVESTIGATION		Number of LSPs	%
Employee band	Micro (0-9)	2	0.5
	Small (10-49)	138	34.2
	Medium (50-249)	207	51.6
	Large (>250)	55	13.7
Industry	Transport	216	53.6
	Logistics services	104	25.8
	Distribution	73	18.4
	Warehousing	9	2.2
Total		**402 LSPs**	

Table 4 highlights also that the majority of LSPs (53,6%) has a core business on transport, 25.8% on value added logistics services, 18.4% on distribution, and 2.2% on warehousing.

United Kingdom

In the United Kingdom, the survey analysis was carried out on a sample of 304 out of 578 LSPs listed in *British International Freight Association* (*BIFA)*, achieving a response rate of 52.6%. *BIFA* is the national association for UK-registered companies engaged in international movement of freight by all modes of transport, air, road, rail and sea. Table 5 highlights that 39.5% of LSPs has a core business in transport, 32.6% in value added logistics services, 17.8% in distribution, and 10.1% in warehousing.

Table 5. Breakdown of the British LSPs investigated

CONTEXT OF INVESTIGATION		Number of LSPs	%
Employee band	Micro (0-9)	44	14.5
	Small (10-49)	93	30.6
	Medium (50-249)	101	33.2
	Large (>250)	66	21.7
Industry	Transport	120	39.5
	Logistics Services	99	32.6
	Distribution	54	17.8
	Warehousing	31	10.1

On the basis of these contextual premises, the results of the empirical analysis will be presented in the next section.

Results

This section is divided into four parts and presents the main findings of the empirical analysis to identify the degree of adoption of green practices and technological systems by the European LSPs investigated. The first three parts analyse respectively the main results regarding the diffusion in Germany, Italy and UK. The fourth carries out a comparison among the different countries.

Diffusion of LSP green practices and technological systems in Germany

The degree of adoption of green practices (technological systems) was defined as the number of LSPs adopting the specific green practice (technological system) divided by the total number LSPs of the sample (295). It shows the percentage of LSPs using a specific green practice (technological system). The degree of adoption ranges from zero, if no LSP uses the specific green practice (technological system) to 100, if all the LSPs use the specific green practice (technological system).

Analysing each of the categories reported in the proposed taxonomies of LSP green practices and technological systems (Table 1 and Table 2), the following three points summarise the main findings of this research in German LSPs:

1. regarding the typology of green initiative, i.e. single-firm initiatives vs supply chain initiatives, the number of logistics service providers adopting at least one of the single-firm practices or one of the single-firm technological systems (294) are always higher than those adopting at least one of the corresponding practices involving supply chain partners (205).
2. as for green practices vs technological systems results, the number of LSPs adopting at least one single-firm practice/supply chain practice (285) is always lower than those adopting at least one of the corresponding single-firm technological systems/supply chain technological systems (295);
3. as for the different phases of the service (i.e. transport, warehousing, logistics services, and management), the difference between the number of LSPs adopting at least one green practice from each category and those adopting the entire set of green practices (285) is always lower than the difference between the number of LSPs adopting at least one and those adopting all technological systems (295).

Diffusion of LSP green practices and technological systems in Italy

As for the degree of adoption of green practices and technological systems in Italian LSPs, the following points summarise the main findings the main findings of this research:

1. regarding the typology of LSP green initiative, i.e. single-firm initiatives vs supply chain initiatives, the number of logistics service providers adopting at least one of the single-firm green practices or one of the single-firm technological systems (367 LSPs) are always lower than those adopting at least one of the corresponding practices or systems involving supply chain partners (399 LSPs);
2. as for green practices vs technological systems results, the number of LSPs adopting at least one single-firm practice/supply chain practice (284) is always lower than those adopting at least one of the corresponding single-firm technological systems/supply chain technological systems (401).
3. as for the different phases of the service (i.e. transport, warehousing, logistics services, and management), the difference between the number of LSPs adopting at least one green practice from each category and those adopting the entire set of green practices (283) is always lower than the difference between the number of LSPs adopting at least one and those adopting all technological systems (401).

Diffusion of LSP green practices and technological systems in United Kingdom

Concerning the degree of adoption of green practices and technological systems adopted by LSP operating in UK, the following three points summarise the main findings:

1. regarding the typology of green initiative, the number of logistics service providers adopting at least one of the single-firm practices or one of the single-firm technological systems (289) are always higher than those adopting at least one of the corresponding practices involving supply chain partners (192).

2. as for green practices vs technological systems results, the number of LSPs adopting at least one single-firm practice/supply chain practice (295) is always lower than those adopting at least one of the corresponding single-firm technological systems/supply chain technological systems (304).
3. as for the different phases of the service (i.e. transport, warehousing, logistics services, and management), the difference between the number of LSPs adopting at least one green practice from each category and those adopting the entire set of green practices (295) is always lower than the difference between the number of LSPs adopting at least one and those adopting all technological systems (304).

Cross-country analysis

This section aims to carry out a comparison between surveyed LSPs operating in Germany, Italy and United Kingdom concerning the degree of adoption of green practices and technological systems. This is subdivided into two parts. The first part deals with a cross-country analysis on green practices, the second part focuses on technological systems.

Green practices

This paragraph presents a comparison between LSPs operating in the three countries investigated concerning the degree of adoption of green practices.

Analysing the degree of adoption of single-firm green practices (Table 6), the following three points summarise the main findings:

- as for Germany, the most widely adopted practices are "routing techniques to minimise travel distances", "packaging recycling", "energy-efficient warehousing" and "materials recycling", whereas less adopted practices are "alternative transportation modes", "alternative vehicles" and "alternative fuels"; German LSPs presents the highest degree of adoption for 7 out of 14 single-firm green practices and never present the lowest degree of adoption for the mentioned practices;
- Italian LSPs present the highest degree of adoption for 2 out of 14 practices, i.e., "alternative transportation modes" and "alternative vehicles", whereas less adopted practices are "alternative fuels", "eco-driving", "alternative energy sources", "materials recycling", and "packaging recycle"; Italian LSPs present the lowest degree of adoption for 12 out of 14 single-firm green practices;
- with regard to the United Kingdom, the most widely adopted single-firm green practices are "materials recycling", "alternative fuels", "certification (ISO 14001)", whereas less adopted practices are "alternative transportation modes" and "alternative vehicles"; LSPs operating in the United Kingdom present the highest degree of adoption for 5 out of 14 single-firm practices (i.e., "alternative fuels", "alternative energy sources", "materials recycling", "certification ISO14001", "environmental performance measurement and monitoring") and the lowest degree of adoption for only 2 practices (i.e., "alternative transportation modes", "alternative vehicles").

Table 6. Comparison concerning the degree of adoption of single-firm green practices

Single-firm green practice	Germany	Italy	UK	Country with the highest %
Alternative fuels	17%	5%	30%	**UK**
Alternative transportation modes	13%	29%	4%	**Italy**
Alternative vehicles	16%	18%	6%	**Italy**
Eco-driving	30%	5%	15%	**Germany**
Empty running	48%	12%	29%	**Germany**
Full vehicle loading	22%	14%	21%	**Germany**
Routing techniques to minimise travel distances	48%	12%	34%	**Germany**
Alternative energy sources	23%	8%	28%	**UK**
Energy-efficient warehousing	34%	10%	20%	**Germany**
Materials recycling	34%	8%	37%	**UK**

Packaging recycling	41%	8%	36%	**Germany**
Certification (ISO 14001)	29%	23%	30%	**UK**
Employee training	28%	13%	14%	**Germany**
Environmental performance measurement and monitoring	24%	12%	29%	**UK**
Mean	29%	13%	24%	
Coefficient of variation	38%	54%	45%	

Concerning supply chain green practices, table 7 shows the following main findings:

- as for Germany, the most widely adopted practices are "collaboration with customers", "coordinated logistics and transportation programs", and "spread of information on carbon footprint", whereas less adopted practices are "coordinated certification programs and green goals" and "spread of information on greenhouse goals". German LSPs presents the highest degree of adoption for 4 out of 6 supply chain green practices and never present the lowest degree of adoption for the mentioned practices;
- considering Italy, the most adopted practice concerns the "spread of information on greenhouse goals", whereas less adopted practices are "spread of information on carbon footprint", "coordinated logistics and transportation programs", "collaboration with customers". Italian LSPs present the highest degree of adoption for 1out of 6 supply chain practices and 5 out of 6 present the lowest degree of adoption.
- with regard to the United Kingdom, the most widely adopted supply chain practices are "collaboration with customers", "coordinated logistics and transportation programs", "spread of information on carbon footprint", and "coordinated certification programs and green goals", whereas less adopted practices are "collaboration with other LSPs" and "spread of information on greenhouse goals"; LSPs operating in the United Kingdom present the highest degree of adoption for 1 out of 6 supply chain green practices (i.e., "coordinated certification programs and green goals") and the lowest degree of adoption for 2 practices (i.e., "collaboration with other LSPs", "spread of information on greenhouse goals").

Table 7. Comparison concerning the degree of adoption of supply chain green practices

Supply chain green practice	Germany	Italy	UK	Country with the highest %
Coordinated logistics and transportation programs	29%	8%	20%	**Germany**
Coordinated certification programs and green goals	11%	9%	13%	**UK**
Spread of information on carbon footprint	25%	7%	16%	**Germany**
Collaboration with customers	32%	8%	23%	**Germany**
Collaboration with other LSPs	16%	10%	10%	**Germany**
Spread of information on greenhouse goals	14%	16%	10%	**Italy**
Mean	21%	10%	15%	
Coefficient of variation	41%	34%	35%	

Therefore, these findings highlight that the European LSPs investigated tend to plan their environmental sustainability strategies without setting in an integrated manner the green practices related to the different typologies of service provided. A focus strategy of LSPs investigated in adopting specific green practices emerges. In fact, apart from a few LSPs, the majority tend to assume a fairly homogeneous behaviour and use a small range of green practices in the different phases of the service. Single-firm green practices are on average more adopted than supply chain green practices (Table 8). Concerning Italy, the green practices with the highest degree of adoption support the phase of management, while the

practices with the lowest degree of adoption support the phases of warehousing and logistics services. On the contrary, as regards the spread in the United Kingdom, the green practices with the highest degree of adoption support logistics services, while the green practices with the lowest percentage support the phase of transport. Finally, the green practices most adopted by German firms support mainly the logistics services provided, while the green practices with the lowest degree of adoption support the phases of transport and management.
In addition, the results of this paper concerning supply chain green practices highlight a fairly homogeneous behaviour of British, German and Italian LSPs. These firms tend to adopt collaborative supply chain practices (e.g., coordinated logistics and transportation programs, collaboration with customers) instead of sharing supply chain practices (e.g., spread of information on carbon footprint, spread of information on greenhouse gas goals);

Table 8. Average percentage of green practices by phase of service

Single-firm green practice	Germany	Italy	UK
Transport	28%	14%	20%
Warehousing	29%	9%	24%
Logistics services	38%	8%	37%
Management	27%	16%	24%

Supply chain green practice	Germany	Italy	UK
Sharing	20%	12%	13%
Collaboration	22%	9%	17%

Technological systems
This paragraph presents a comparison between LSPs operating in the three countries investigated concerning the degree of adoption of green practices.
Analysing the degree of adoption of single-firm technological systems, the following three points summarise the main findings (Table 9):

- as for Germany, the most widely adopted practices are “warehouse management systems”, “GPS applications”, “material management systems”, and “order management systems”, whereas less adopted practices are “expert systems”; Table 9 shows that German LSPs presents the highest degree of adoption for 3 out of 12 single-firm green technological systems and present the lowest degree of adoption only for 1 out of 12 technological systems;
- Italian LSPs present the highest degree of adoption for 2 out of 12 practices, i.e., “logistics management systems” and “emission control systems”, whereas less adopted practices are “learning management systems”, “environmental management systems”, and “real-time locating systems”; Italian LSPs present the lowest degree of adoption for 9 out of 12 single-firm technological systems;
- with regard to the United Kingdom, the most widely adopted single-firm green technological systems are “warehouse management systems”, “material management systems”, and “order management systems”; LSPs operating in the United Kingdom present the highest degree of adoption for 7 out of 12 single-firm technological systems (i.e., “real-time locating systems”, “warehouse management systems”, “material management systems”, “environmental database systems”, “ERP”, “expert systems”, “order management systems) and the lowest degree of adoption for 2 technological systems (i.e., “emission control systems”, “logistics management systems”).

Table 9. Comparison concerning the degree of adoption of single-firm technological systems

Single-firm technological system	Germany	Italy	UK	Country with the highest %

Emission control systems	19%	32%	13%	**Italy**
GPS applications	49%	36%	38%	**Germany**
Real-time locating systems	20%	14%	37%	**UK**
Warehouse management systems	56%	42%	62%	**UK**
Logistics management systems	40%	41%	28%	**Italy**
Material management systems	45%	40%	57%	**UK**
Environmental database systems	17%	16%	18%	**UK**
Environmental management systems	23%	5%	14%	**Germany**
ERP	18%	16%	20%	**UK**
Expert systems	12%	16%	17%	**UK**
Learning management systems	12%	4%	9%	**Germany**
Order management systems	41%	23%	47%	**UK**
Mean	29%	24%	30%	
Coefficient of variation	53%	59%	60%	

Regarding supply chain green practices, Table 10 shows the following main findings:

- as for Germany, the most widely adopted technological systems are "email", "social media", "mash-up", whereas less adopted practices are "syndication systems" and "cloud computing". German LSPs presents the highest degree of adoption for 5 out of 12 supply chain technological systems and present the lowest degree of adoption 3 out of 12 systems (i.e., "syndication systems", "collaborative systems", "customer relationship management systems");
- considering Italy, the most adopted technologies are "email" and "customer relationship management systems", whereas less adopted systems are "cloud computing", environmental apps", "syndication systems", and "wiki". Italian LSPs present the highest degree of adoption for 2 out of 12 supply chain technological systems and 10 out of 12 present the lowest degree of adoption.
- LSPs operating in the United Kingdom present the lowest degree of adoption for 1 out of 6 supply chain green technological systems and the highest degree of adoption for 7 out of 12 technological systems (i.e., cloud computing, "collaborative systems", "content management systems", "mash-up", "social media", "syndication systems", "videocasting").

Table 10. Comparison concerning the degree of adoption of supply chain technological systems

Supply chain technological system	Germany	Italy	UK	Country with the highest %
Cloud computing	10%	2%	15%	**UK**
Collaborative systems	16%	19%	19%	**Italy, UK**
Content management systems	53%	41%	53%	**Germany, UK**
Customer relationship management systems	24%	53%	32%	**Italy**
Email	99%	95%	95%	**Germany**
Environmental apps	15%	7%	11%	**Germany**
Mash-up	75%	64%	85%	**UK**
P2P resource sharing	70%	63%	65%	**Germany**
Social media	82%	33%	92%	**UK**
Syndication systems	7%	7%	10%	**UK**
Videocasting	26%	19%	35%	**UK**
Wiki	13%	7%	10%	**Germany**
Mean	41%	34%	44%	
Coefficient of variation	81%	86%	77%	

These results emphasize that LSPs are not a homogeneous world that makes the same choices without distinction and adopts the same technological solutions, but they tend to adopt a differentiation strategy characterized by a combination of variety of experiences, approaches

and behaviours to support their green practices in order to achieve their green aims. Single-firm technological systems are on average less adopted than supply chain technological systems (Table 11). Concerning the three European countries investigated, the green practices with the highest degree of adoption support the logistics services provided for German and Italian LSPs, and the phase of warehousing for British LSPs. The technological systems with the lowest degree of adoption support the phase of management for British, German and Italian LSPs. As regards the spread of supply chain technological systems, British, German and Italian LSPs tend to assume a fairly homogeneous behaviour and tend to adopt collaborative supply chain technological systems (e.g., customer relationship management systems, P2P resource sharing) instead of sharing supply chain technological systems (e.g., content management systems, environmental apps, syndication systems).

Table 11. Average percentage of technological systems by phase of service

Single-firm technological system	Germany	Italy	UK
Transport	34%	34%	26%
Warehousing	38%	28%	50%
Logistics services	43%	41%	43%
Management	21%	13%	21%

Supply chain technological system	Germany	Italy	UK
Sharing	35%	28%	39%
Collaboration	45%	39%	47%

Moreover, the results of this paper highlight misalignment problems between the diffusion of green practices and technological systems. As for the misalignment between the adoption of a set of green practices and technological systems that are more focused on specific services (e.g. warehousing, logistics services), it underlines that LSPs do not have a not full understanding of their integrated role so as to be able to perform a variety of logistics service activities such as transportation, warehousing, management and other functional activities that constitute a complete service package. Firms providing such services typically have a good understanding of their customers' needs. Concerning the misalignment between the adoption of a set of technological systems higher than green practices, the findings show that LSPs nowadays are technologically prepared for the adoption of green strategies. In fact, logistics service providers already own technological systems before the adoption of ES programs, but they are adopted with other aims in view, and to manage other business processes. Not fully understanding their green initiative adoption processes and consequently how to achieve their green aims leveraging on green practices with the support of technological systems, logistics service providers tend not to exploit the potential of technological assets. Therefore, they are achieving their green goals with an unexploited potential and this is a cultural gap among LSPs.

The above misaligned problems also allow us to identify a managerial gap among LSPs. In fact, considering their role as integrators in the supply chain, they should continuously align not only single-firm initiatives and supply chain initiatives, but also green aims, green practices and technological systems during each of the different phases of the service provided. The results of the empirical analysis enable us to address the *RQ2*.

Conclusions and implications

The main aim of this paper is to contribute to increasing the body of knowledge concerning the diffusion of environmental sustainability in the logistics service industry and provide an answer to two research questions identified. The first concerns a comprehensive taxonomy of green practices and technological systems that could be adopted by LSPs to achieve their

green aims, and the second regards the degree of adoption of green practices and technological systems among European LSPs.

As for the first research question, we proposed a definition of green initiative as a concept which incorporates three different, but complementary perspectives: a managerial perspective (the green aim), an organizational perspective (the green practice), and a technological perspective (the technological system). The green aims are objectives leading to environmental sustainability strategies (e.g. adoption of recycled materials, reduction of oil and other fuels). The green practices are defined as the techniques or organisational methods implemented to achieve the aims (e.g. alternative fuels, alternative vehicles, alternative transportation modes). Finally, technological systems are the specific technologies supporting green practices (e.g. ICTs such as emission control systems, GPS applications, real-time locating systems). Starting from this conceptualization, a literature review on the adoption of green initiatives in freight transportation and logistics service industry was conducted to provide a taxonomy of LSP green practices and a taxonomy of LSP technological systems supporting an LSP green aim. The proposed taxonomies of green practices and technological systems consists of two main types: single-firm practices/technological systems and supply chain practices/technological systems. In addition, in order to focus on the phase of the service affected by the green practice/technological system, single-firm practices/technological systems have been divided into four sub-categories (transport, warehousing, logistics service, management). The two taxonomies are complementary to the previous ones (Lieb and Lieb, 2010a; Pieters et al., 2012; Perotti et al., 2012; Colicchia at al., 2013), insofar as we define a green initiative as a multifaceted concept, and our framework analyses two perspectives at the same time: the typology of initiative and the phase of the service.

With regard to the second research question, a web-based document analysis methodology has been used to investigate the degree of adoption of the green practices and technological systems identified in the taxonomies. The analysis was carried out on a sample of 304 British LSPs, 402 Italian LSPs and 295 German LSPs. This methodology has been conducted through the following six main phases: 1) document search; 2) document selection; 3) manual analysis; 4) computer-assisted analysis; 5) confirmation analysis; and 6) triangulation of findings.

From the point of view of green practices, we found that European LSPs are generally inclined to adopt green practices because of immediate environmental and cost efficiency issues rather than an interest in environmental sustainability issues. Single-firm green practices are on average more adopted than supply chain green practices. Italian LSPs tend to adopt the green practices supporting the phase of management instead of the phases of warehousing and logistics services. On the contrary, British LSPs tend to adopt green practices supporting the logistics services provided, whereas the green practices with the lowest percentage support the phase of transport. German LSPs have a more homogeneous behaviour than the other countries and tend to adopt green practices supporting mainly the logistics services provided. Concerning supply chain green practices, the findings highlight a fairly homogeneous behaviour of British, German and Italian LSPs that adopt collaborative supply chain practices instead of sharing supply chain practices. In summary, the low level of diffusion of green practices shows that the logistics service providers investigated tend to underestimate the competitive potential of environmental sustainability. This aspect is reflected in the adoption of specific single green practice, highlighting the attempt by LSPs to combine management and environmental efficiency without a defined environmental sustainability strategy roadmap. These findings partially confirm, and partially modify, the conclusions of the multiple case study carried out by Colicchia et al. (2013). According to Colicchia et al. (2013) a growing interest has been observed in collaboration with both

customers and suppliers, though they evidence a dearth of effective collaborative actions to improve the environmental sustainability of the supply chain. Contrary to Colicchia et al. (2013), today's results highlight that LSPs have not adopted a large number of green practices. We can note another difference compared with previous results, such as the web survey carried out by Pieters et al. (2012) on 41 Dutch logistics services providers, as it emerges that the LSPs more sensitive to environmental sustainability tend to adopt innovative and optimizing internal green practices in addition to optimizing external green practices. Therefore, they do not seem unaware that cooperation with customers and other LSPs represents a critical and successful factor in achieving green aims.

The results on technological systems highlight that the technological scenario in which LSPs operate has changed in the space of a few years. Technological systems are more commonly adopted than green practices. In fact, in recent years, technology dynamics and innovation have reduced the weight of barriers hindering the adoption of technological systems in the manufacturing and service industries (Cerchione et al., 2015, 2016; Cimoli and Dosi, 1995; Dosi and Labini, 2007). In tune with this rapidly evolving scenario, LSPs keep abreast with technological developments and are able to perceive the strategic value of technological systems, adopting a variety of systems and web-based solutions.

The results of our research highlight that German LSPs have a more homogeneous behaviour than British and Italian LSPs in adopting single-firm technological systems. As for the spread of supply chain technological systems, British LSPs tend to assume a fairly homogeneous behaviour and tend to adopt collaborative supply chain technological systems rather than sharing supply chain technological systems. The findings also highlight that German and Italians LSPs. are more inclined to adopt sharing supply chain systems instead of collaborative supply chain systems. The technological systems with the highest degree of adoption support the logistics services provided for the LSPs operating for German and Italian LSPs and the phase of warehousing for German LSPs. More specifically, Italian LSPs are more inclined to adopt technological systems supporting the phase of logistics services (which is the phase of service with the highest percentage of adoption) than technological systems supporting the phase of management (which is the phase of service with the lowest percentage of adoption). As regards the United Kingdom, the LSPs surveyed are more inclined to adopt technological systems supporting the phase of warehousing (which is the phase of service with the highest percentage of adoption) than technological systems supporting the phase of management (which is the phase of service with the lowest percentage of adoption). German LSPs are more inclined to adopt technological systems supporting the phase of logistics services (which is the phase of service with the highest percentage of adoption) than technological systems supporting the phase of management (which is the phase of service with the lowest percentage of adoption).

Moreover, As regards the spread of supply chain technological systems, British, German and Italian LSPs tend to assume a fairly homogeneous behaviour and tend to adopt collaborative supply chain technological systems (e.g., customer relationship management systems, P2P resource sharing) instead of sharing supply chain technological systems (e.g., content management systems, environmental apps, syndication systems). In fact, although these latter are cheap and easy to use, they are still poorly suited to managing green practices.

This aspect is even more significant considering that LSPs are becoming third-party supply chain management providers (3PSCM), supplying value-added services connected with the production or procurement of goods to customers operating in different complex industries, and tend to adopt the most updated technological systems. The result is a technology gap between the LSP and the customer. To overcome this gap, logistics service providers should exploit the new opportunities provided by ICTs. Consequently, they should dedicate resources who can use the Internet to monitor the technological changes affecting other LSPs and the

evolution of environmental sustainability strategies employed by customers in order to systematically align their single-firm practices with supply chain practices and their single-firm technological systems with supply chain technological systems, as well as to disseminate their best environmental practices online. In summary, despite the clear signs of a focus strategy by the LSPs investigated in adopting green practices, the findings nevertheless emphasize that LSPs do not constitute a homogeneous world making the same choices and adopting the same technological solutions. In reality, they tend to adopt differentiation strategies marked by a combination of their various experiences, approaches and behaviours to support their green practices and achieve their green aims.

Future research and implications

The above conclusions suggest that further research on the topic is needed, and the proposed taxonomies could be applied by an individual LSP as a managerial tool to evaluate and improve the process of adoption of green practices and technological systems. The results of this paper highlight problems of misalignment between the diffusion of green practices and the technological systems used. With particular regard to misalignment between the green practices adopted and the technological systems more focused on specific phases of the service provided, it emerges that LSPs lack a full understanding of their integrated role in performing a variety of logistics service activities such as transportation, warehousing, management and other functional activities making up a total service package. Concerning the misalignment between the adoption of a set of high-level technological systems on the one hand, and the green practices adopted on the other, findings show that LSPs are technologically now well prepared for the possible adoption of green strategies. Logistics service providers already have the technological systems before adopting any environmental sustainability programs, as they are needed for other uses and to manage other business processes. As logistics services providers lack a full understanding of their green initiative adoption processes, they are also uncertain how they may achieve their green aims leveraging on green practices with the support of technological systems, so they tend not to exploit the potential of their existing technological assets. They are therefore achieving their green goals with an unexploited potential, and this represents a cultural gap among LSPs.

The above misalignments also reveal a managerial gap among LSPs. Given their integrating role along the supply chain, they ought to continuously align not only single-firm initiatives and supply chain initiatives, but also green aims, green practices and technological systems at each of the different phases of the service they provide.

The results of this research highlight some implications for further inquiry. A first issue is that the majority of green practices and technological systems present a low degree of adoption. This circumstance requires further and in-depth analysis to investigate the intensity of use of single green practices and technological systems adopted by LSPs. A second factor is that the LSPs surveyed seem to prefer not updated technological systems. This issue requires further and in-depth analysis of the degree of alignment between green practices and technological systems. There is also the need to investigate the alignment between the green practices and technological systems adopted by LSPs and those adopted by their customers. A third research implication concerns the necessity to identify a taxonomy of strategies for adopting green practices and technological systems by logistics service providers. This issue requires an in-depth analysis to verify whether the strategy used affects LSP performance.

From the LSPs' point of view, this paper highlights that they could follow up their environmental sustainability strategies better by exploiting the opportunities offered by the new technological systems (e.g. cloud computing, crowdsourcing systems, collaborative filtering). From the customer's point of view, LSPs may be contracted to perform a specific function or consolidate any number of activities required to satisfy the customer's needs.

Firms that provide such services should typically have a good understanding of their customer's needs and execute services in accordance with contractual documents. To address these needs, this paper stresses that it is necessary to encourage the creation of (even technology-based) direct channels of communication between LSPs and customers. In fact, in many cases LSPs are technologically capable of following their environmental sustainability strategies, and the degree of adoption of technological systems is higher than that of green practices. This means that logistics service providers have not learned their environmental and emerging sustainable practices from customers. In sum, LSPs are pursuing their green aims, but with a scarcity of green practices in contrast with the innovation potential represented by the support that their technological systems could give. Exploiting this innovation potential could allow LSPs to play a critical role in greening the supply chain.

(Work-in-progress paper)

Abstract

Extant servitization research generally adopts a provider perspective to examine what leads to the effective provision of offerings to satisfy customer needs. The lack of systematic empirical work adopting the perspective of buyers or the users of servitized offerings would suggest that various parameters of the buying decision are poorly understood. Whilst it is acknowledged that servitization entails different types of offerings, the literature does not adequately delineate the operational differences between offering types. We undertook a survey with 325 respondents to uncover the differences in customer needs (i.e., buyers and users), with respect to basic and advanced servitized offerings.

Keywords: servitization, competitive priorities, survey, customer perspective

Introduction

Servitization offers a 'new' means of competitiveness for many in Western economies (Baines et al., 2007; Raja et al., 2018). This has led to numerous scholars discussing the type of capabilities necessary for traditional manufacturing firms to compete in the provision of services and solutions (Gebauer et al., 2011; Sousa and da Silveira, 2017; Kindström et al., 2013). Tuli et al. (2007) pointed to the dominance of the manufacturer's perspective in the extant research, which is at odds with the definition of the concept that is to meet customers' needs. Thus, it is argued that customer factors must be taken into account for the effective delivery and support of servitized offerings (Tuli et al., 2007; Raja et al., 2013). Recent research has started to address the customer perspective, but this tends to ignore the granularity of those who *buy* and those who *use* servitized offerings (Kowalkowski, 2011). Thus, to date, little known about what leads to effective provision of different types of servitized offerings that, in turn, satisfies the needs within the customer organization.

For providers of servitized offerings, understanding customer needs and requirements is fundamental for achieving satisfaction and customer 'lock-in' (Lockett et al., 2011). To this end, the provider can develop capabilities and offerings that match those needs and requirements. Inevitably, this understanding can also impact the design and management of firm-level relationships that can further increase satisfaction (Johnson and Mena, 2008). For example, it is reasonable to expect that the higher the quality of the core product, the more satisfied the customer will be, while it is an almost ubiquitous finding that, in servitized contexts, inter-organisational relationships based on trust and high levels of information exchange are beneficial for both providers and customers (e.g. Karatzas et al., 2016).

However, should one assume that such empirical relationships between provider-specific variables, firm-level relationship dimensions, and customer satisfaction are common across all instances of product-service provision? In other words, are the effects of the various determinants of customer satisfaction the same, irrespective of the type of the customer? For example, customers of product-service offerings may vary in terms of their function; commonly, manufacturers interact with the customer's buying center in the early stages of the offering's life-cycle, but with the actual user when the product is in-service and requires ongoing support. In this regard, assuming that *buyer* and *user* needs differ, Kowalkowski (2011) and Michel et al. (2008) highlight the importance of understanding the perspectives of the different functions inside customer firms. In addition, customers may vary in terms of the offering they are provided with. This offering could range from a simple add-on maintenance agreement, to a sophisticated solution that contractually guarantees certain levels of performance or product availability (Smith et al., 2014). This difference in operational complexity and sophistication places differential weights on different customer needs, suggesting that it could exacerbate or attenuate the effect of the determinants of customer satisfaction.

The departure point of this work is the premise that different customer types place differential importance on the various aspects of the offering and its provider, i.e. they will have varying needs and wants. To this end, we investigate the effects of various buyer-supplier relationship dimensions (e.g. formalization, information exchange) and provider-specific variables (e.g. service orientation, responsiveness, innovation capability) on customer satisfaction with the product-service provider. But more importantly, we examine how these effects vary with the *level of sophistication* of the product-service offering (basic and advanced), and with the *role* of the customer of the offering (buyer versus user). In other words, this research *uncovers the moderating roles of offering type and customer role for customer satisfaction.*

The paper is structured as follows. The next section synthesizes the relevant literature, culminating with the development of two overarching hypotheses. The methodology is then briefly presented, followed by the results obtained to date. A short discussion to wrap up the implications of this work concludes the paper.

Research background

Competitive priorities and manufacturing strategy have been of interest within the Operations Management (OM) domain for nearly half a century (e.g. Skinner, 1969; Hayes and Wheelwright, 1984; Swamidass, 1986; Anderson et al., 1989). Typically, the competitive priorities for manufacturers are those associated with cost, quality, speed, delivery and flexibility (Adam and Swamidass, 1989; Leong et al., 1990). For servitization, it has been recognized that manufacturers ought to take a different approach to traditional operations (Johnson and Mena, 2008; Baines et al., 2009), with the consequence that the competitive priorities will be different (Raja et al., 2015).

Moreover, the majority of the extant studies do not adopt the customer perspective when trying to ascertain customer priorities, but rather a provider perspective. This is an oversight given that understanding customer requirements is core to operations strategy formulation (Womack et al., 1990; Baines et al., 2009). It is the customer perception that should inform the competitive priorities of a manufacturer. Whilst the competitive priorities for manufacturing—the domain of operations strategy research—are well discussed in the extant literature (e.g. Fine and Hax, 1985; Miller and Roth, 1994; Joshi et al., 2003), there is little consideration given as to what these may be for manufacturers deploying a strategy of

servitization. It is advocated within the servitization literature that we should seek to understand how customers value services (Vandermerwe, 1990; Baines et al., 2009) and to do so necessitates seeing value through the eyes of the customer (Brady et al., 2005; Raja et al., 2013). This then underscores the need to address this gap by identifying and understanding these priorities for servitized manufacturers.

The customer perspective

Lele and Karmarker (1983) in their early work recognized the need to understand customer expectations of goods and services, whereas others were slow off the mark in addressing the customer perspective. This included those in the marketing discipline, where the voice of the customer is normally of central importance (cf. Griffin and Hauser, 1993; Naumann and Giel, 1995; Tuli et al., 2007); much of the literature still adopted a provider perspective (Neu and Brown, 2005; Gebauer et al., 2011; Sjödin et al., 2016).

Manufacturers need to understand the key stakeholders in the customer organisations (Kowalkowski, 2011) and accordingly attend to their needs in an efficient manner. The decision as to whether to purchase maintenance and support services for product offerings is often determined by buyers and end-users (cf. Cohen and Whang, 1997; Kowalkowski, 2011). The key individuals involved in buying decisions are typically based in procurement, maintenance, supply chain, as well as plant managers; it is these people who decide which goods and services are acquired (cf. Stremersch et al., 2001; Narayandas, 2005). This is particularly the case larger organizations operating in industrial markets. User also play an important role in influencing buyers in their decision-making. It is their actual usage experience that influences and provides valuable input to those in the buying group. This leads to the first working hypothesis:

H1: Customer role (buyer and user) will moderate the effects of provider-specific and relationship-specific determinants of customer satisfaction

The offering types

In practice, manufacturers that offer a type of servitized offering tend to create the term in line with their own corporate strategy (e.g. Rolls- Royce's Total Care or Xerox's 'document management'). Hence, there exists a plethora of definitions, which has led some scholars to classify different types of offerings into categories. Scholars have generally classified offerings into two (Gebauer et al., 2005; Mathieu, 2001) or three categories (Baines et al., 2007; Mont, 2004). The classification proposed by Tukker (2004) describes different types of product/service combinations in terms of product-, use- and result-oriented services. Cusumano et al. (2014) proposed smoothing, adapting and substituting services to classify different offerings. Conversely, base, intermediate and advanced services were used to identify three broad categories by Baines and Lightfoot (2013).

These studies largely focus on the characteristics or the function of the offering itself to categorize offering types. It must be noted that, in practice, these categories are highly customized. Therefore, in terms of what services are included in one category does not necessarily mean that these cannot be included in another. These categorizations are mainly around the function of the offering whether it is sold as a 'product' or 'use' or 'result'. As such, these definitions focus on the offering rather than the provision process. However, servitized offerings are delivered over longer periods and involve different degrees of integration and co-creation between manufacturers, customers and the rest of the network. To this end, a value driven co-creation process classification based on 1) basic service and 2) advanced service offerings has been proposed (Gebauer et al., 2005; Sousa and da Silveira,

2017). Mathieu's (2001) earlier work which discusses product-oriented services (i.e., product installation, spare parts provision and, maintenance and repair service) and customer support services (i.e., advanced form, such as use and result-based).

In this study, we build on previous research (Mathieu, 2001; Sousa and da Silveira, 2017), by considering servitized offerings in two broad categories: 1) *basic services:* that is, product-oriented services, such as installing and maintaining "*basic product functionality in an efficient and effective manner for the customer",* and 2) *advanced services,* that is, those concerned with customer support services which entail "*working closely with customers to co-create value that goes beyond basic product functionality, involving the customer's actions in relation to the product and the adaptation of the product use to the customer's unique needs, usage situations, and behaviors*" (Sousa and da Silveira, 2017, p. 446). The extant literature however does not detail the differences between basic and advanced offerings in terms of buyer and user groups. This leads us to argue for the need for clarity between different types of offerings to identify operational and relational idiosyncrasies pertaining to the different customer needs (i.e., buyers and users) and requirements from basic and advanced servitized offerings. This leads us to the second general hypothesis:

H2: The type of offering (basic and advanced) will moderate the effects of provider-specific and relationship-specific determinants of customer satisfaction.

Research methodology

This research used a grounded quantitative approach to understand the nuances in factors that affect the customer satisfaction of buyers and users of basic and advanced servitized offerings. We argue that this approach is more fitting than making an epistemic leap to a path model due to the lack of work on the phenomena we focus on. Drawing from extant research (Gebauer et al., 2005; Tuli et al., 2007; Kowalkowski, 2011; Raja et al., 2013), we identified and synthesized customer priorities that were posited to affect customer satisfaction. These constructs included, for example, information exchange and formalisation of the relationship, and customer-focus and innovation capability of the provider. We adopted established scales to design a questionnaire, which was administered broadly to business customers of servitized firms. The research adopted and adapted a range of multi-item scales1, as illustrated in Table 1. For instance, for customer focus, a seven-item scale from Chen and Paulraj (2004) was adapted. Each scale used seven-point Likert scales, anchored by "strongly disagree" to "strongly agree". For innovation, a three-item scale from Krause et al. (2001) was adapted. This was tested using seven-point Likert scales, anchored by "strongly disagree" to "strongly agree".

The deployed survey yielded 320 usable responses. The survey was targeted towards individuals in customer organisations that purchase and use servitized offerings. 125 of the respondents were solely buyers within their organisation, 85 were users, while the remaining 110 respondents occupied both roles. In terms of offering types, 177 respondents identified their respective offering as basic, whereas 143 as advanced services. The analysis of the survey was conducted using R software. The first necessary step of the analysis was to assess the validity and reliability of the scales. To that end, exploratory and confirmatory factor analyses were conducted in turn, following established procedures. Various items needed to be deleted to ensure that factors where distinct; discriminant validity was satisfied when all squared correlations between constructs were lower than the Average Variance Extracted (AVE) of the constructs.

To test the hypotheses, moderated hierarchical regression analysis using OLS estimation was used. Two dummy variables were firstly constructed: 1) for customer role we grouped

[1] Instrument is available upon request

customers who were solely buyers with those that were both buyers *and* users, to separate them from *solely* users who have not had buyer experience; 2) for offering type, product-service offerings were classified into basic and advanced. Analysis started by including the various factors of interest and two dummy variables in a regression model with customer satisfaction as the response variable. The second step comprised the addition of interaction terms between the dummy variables and all determinants of satisfaction (i.e., two interaction terms per factor), to directly test the hypotheses. As a last step, marginal effects were calculated in order to compare the effect of the variables between the four groups (i.e., buyers of basic offerings, buyers of advanced offerings, users of basic offerings, users of advanced offerings).

Table 1. Satisfaction related customer priorities as indicated by the extant research

Identified Construct	Indicative Sources	Measurement Scale
Customer focus	Galbraith (2002); Miller et al. (2002); Tuli et al. (2007); Baines et al. (2009)	Chen and Paulraj (2004)

Analysis and Results

For parsimony, we are not able to report the full results of the regression (which are available upon request). Instead, Table 2 contains the results of the tests of significance for the interaction terms between the various predictors of interest, and the dummy variables denoting customer function (*user* versus *buyer*) and offering sophistication (*basic* versus *advanced*) that were included in the regression model. Customer satisfaction was the response variable. Statistical significance of an interaction term between a factor and a dummy variable would suggest that the effect of the respective factor varies between the two respective groups.

The results suggest that the effect of two variables (support systems and innovation capability of the provider) on customer satisfaction is statistically significantly different for customers who are *just users* of the offering versus customers who are *buyers* (that is, solely or buyers *and* users). Similarly, the effect of two variables (product quality and achieved cost savings) on customer satisfaction is statistically significantly different for customers of *advanced* versus customers of *basic* product-service offerings.

Table 2: Condensed results of significance testing for the interaction terms with customer satisfaction as the dependent variable

	. Qual.	. Range	Long-term Orient.	Formali-sation	Customer Focus	Info Exchange	Supp. Syst.	Innov.	Cost	Prev. Maint.
User (v. buyer)	--	--	--	--	--	--	**	*	--	--
Advanced (v. basic)	**	--	--	--	--	--	--	--	*	--

Note: Cells report the test for the statistical significance of the interaction term between the respective predictor and dummy variables.

**, * indicate statistical significance at 5% and 10% level, -- indicates that there is no difference between the two groups

To better demonstrate the implications of these results, it is worth directly comparing the total effects of the variables on the satisfaction of the four distinct groups of customers, in terms of both direction and strength. This was done by deriving the *marginal* effects of each variable, while controlling for the influence of the remaining variables. These are included in Table 3, and summarized in what follows, by taking each independent variable in turn.

Table 3: Marginal effects for the different groups of customers

	Qual.	Range	Long-term Orient.	Formali-sation	Customer Orient.	Info exchange	Supp. Syst.	Innov.	Cost	Prev. Maint.
Buyers of basic offerings	0.077	0.034	0.045	0.089	0.38***	0.12	-0.14**	0.18	0.29***	0.19**
Users of basic Offerings	-0.001	0.22*	0.23	-0.05	0.53***	0.14	0.045	-0.13	0.11	0.11
Buyers of advanced offerings	0.35***	-0.06	0.02	-0.05	0.41***	0.1	-0.05	0.07	0.08	0.23***
Users of advanced offerings	0.27	0.12	0.2	-0.18	0.56***	0.12	0.13*	-0.24	-0.09	0.15

Note: ***, **, * indicate statistical significance at the 1%, 5% and 10% level respectively

Quality is found to be significant for customers of advanced offerings, and particularly for *buyers* of these offerings, where the effect on satisfaction is very strong and positive (p-value < 0.01).

Product-service range is more important for *users*, and in particular for users of basic products. We suggest that this is because they have more leeway to customise the servitized offering of the provider (p-value < 0.1), while the offering is *in-use*.

No statistically significant effect of long-term orientation is detected; however, the sign and magnitude of the coefficients suggest that it is more important for users. This implies that users would like to see a continuity of the relationship with the manufacturer, as opposed to buyers who may be more oriented towards individual transactions. Moreover, this long-term

orientation, or lack thereof, may be a factor of the inherent short-term perspective of buyers who maybe focused on a short-term gain on costs rather than sustaining long-term relations.

No statistically significant effect of relationship formalisation is detected. However, the sign and magnitude of the coefficients suggests that the satisfaction of users of advanced offerings may be negatively affected if the provider maintains a strictly formal relationship with the customer. This suggests that more advanced offerings require the flexibility of an inter-organizational governance regime that meshes both formal and informal mechanisms.

The effect of customer orientation on satisfaction is always positive and strongly significant. Interestingly, this positive effect increases as we move from buyer to user and from basic to advanced offerings. This suggests that users may view themselves more as the customer, while advanced offerings require greater customer orientation to understand the nuances of the servitized offering in context.

Information exchange has a universally positive (but insignificant) effect. The insignificance of the effect could be justified due to its effect being confounded with the effect of other predictors (and in particular customer orientation, which reflects information exchange to some extent).

An interesting picture emerges for support systems. For buyers of basic offerings, the effect on satisfaction is negative and significant (p-value < 0.05). This may be because, for them, support systems could be a 'nuisance' leading to information overload, unnecessary effort and wasted time, since they are unlikely to see the benefits of these systems. Conversely, and reasonably enough, the effect is positive and significant (p-value < 0.1) for users of advanced offerings, who could be making use of these systems, and derive benefits out of them, on a day-to-day basis.

No significant effect of the provider's innovation capability on customer satisfaction is detected. However, buyers seem to see an innovative provider positively, as opposed to users who see it negatively. This suggests that users view innovation as a form of unwanted change, hindering them to get on with the standard service task at hand.

Cost savings affect positively and significantly (p-value < 0.01) the satisfaction of only buyers of basic offerings, supporting the idea that this type of customers are the ones who are more likely to consider the buyer-supplier exchange as a transaction that should produce measurable, short-term results.

Preventative maintenance has a universally positive effect on satisfaction. However, this effect is significant only for buyers, and very strong for buyers of advanced offerings. This may be because buyers could consider preventative maintenance as an important factor (or simply as a safeguard) to proceed to the product-service provision agreement.

Concluding summary

This research examined the differences in priorities of i) buyers, and ii) users of *basic* and *advanced* servitized offerings. The research used a more grounded, quantitative approach than typically seen when deploying an approach such as path modelling. By adopting this approach, we determined that there are distinct nuances between the four distinct groups of:

- buyer of basic offerings,
- user of basic offerings,
- buyer of advanced offerings, and
- user of advanced offerings.

Customer orientation was positively associated with customer satisfaction for all four groups. However, the customer satisfaction of only buyers of offerings, both basic and advanced, was positively influenced by preventive maintenance. Moreover, support systems negatively affected customer satisfaction for users of basic offerings, while users of advanced offerings were positively affected by it.

These results indicate that manufacturers need to acknowledge that there is no 'one size fits all' to delivering and supporting servitized offerings. Instead, they need to understand which priorities matter and how to best deliver them.

Abstract
This paper proposes an iterative model for the make or buy of procurement linked to organizational change management. Based on an in-depth, longitudinal, action-intervention case study of the procurement function at the French Railway company, a five-step model was developed that links the make or buy decision to organizational change. Both the outsourcing of procurement, as a strategic activity of the firm and the proposal of a model for the outsourcing process remain underexplored in the academic literature. This paper aims to contribute knowledge to how the key function of procurement can be successfully reorganized in a large firm as part of a change process.

Keywords: Make or buy; Outsourcing; Procurement; Organizational change management

Introduction

Outsourcing the procurement function might appear to be counter-rational, given that this department is a strategic part of any organization with responsibility for both the purchasing budget, representing between 50 and 90% of the cost of goods sold in industrial firms (Emiliani, 2010), and for setting up cooperative supplier relationships to enhance a firm's competitive stance. However, the drive for efficiency savings and the availability of specialist skills on the market in recent years have pushed firm boundaries further inwards to include core activities. A range of more strategic functions are now considered as candidates for outsourcing, including, for example, human resources (Belcourt, 2006; Norman, 2012) and R&D (Contractor et al., 2010; Martinez-Noya and Garcia–Canal, 2012).

The Resource Based View (RBV) (Barney, 1991) advocates that a firm's core activities should be developed and protected internally, while non-core activities can be more readily outsourced. Transaction Cost Economics (TCE) (Williamson, 1975; 1985) suggests that where both the asset specificity level of an activity is high, and the transaction costs involved in performing the activity externally are greater than the internal costs, then the activity should be retained in-house. From these theoretical perspectives, outsourcing the strategically important procurement function, which can be considered as both high human asset specificity and a core strategic activity, appears non-rational. Nonetheless, the focus of this study is on the restructuring of the procurement function, including its outsourcing, in a case study of the French national railway company.

Therefore, the research questions that this paper seeks to address are how can such a reorganization of the make or buy of procurement be explained and what is the appropriate process framework? Since there is a need to go beyond the TCE and RBV paradigms in trying

to understand rationale and processes, the theoretical net was cast wider to include organizational theory and endogenous factors. This study of the make or buy of procurement is based on organizational change management and in particular internal dynamics and interests that need to be taken into account alongside rational transactional considerations.

The originality of this research is that it is one of a small number of academic studies that focuses on an unusual area for outsourcing, namely the organizational function that is usually, itself, responsible for outsourcing. Against a theoretical background which acknowledges both rational and non-rational explanations to outsourcing, an action-intervention research programme (Rispal, 2002; Naslund et al., 2010) was carried out, in which the researcher actively participated in the preparation, scope, analysis and decision making process of a make or buy procurement project in the French national railway company. Based on this case study, we developed a process model for the review and reorganization of the procurement function in a large firm.

This paper begins with a review of the literature relating to outsourcing procurement, followed by consideration of TCE, RBV and supplementary theoretical perspectives. Having examined the literature relating to organizational change management and presented the methodology employed, the authors explain in detail the make or buy procurement model. This is followed by a discussion and conclusion.

Literature Review

Outsourcing procurement: a step too far?

Although a number of articles on the subject of outsourcing procurement can be found in trade and professional journals, there is a dearth in academic journals and in those that have been published, there are noticeable differences: ranging from the advantages of outsourcing procurement as a means of controlling costs (Olson, 2010) to warnings of the risks of losing control over supplier costs through loss of visibility (Parry et al., 2006). The initial problem is that procurement not only encompasses both strategic and tactical activities (the purchasing and sourcing of more or less essential supplies of goods and services), it is also a function that necessarily spans the boundaries of the firm through its links with the supplier base. As a strategic function it is the key organizational link between internal requirements and the external market. Chen and Paulraj (2004:121) emphasize the criticality of this linking function, in the following terms: “The buyer–supplier dyad […] is of paramount importance to the effective management of the supply chain”. Furthermore, one of the main constituents of an efficient real world social network (Borgatti and Li, 2009; Hearnshaw and Wilson, 2013) is a short characteristic path length (a small number of tiers or firms between any two nodes). This leads onto the question of whether outsourcing this function and placing an intermediary between buyer and supplier can be viewed as an outsourcing too far?

To respond to this question it is important to distinguish between strategic and tactical procurement. Brewer et al. (2013) studied outsourcing procurement as a logical further step after the outsourcing of manufacturing. They saw the growth of contract manufacturing (CM) not just as sign of a “temporary relief valve” but as a “strategic supply chain partner” (Brewer et al., 2013: 91). From this perspective, following manufacturing out of the door with procurement of basic inputs or tactical activities was found to be coherent. This study focused on the electronics industry, where contract manufacturing is highly developed and competent large sub-contractors exist. However, the researchers found that CM competence only influenced the outsourcing of tactical activities, suggesting that firms still view outsourcing strategic activities as a step too far or as vital “crown jewels” (Venkatesan, 1992).

Indeed Chraibi et al. (2017: 146), in their recent study of six large firms from different sectors, confirm the delicate nature of outsourcing the purchasing of strategic or core activities: "Our research also indicates that outsourcing strategic purchasing can be very risky and cannot be undertaken without the required maturity level and without fully prepared contract management." Brewer et al., (2014) reviewed the outsourcing procurement literature and found that extant published research on this subject was mainly exploratory and atheoretical. Their research is based on TCE and RBV theoretical perspectives, which these authors see as "the most concise lenses for examining the outsourcing decision" (Brewer et al., 2014: 187).

TCE and RBV perspectives

Researchers that have studied outsourcing from the TCE perspective (Walker and Weber, 1984; Poppo and Zenger, 1998; Osei-Bryson and Ngwenyama, 2006; Busi and McIvor, 2008; McIvor, 2009; Kirkman and Phillips, 2011; Nordigarden et al., 2014; Tjader et al., 2014), argue that firms can outsource when transaction costs are lower than production costs. Williamson (1975) identified three dimensions of transaction: operation frequency, uncertainty and, most crucially, asset specificity. Outsourcing highly specific assets may be critical (Quinn and Hilmer, 1994), as it can generate two capital dangers: the standardizing of transferred assets (Ang and Cummings, 1997) and hold-up (Klein et al., 1978). Williamson highlighted other dangers such as complexity, opportunism, uncertainty and information asymmetry, which result in outsourcing creating additional costs generally ignored in the decision-making phase. In addition, researchers pointed out other dangers like dependency (Kirkman and Phillips, 2011), competition from an external vendor which benefits from the firm's transferred knowledge (Kirkman and Phillips, 2011), cultural lag, loss of competencies and loss of control (Barthélemy and Quélin, 2006).

Transaction cost theory is based on two key assumptions: bounded rationality and opportunism. Williamson maintained that the potential costs engendered by bounded rationality and guarding against the risk of opportunistic behaviour are best mitigated through internalization: through hierarchical organizations which can manage and contain the uncertainties of the marketplace: "Agents who are skilled at dissembling realize transactional advantages. Economic man…is thus a more subtle and devious creature than the usual self-interest seeking assumption reveals" (Williamson, 1975; 255). Williamson posed the problem that daily economic life is riddled with mistrust and dishonesty and that the solutions are to be found in legal, financial, political and social institutions to provide order to the economic jungle. These institutions render malfeasance too costly to engage in. Williamson argued that where transactions are uncertain, frequent and require considerable investment, they will take place in-house, whereas those that are relatively simple, one-off and standard will be carried out in the marketplace: only where transaction costs are lower than the costs of carrying out the activity internally is outsourcing recommended. In effect, Williamson sees the authority-based relations inherent in corporate hierarchies as a means of controlling risk and taming the opportunistic behavior inherent in market transactions.

RBV is more recent than TCE but several researchers have relied on RBV to analyze the outsourcing question (Quin and Hilmer, 1994; McIvor, 2005; Di Serio et al., 2011; Nordigarden et al., 2014). They recommend that, while firms invest in resources that they believe can provide a competitive advantage, only "strategic" resources can give the advantage sought (Wernerfelt, 1984). The strategic character of resources is determined by indicators that differ depending on the adopted model (Amit and Schoemaker, 1993). While researchers recommend that strategic resources remain in-house, they also argue that the transfer of material resources is more easily achievable than the transfer of human resources, since, in the latter case, there is a risk of a loss of individual expertise to the organization. In general, from the RBV perspective, the outsourcing decision can be considered when the best external service providers are more

efficient than the internal service available (Teng et al. 1995). However, the core/non-core dichotomy remains the central plank of the RBV perspective and thus the researcher must return to the question of what is and what is not a core activity, where is the border between the two drawn and perhaps most importantly, by whom. In so doing a rationalist paradigm is brought into question by subjectivism.

TCE and RBV have provided a framework for understanding the outsourcing decision on the basis of rationality: such that where an activity is non-core and has low asset specificity, it can be outsourced. Therefore organizational objectives will include protecting core functions and outsourcing non-core in order to secure competitive advantage (Holcomb and Hitt, 2007). However the theoretical prisms of TCE and RBV are not the only frameworks for understanding the outsourcing process.

Supplementary theoretical perspectives

Recent research has taken a more critical view of understanding outsourcing on the basis of TCE and RBV. McIvor (2009) acknowledges that the complexities of outsourcing cannot be fully explained by TCE and RBV. Research has also shown that organizational politics and behaviour (Marshall et al., 2015) play an important role in outsourcing decision making and implementation processes. The qualitative research of Bidwell (2012: 1622) shows "the value of understanding make-or-buy decisions as an endogenous consequence of the structure in which those decisions take place, rather than as isolated decisions that are maximized regardless of their context". This research stream suggests that the notions of rational behavior inherent in TCE and RBV may be a necessary, but not sufficient, theoretical perspective for explaining outsourcing and that in particular; rational processes do not inevitably lead to successful outcomes. Therefore a move towards a multiple theoretical framework has begun that also makes reference to economics, strategy and organizational behavior (Ellram et al., 2008).

The outsourcing decision may be motivated by optimizing costs and improving flexibility (Kelly, 1995; Kirkman and Phillips, 2011; Di Serio et al., 2011), technological transfer and access to knowledge and expertise (Kirkman and Phillips, 2011). Other anticipated benefits from outsourcing include refocusing on the core business or improving product or service quality perceived by users of the external provider (Fimbel, 2003). Kumar et al (2010) pointed out the concept of time and external dimensions related to market analysis. McIvor (2000) highlighted the importance of the existing relationship with the external provider. Therefore, research shows that endogenous and exogenous, rational and non-rational factors drive the outsourcing process. In this research, we focus on organizational change as an important driver of the outsourcing procurement process.

Organizational change management

Theoretical perspectives on organizational change management begin with Lewin (1951), who suggested a three-step process of change: "unfreeze" which is to recognize the need for change; "move" which is to plan actions toward change; "refreeze" which is to maintain change. Bullock and Batten's (1985) change model is divided into four phases: exploration, planning, action and integration. Kotter (1995) suggested eight steps of change: establish a sense of urgency; form a powerful guiding coalition; create a vision; communicate the vision; empower others to act on the vision; plan for and create short-term wins; consolidate improvements and produce yet more change; institutionalize new approaches (Cameron and Green, 2009). More recently, Walsh and Renaud (2010) discussed five moments of change: perception of the need for change; identification of the resources involved and problematization; profit-sharing and alliances; roles distribution, engagement and mobilization of spokesmen. Prochaska and Clemente (1982) pointed out four stages of change: contemplation; determination; action and holding. In an extensive literature review, Hornstein (2015) emphasized the importance of the change process in project management. He found that the success of a project depends on the

success of the change management process and, furthermore, the importance of close collaboration between the project leader and the change leader.
Pinto (2005) developed a scheme for the combined management of a project cycle (launch, deployment and result) and change cycle (unfreeze, move and refreeze) (based on Lewin, 1951). Every step of the project cycle requires actions arising from the equivalent change steps. Thus, the launch and deployment steps meet an unfreeze phase induced by the organizational change. In this stage, it is recommended to communicate about the project to ensure good understanding and monitor its implementation. During the result phase of the project, it is recommended to ensure the alignment of results in response to movements, disturbances and variations induced by change. After the result phase, a stabilization phase of change sets in, during which it is recommended to measure results in order to evaluate the contribution of the project and draw relevant lessons.
Using the organizational change process of Lewin (1951) and the literature review, we developed a scheme that summarizes, in our view and in a simplified manner, the process of organizational change:

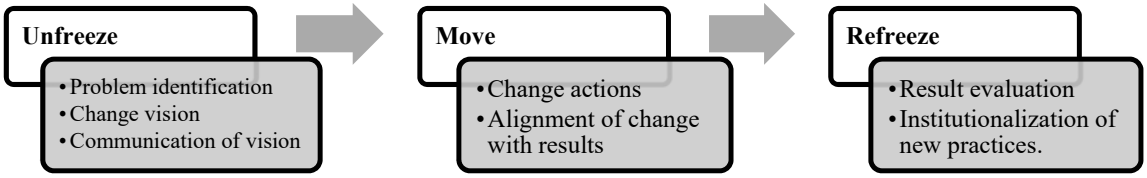

Figure 1: Organizational change management process (simplified version).

Methodology
The methodology followed is an in-depth, longitudinal case study, over a period of four years, based on action-intervention research (Naslund, 2002; Rispal 2002), given that this project involved both observation and involvement in an organizational change process.
The literature shows that the decision to outsource plays a key role in an outsourcing project. Outsourcing needs to be sufficiently considered and studied before any decision is taken. For Barthélemy and Quélin (2006) the decision to outsource needs to take into account the strategic perimeter, financial estimations, drawing up specifications and contracts. For Quèlin (2007) it begins with a risk analysis, a comparison of organisational options, an analysis of the outsourcing conditions, choice of the service provider and the type of relationship expected.
For the outsourcing of purchasing, we refer principally to Chraibi et al. (2017), which presents the seven stages, namely: analysis of purchasing core business, analysis of costs and performance, plan, service provider selection, negotiation, ensure smooth transition and finally, manage the relationship. The integration and involvement of the researcher in the early stages of this project, through observation, interviews and focus groups allowed her to note that the different steps recommended in the literature were not followed in their entirety. Instead an approach specific to the company was adopted, in response to its requirements, such as urgency, resource constraints and context. However lessons were drawn which added to the findings of the literature.

A make or buy procurement model
Marshall et al. (2005) have noted that, despite the abundance of articles on outsourcing, there is a lack of outsourcing process models. In response, they developed their own iterative model. In this research a connection is made between organizational change management and the make or buy decision involving procurement activities, with reference to the project/change cycle of Pinto (2005). Based on the literature review, presented earlier, we developed the following

three-step preliminary model, which was subsequently tested in the field and improved to apply to the operational make or buy context. It starts with the **Launch** step:
Once a problem is identified, the Purchasing management team studies the options and chooses a make or buy solution, which could be linked to a need for alignment with company strategy. Once a make or buy project has been launched, in depth objectives are set out and a project team created. Several configurations are possible, depending on the nature of the firm, the maturity of the purchasing function and expectations of make or buy.
Secondly the **Deployment** step: elaborate the action plan, risk analysis, strategic alignment with top management, analysis of internal and external procurement scope, costs and performance analysis, choice of either make or buy, communication about the choice, preparation for implementation with new structures, staff training and skills management. This step also includes the implementation of the make or buy solution, a transition phase and driving the make or buy of procurement activities (monitoring the project's deployment, management of the external vendors and incentive actions). Finally, we reach the **Results** step: results evaluation; corrective or/and holding actions; institutionalization of new practices; monitoring of the reversibility of the outsourcing program and benefiting from lessons learned.

Figure 2: Preliminary three-step process of make or buy (Simplified version).

The preliminary study based on interviews and focus groups with team leaders produced the model in figure 2. The researcher was an active participant in a project team composed of representatives from various procurement entities of a French Railway company (SNCF Réseau) – 12 people in a project team.
The case involved is one of the most ambitious, significant and complex outsourcing of procurement projects in Europe and therefore is of considerable value as a unique subject for study. Flyvberg has underlined the value of a single case, both for generalization and as example (2006; 228):

> "One can often generalize on the basis of a single case, and the case study may be central to scientific development via generalization as supplement or alternative to other methods. But formal generalization is overvalued as a source of scientific development, whereas "the force of example" is underestimated".

The driving force behind the project was the merger of two separate entities within SNCF. Each of these entities presented different procurement practices, in particular in relation to the situations in which external procurement expertise were sought. In one case a lack of internal specialists led to a regular demand for external services and in the other case, outside procurement firms were only solicited at times of peak activity or for particular missions. Consequently, the organization perceived the need to harmonize these two different approaches into a single coherent strategy through a change management project.
The data used is collected from internal documentation and discussion (Rapley, 2007), brainstorming, focus groups, observation (Flick, 2009), experiments and the contribution of the project team to research. The validation of our model is based on experiments, because our intervention is at the heart of the project and therefore proposals were adapted following discussions and observation of the evolution of different phenomena. The project team was composed of managers and responsible staff from several procurement entities, and was monitored periodically by the Purchasing Director, to check work progress and ensure the feasibility of work done.
Thus, we used this preliminary three-step process (Figure 2) in our fieldwork to test its validity and to make it more suitable operationally. For this purpose, we took into account the constraints and characteristics of the research field that had been observed and communicated

by the project team. As a result of these observations and discussions, our three-step make or buy process evolved into a more developed five-step model, presented below (Figure 3). For reasons of confidentiality the study results are not presented, only the methodology and process are developed in this article.

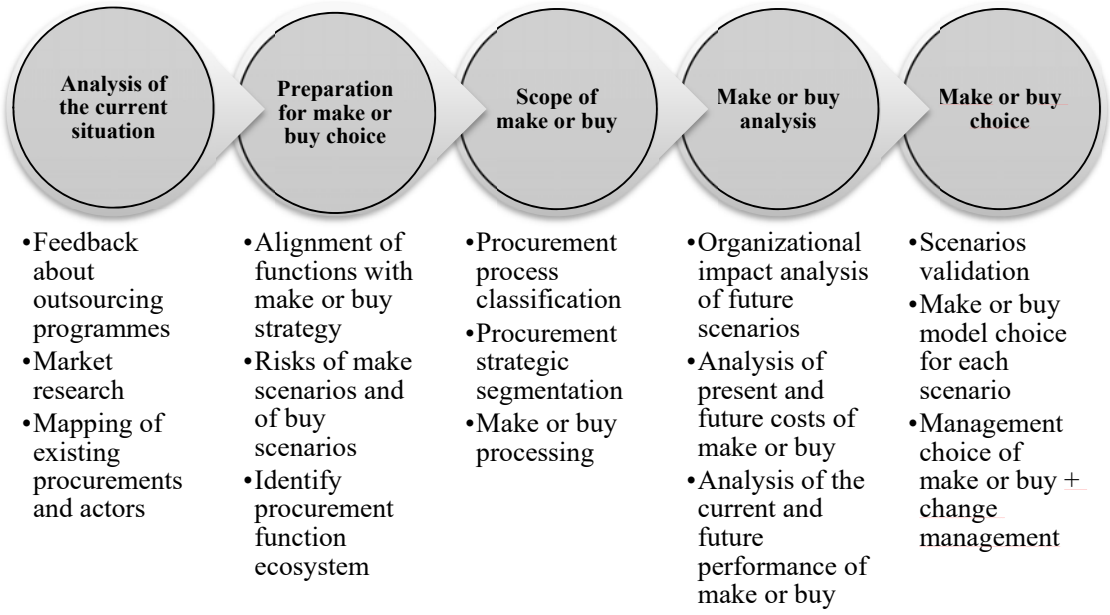

Figure 3: Five-step process of make or buy of procurement activities

The five steps in the make or buy of procurement activities are described as follows:

Step 1 – Analysis of the current situation:
The analysis of the current situation is dedicated to studying the outsourcing practices of the procurement function, namely the nature of outsourced procurement, the typology of outsourcing contracts, the challenges, and the key success factors. This step took six months, because it raised the fears of the managers of the different purchasing teams, such as: *"why do we need to outsource?", "will there be a loss of jobs?", "will outsourcing change our way of working ?*
At first the representative from the different teams focused on the dangers of outsourcing, and explanations were given to them, including the arguments that there is also internalisation in a make or buy project and that the objective was to find the optimal solution for Purchasing senior management. Once the information from interviews and documentation had been collected and analysed, the fears expressed impacted on the time taken and required the intervention of the Purchasing Director to unblock situations.
The main objective of this step is to draw the key lessons from previous and current outsourcing programs and to obtain a better knowledge of the firm's own practices, strengths and weaknesses. This step identifies the procurement practices currently outsourced by SNCF Réseau and by the parent company – those areas where competence levels are high and those where improvements need to be made. So the composition of the procurement activities is ascertained and this is clearly mapped (Bruel et al. 2014), allowing greater control of the process. Additionally market research gathers information about the external availability of procurement services that could meet outsourcing needs.

Step 2 - Preparation for the make or buy choice:

During this step, with the apprehensions of the different members alleviated and their involvement increased, the project was able to advance more rapidly. Brainstorming and focus groups were the working methods employed.
The preparation for the make or buy choice starts with the alignment of the procurement function with the company's strategy (Bruel et al. 2014). It is important to understand and assimilate the vision and overall strategy of the company to guide the make or buy choice and in order to secure both financial support and commitment from top management. To study the negative and positive risks, we focus on the international standard ISO 3100: 2009 (Purdy, 2010) to apply it to the make case first, and to the buy case afterwards, before relating them to the particular case of SNCF Réseau, taking into account its context, environment, the sector and inner working mechanisms.
Finally, the project team defines the ecosystem (Peltoniemi, 2006) of the procurement function to identify entities that may be affected by a make or buy decision. The ecosystem can be internal, such as stakeholders, top management, other functions, etc. or external, such as suppliers, competitors, government, etc. Defining the ecosystem of the procurement function enables the organization to identify potential opportunities for collaboration and target its communication and actions.

Step 3 - Scope of make or buy:
Focus groups and analytical reports prepared the project team for the make or buy choice. With this information, the team was able to analyze the scope of procurements affected by this choice and classify procurements according to the purchasing-procurement process; from tactical to strategic (Kaufmann, 2002), and according to their complexity; Class A, Class B and Class C (Roy and Guin, 1999). The project team also focuses on the strategic segmentation of the purchasing activity, on its maturity (potage, 2017), practices, methods and tools used in the company. Each purchasing entity is evaluated separately on the maturity of its purchases and purchasers in each of the distinct families, which are individually mapped. This issue raised another set of difficulties, since team managers were reluctant to declare that their buyers lacked skills, in case external skills were sought to make up for the lack of internal skills, or that they were overloaded, in case the «extra» workload was then outsourced. They also did not want to declare that the buyers did not have enough work, in case they were given extra responsibilities outside the perimeter of their department. The Purchasing Director had to intervene to repeat the objectives of the study and its importance. The step lasted three months.
The consolidation of this data, reviewed by the Purchasing Director, enables a global analysis of the company's purchasing function.
For an in-depth analysis, the project team conducts a SWOT analysis (Helms and Nixon, 2010) of the procurement function. In our case, the objective of the SWOT analysis is to examine the strengths, weaknesses, opportunities and threats related to the procurement function as a whole, and related, in particular, to procurement segments and macro-segments.

Step 4 – Make or buy analysis:
The SWOT analysis helps in the proposal of improvements, correction and capitalization of the procurement function. Based on these proposals and the previous analysis, the project team suggests the first future scenarios of the make and the buy, and then analyzes their organizational impact and their costs and performance. Furthermore, a comparative study focuses on the existing and future costs of the different scenarios, and on the existing and future performance forecasts. Thus, these projections greatly help in the final choice of whether to carry out each procurement activity internally or externally. This step lasted two months.
The presence of representatives of the different entities in the project team enabled specific problems to be raised and taken into account in the choice of future scenarios. These

representatives possess a more operational vision of purchasing which was confronted with the more strategic vision of section managers and the Purchasing Director. Consequently, different propositions were modified and a consolidated make or buy organisational vision was reached. This step of the process shows the confrontation of objectivist and rationalist (TCE and RBV) approaches, as exemplified by a comparative study, with endogenous factors (Marshall et al., 2015), represented by the input of the operational teams with concrete experience of the organisation's day-to-day procurement activities.

Step 5 – Make or buy choice:
Once a decision to make or buy a procurement activity has been confirmed, the project team submits its proposal to top management for approval. The project team focuses on the validated scenarios to develop the implementation model, which includes progress monitoring and effectively managing the change process for each scenario. The project team also defines the roles and functions of the resources involved in each case (Walsh and Renaud, 2010), communicates more officially about the selected scenarios, manages the transition process and ensures the monitoring of key performance indicators.
For the buy scenarios, the project team participates in the writing of specifications, in the selection of the buy management committee, in setting up the basis of the management of the relationship with the suppliers of external services, in order to ensure practice standardization over the procurement function. For the make scenarios, the project team participates in establishing reversibility and contract termination of the affected outsourcing programs in order to ensure compliance with practices introduced by the scenarios. It took one month to formalize this step. Fig 4. shows the timeframe for the whole process.

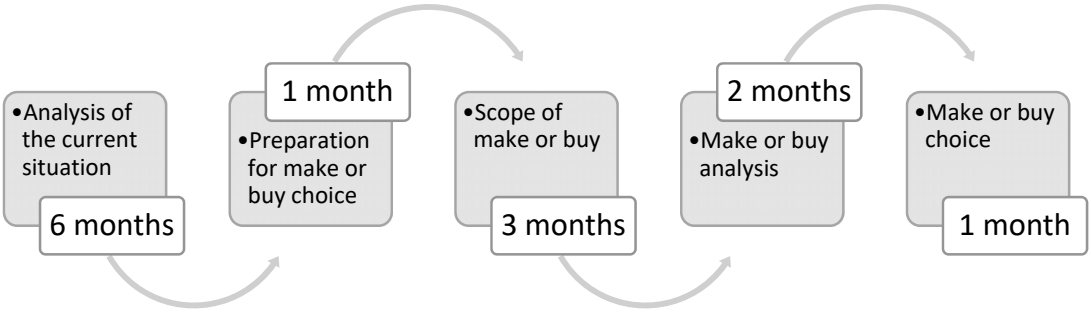

Figure 4: Timeframe for the five-step process of make or buy of procurement activities

Discussion
Following the findings of recent research that outsourcing decisions can be related to endogenous organizational factors (Bidwell, 2012; Marshall et al., 2015), this research, equally, sees the reorganization of make or buy as linked to internal dynamics: in this case the merger of two previously distinct entities and the need for a global company approach to procurement. We then produce a model to show how this reorganization was part of a change management process and was implemented in practice. Our research identifies four key elements underlying this process, which need to be taken into account in the management of change in a large firm's procurement department:

1. Change within change. It is important to note that the participants evolved over the course of the project – that the project team itself was subject to change. The number of middle managers involved in the project team grew and in some cases their role changed. For example, middle managers that initially represented a purchasing team in one of the merging entities, switched to represent another to which they subsequently belonged. This produced changing dynamics within the project team.

2. Managing the new buy process. Our experience shows that in the case of buy, before drawing up specifications, there is a need to share the results of analysis with management to ensure their alignment with the company's global strategy. Also, there is a need for the teams that work on a daily basis with the service providers to contribute to the specification process and to the selection of service providers, given that they will have to manage them in the future. During the project some difficulties were encountered mainly linked to fears around the critical nature of the negative risks (Purdy, 2010) associated with a buy scenario. In fact, some members of the project team (representatives at the middle management level) regularly expressed their reticence to a buy scenario and the negative implications for the company *"We don't need to outsource purchasing, it's a bad idea […] we know very well how to purchase ourselves"* (One Manager of a Purchasing department). Thus, buy scenarios, generated by rational evaluations and projections, were often challenged by internal resistance.

3. Listening to protest. In the terminology of Autissier and Vandangeon-Derumez (2007) these middle managers represent *« the change protesters »*. In order to encourage an objective approach in the choice of scenarios, brainstorming sessions on the risks of make or buy and reminders of project aims allowed the whole project team to 'buy into' the resulting decisions. The success of the project was aided by the presence of 'opinion leaders', with objective or non-partisan views on the subject. *"The Purchasing Director's close interest in the project was key to its success […] this meant that areas of disagreement could be negotiated, the strategic importance of the project was regularly underlined and that the project was aligned with company strategy and policy"* (Member of the project team). Project team meetings with the Purchasing Director at regular intervals provided arbitration over points of difference or conflicts within the team and ensured that the project progressed in line with the company's global strategy. The resistance expressed by certain middle managers gave the project team an understanding of the perception of the members of the purchasing teams, which enabled the project team to develop its internal strategy and to anticipate reactions on the ground. Additionally, early informal feedback from the middle managers to their teams meant that the state of progress of the project was widely known.

4. Effective communication. The literature review (Kotter, 1995; Pinto, 2005) shows that one of the most important determinants of a successful organisational change management project is communication. The proposed make or buy scenarios constituted a significant transformation of purchasing activities and team organisation. Both internal and external communication were essential via information sessions and newsletters. Particular attention was paid to buyers, who experienced major changes to the organisation of their workload and required explanations of the rationale behind these changes and the results anticipated. It was also essential to communicate with suppliers affected by the reorganisation, who were beginning to receive orders from subcontractors, rather than internal buyers. Articles published in the professional press were monitored to ensure that they did not contain information likely to stoke tensions within the firm or cause misunderstandings.

Conclusion

To conclude, it is important to underline some points about the implementation of this process and model in the case study. The integration of representatives of the different procurement entities in the project team helped to have a global vision at the operational level and meant that our model was the result of the collective input of a number of professionals. From a methodological perspective, this added validity to the research. The integration of these representatives in the project team facilitated an effective preparation phase (Step 2) for what was a transformative project. We noticed throughout our research that some members of the

project team showed some unwillingness and resistance to the buy scenarios. Behind this resistance lay the fears of their teams and sometimes of themselves. Their participation in the project team helped to adapt our model in order to anticipate and master these apprehensions at the earliest stages of the project and to enable effective two-way communication channels between the procurement entities and the project team. This inclusion in a major strategic project reveals the importance of an organizational change management process for a reorganization of the make or buy function.

With reference to the literature review, the change process can be seen as a minor struggle between those who represent day-to-day procurement experience, maintain the status quo and defend their interests and the drivers of change, who employ rational and objective criteria as tools of persuasion. The managerial authority of the latter group meant that, ultimately, they prevailed, but not without concessions, being secured and adaptations made. Therefore, explanations for the outcomes of the make or buy review project would need to consider both rational (TCE and RBV) and organizational factors (Marshall et al., 2015), that operate simultaneously and are often confronted one against the other, requiring arbitration and eventual compromise.

This paper suggests a model for the reorganization of a company's make or buy function, regardless of its class (ABC) and its strategic level (from purchasing to procurement). This model is based on academic research in the field of make or buy, and change management. We strengthened and improved the model through an in-depth case study applied to SNCF Réseau. In this case, the driving forces behind the project to review and reorganize procurement activities were the merger of two separate entities, the need to progress organizational change and the objective of coherent and comprehensive make or buy strategy and practice. We have not applied this model yet to other companies but we do not exclude this approach for further research. However, we believe that an in-depth case study can be relevant. In this paper, we have not presented the results of our model applied to the case of SNCF Réseau, for reasons of confidentiality and we prefer to focus on how we developed a model of the decision making process for the make or buy of procurement activities, since this subject is still underexplored by scholars. We hope that our research will open the way to further reflections.

Demand aspects of RoRo shipping services

Anastasia Christodoulou, Postdoctoral Researcher, Department of Business Administration, School of Business, Economics and Law at University of Gothenburg, P.O Box 610, 405 30 Gothenburg, Sweden, Anastasia.christodoulou@gu.se, Phone +46 31 7866437.

Summary

The integration of shipping into 'green' supply chains represents a big challenge for the transport industry. This paper analyses the purchasing chain of RoRo shipping services and identifies the determinants that have impact on its competitiveness. A taxonomy of determinant factors in the purchasing process of RoRo shipping services is developed highlighting the interactions between them and drawing attention to the barriers that prevent the further employment of this transport mode. The results suggest that a different management 'culture' on carriers-shippers' relationships and efficient port operations are key determinants for the establishment of successful intermodal RoRo services.

Key words: purchasing, RoRo shipping, intermodal chains.

Introduction

The 'green' transportation of goods has been an issue of major concern during the last decades with a special focus on the development of intermodal supply chains and the further use of environmentally friendly and energy efficient transport modes. Maritime transportation offers significant environmental advantages as it transfers more than 90% of the global trade in volume while emitting around 2.2% of the total global greenhouse gas (GHG) emissions (Smith et al., 2014). The integration of shipping into 'green' supply chains represents a big challenge for the transport industry and has not been achieved until now despite the various initiatives taken by various stakeholders (European Commission, 2011; Ng et al., 2013). Various segments of the shipping industry present great differences in their purchasing and supply chain management, which need to be taken into consideration for the adoption of effective policies and incentives that could lead to the further use of shipping in intermodal transport chains (Casaca and Marlow, 2005).

Roll on-Roll off (RoRo) shipping represents a maritime segment that could easily form part of an intermodal transport system and contribute to the development of sustainable transport chains, as cargo does not need to be transhipped in ports, it is 'rolled' to and from sea on its own wheels (Perakis and Denisis, 2008). In this respect, sea could be seen as an extension of land-based transportation and 'motorways of the sea' is a relevant expression that refers to the establishment of specific routes for the employment of short sea shipping. The purchasing of RoRo shipping services presents some distinct characteristics that differentiate this shipping segment largely from the deep sea segments, like the containerships, the tankers, the general cargo carriers (Woxenius, 2012).

The purpose of this paper is to investigate the purchasing chain of RoRo shipping services and identify the determinants that have impact on its competitiveness. Given the fact that RoRo shipping faces a strong competition from land-based modes of transport and the supply of RoRo services is strongly influenced by the shippers' demands, this paper's results could assist

the efforts for the further employment of this maritime segment and its integration into efficient sustainable logistic chains.

Methodology

In order to examine the purchasing and supply aspects of RoRo shipping services and identify the main factors that have impact on the competitiveness of RoRo vessels operations, a thorough literature review was conducted and a taxonomy of these determinants was developed. Given that the literature body on RoRo shipping demand is limited, purchasing and transport mode selection literature were also examined and the data were tailored to reflect the determinant factors for the employment of RoRo shipping services. The factors are categorized into eleven groups: (i) economic factors, (ii) timing factors, (iii) service quality factors, (iv) cargo related factors, (v) environmental factors, (vi) marketing factors, (vii) geographical factors, (viii) technological factors, (ix) safety factors, (x) 'cultural' factors and (xi) port factors. This taxonomy enables the identification of the determinants that impact the competitiveness of RoRo shipping, highlights the interactions among these factors and gives an insight of the possible policies and incentives that could lead to the further use of this maritime segment and its effective integration into intermodal transport chains.

Purchasing of transport services

In order to identify the determinants that affect the competitiveness of RoRo shipping services, the purchasing process of freight transport services is analysed with a special focus on the factors that influence transport mode choice for shippers and freight suppliers. According to Kraljic (1983), the purchasing process of products or services includes four phases: the classification of all purchased services with regard to profit impact and supply risk (Kraljic's matrix), the analysis of the supply market for these services, the identification of the strategic supply services and the design of strategies and action plans. Andersson and Norrman (2002) argue that the purchasing of more advanced logistics services shares similar characteristics with the purchasing process for physical products, but the complexity and the development of some logistics services tend to position them in more strategic decisions. Several authors have mentioned the influence of different contextual variables on the purchasing process of freight transport services, focusing on the heterogeneity of these services and the benefits for shippers from the integration of their transport activities (Hedvall et al., 2017; Rogerson et al., 2014).

The second phase of Kraljic's approach – the analysis of the supply market for transport services - is directly linked to the scope of this paper and is related to the decision process for transport mode selection. Many articles have dealt with the factors that influence the transport mode choice, as this is a quite complicated issue and the interactions of various parameters need to be taken into consideration (Cullinane and Toy, 2000; Flodén et al., 2017; Loetveit Pedersen and Gray, 1998; Meixell and Norbis, 2008); Murphy and Hall, 1995). There is a large differentiation in the way these factors are classified in the purchasing literature, while the relative importance of different factors has changed over the years. McGinnis (1989) made a comparative evaluation of freight transportation choice models and suggested that transport mode choice results from an array of interactions among freight rates, reliability, transit time, loss and damage experience, shipper market needs, carrier capabilities and product characteristics. According to his findings, many of these factors vary among shippers. An understanding of the variables associated with the employment of a specific mode in addition to a thorough analysis of the shippers' needs would help carriers gain a competitive advantage in the market. Liberatore and Miller (1995) classified the transport mode selection criteria in

6 clusters - perceived quality of customer service, shipment tracking and tracing services, electronic data interchange (EDI) capabilities, potential to develop mutually beneficial long-term partnership, cargo capacity limitations of the carrier and the total costs of shipping – and pointed out that the decision for transport mode choice is based on the trade-offs of these variables. Cullinane and Toy (2000) identified the five most common factor categories in the transport mode choice literature as well as their relative importance: cost/price/rate, speed, transit time reliability, characteristics of the goods and service (specific service characteristics). Most recent scientific articles have underlined the importance of environmental considerations in the purchasing process of transport services (Evangelista, 2014; Lammgård and Andersson, 2014; Large et al., 2013). Danielis et al. (2005) highlighted a strong preference of logistics managers for freight service attributes of quality (time, reliability, and safety), in contrast to findings of previous research works, where the cost was the predominant factor for transport mode selection.

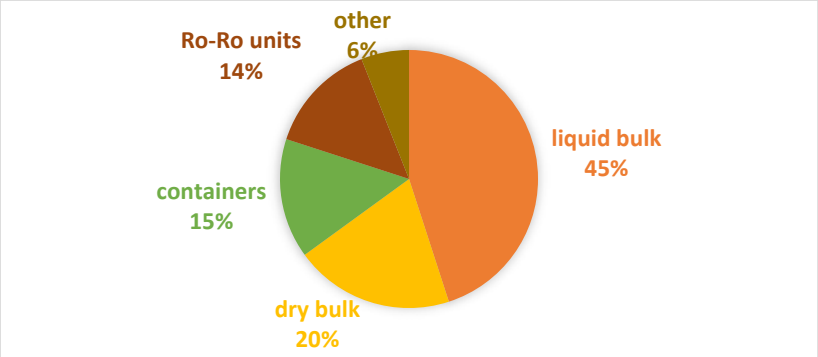
RoRo shipping features

Coming to the purchasing process of RoRo shipping services, which is the focus of this paper, a short description of this shipping sector is necessary in order to give some insight in the specific features of this transport mode and the way this market is structured. Maritime transportation is divided in various segments that present substantial differences in their operations as well as their market structure (Stopford, 2009). RoRo shipping is largely differentiated from the other maritime segments due to its elasticity of demand that is much higher than the other segments, as it faces a strong competition from land-based modes of transport. RoRo shipping suppliers constantly seek to satisfy shippers' needs and their supply of RoRo services is strongly influenced by the shippers' demands that 'define' its operations. In general, RoRo services are similar to liner services where frequent, scheduled and customary seaborne transport services are offered between predestined ports of call.

The topography of countries or geographical areas represents a determinant factor for the use of RoRo shipping. Long coastlines in addition to industrial and production centers located near the coast provide RoRo shipping with a geographical advantage over other modes of transport and thereby facilitate the transport of certain cargoes by RoRo vessels (Paixão and Marlow, 2002). Apart from the geographical position of a country or region, the type of cargoes imported and exported may favor the use of RoRo shipping in relation to other shipping segments. Automobile industry, manufacturers of paper and paper products, electric equipment industries as well as imports and exports of food and drinks are some of the major shippers in the RoRo shipping market.

RoRo shipping – as part of SSS - represents an environmentally-friendly, energy-efficient and safe alternative to road transport that can facilitate the connection of remote and peripheral regions cost-effectively, as it does not require high infrastructure investments (Blonk, 1994). RoRo vessels are characterized as horizontally-loading vessels, as their cargo can be towed into the vessel or brought in on wheeled vehicles, without requiring any special equipment. This characteristic of RoRo shipping enhances its competitive advantage as well as its potential for a modal shift in Europe, as it implies low logistics costs and fast cargo handling (Medda and Trujillo, 2010). The shortsea RoRo shipping segment plays a significant role in the European seaborne trade, accounting for 14% of the total short sea shipping of goods to and from main EU ports in 2015 (figure 1).

Figure 1. Short Sea Shipping (SSS) of goods by type of cargo in 2015 (% gross weight of goods in Mio tonnes)



Source: Own elaboration based on data from Eurostat, 2017

However, RoRo operations require large cargo volumes and high frequency of departures in order to be economically feasible due to the high construction and operational cost of RoRo vessels and 'their inevitably lower load factor compared with containerships' (Casaca and Marlow, 2007). Adequate cargo volumes that 'guarantee' high frequency of departures for the shippers and high capacity utilization for the shipping companies are both vital for the economic feasibility of the RoRo services (Styhre, 2009). According to Ng (2009), 'reasonable frequency, regularity and interoperability between land and maritime components' represents a key factor for the competitiveness of SSS. In addition to the economical parameter, efficient RoRo logistics operations require a 'cultural' change from the side of both the shipowners and the shippers on the basis of the complementarity of inland and maritime carriers' operations (Zachcial, 2001).

The crucial role of ports for the establishment and successful operation of intermodal RoRo services in addition to the importance of adequate port infrastructure for the development of efficient maritime transport chains have been mentioned in various articles (Ng et al., 2013; Song and Panayides, 2008; Suarez-Aleman et al., 2015). Good intermodal connections between ports and inland transport networks are essential for the employment of RoRo shipping, as RoRo shipping suppliers usually do not offer door-to-door services and maritime RoRo transport consists part of an intermodal transport chain that requires sufficient connecting links to inland port infrastructure (Casaca and Marlow, 2009).

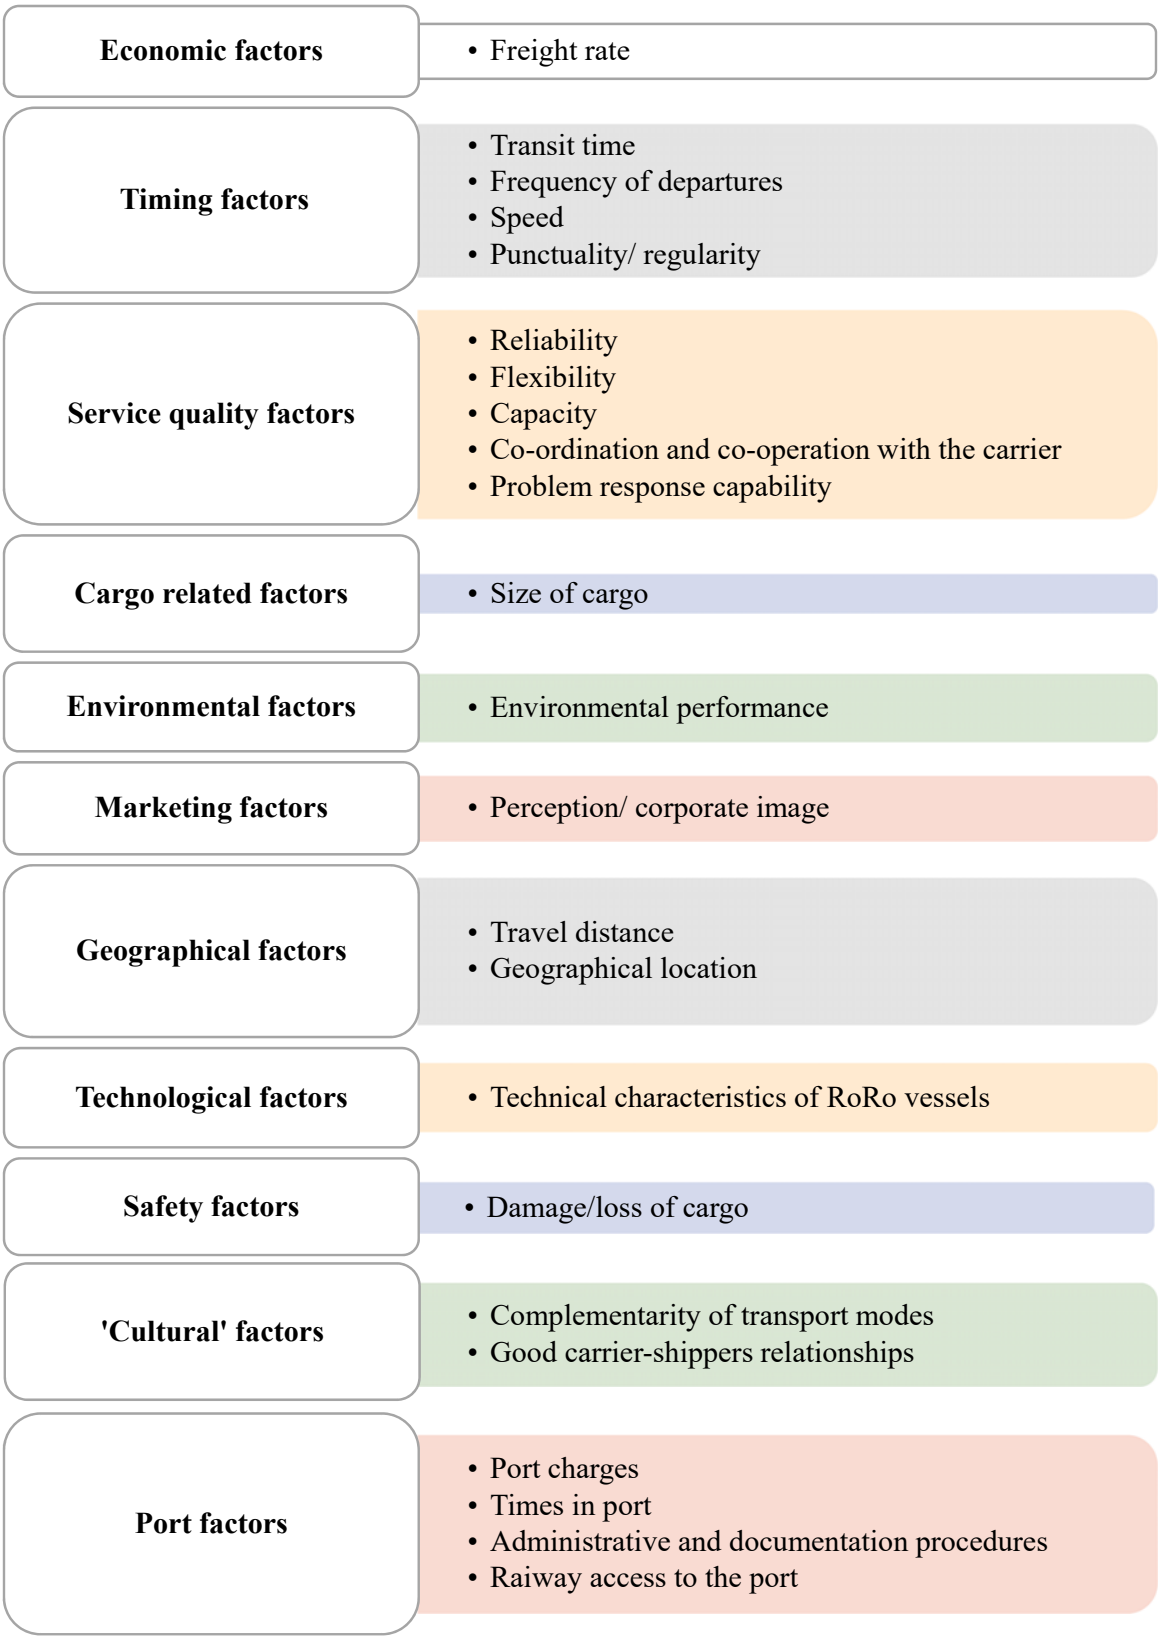
A taxonomy of determinant factors in the purchasing process of RoRo shipping services

After the identification of various factors influencing the purchasing process of RoRo shipping services, a taxonomy of these determinants is developed. The factors are categorized in eleven groups: (i) economic factors, (ii) timing factors, (iii) service quality factors, (iv) cargo related factors, (v) environmental factors, (vi) marketing factors, (vii) geographical factors, (viii) technological factors, (ix) safety factors, (x) 'cultural' factors and (xi) port factors (fig. 2).

(i) Economic factors

Cost is a predominant factor in the decision process for transport mode selection, but its ranking differs according to the contextual variables of freight transport services. Previous studies highlighted cost as the most important factor for the selection of transport mode, but in most recent articles it is ranked below service quality and/or timing factors (Brooks and Trifts, 2008;

Figure 2. Determinant factors in the purchasing process of RoRo shipping services



Source: Own elaboration

Casaca and Marlow, 2005; Cullinane and Toy, 2000; D'Este and Meyrick, 1992; Danielis et al., 2005; Flodén et al., 2017; Loetveit Pedersen and Gray, 1998; McGinnis, 1989; Meixell and Norbis, 2008). For RoRo shipping services, cost is an important parameter, but its ranking depends on the value of the transported cargo. For low value cargoes, where the transportation cost stands for a relative large part of the total production cost, cost is ranked as the most important factor in the transport mode selection process.

(ii) Timing factors

RoRo shipping competitiveness is largely affected by the regularity/punctuality and frequency of departures, as shippers require frequent, scheduled and customary seaborne transport services between predestined ports of call for the satisfaction of their transportation needs (Casaca and Marlow, 2007; Ng, 2009; Styhre, 2009). Transit time and speed are significant factors for RoRo shipping services, strongly interrelated to the value/perishability of the cargo (Brooks and Trifts, 2008; Casaca and Marlow, 2005; D'Este and Meyrick, 1992).

(iii) Service quality factors

Reliability is a crucial factor for the selection of RoRo shipping services, ranked high in the whole body of transport mode literature (Brooks and Trifts, 2008; Casaca and Marlow, 2005; Cullinane and Toy, 2000; D'Este and Meyrick, 1992; Danielis et al., 2005; Flodén et al., 2017; Loetveit Pedersen and Gray, 1998; McGinnis, 1989). Capacity is an important factor for the competitiveness of RoRo shipping services, ranked much higher than in other transport modes. High capacity utilization is vital for the economic feasibility of the RoRo services, but it implies the probability of capacity shortage – 'bottleneck' – in peak periods (Kraljic, 1983; Styhre, 2009). The flexibility and problem response capability of the RoRo service provider – ability to handle special consignments or urgent deliveries – as well as the good coordination and cooperation between shipper and carrier are determinant factors for efficient RoRo shipping services. Many RoRo vessels are time chartered for long periods and 'committed' to specific trade routes through long-terms contracts, leading to the formation of long-term partnerships (Casaca and Marlow, 2005; D'Este and Meyrick, 1992; Liberatore and Miller, 1995; Loetveit Pedersen and Gray, 1998).

(iv) Cargo related factors

The weight or size of the cargo is a determinant factor for the employment of RoRo shipping, as cargo needs to be towed into the RoRo vessel or brought in on wheeled vehicles and therefor is subject to certain restrictions. The value and perishability of the cargo is negatively related to the use of slow transportation modes, but it does not seem to affect the choice for RoRo shipping services (Ng, 2009). Automobile and forestry industry are both major shippers in the Swedish RoRo shipping market, whereas the value of their transported cargo is totally different.

(v) Environmental factors

RoRo shipping represents an environmentally-friendly, energy-efficient and safe alternative to road transport and its environmental performance is one of its major assets (Blonk, 1994). The fact that environment is ranked high in recent transport mode literature suggests that RoRo shipping competitiveness is strengthened from its environmental performance (Flodén et al., 2017; Lammgård and Andersson, 2014).

(vi) Marketing factors

The market perception and corporate image of RoRo shipping services affects the competitiveness of this transport mode and its 'reputation' needs to be improved for the achievement of its further employment (Blonk, 1994; Casaca and Marlow, 2005).

(vii) Geographical factors

Travel distance and geographical location can favour the employment of RoRo shipping services. There is a distance range within which RoRo shipping can successfully compete with land-based modes of transport; short distances (<700 kms) are dominated by road transportation (Brooks and Trifts, 2008; Jiang et al., 1999). Long coastlines in addition to industrial and production centers located near the coast provide RoRo shipping with a geographical advantage over other modes of transport and thereby facilitate the transport of certain cargoes by RoRo vessels (Paixão and Marlow, 2002).

(viii) Technological factors

The technical characteristics of the RoRo vessels have some influence on the competitiveness of RoRo shipping services, as several RoRo vessels are purpose built - predestined to be employed in specific trades and routes – and possess beneficial technical features that add value to their transport services (D'Este and Meyrick, 1992).

(ix) Safety factors

The damage/loss of cargo is a determinant factor affecting the competitiveness of RoRo shipping, mentioned in many research articles (D'Este and Meyrick, 1992; Danielis et al., 2005; Flodén et al., 2017; Loetveit Pedersen and Gray, 1998; McGinnis, 1989).

(x) 'Cultural' factors

The development of a management 'culture' that promotes the complementarity of different transport modes and relies on carriers-shippers' relationships can have significant impact on the further employment of RoRo shipping services, as these services usually do not offer door-to-door transportation, but consist part of an intermodal transport chain (Casaca and Marlow, 2009; Zachial, 2001).

(xi) Port factors

Efficient port operations are essential for the employment of RoRo shipping. High port charges and long times in ports in addition to complex administrative and documentation procedures can influence negatively the competitiveness and feasibility of intermodal RoRo services (Ng et al, 2013; Suarez-Aleman et al., 2015). The access of railways to the port is a determinant factor for the use of RoRo vessels for the transportation of certain cargoes (D'Este and Meyrick, 1992). The transportation of Swedish forest products consists an example of these cargoes, where intermodal logistics chains have been developed, combining rail and RoRo shipping.

Discussion and conclusion

RoRo vessels represent one of the main categories of the SSS market that offer the potential for a modal shift in Europe due to their technical characteristics - horizontal handling of RoRo units – that imply low logistics costs and fast cargo handling, essential for the enhancement of the competitiveness of SSS. RoRo services face a strong competition from land-based modes

of transport and their elasticity of demand is quite high, which implies that RoRo service providers need to have a good knowledge of their shippers' needs and adjust accordingly their operations. Throughout this paper, the determinant factors that influence the employment of RoRo shipping services are analysed and categorized in order to highlight the interactions among the valued service qualities that derive from shippers' requirements in the transport mode selection process.

Identified key determinants for the employment of RoRo shipping services are reliability, price, frequency of departures, flexibility, transit time, regularity, damage/loss of the cargo, problem response capability. Apart from these factors that are common for any transport mode, RoRo shipping demand is strongly influenced by capacity utilization, cargo characteristics and travel distance. The environmental performance of RoRo shipping is one of its main assets and should be promoted by the RoRo shipping providers as environment is ranked high in recent transport mode literature and this factor strengthens the competitiveness of RoRo shipping services. The corporate image of RoRo shipping needs to be improved for the achievement of its further employment.

The integration of RoRo shipping services in intermodal transport chains represents the greatest challenge for the enhancement of the competitiveness of this transport mode and it is dominated by 'cultural' and port-related factors. A different management approach and 'culture' that rely on carriers-shippers' relationships and are based on the complementarity of different transport modes' operations need to be developed. The competitiveness and feasibility of RoRo shipping services are strongly influenced by the port operations. Ports serve as 'nodes' in an intermodal transport chain and their efficient operations – low port costs, short times in ports, simplification of administrative and documentation procedures – are vital for the establishment of successful intermodal RoRo services.

This paper's results could contribute to the identification of the best performing policies and incentives for the further employment of this maritime segment and its integration into efficient sustainable logistic chains. In future, empirical research among Swedish shippers will be conducted to map their attitudes towards RoRo shipping services.

Innovated outside: examining precedents to purchasing's contribution to innovation exploration

François Constant[1], Thomas E. Johnsen[2]

Abstract
This study investigates motivations and capabilities that are necessary to the purchasing function for contributing to innovation exploration, under high technological and market uncertainty. Drawing upon dynamic capability and cognitive theories, we use the awareness-motivation-capability (AMC) framework to examine innovation exploration as a process in which purchasing can contribute to enhance firms' innovation capabilities. We report on two in-depth case studies through 28 semi-structured interviews. The findings highlight four necessary factors that facilitate purchasing's contribution to innovation exploration. Our study provides a contribution to purchasing literature, and has implications for managers intending to shape, adapt or redesign their purchasing organizations to better explore innovations.

1. INTRODUCTION

There is a growing interest in the role purchasing can play in sourcing organisational and technological capabilities (Spina, Caniato, Luzzini and Ronchi, 2013). West and Bogers (2014) even suggest that sourcing innovation from external sources can create a competitive advantage. As companies concentrate more and more on their core business, their ability to "innovate outside" is important, and sourcing innovation from external partners is becoming a key success factor (Narasimhan and Narayanan, 2013). Although it is often in charge of external resources management, purchasing is traditionally not regarded as a key contributor in the innovation process (Melander, 2014). Despite its usual responsibility for sourcing, purchasing also is not seen as a key contributor in innovation exploration (Gualandris et al., 2018), as it is commonly accepted that R&D has the premium role as innovation provider. The role of purchasing in exploring new sources of innovation has been investigated mainly in the context of New Product Development (NPD), linking innovation capabilities and purchasing involvement in the NPD process (Van Echtelt, Wynstra, Van Weele and Duysters, 2008), typically characterized by low technological uncertainty.

Exploration in the context of high technological uncertainty is about finding external capabilities, which are new to the firm, and outside the existing supply network. We rely on the definition of an innovation as "an iterative process initiated by the perception of a new market and/or new service opportunity for a technology-based invention which leads to development, production, and marketing tasks striving for the commercial success of the invention" (Garcia and Calantone, 2002). Under high technological uncertainty, firms may scout for innovations which are not available within the focal firm's existing environment (Melander, 2014; Narasimhan and Narayanan, 2013). This calls for the notion of "distance" in the supply network (Phillips, Lamming, Bessant and Noke, 2006). In this case, exploration involves distant search for new capabilities, bringing opportunities to the firm in achieving new-to-the-world innovations (Nerkar and Roberts, 2004). Exploring innovations within new markets and technologies implies evolving in higher uncertainty and higher risks (O'Connor and Rice, 2013). To succeed in managing within a highly uncertainty context, companies need to develop new capabilities i.e. to make changes in their strategies, organizational structures, processes,

management resources and culture (Slater, Mohr and Sengupta, 2014). In uncertain environments, organizations need to modify their approach to source innovation with flexibility which may call for a new role of purchasing function and the creation of new linkages with other functions (Narasimhan and Narayanan, 2013). Despite the traditional passive role of purchasing in innovation exploration, the latest research suggests that purchasing can in fact play a key role in this process (Gualandris et al., 2018). But the understanding of these changes at the purchasing function level is still limited.

We build on the dynamic capability theory, providing that an innovation can be developped from outside the firm (Teece, David, Pisano and Shuen, 1997), in other words, it can be "innovated outside". We use also the Awareness-Motivation-Capabilities (AMC) framework which helps to identify business cooperation and behavioural drivers in an organization (Chen and Miller, 2015; Chen, 1996). AMC framework has rarely been used in purchasing field (Schweig, 2015) but provides an interesting frame to analyse cognition and behavioural causes, which complete the traditional drivers found in business management and purchasing theories. Simply stated, purchasing will not be able to explore innovation unless it is Aware of the innovation, Motivated to explore innovations, and Capable of exploring outside the firm. Adapting the AMC framework, we argue that purchasing contribution to innovation exploration will be driven contingently by *purchasing's awareness* (defined as the accessibility to the innovation and purchasing's visibility), *purchasing's motivations* to explore innovation (related to incentives, intrinsic and extrinsic motivations to explore innovation), *purchasing's capabilities* (depending on firm resources, experience and practice, as well as resource-rich supply environment).

Our aim is to investigate the drivers and capabilities fostering purchasing's contribution to innovation exploration and how technological and market uncertainty moderate these drivers. We pose the following three research questions:

1. *How is purchasing made aware of innovation opportunities?*
2. *What motivates purchasing to explore technological innovation?*
3. *Which capabilities are required to make purchasing contributing to innovation exploration?*

We have done two in-depth case studies and conducted 28 semi-structured interviews in two firms from the same innovation-intensive sector. After having analysed the data we collected, we suggest that four factors are necessary to facilitate purchasing's contribution to innovation exploration: 1/ Purchasing awareness of an innovation is facilitated by purchasing integration into Business Development knowledge, in addition to the integration into R&D 2/ Purchasing's motivation to innovation exploration come mainly from extrinsic incentives (technological shift in the market) 3/ A specific purchasing unit dedicated to exploration tasks full time is a core capability 4/ Skilled resources, such as purchasers' culture, experience and creativity are key factors influencing innovation exploration capabilities. This article report on the theoretical background of our research, our methodology and our findings (within-case and cross-case finding). It provides a contribution to purchasing literature, and has implications for managers intending to shape, adapt or redesign their purchasing organizations to better explore innovations.

2 - LITERATURE REVIEW

2.1. Exploration from a dynamic capability perspective: Dynamic capability (DC) theory can put light on issues related to innovation and knowledge transfer (Weeks, 2009). DC are the "firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environment" (Teece et al, 1997). DC approach takes its main advantage compared to other theories in the process of *capability development* (firms can develop or acquire a capability which will provide a competitive advantage), providing that an innovation can be acquired from outside the firm (Teece et al, 1997). This is a concrete attribute of DC

theory, which opens broadly the possible investigations of its application to purchasing field. Managing relationships with suppliers (referring to concepts like communication, integration, coordination) can be considered a dynamic capability itself (Spina et al, 2016): "Both capabilities on the supplier and the buyer side can be studied as a source of competitive advantage". Contributing to firm's innovativeness through sourcing relationship is also considered as a dynamic capability in the literature (Weeks, 2009).

Although DC theory is relevant in external source acquisition, it does not refer to any degree of uncertainty. Literature suggests DC is about changes in resource base via routines, processes and capabilities: "dynamic" is a word calling for the study of firms' adaptation, and wet think it is valid to investigate a fast-paced and ever-changing environment, i.e. a context of high technological and market uncertainty, where exploration becomes necessary. It is therefore valuable to describe DC as a result of firm's constant adaptation, but Teece's (1997) paper is not clear on how firms should adapt over time. It does not explain the transformation path firms should follow with these resources (how they proceed), neither presents factors other than capabilities which could influence firms' performance (i.e. other drivers). For instance, it is unclear how resources, routines, assets, capabilities and knowledge relate to dynamic capabilities and how managers can make good strategic decision based on this theory. DC authors say that performance result from organizational capabilities developed by individual organizations, but they should define the term capabilities in a more precise way, focusing for instance on resource transformation process itself, and other factors such as motivations. For this reason, and to increase managerial implications of our research, we need to complement DC with another theoretical frame.

2.2. Awareness Motivation Capabilities framework: The Awareness, Motivations and Capability (AMC) framework derives from cognitive science and is now part of the strategic management field. AMC relies on cognitive components to explain why an action occurs. The AMC concept has first been used to investigate the interfirm tensions and competitive dynamics (Chen, 1996). Chen and Miller (2015) propose that AMC framework might support the understanding of reasons, sources, concerns and consequences of cooperative actions (Chen & Miller, 2015). It analyses "the extent of awareness, the level of motivation, and, finally, the capability to respond" (Livengood and Reger, 2010). The AMC framework is advocated to be a powerful tool in the field of strategic management for highlighting behavioural drivers of competitive dynamics but also cooperation. Cooperation is of interest for us, because it refers to relation and decision among business partners (Gnyawali and Madhavan, 2006). Innovation can be a result of a cooperation between customers and suppliers and partnering in an innovation can be considered as business cooperation (Schiele, 2010). Awareness is initially defined as the accessibility to knowledge from firm's rivals and its competitive environment; motivation is about firm's willingness to react and respond to competitor's actions, and capability represents firm's resources to move and take a competitive decision (Chen, Kuo-Hsien and Tsai, 2007). "Awareness and motivation are conditioned mainly by market relationships, and capability depends largely on strategic or resource endowments" (Chen, 1996). The AMC framework has been applied recently to study the perceived and objective relationship between companies (Chen et al., 2007; Chen and Miller, 2015). The relational approach, defined by Chen and Miller (2015) explains how firms' competitive advantages might be enhanced by increasing collaboration with partners to develop core competencies (Brandenburger and Nalebuff, 1996). This stream of research emphasizes the need to build upon supplier's cooperation (Markman, Gianiodis and Buchholtz, 2009) "to build up core capabilities and increase cooperative network" (Chen et al, 2015). In the relational approach, the AMC framework has a specific shape where cooperation is moderated by organization type and industry culture. A few scholars have linked the AMC framework with supply chain management (Schweig, 2015). According to the recent usage of the AMC framework focusing on cooperative decisions (Chen

et al, 2015), this model is relevant because we can adapt it to investigate how purchasing adapt its awareness, motivations and capabilities to better contribute to innovation exploration.

2.3. Innovation exploration: Exploration involves scouting for unfamiliar, distant and remote knowledge (Ahuja and Lampert, 2001; Rosenkopf and Nerkar, 2001; Nerkar, 2003). Innovation exploration refers to scouting innovations outside the existing supply base and calls for distant search for new capabilities, bringing opportunities to the firm in achieving new-to-the-world innovations (Nerkar and Roberts, 2004). Exploration is a managerial opportunity and a critical necessity in a context of technological uncertainty. Exploration "entails a shift away from an organization's current knowledge base and skills" (Lavie, Stettner and Tushman, 2010). Research has demonstrated that the nature of these shifts is related to new technical skills, market expertise, or external relationships (Lavie and Rosenkopf, 2006). Innovation exploration in a context of high technological uncertainty means facing unexpected challenges, tensions, and disillusions. Exploration relates to high degree of uncertainty and involves suppliers that are distant from the incumbent firm: this requires working with new markets, new routes of sourcing and innovations which bring higher uncertainty and risk (O'Connor and Rice, 2013). Explorers need to manage unanticipated obstacles, learn a lot from what they discover, and have a creative mindset (Day, 1994). This makes it more difficult to keep motivation alive in such a context (Kelley, O'Connor, Neck and Peters, 2011). Exploring supply networks to find innovations is highly demanding because of high uncertainties, unpredictable discoveries. Current literature has reported a lack of motivation as an obstacle to innovation in a context of high uncertainty (Alexander and van Knippenberg, 2014). Therefore, understanding drivers of innovation exploration is of high interest, because it is an important component of the innovation exploration success, especially in large firms (Kelley et al, 2011; Stringer, 2000).

2.4. Purchasing contribution to innovation exploration: In most economic models, technological innovation comes from the incumbent firm (Henderson and Clark, 1990; Utterback, 1994), as it is commonly accepted that innovation is supposed to emerge from R&D (Damanpour and Aravind, 2012), especially under high technological uncertainty (Oh and Rhee, 2008). Purchasing is rarely seen as a real technology importer (Melander, 2014). Purchasing can contribute to innovation through exploration within current resources under low-market uncertainty. Through purchasing, companies are aware of suppliers " [...] relatively close in terms of product type, geography, and other salient characteristics" (Peteraf and Bergen, 2003). As a corollary to this assumption, companies tend to ignore suppliers who are more distant from them in terms of product type, geography and other knowledge (Livengood and Reger, 2010) which is a characteristic of technological and market uncertainty. This is typically the role of purchasing when it is involved early in NPD, as it is expected to source suppliers capable to execute innovations designed internally.

However, new research suggests that purchasing can be involved in innovation acquisition from external suppliers (Henke and Zhang, 2010), can facilitate involvement and collaboration with suppliers early in the NPD process to benefit from the joint R&D (Johnsen, 2009; Patrucco, Luzzini, and Ronchi, 2017), or can use open innovation practices within buyer-supplier relationship to leverage external sources of innovation (West and Bogers, 2014). There is a growing trend towards the consideration of purchasing involvement in innovation sourcing (Spina et al., 2013), where sourcing involves external suppliers which are considered as sources of innovation and competitive advantage (West and Bogers, 2014; Li and Vanhaverbeke, 2009; Schiele, 2010; Narasimhan, 2013; Lau, Tang and Yam, 2010, Grimpe and Sofka, 2009). According to a few scholars, purchasing is therefore well placed to contribute to innovation exploration (Narasimhan and Narayanan, 2013).

2.5. Purchasing Awareness of an innovation: Awareness is defined as the accessibility to a knowledge (Chen et al., 2007) and is conditioned mainly by market relationship (Chen, 1996). We define purchasing awareness as purchasing capability to be aware of (detect, identify) an innovation "designed outside" or any external knowledge: here knowledge concerns suppliers'

innovation. If purchasing is aware of a source of innovation within the extended supply network, then it can decide whether to act or not to study this innovation deeper in details, or to leave the opportunity aside. Also, purchasing awareness may concern the need to find external knowledge to develop an innovation "designed inside", for which the firm wants to outsource the execution and search for a supplier. In a context of rivalry, the literature reports that awareness drivers include action visibility and firm size (Chen and Miller, 1994). We argue that awareness enables purchasing contribution to innovation exploration: purchasing will increase its contribution to innovation exploration once it increases its market visibility. Awareness is also about *visibility*: purchasing has a better visibility on the supply market by increasing supplier integration (Ragatz, Handfield and Petersen, 2002; Petersen, Handfield and Ragatz, 2005). Supplier integration includes the timing of supplier involvement in a new program, the degree of supplier design responsibility, and the frequency of buyer/supplier communication (Hartley, Zirger and Kamath 1997). Firm size may increase action visibility (Chen & Miller, 1994), and applied to purchasing this means better market knowledge. Purchasing integration also enables the awareness of innovations needs. Also, accessibility to external knowledge depends on the structure of the organization: literature highlights that the structure of firm's organization may influence its performance about explorative tasks (Boumgarden, Nickerson and Zenger, 2012).

2.5. Purchasing motivations and capabilities fostering innovation exploration:

Purchasing Motivation: Innovation development under high uncertainty is a process which depends on motivation (Alexander and van Knippenberg, 2014). Motivation here refers to drivers fostering an action and calling for the acquisition and use of specific skills and abilities (Locke and Latham, 2004). Motivation fosters tasks which enhance innovation performance, such as idea creation, taking initiatives outside traditional firm's barriers. Thus, purchasing motivation represents purchasing's willingness to explore supply networks to detect new sources of innovations, but this requires specific skills and abilities. "Motivating innovation" is an important concern in many incentive problems (Manso, 2011). Motivation theory helps to define motivational drivers and to narrow down to specific drivers that purchasing may encounter to increase its contribution to innovation exploration. Pihlajamaa (2017) has suggested purchasing key motivations to explore innovations in a context of high uncertainty: motivations may come from the setting of moderately challenging goals assignment, and moderately specific goals. He reported that conflicting goals may decrease motivation for innovation (Pihlajamaa, 2017). Explicit incentives, such as bonuses and rewards, may push purchasing to create market opportunities to source innovation (Amabile, Conti, Coon, Lazenby and Herron, 1996). Purchasing can explore to gain better visibility of the supply network (Ragatz et al, 2002) or to increase firm visibility (Chen and Miller, 1994). A recent study suggests that rewards are critically important especially high with uncertainty context (Sergeeva, 2015). Motivation to explore can be also exacerbated by the territorial interests in different markets (Gimeno, 1999), or cost reduction targets. Obtaining or sharing the rights to use the innovation patent may increase purchasing motivation, as well as the wish to capture long-term relationship with the supplier. We rely on the influence of "innovation champions", i.e. managers intensely interested in new ideas, who spread enthusiasm to other employees and facilitate the development process (Gemünden, Salomo and Hölzle, 2007). Attitude towards risk taking and creativity is widely influenced by organizational culture in a context of high technological uncertainty (Slater et al., 2014; O'Connor and Ayers, 2005). Organizational culture is made of concepts, values and beliefs in a company (Schein, 2010). A motivating culture does not only tolerate risk taking but encourage it, accept failures (Kyriakopoulos, Hughes and Hughes, 2016) and allow individual to try their ideas (Green and Cluley, 2014). Also, companies whose governance and culture build on long-term view will promote relational approach with suppliers rather than rivalrous competition (Chen and Miller, 2015). This will enhance motivation to build relationship with suppliers.

Purchasing Capability: Recent studies have begun to explore core purchasing capabilities to succeed on innovation sourcing: gathering unmet needs, involving suppliers in innovation projects, exploring external opportunities (Legenvre and Gualandris, 2017). We believe we can go further in determining multilevel core capabilities supporting purchasing's contribution to innovation exploration. Core capabilities are "a set of differentiated skills, complementary assets, and routines that provide the basis for a firm's competitive capacities and sustainable advantage in a particular business" (Teece, Pisano and Shuen, 1990). This definition emphasises the study of core capabilities at organizational (firm), which includes employee knowledge and skills, processes and managerial systems (Leonard-Barton, 1992). Other scholars consider that exploring a rich business environment is also a capability (Chen and Miller, 2015). At a functional level, the literature identifies core and non-core competencies or capabilities for purchasing professionals. Any function has a limited set of capabilities, representing "a collection of knowledge, skills, abilities, and other characteristics that are needed for effective performance in the jobs in question" (Campion, Fink, Ruggeberg, Carr, Phillips and Odman, 2011). A capability relates to the execution difficulty and information processing (Smith, Grimm, Gannon, & Chen, 1991). We use the following definition of purchasing capabilities: "Purchase-related capabilities may be defined on two dimensions: (1) capabilities related to the assimilation and dissemination of information on suppliers and markets and (2) relationship-building capabilities" (Quintens, Pauwels and Matthyssens, 2006). Relationship-building capabilities are relevant when considering close partnerships on new product development and innovation (Cavusgil and Zou, 1994). Chen (1996) further argues that a capability "depends largely on strategic or resource endowments", which calls for the consideration of purchasing budget and policies for innovation search (Pihlajamaa, 2017). Corporate culture seems also to be a relevant driver (Narasimhan and Narayanan, 2013). Table 1 represents AMC framework adapted to purchasing, and table 2 report on A, M, C themes and sub-themes found in the literature. Fig 1 presents our theoretical model that respects the theoretical foundation found in the literature :

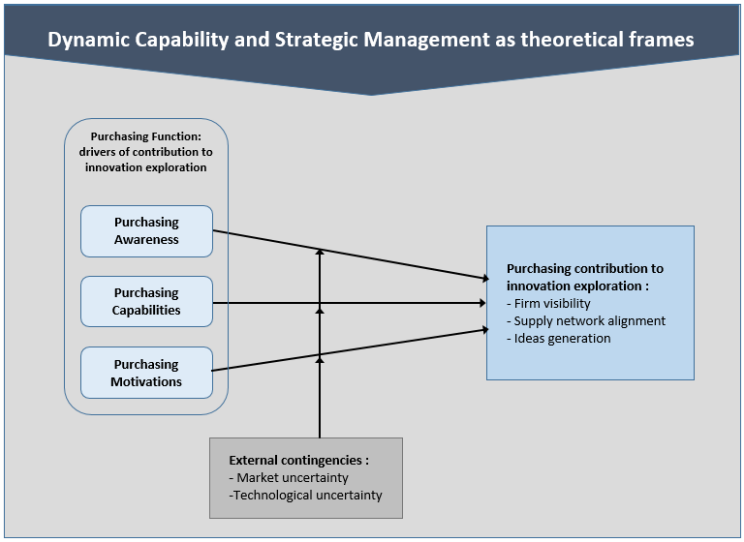

Fig 1: Theoretical model

4 - RESEARCH METHODOLOGY

4.1. Case presentation: We aim at answering the questions: *How is purchasing made aware of innovation opportunities? What drives purchasing to explore technological innovation? Which capabilities are required to make purchasing contributing to innovation exploration?* We have selected two cases replicating current research about purchasing involvement in innovation

exploration, i.e. two companies which have already started to involve purchasing innovation exploration process (Table 3). These cases were chosen because of the similar nature of their businesses (industrial but innovation intensive), the firm sizes (the two firms have very different sizes, ratio x20) and their maturity degree (a-priori different). Moreover, we selected two companies where the specific outcome of our planned research occurs, which is not an easy task nowadays because few companies started to bridge purchasing and innovation exploration. We follow Pettigrew (1992), who suggested that it makes sense to select such rare cases where the process of interest is "transparently observable", not to say exacerbated. In-depth case studies "capture the dynamics of a studied phenomenon and provide a multidimensional view of the situation in a specific context" (Järvensivu and Törnroos, 2009). Our unit of analysis is the organization, where the purchasing function is the centre of an internal network, i.e. other functions within the firm. We focus therefore on organization-level factors, excluding suppliers themselves: studying buyer-supplier relationships is out of our scope because it might force to extend the data collection to supplier' perspective on the topic (i.e. interview them), while we want to capture within-purchasing firm perception. Table 3 presents the two firms.

a) **Company SE Corp overview**: SE Corp is an international group, worldwide leader in connected solutions for building, infrastructures and industry. The company is deeply oriented towards innovation and technological progress. Purchasing department is deeply involved in the process of innovation exploration. Purchasing's contribution to explore innovation is good: 35% of the total innovation "sourced externally" came from purchasing. This exceptional maturity is rare. However, involving purchasing in innovation exploration is a recent change at SE Corp. Until recent years, SE Corp considered innovations should come only from inside the firm (R&D). This strong culture is still present in the company, but has started to change, while innovations coming from outside are more and more considered as valuable. Thus, two years ago, SE Corp has implemented a specific function "purchasing innovation", independent from the rest of the purchasing department (purchasing operations, projects and category management) but reporting to the Chief Purchasing Officer. This entity remains small (5 people full time) compared to the rest of purchasing department (1800 people in total), but has functional management on about 50 people inside or outside purchasing department. This team keep listening to the market to detect any innovation which could be valuable for their firm, and manage innovation exploration as full-time jobs. On a corporate level, SE Corp culture is oriented to long-term views where innovation is a priority.

b) **Company DD Corp overview**: This family-owned company designs, manufactures and sells electronic products for home applications and buildings. In 2013, the managing director has decided to nominate R&D director at the head of purchasing department. This move has been full of signification: the idea behind was to benefit from this organisation change to ask purchasing to be involved more in R&D, and vice-versa. Purchasing started seeking to innovation exploration but without clear success yet. DD Corp suffered from a management in "silos", where a strong "designed-inside" culture is still spread among departments. Today, DD Corp faces drastic changes in its core market, forcing to adopt new technologies which are not well known inside, such as cloud services and iOt, whereas traditionally DD Corp use to manage low-service procurement (electrical and mechanical components). R&D has still a strong position, whereas purchasing is challenged to adapt and to shift the paradigm in sourcing, but this is far to be a success They have implemented another department supporting innovation, Research and Innovation (R&I), which is in charge of providing inputs about technological changes an pushing new demands to purchasing. Purchasing is therefore more an executant than an importer of the innovations although DD Corp has understood the opportunity to get complementary assets from suppliers.

4.2. Data collection: We interviewed 28 people in total (18 at SE Corp and 10 at DD Corp) and multiple stakeholders from various departments in each firm: purchasing department (various hierarchical positions from director's level to operational, but also each function with

purchasing department: project purchasing, category purchasing, innovation purchasing), other departments (R&D, business development, R&I i.e. Research and Innovation). We asked questions about macro-level (firm environment), within-firm level and individual level to increase the deepness of the observations. These multiple angles of observation create rich findings and support "the vital understanding of complex business relationships" (Dubois and Araujo, 2007). Although we do not claim triangulation, we have collected secondary data about both companies, from the web, annual report and industry associations, to complete the primary data. Table 4 presents the interview plan. We adopted active interviewing methodology, which treat the interview as a social experience in which knowledge is jointly created by the interviewer and the interviewee (Holstein and Gubrium, 2004). The interviews were semi-structured: the topic was fixed but the scope was relatively broad, focus on processes and events. We designed three types of interview guides, to adapt the questions to the interviewees' profile. The aim of this distinction was to develop a 360° overview of the topic, considering the assumption that people belonging to a specific function may not have the entire understanding of capabilities needed to succeed in this function.

During the interview phase, we asked how the measurement of purchasing contribution to innovation is made. Counting contribution to innovation is not easy, it is even more difficult when we want to link innovation exploration to commercial success or profit impact. Patents acquired over a given period is a frequent metric used to measure innovation. There is a substantial micro evidence that patent counts are associated with firm value and industry dynamics (Azoulay and Lerner, 2012). Another metric is to measure R&D expenditures, although Griliches (1990) reviews suggest that patent counts can better explain firm market value even beyond R&D expenditure. In our research, the measure of the contribution is not related to any economic success, but more on the effort to detect (find) the innovation and to communicate it internally. This statement is important to make, otherwise, key outcomes of the process would remain under-examined. We do so, because literature reports that some innovations that are technologically and even economically superior fail to be marketable, or ultimately accepted by customers (Rogers 1995). Assuming that innovation "discovery" is the result of the innovation exploration process, we follow the idea that the success of innovation "discovery" is proportional to "level" of exploration effort (Azoulay and Lerner, 2012). We will therefore measure this effort (i.e. contribution) providing the count of innovations discovered (i.e. by purchasing here). Therefore, the success of overall innovation exploration depends on the quantity of innovations discovered by purchasing. We exclude the quality of the innovation, although there is a clear correlation between quality of the innovation and firm's value (Hall, Jaffe, Trajtenberg, 2005), because it is extremely hard to assess in respect with measurement characteristics as of Jaffe (2008).

4.3. Data analysis: Our aim is to make sense of our empirical data collected during two case studies. We engaged in the process of coding data to make sense of interviews, following DeCuir-Gunby, Marshall and McCulloch (2011). We proceeded to manual data coding to introduce our findings. We did a code-book including theory-driven codes, as well as code coming from the context itself (Ragin, 1997). The aim of the coding process is to identify themes that come repeatedly during the interviews, and to analyse them. Our goal is not to construct a generalizable theory from a positivist perspective but to explore and understand a phenomenon in its specific context. The term "validity" has a different meaning here from the positivist approach (Järvensivu and Törnroos, 2009). Doing two case studies will increase a little bit the generalisability of the findings (Eisenhardt, 1989), and will aim at contributing to a better understanding of the reality in its context, from multiple perspectives. Our research is "authentic and fair" (Lincoln and Guba, 2000), meaning that all stakeholder voices have been heard and considered in the result.

5. WITHIN-CASE STUDY FINDINGS

In this section, we present the findings from each case independently, reporting on purchasing awareness, motivation and capabilities relatively to innovation exploration within each firm.

5.1. Findings within DD Corp

a) DD Corp purchasing awareness*:* At DD Corp, the main source of innovation awareness is the R&I department. Purchasing is able to stay aware of innovation through a joint work with R&I. R&I identifies innovations, and communicates objectives to purchasing through technical datasheets. "*I work a lot with R&I. When we share our views, I can show suppliers' technological road maps, analyse costs and risks, whereas R&I provides feed-back about the potential performance of suppliers' innovations. Purchasing acts as a filter between suppliers and R&I*" (DD Corp Purchasing Director). DD Corp purchasing is still transmitting technical datasheets to suppliers, to source innovation "*if you want to innovate, you need to formalize your needs. Some people here think that we should keep it open. But I think instead that we must pose boundaries to suppliers and formalise: we do innovation like this*" (DD Corp Purchasing Director). Purchasing organizes "tech days" on a yearly basis to stay closer to suppliers' innovations: during these events, current strategic and non-strategic suppliers are invited to come and present their innovations. The aim is to survey the market and innovations. "*We organise this event since 2013, but we hardly succeed to make our [DD Corp employees] staff coming and attend. Even if we insist, even if we impose, it remains very hard to make people join. They always have a good excuse to avoid coming, although suppliers are here with very interesting things to share with us*". Another source of knowledge is made of external service providers, who disclose market studies which are shared internally. DD Corp emphasizes also the use of scientific knowledge, building partnerships with universities through R&D, but this is rarely under purchasing's incentive. Non-regular contacts with innovators during exhibitions, trade shows may also provide opportunities, but this is rare. "*Apart from innovations designed inside that we need to source outside, it remains a coincidence when purchasing discovers an innovation outside and bring it back into the firm, even more rare to make it accepted by internal teams*".

b) DD Corp Purchasing motivations: The main incentive to go and explore innovation in the supply base are related to the need to source new technologies, under the request of R&I. For instance, the traditional set of categories (electronic components, PCB, electro-mechanical components, etc…) are still sourced but purchasing is now expected to source new categories: cloud and data services, integrated software, immaterial products. Purchasing must adapt and build new skills. At the purchasing level, the governance, corporate culture and incentives seem to have little influence on the motivation to explore innovation. The top management has a vision oriented towards technology, in its original meaning of technical development (engineers must develop innovations, not purchasing). For this reason, the mission given by the management to purchasing is limited to traditional sourcing and transactional tasks, thus do not represent an explicit incentive to go and explore innovations. However, innovation sourcing is part of the mission "*Motivation to explore innovation is not a wish, it is part of the mission… It is written in the mission profile, so this is a chance because I am obliged to do it… We have less work to support operations on daily crisis and logistics, but more work to make a technological market survey*" (DD Corp purchasing Director). At the individual level in purchasing, the intrinsic motivation to move naturally towards innovation exploration is limited. Some buyers have personal interests in certain technologies, which helps at transposing ideas found outside into professional knowledge. This personal knowledge is acquired more through personal investigations, interests, readings and participation to social networks, but is limited and is not enough to provide sufficient background to pull an innovation back to the firm. There is no clear track of any positive contribution.

c) DD Corp purchasing capabilities: DD Corp is a smaller company compared to SE Corp, and they cannot develop a specific purchasing team to focus on innovation exploration. *"Due*

to our limited size, we cannot create specific positions focused entirely on innovation exploration. Our buyers use to take a limited portion of their time to stay tuned with the market, but we know it has a limited impact" (DD Corp purchasing Director). Consequently, purchasers struggle at balancing daily tasks and innovation explorations. However, purchasing considers that the richness of firm's supply network is a competitive resource. "A resource-rich environment contributes to provide idea generation" *(DD Corp R&I director),* and they invest time and resources to develop their supply network's capabilities. The ever-changing technological environment makes DD Corp to consider individual technical knowledge as a core capability in purchasing to better contribute to innovation exploration: *« purchasers must have a minimum of technical background, a good understanding of how the firm processes to develop technological innovations. Purchasers must be curious, capable to learn from new technologies in a very fast-changing environment » (DD Corp purchasing Director).*

5.2. Findings within SE Corp.

a) SE Corp purchasing awareness of innovations: At SE Corp, the first source of purchasing awareness comes mainly from purchasing integration to other departments, but surprisingly Business Development function is a better source of awareness than R&D. Purchasing team objective is "*to first understand market needs and R&D needs and then match with the supply network capabilities. Therefore, we have trained our team to talk to R&D, but it also capable to listen to marketing, sales, business units, etc… because we want to pull the knowledge up from the market*". It's a process where a need for an innovation is identified within the customer base (SE Corp calls this "customer pain"), where Business Development teams or marketing identify a "pain" explicitly or implicitly raised up by a customer. Then purchasing is solicited to check whether the supply market can provide an answer to this "pain", and starts exploring. This integration avoids purchasing to explore un-relevant areas and new technologies that do not match with current SE Corp business needs. More than 80% of SE Corp interviewees reported that awareness come mainly from "*the understanding of customer market needs*" rather than "*getting technical demand from R&D*". The reason is that in the past, SE Corp had unsuccessful experiences of innovation sourcing, when purchasing imported too many innovation opportunities but few were *real* marketable innovations. Another mean to be aware of innovation opportunities is R&D, which also detects technological opportunities, listening to the technological market, trade shows, exhibitions and start-up clusters. In that case, purchasing works with the supplier (often a start-up) to carry on putting a contractual frame in the business relationship. Another path of awareness is when SE Corp R&D uses functional datasheets to search for an innovation from the supply base: purchasing transmits the request to suppliers in a form of a functional frame. Thus, purchasing is never left alone to explore innovations: SE Corp clearly emphasize on the integration with business development (to better understand the customer market) and R&D (to get technological inputs). Purchasing needs therefore to build a solid internal network made of formal or unformal links tied among the community of colleagues working close from customers, in other terms business and marketing functions. The aim of this network is twofold: 1/ purchasing gets aware of customer needs and potential innovations that can be sourced outside and 2/ this network is also capable to listen to the result of the exploration phase when purchasing comes back with an innovation "*We have about 20 people from various department working full time on innovation exploration, making an internal community, but we have also contributors working part-time on the topic*".

The second source of awareness comes from the physical proximity with supply network (the suppliers and any stakeholder having innovative activities). Quality of the ties between purchasing and the "geography" of the supply network influence purchasing's awareness of new opportunities. Purchasing does efforts to stay close from sources of innovations, because the distance to innovative suppliers seems to be a key parameter. For example, SE Corp purchasing is involved in various innovation clusters, because "*clusters provide new*

opportunities of sourcing innovation. It makes us aware of an unknown firm's strength, product or service". These clusters attract specialized suppliers, start-ups and new entrants. Clusters consequently become a source of knowledge and a facilitator of complementary alliances. SE Corp is also more likely turned towards trade associations or start-up incubators. "*These sources all serve as platforms to share data, to enlarge the scope of supply network. We find opportunities for exploring new technologies, to communicate our needs, and to interact with our pairs"*.

b) SE Corp Purchasing motivations to explore innovations: At SE Corp, culture and strategic priorities related to innovation are shaped by those who govern and this is spread through firm's values and missions to all employees. SE Corp's culture is oriented to long-term views where innovation is a priority. SE Corp's CEO, who is in this stable position for more than a decade, leads the vision about innovation: "*innovation comes first from the CEO. Our CEO has an excellent strategic vision and has inspired many transformations in the company since he arrived. He can anticipate the market and push innovation forward, guiding us to the right direction*" (SE Corp Purchasing-Innovation Director). Focus towards innovation comes therefore from the top management and it impacts employees' motivations to align functional strategies to corporate strategy: "*corporate strategy is clearly oriented towards innovation, which facilitates alignment with functional and operational tasks and make people move forward. It is coherent*". At SE Corp, another incentive for purchasing is that buyers are more and more solicited by other departments to support them in tricky relationships with innovative suppliers. "*We realized that innovations which are dealt with suppliers directly by R&D would come back, in fine, under purchasing management. Therefore, that's logical to involve purchasing early in these activities, to avoid discovering problems later in a program"*. Purchasing is more and more expected to be involved early in innovation programs (which are different from development programs), to know what's happen and to be part of decisions. *"Our motivation comes from the incentive that purchasing must be involved in everything about supply relationship management. So, let's apply our best practices with innovation sourcing as well"*. SE Corp has implemented a few metrics to measure innovation sourcing performance "*we count the number of suppliers' innovations that have been adopted"*. This provides a strong incentive to find innovation opportunities. However, they still struggle at measuring the impact of suppliers' innovations, although they feel the impact is in a continuous progress "*measuring the adoption is a first step. It is the most important motivation factor, because we measure purchasing work*". SE Corp has two other metrics measuring collaboration level with strategic suppliers, where contribution to innovation is also assessed. Motivations are also from extrinsic origins. Until recent years, SE Corp as seen as a technological company, "*targeting product performance, reliability and safety*". A recent shift of market expectations towards service-integrated products, which was not the core technology in these firms, imposed a new product positioning and "re-birth" of the company. Applied to the context we are studying, we build on Chen et al (2015) and we assume that "industry crisis" can be this huge change in the market associated with sales warning, pushing both companies to "get together" with suppliers in order to innovate and "renew technologies". Motivations are expected to be change as well when the market evolves and calls for new innovative products. Drastic changes in the market is an extrinsic motivation to engage for a change, and to increase risks taken "*It is sometimes better to arrive first on the market with an un-perfect product, rather than being second with a perfect product: the first launch will shape the market and take position. Perfect means "the best" for us, this was the only market approach we had. Launching an innovative but un-perfect product is really a huge cultural change, while we use to launch only mature products with fully certified performances. We start to understand that segmenting the product portfolio is necessary to adapt the performance to the market"*. SE Corp has understood the opportunity to get complementary assets from suppliers. "*We have a strong conviction that suppliers can contribute to our firm's innovation capabilities, but that this resource is under-exploited. Ten*

years ago, suppliers were expected only to execute innovations designed inside, or to contribute to product/process performance improvement ». Finally, motivations raise up at the individual level (intrinsic motivations): At SE Corp, main intrinsic motivation comes from the willingness to influence all strategic decision related to outside supplies (incl. innovation). "*We [purchasing] want to be associated to innovation and we accept to have limited control on decisions, rather than being involved late or at the end of the product development, i.e. when the product is mature. The problem of being involved late is that we discover the context of the innovation too late and therefore our contribution is very limited. We want to be involved as early as possible and, at least, to know what's happen. We want to influence decisions, raise alerts or identify risks in the relationship with an external partner"*.

c) SE Corp purchasing capabilities: SE Corp emphasized the opposition of traditional strategic resources (core capabilities) and new core capabilities: the first relates to the ability to "*develop performing, reliable and robust products, designed inside, because we have a heritage of safety-related products. To do that, we need experts in various engineering domains, and a good capacity to develop what the market demands, where purchasing is expected to source what is designed inside"*. Purchasing is traditionally involved during new product developments, when purchasers look at their network to find suppliers capable to execute an innovation designed inside. SE Corp reports that "*Traditional capabilities have a reverse effect that inhibits innovation*". Therefore, they have developed new core capabilities to explore innovation designed outside the firm, among which a specific function to explore innovation ("Purchasing Innovation"), capable to focus on innovation exploration full time. At SE Corp, this differentiated structure exists, but not at DD Corp where purchasing function deals both with daily tasks and explorative activities. This new function "Purchasing Innovation" is independent from purchasing category management and purchasing product development but still belong to purchasing organisation. A few purchasers belong to this differentiated entity. This organisational design imposes two distinct and autonomous units, one dealing with innovation exploration, another with innovation development (new products), category and project management. SE Corp considers that this structural differentiation is the best way to achieve concrete results in innovation: *"... the best is to have fully dedicated teams, because we've well understood that we cannot explore innovation only working 5% of the time on this topic. The reason is that if you're too much involved in daily operational tasks and program development, the priority will be operational or program emergencies. There is a critical size to reach, let's say the minimum is 50% of your time involved in innovation, the better is full time of course*". This explorative unit is smaller, more decentralized, and more flexible than the core purchasing team. SE Corp emphasize the importance of strong linkages between explorative unit and the rest of the firm, this is ensured by a set of routines and directives, also enhanced by resource sharing, coordination and control.

The way purchasing has shaped its supply network is an important driver of exploration at SE Corp. Purchasing exploration capabilities are enhanced if the firm has of a good access to abundant and various innovation providers. At SE Corp, "*the external environment supporting innovation is made of four different layers: 1/ Existing strategic suppliers with whom they already have a partnership 2/ Known suppliers but not previously identified as innovators 3/ Large ecosystems, clusters of innovations, some geographical regions where innovators are more concentrated (two zones in the US) and 4/ Universities and academics.*" Purchasing is therefore connected with start-ups incubators and competitive poles, such as "The French Tech" in France. SE Corp considers also that purchasing must be able to investigate distant but localized innovative ecosystems (ie same as French tech but in other countries). "*This might depend on state policies, but innovative clusters are present in many countries*". However, SE Corp purchasing has very few contacts with academics and universities.

Last, the individual level can provide exploration capabilities as well. Capabilities are enhanced by individual culture. Innovation purchasers are curious, listen to multiple sources of potential

innovations. "*This is a non-ending process of surveying the market outside the firm, to take notes of each and every little sign of opportunity, and to think permanently of the potential use and benefit for SE Corp*". SE Corp pointed out the importance human resources hiring from other industrial sectors, to merge external knowledge with existing "traditional" knowledge. Hiring, training and exploiting talented people from other industries is considered as a new core capability, because it brings a real competitive advantage. People have a different mindset and another business perspective compared to the traditional SE Corp view. "*We hire people from other industries, such as IT, to get fresh blood in our resources and to boost our ability to explore markets*". To complete this extra-ordinary view, SE Corp invests heavily in people's training to make them merge their view with firm's own culture.

6 – CROSS-CASE ANALYSIS

In this section, we present the cross-case analysis: we compare the two cases and their contexts. We have summarized all cross-case findings within the Table 5, but we took the most relevant findings respectively from Awareness, Motivation and Capabilities.

a) Cross-case findings about Awareness: *Purchasing awareness of an innovation might come from various origins, but is facilitated by purchasing integration into Business Development knowledge, in addition to the integration into R&D.*

In the context of fast-paced environment and ever-more demanding markets, companies must stay very close from their customers and adapt their products to potential future customer needs. In both companies we studied, suppliers' resources are increasingly considered as potentially provider of innovation, but the two firms have different approaches to bridge suppliers' capabilities and customer future needs. At DD corp, purchasing get incentives to find resources in order to develop an innovation designed inside, whereas at SE Corp, purchasing is works closely with business development and marketing to stay aware of future business needs. For them, bridging marketing function with purchasing enhance functional alignment to better share informations and decisions. We consider that SE Corp is the more mature company we studied in terms of purchasing contribution to innovation management: purchasing collects data from customers through business development department. We think this is a fundamental approach to increase purchasing awareness of new needs and to better contribute to innovation exploration process. Reviewing technological road-map with R&D is not sufficient to acquire the necessary understanding of which innovation will be likely "marketable" after it is absorbed by the firm. This idea is supported as well by the notion of marketing and purchasing co-management synergies (Lindgreen et al., 2016). This co-management calls for continuous alignment of customer needs with supply network capabilities, sequentially or simultaneously (Wagner and Eggert, 2016), and provides positive influence on product development speed (Gonzales-Zapatero et al., 2017). This calls for inter-dependant tasks, specific processes, what scholar name "functional integration", referring to "intra-firm collaboration and information sharing activities" (Swink and Schoenherr, 2015). Gonzales-Zapatero et al (2017) describe the functional integration as a bi-dimensional process, which needs shared and understood information as well as aligned decisions. In our study, we noted that purchasing function in charge of innovation exploration and business development functions were highly inter-connected, exchanging information about customer needs and suppliers capabilities. This provides an efficient stream of communication which improves the efficiency of the innovation exploration process within the supply market. These findings suit with those raised by Information Processing Theory, where scholars suggest that companies in a context of uncertainty must organize themselves into specialized but inter-dependant sub-units, and build information processes between sub-units to better deal with the uncertainty (Tushman and Nadler, 1978). These findings are also compatible with those of Gonzales-Zapatero et al (2017), providing insights about the benefits of purchasing-marketing integration on product development, as well as creativity or suppliers' innovation capabilities (Schoenherr et al, 2012).

b) Cross-case findings about Motivations: *Incentives to encourage purchasing to innovation exploration come from multiple factors: intrinsic (human factors like curiosity and experience), firm factors (values, culture, managerial targets) but in our case both firms are mainly influenced by extrinsic motivations (market evolution, incentives from customers).*

Managers of large corporations often complain that it is hard to induce their employees to be more innovative (Manso, 2010). In both cases we studied, we see that SE Corp has a better success to involve purchasing in innovation exploration because purchasers feel involved in this process, they're intrinsically motivated to leave their comfort zone, take risks and explore. HR management and hiring process is therefore important. But what characterize purchasing motivation in both cases is a radical technological shift in the market which forces firms to change and to renew technology. This market and technological uncertainty influence purchasing contribution to innovation, provided that these changes are important and put firm's market at risk. At DD Corp, firm's traditional market is at risk because now customers expect services in addition to the product (connectivity, cloud services, data management, customizability), whereas at SE Corp, solving "customers pains" represent the main motivation. These technological shifts might be considered as "crisis", as Chen et al (2015) explains that "when industries are facing crisis, there is an incentive for firms to get together to set standards, renew technologies, and develop more appropriate business models » (Chen et al 2015).

c) Cross-case findings about Capabilities (1/2): *In both firms, a big difference resides in the purchasing organization structure, and the way purchasing deals with tasks related to exploration: at SE Corp, there is a specific unit dealing with exploration full time, whereas this specific unit does not exist at DD Corp.* By comparing the two cases studies, we discovered that purchasing contribution to innovation exploration reach a better success in the firm which set up a dual functional structure within purchasing function. In this company, one functional structure oversees "traditional" exploration, i.e. supports R&D in new products developments and sources "designed inside innovation"; the other functional structure is clearly distinct because it is fully focused on innovation exploration. This notion of organisational structure differentiation is already found in the literature, for instance when Boumgarden et al. (2012) argue that organisations promoting exploration are different from traditional organisations. This suggestion has never been confirmed in purchasing field, and our case study put more light in how purchasing function might better contribute to innovation exploration with a distinct and autonomous unit focused on exploration. We saw that this structure needs complementarities and has strong links with the rest of the firm to reach a balance in execution, for instance it needs a very strong internal network. Linkages between explorative structure and the rest of the firm are ensured by a set of routines and directives, also enhanced by resource sharing, coordination and control (Boumgarden et al, 2012). Looking at the findings of our study, we suggest that the organisational structural differentiation is better to promote purchasing contribution to innovation exploration. Purchasers, if they deal with daily tasks as well as explorative tasks in the same time, are not efficient enough. At SE Corp, the best level of maturity we investigated, we can see that purchasing is at the heart of an ecosystem to succeed in explorative tasks. This confirms recent views from the literature (Gualandris and Legenvre, 2017). Also, this matches with the need of a "smaller, more decentralized, and more flexible unit", if companies want to better explore (Raish et al 2009).

d) Cross-case findings about Capabilities (2/2)*: Purchasers' individual particularities such as experience and practice are the key factors influencing innovation exploration capabilities. This refers to people's culture, background, experience, creativity, agility to explore innovation.* This topic emerges during several discussions with both firms. This dimension is related to knowledge and skills embodied in people. Our findings report a clear distinction between traditional individual capabilities, and specific individual capabilities needed to innovation exploration. At SE Corp, traditional capabilities are embodied in people's head for a long time and reflect the accumulation, codification and structuration of knowledge. The

traditional approach is focused on technology developed inside the company, when purchasing raises expectations to suppliers and expects an answer. "*People have a monocultural approach to product innovation: always the same methods ("designed inside"), same focus on "product performance and safety" and same typology of response to the market"*. One challenge is to change this culture, and to develop new individual behaviours, without jeopardizing the brand image if it fails. *"It depends on people's culture, their exposure to outside the firm, and their background, and on their position inside the firm. The better push comes from people that are not coming from R&D or technical functions, because they're more used to exploration techniques."* Better opportunities to source innovations are given to those who can evolve from the historical behaviour "make or buy, but design inside": "*we're tempted to make everything ourselves, and to buy only if we have no other choices. You can imagine that asking our suppliers to support our manufacturing is quite common, but asking them to support R&D as well as innovation is quite disruptive for our R&D*". another difference is about the sourcing practice: purchasing has to look for suppliers based on functional specifications, not technical where the needs are precisely explained. Also, purchasing need to show the ability to convince others: "*our challenge is to convince our internal partners that our suppliers are not only executants but can also innovate*".

7- CONCLUSION

We summarize here our conclusions and their implications. We give future research directions as well as inputs for practitioners. This study has investigated three research questions: *What drives (motivates) purchasing to explore technological innovation? Which capabilities are required to make purchasing contributing to innovation exploration? How is purchasing made aware of innovation opportunities?* Following Chen and Miller (2015), we've used the lens of the AMC framework to investigate the content of the interviews, and we report on awareness, motivation and capabilities facilitating innovation exploration in the purchasing function. We have discovered many sub-drivers involved in the contribution to exploration, which are likely to be considered also but we selected four major factors among all others. Among them, we have highlighted that four factors are necessary to facilitate purchasing's contribution to innovation exploration: 1/ Purchasing awareness of an innovation is facilitated by purchasing integration into Business Development knowledge, in addition to the integration into R&D 2/ Purchasing's motivation to innovation exploration come mainly from extrinsic incentives (technological shift in the market) 3/ A specific purchasing unit dedicated to exploration tasks full time is a core capability 4/ Skilled resources, such as purchasers' culture, experience and creativity are key factors influencing innovation exploration capabilities. We suggest that these four factors are valuable for research purposes, because they do not appear in any literature on the field and might open future investigation about purchasing involvement in innovation eploration. Also, this study may help practitioners to assess purchasing involvement into innovation exploration phases, and help managers intending to shape, adapt or redesign their purchasing organizations to better explore innovations. However, we know that AMC framework suffers from lack of credibility, reliability and validation in the literature (Schweig, 2015). It is difficult to limit the understanding of purchasing contribution to only three factors (A, M, C), and even more difficult to attempt generalizing, but we think this model can be more used in purchasing field. We hope this paper will open future roads of research and attempts to empirically validate the AMC framework in purchasing.

	Purchasing Awareness	Purchasing Motivation	Purchasing Capabilities
Organization	Purchasing organizational structure and systems	Firm governance, culture, incentives	Strategic resources and core capabilities
Industry	Physical proximity with supply network	Market technological shifts	Resource-rich environment
Culture	Upbringing and socialization	Values and mores	Experience and practice

Table 1 – Purchasing AMC model adapted from Chen et al (2015)

Themes	Sub-themes	Source
Purchasing awareness	Action visibility (firm size)	Chen and Miller, 1994
	Visibility on the supply network	Ragatz et al, 2002
	Purchasing internal integration (interdisciplinarity)	Jansen et al, 2009
	Participation to innovation-oriented industrial clusters	Alfonso-Gil and Vazquez, 2010
	Dissemination of the information (accessibility)	Quintens et al, 2006
	Organizational structures and systems	Chen et al, 2015, Boumgarden et al, 2012
	Physical proximity	Chen et al, 2015
	Supplier integration	Narasimhan, 2013, Ragatz et al, 2002
Purchasing motivations	Competitive advantage and cost reduction gains from the innovat	Choi and Krause, 2006
	Getting or sharing the rights to use the innovation	Aghion and Tirole, 1994
	Territorial interests in different markets	Gimeno, 1999
	Innovation performance monitoring (formal v/s flexible)	Zimmermann et al, 2015
	Contracting long-term relationship with supplier	Clauss and Spieth, 2016
	Firm's governance, culture, values	Narasimhan, 2013; Pihlajamaa, 2017
	Explicit incentives (bonuses, rewards…)	Pihlajamaa, 2017; Sergeeva, 2015; Jansen et a
	Organizational support and involvement of innovation champions	Pihlajamaa, 2017
	Increase customer attractiveness	Schiele, 2010
Purchasing capabilities	Organizational structure and design (structural differentiation)	Birkinshaw et al, 2016
	Budget and policies for innovation search	Pihlajamaa et al, 2017
	Setting exploration tasks as routines	Lazear 2000; Shearer 2004
	Managerial systems	Leonard-Barton, 1992
	Information processing	Smith et al, 1991
	Creative mindset; curiosity-driven behaviour	Bessant et al., 2005; Amabile, 1996
	assimilation and dissemination of information on suppliers and markets, communication tools	Quintens et al, 2006
	Lnowledge and skills, abilities for the job in question	Campion et al, 2011
	relationship-building capabilities	Quintens et al, 2006
	A resource-rich supply environment	Chen and Miller, 2015

Table 2. Summary of themes and sub-themes found in the literature

Firm's name	Firm's core business	Date of Creation	Country of origin	Employees	Total nb of patent (as of 2016)	Innovations developped in 2016	Innovation in which purchasing contributed (2016)
SE Corp	Develops, manufactures and markets home/building automation systems, electric power distribution systems and industrial safety systems.	1836	France	150 000 (among which 1 800 employees in purchasing dept = 1,2%)	20 000	115	40 (35%)
DD Corp	Develops, manufactures and markets home/building automation systems, communication systems and energy management solutions.	1998	France	800 (among which 15 employees in purchasing dept = 1,8%)	350	25	1 (4%)

Table 4: Interviews conducted (Source: Authors)

		DD Corp	SE Corp
Purchasing Awareness	Main internal source of innnovation awareness	R&I first, then R&D	Business devpt + marketing first, then R&D
	Ratio of innovations designed in/outside	designed mainly inside, rarely outside (less than 10%)	designed outside 50%, 50% still inside
	Formulation of the needs	precise tech specifications, detailed datasheets	functional datasheets
	Supplier tech days	yes 1x year(tech day)	yes very often
	Frequency of use of open innovation techniques	never	continuously, specific tool designed for SE Corp.
	Process to share data between Puchasing and R&D	unformal, R&D benefits more from this communication	Specific communication tool implemented
	Internal start-up incubator	No	Yes (implemented internally)
	Participation to innovation-oriented clusters	No	Yes, frequent contacts with french / local clusters
	Distance with innovative suppliers	Large. Current base is made of trad strategic suppliers	Close. Exploration among new, distant innov. suppliers
Purchasing Motivation	Firm historical culture, values and positionning	Firm oriented towards technology development (market follower)	Innovation oriented (pro-activity, want to be the first)
	Governance and management incentives	Not clearly established, no incentive process.	Strong, and officialized within mission profile
	Impact of market shifts on motivation	Market impose changes, firm follwo the competition	Firm identifies "customer pains", i.e. implicit problems discovered among end user or customers, that can be solved through an innovation
	Metrics, KPIs to measure contribution to innovation	Vague description of a target within the mission profile.	Yes (clear count of innov sourced by purch and adopted)
	Corporate strategy refers to innovation sourcing	No	Yes
	Early purchasing involvement in innovation process	No	Yes, as soon as R&D feels the need to have a contract n the relationship with a new partner, to manage IP or secure costs.
	Intrinsic motivation to be part of innov process	Not really, because this is against firm's culture, internal reservations to listen to purchasing as an "innovator"	Yes, purchasers strongly want to be part of innovation sourcing, and take each opportunity to participate. Each innovation buyer feels embarked in the mission to be creative and innovate.
Purchasing Capabilities	Purchasing organization to develop/explore innov	Not differentiated: same purchasing unit to devlp/explore innovations. But hard to find time to explore innvovations.	Differentiated units : 1 unit to explore innovation, 1 unit to develop innovations. explorative unit is smaller, more decentralized, and more flexible than the core purchasing team,
	Perception of the supply network's capabilities	Current strategic suppliers are best placed to innovate	Classification of 4 different types of partners, defined as
	Individual capabilities	Good technological background, knowledge about firm process, curiosity, openness to new techs, learning capabilities	Curious, creative, rik-taking, trial/error mindset. SE Corp invest a lot in people hiring, to get "fresh blood" in the company and key competencies from different sectors.

The role of Total Cost of Ownership Tools in health care technology assessment – A case study in AAL

Dr Paul Davis (lead Author)
Dublin City University, Ireland

Eoghan McConalogue
Dublin City University, Ireland

Prof Regina Connolly
Dublin City University, Ireland

Abstract

Unless an appropriate route to market is found for healthcare technologies these benefits will not be realised. This paper highlights the role of Total Cost of Ownership when conducting a technology assessment by reviewing existent literature. In particular, this paper recommends that Total Cost of Ownership tools be developed in conjunction with industry collaboration and that these tools be incorporated as a key award criterion during the assessment and procurement process.This paper examines a case of Ambient Assisted Living technologies. These offer a unique opportunity to improve the quality of life of persons with mild cognitive impairments while also reducing economic pressures currently experienced by European health systems.

Keywords: technology, ambient assisted living, total cost of ownership, health systems, procurement

Introduction

World age profiles are changing. It is estimated that there will be two elderly people to every young person in the European Union by 2060, with 10% of the population estimated to be over the age of 80 by 2060 (Eurostat, 2011). In some cases, the change is more immediate. By 2010, 23% of the population of Japan was 60 years of age or older and that figure it is predicted to reach 39% within the next 40 years (SBJ, 2011). While in 2011 there were 535,393 people over the age of 65 in Ireland, a 14% increase from 2005. (CSO, 2011).

In tandem with a change in world age profiles has been the development of ambient assisted technologies (AAL), (Novitzky et al. 2014; Jacquemard et al. 2014). AAL technologies attempt to utilise sensory and cloud technologies as an eHealth solution. It is envisioned that these solutions will provide assistance and support to persons suffering various diseases such as cardio vascular disease (CVD) and mild cognitive impairment (MCI). Two horizon 2020 projects are currently tasked with the development of AAL technologies with the aim being to allow users suffering from a disease to aspire to an improved quality of life (QoL). Those suffering might enjoy the comforts of their own home. In addition, the application of AAL technologies can reduce the economic burden that currently rests on stressed health care systems, caregivers and patients, (Novitzky et al. 2014).

The promise of economic advantage and relief of health systems cannot occur unless appropriate market assessment tools for of AAL technologies are developed. The procurement and assessment of AAL technologies is a complex multi-layered process, particularly in the context of fragmented European health systems. A review of the healthcare delivery systems of partner countries within said projects elucidates the various and fragmented systems across Europe. Individual partner countries show varied combinations of public and private sector health care delivery systems (WHO, 2016). This analysis along with the experience of the two Horizon 2020 projects to date highlights the necessity to develop bespoke tools for assessment.

The two Horizon 2020 projects related to this paper present a timely opportunity. Both projects require the bespoke development of total cost of ownership tools. At project maturity both solutions will have trialled suitable total cost of owner ship tools and commercialisation routes. This knowledge, in conjunction with a review of various European health systems it has made it clear that developing a bespoke total cost of ownership tool for European-wide AAL technological solutions is imperative to their successful diffusion through health systems. This paper presents an initial review of the placing of TCO in the Health Technology Assessment Process. Primary data was gathered from the participating partners in the H2020 projects and a model for TCO is presented in the results. An Initial discussion is presented highlighting some of the issues associated with the models and in particular in costing activities that in the main are at a pre-commercial stage.

Literature Review

The World Health Organisation states that health technology assessment involves a systematic approach to the evaluation of properties, effects and impacts of a technology. It is a multidisciplinary task that incorporates social, economic, organisational and ethical considerations with an objective to inform policy decision making, (WHO, 2017)

An important precursor to the costing of medical technologies within a procedure is the acknowledgement that the procedure itself, including the medical technology, is of value to the health care system. Procurement authorities globally are increasingly using Health Technology Assessments when evaluating and sourcing medical technologies (IMSTA, 2014).

A Health Technology Assessment (HTA) is a systematic evaluation and multidisciplinary process used to evaluate the social, economic, organisational and ethical issues of a health intervention or health

technology. The purpose of an HTA is to provide independent evidence to justify the purchase of best-in-class medical technologies when finite budgets need to be balanced. HTA information should always be generated with reference to unbiased experts involved in clinical practice (IMSTA 2014).

Table 1: Benefits of Health Technology Assessments (HTAs)6

1	Provides appropriate health care decision making platform
2	Proven effectiveness, safe & cost effective
3	Exposes the decision making process to scrutiny
4	May be required for reimbursement
5	Ensures rational use of resources
6	Establish systematic & predicable process for introduction of new innovative treatments
7	Can assist in removing obsolete technologies
8	Provides Patients with quick access to new treatments
9	Increases coordination, cooperation & transparency
10	Provides for suitable KPIs as a method to assess performance objectively

The process of undertaking medical technology HTAs varies between and within countries. There are numerous HTA units and initiatives across member states in Europe (WHO, 2015). Currently however, the majority of these units are assessment units for pharmaceuticals. The role HTAs play in pharmaceuticals is very different from that played in medical technologies. Typically, assessments on innovative drugs inform decision makers about pricing and reimbursement, the same is not true for medical technologies where a necessary strategic link between assessment and decision can be missing in many EU countries (MedTech Europe, 2017). Focusing on pharmaceuticals alone distorts medical decision making with regard to resource investments and patient care.

The dichotomy of European health systems, between public and private systems of delivery, elevates the role and influence of the assessment process relating to eHealth services. As assessors must evaluate the costs associated with the procurement of eHealth solutions during the technology assessment process, a clear understanding must be obtained of where costs gather along a product lifecycle; on the public or private side for example.

A big picture understanding of product or service life cycles is therefore required to complete a technology assessment. Models that assess the life cycle of a technology must reflect the particular industry and body of stakeholders for which it is intended.

The procurement process is not always fully documented, particularly in the public sector. In an effort to harmonise methodologies Caldwell et al (2007) has outlined a procurement process based on Van Weeles (2004) model. The result is a six stage process; specification, supplier selection, contracting, ordering, expediting and follow-up / evaluation.

The assessment and procurement of AAL technologies is particularly complex. Consideration must be given to existing medical support infrastructure, the supply of utility services such as electricity, cloud services, staff training and implementation. In some institutions the assessment and procurement of AAL technologies can be perceived as a strategic activity, necessitating a medium to long-term scope. Aiding this process the Total Cost of Ownership tool (TCO) (Hurkens and Wynstra, 2006) is used to understand indirect costs. This allows organisations to assess the lowest possible cost to be incurred when in negotiation with suppliers (Van Weele, 2004).

Ellram and Siferd (1998) have identified three segments to successful TCO analysis; operational, tactical and strategic. Through the TCO analysis organisations can uncover opportunities to either avoid or reduce cost. Due to the fragmented nature of European health systems this can prove to be a difficult task. Not only is there a lack of a common framework for deployment but cost structures vary from state to state.

TCO analysis highlights the many layers involved in the assessment of a technology. For example, it is often the case that the assessment and acquisition of an AAL technology includes the considered procurement of a product and service. As a result, performing TCO analysis during a technology assessment not only informs matters relating to direct and indirect cost (Leenders et al, 2006) but also elucidates a number of other influential factors:

- cost reduction opportunities
- supplier evaluation and selection criteria
- data for negotiations
- points to focus suppliers on cost reduction opportunities
- advantages of expensive, high quality items
- clarification and definition of supplier performance expectations
- a long term supply perspective
- forecasting for future performance.

A variety of TCO models have been proposed (Ferrin et al (2003)) and many studies (Zachariassen et al, 2011) have shown that TCO can effectively support sourcing decisions at different levels. However the tools themselves are not widely adopted (Hurkens et al , 2006) due to the complexity of data that has to be gathered and the complex activity based costing that has to be done. In general though there are a number of methods for estimating TCO. Organisations generally choose a TCO approach from one of two overriding methodologies; a standardised TCO tool approach or the development of a bespoke tool.

Hurkens et al (2006) highlight a number of methods to use when estimating costs. The first of these, the monetary based method, which allocates the costs of purchasing a service or product to the different true costs of components in the offering.

The second method is the cost-ratio or value based method, (Carr and Ittner, 1992; Ellram 1995). This method incorporates the monetary method with qualitative performance data. By evaluating non-monetary data, a suppler rating score can be amassed, resulting in a total cost factor, (Wynstra and Hurkens, 2006).

Benton and Shin (2007) offer a third model that introduces five performance factors; quality, delivery, technology, price and service. Suppliers are given a numeric rating, the highest being 1.0, indicating hidden cost of ownership.

Methodology

Over the course of the three years of both H2020 projects the assessment of the technologies and their impacts were approached through a variety of means. Initially a review of current models of HTA was undertaken. Secondly a review of the current practices in health systems (in particular the use of procurement regimes implemented in EU member states participating in the projects) was undertaken. Both of these pieces of work have been published previously as part of the deliverables for the H2020 projects.

A primary data tool was developed. This was designed to capture both supply and cost information from the parties participating. Initial data was to capture the approach to market and initial pricing models being looked at. A total of 26 partners received and fill in the initial data set.

Payers	After the end of the project, who do you think could pay for IN LIFE tools? (you can select more than one option)	☐National public authority ☐Regional public authority X Local public authority ☐Hospitals X Residential homes ☐Insurance companies X Elderly X Carers ☐NGOs ☐Advertisers. ☐Private companies. Specify the type: ☐Nobody ☐Others (specify):
	Which of these stakeholders will probably pay a higher price? Why?	
	After the end of the project, who do you think could pay for the IN LIFE platform? (you can select more than one option)	☐National public authority ☐Regional public authority X Local public authority ☐Hospitals ☐Residential homes ☐Insurance companies ☐Elderly ☐Carers ☐NGOs ☐Providers of services included in IN LIFE ☐Advertisers. Specify the type: ☐Private companies. Specify the type: ☐Nobody ☐Others (specify):
	Which of these stakeholders will probably pay a higher price? Why?	

Pricing model	Which pricing model do you consider more suitable for IN LIFE tools? (you can select more than one option)	☐ Fee per transaction/purchase x Subscription fee ☐ Monthly x Yearly ☐ Other: ☐ Pay-per-use X Licensing ☐ Freemium (the tool is offered for free but there are fees for extra components) ☐ Advertising. (The tool is provided for free or a cheaper price in exchange of ads)

		☐ Data model. (The tool is provided for free or a cheaper price in exchange of collecting some data from the user) ☐ Other(s) (specify):
	Why?	
	Which pricing model do you consider more suitable for the IN LIFE platform? (you can select more than one option)	☐ Subscription fee ☐ Monthly ☐ Yearly ☐ Other: ☐ Pay-per-use X Licensing ☐Freemium (access is offered for free but there are fees for extra components) ☐ Advertising (Access is provided for free or cheaper in exchange of ads) ☐ Data model. (Access is provided for free or cheaper in exchange of collecting some data from users) ☐ Other(s) (specify):
	Why?	Licencing might allow a licence holder for a certain area to personalise the services offered through the platform and to add others.

A second set of data sheets was then sent to all partners this time capturing the cost information and further information about the approach to commercialisation. This involved all 26 partners over the two projects. Further information was also sought through a series of workshops where a total of 17 partners were present. The second set of data was based around a similar toolset to the above but now included information on

- Production and delivery costs (one-off).
- Usage cost..
- Maintenance costs.
- Monitoring of a health professional.
- Other costs.
- Cost per user:
- Payers:.
- Pricing mechanism:
- Current/expected price:

Results

Because of the wide nature of products being developed for AAL as part of the H2020 projects and also because many were in a pre-commercial stage there was little hard data on costs. Instead categories were developed for the tools and a generic TCO toolset was piloted for the two H2020 projects.

A workbook was developed for each partner to fill in. The main headings used were

Direct Costs	
Hardware & Software	The capital expenditures and lease fees for servers, client computers, peripherals, network components, and software.
Management	The costs associated with network, system and storage management, including labor staffing, maintenance contracts, and professional services or outsourcing fees.
Support	The support staff labor hours and costs, training labor and fees, travel, support contracts and management overhead.
Implementation	Cost associated with the implementation of the application. These usually include development (customization and integration), testing, training, and consulting.
Communications fees	The inter-computer communication expenses for leased lines, remote access, and allocated WAN expenses.
Indirect Costs	
End user IS	The cost of formal end-user training, casual learning, informal support outside recognized IT support channels, self-development of applications, and local file maintenance.
Downtime	The lost productivity due to planned and unplanned network, system, and application unavailability.

These categories were further broken down into a more detailed model.

Direct Costs	Year 1	Year 2	Year 3	Year 4	Total (€)	% of Total Cost
Hardware						
Servers	€ -	€ -	€ -	€ -	€ -	#DIV/0!

This model was tested across 19 of the 26 partners who had sufficient data to use it.

Discussion and conclusion

Although research exists on TCO models it should be noted that there is little analysis existing on its application in the context of AAL technologies to be diffused on a European-wide scale across varying health care systems. There is an opportunity for further research to develop this area particularly with regard to public and private sector collaborations. It is recommended that future TCO models be developed in conjunction with industry partners. It is also recommended that the TCO process be developed into a key award criterion when conducting AAL technology assessment and procurements, thus aiding long term strategic decision making.

In developing the models and the toolsets one of the key problems is the lack of information on behalf of suppliers , in the case of the H2020 projects this may have been University, Campus Companies or SME's. This information may seem basic but it hampered the development of the models further. One of the key deficits in the developing the models was also the lack of information on Quality of Life Indicators which would have given an economic benefit. Many organisations lack both basic accounting information but have little knowledge of complex calculations such as QaL which are being by procurement authorities in assessing Health Technologies.

There is limitations in the methodology employed, future studies should consider qualitative interviews with practitioners. This is only an initial working paper which set out to explore the usefulness of these tools in a unique environment.

Summary
The use of financial constructs to support coordination across supply chains is generally underdeveloped. This lack of integration is particularly affecting small and medium enterprises, because their access to capital is seen as challenging. Supply chain finance (SCF) is an effective approach to improve financial collaboration, offering a wide variety of mutually beneficial schemes. This paper aims at analyse SCF and integration between supply chain and finance in light of relevant theories of the firm, conducting exploratory research based on a focus group study among Scottish companies representing different industries. The results are analysed against relevant theories to provide a better understanding of the underlying theoretical implications and determinants in financial supply chain management.

Keywords
Financial Supply Chain Management, Supply Chain Finance, transaction cost economics; Agency Theory; Network Theory; Collaborative Networks; Social Exchange Theory

Introduction

Finance has traditionally be represented solely as a department (or function) within organisations in logistics and supply chain management literature, as in Lambert and Cooper (2000). However, more recently authors argue that financial flows across organisations should receive the same amount of attention as goods and information (Martin, 2017). Even Mentzer et al. (2001), in their seminal contribution towards the definition of the concept of supply chain management, (SCM) expanded the conceptualisation of flows in supply chains by including finance; thus: products (or services), information and finance constitute the backbone of a supply chain. However, it is safe to say that these three types of flow have received different levels of attention from the academic community so far. Product flows are arguably the most consolidated stream of research in SCM, with several sub-streams focused on their management and optimisation (e.g. Zhang et al., 2014). Along the same lines, recent developments resulted in more complex information management systems intra- and inter-firms in the supply chain (e.g. Koh et al., 2011). For the third type of flow, as highlighted by several authors (Blackman et al., 2013; Pfohl and Gomm, 2009), finance has received considerable less attention compared to product or information flows. This gap is not only restricted to the management of financial flows, but extends to holistic management of the three flows in integrated supply chain

frameworks (Hofmann, 2005; Pfohl and Gomm, 2009; Wuttke et al., 2013b). However, since the late 2000s, the concept of Supply Chain Finance (SCF) has sprung in literature, strongly contributed to a burst of attention of both practitioner and academia towards the management of financial flows at the supply chain level.

Background

The literature on SCF can be divided into two strands. The first address the financial aspect of supply chains as a set of financial arrangements, usually driven by a large, credit-worthy buyer (More and Basu, 2013; Wuttke et al., 2013a) The second addresses it from a SCM standpoint, highlighting its impact on the financial performance of an entire supply chain, and enlarging its scope to typical collaborative solutions and fixed assets (Gomm, 2010; Hofmann, 2005; Pfohl and Gomm, 2009; Randall and Farris II, 2009). For the purpose of the current paper, SCF can be defined as the optimisation of the financial flows and allocation of financial resources in a supply chain with the aim to increase value, requiring the collaboration of at least two primary supply chain members. The financial flows and allocation of financial resources can be possibly facilitated by external service providers. Benefits of SCF are derived from an improved management of financial flows at the level of supply chains and of a more adequate allocation of financial resources to actors in these chains. Such better management is translated in reduced cost or need for financial resources: an example of this thinking is the 'SCF cube' (Gomm, 2010; Pfohl and Gomm, 2009), describing the positive impact of SCF in terms of reduction in volume, duration and cost of financing. Additional benefits are reduced risk of bankruptcy along the supply chain (Klapper, 2006) and easier access to liquidity for small-high risk suppliers (Berger et al., 2004; Klapper, 2006; Tanrisever et al., 2012). Moreover, SCF increases visibility for supply chain members and it enhances further information sharing, integration and collaboration (Hofmann and Belin, 2011; Lamoureux and Evans, 2011; Pfohl and Gomm, 2009). Thus, SCF as defined in this paper could be classified as belonging to the second stream.

Paper scope and outline

Despite the expanding literature base about SCF, contributions so far are relatively a-theoretical; the development of more solid theoretical bases has already been identified as one of the major gaps (Gelsomino et al., 2016). Thus, empirically-based literature correctly positions the topic of SCF within existing foci of SCM (e.g. supply chain collaboration), but seldom frames results in theoretical lenses, and, if so, limiting them to sporadic referral (Caniato et al., 2016; Wuttke et al., 2013b). Although this is understandable, considered the relatively novelty of the topic and its practical orientation, it is time to address this gap in literature. Therefore, the purpose of this article is to connect theories of the firm and theories for collaborative networks with the concept of integrated Supply Chain and Finance management, driven by an empirical study.

To do so, the paper provides a review of theoretical lenses and connects these to the results of a focus group conducted in Scotland in 2017. The literature review follows the guidelines from Green et al. (2006). After the narrative review of theories, the third section sets out the research methodology for the focus group. Its results are presented in Section 4, followed by a discussion of the findings in the fifth section. A final section concludes with practical implications and an extensive research agenda.

Theoretical perspectives pertaining to Supply Chain Finance

These implications and this research agenda are derived from theoretical lenses. Such theoretical lenses should cover at least (i) the interaction between two actors in the supply chain following our definition of SCF and (ii) be suitable to cover financial aspects. We have limited these lenses to five different theories that present potential explanatory power for SCF: transaction cost economics (TCE), agency theory (AT), Network Theory (NT), Collaborative

Networks (CNs), and Social Exchange Theory (SET). Table 1 summarises the key theoretical concepts streaming form literature on those theories.

Transaction Cost Economics

As the first of the five theories, TCE (Williamson, 1979) is considered a foundational theory that provides understanding of firms' motives and behaviour concerning entering and governing inter-organisational arrangements. As a result, it has been very influential in supply chain management literature addressing themes, such as strategic sourcing and outsourcing decisions (Williamson, 2008), market entry strategy (e.g. Anderson and Gatignon, 1986), buyer-supplier relationships in general (e.g. Heide and Stump, 1995) and more recently supply chain risk management (Blome and Schoenherr, 2011; Ellram et al., 2008). TCE assumes that organisations in their attempt to improve efficiency not only concentrate on production costs, but also include transaction cost in their evaluation representing 'the cost of running a relationship' (Carr and Pearson, 1999). These costs to 'contact, contract, and control' (Halldorsson et al., 2007) include both *ex ante* transaction cost (searching, evaluation and negotiation) cost as well as *ex post* (measuring, monitoring and enforcing) control cost Within the framework of transaction cost economics, decisions are not only influenced by Coase's (1937) transaction cost, but also, among other things, determined by frequency of transactions, uncertainty about future transactions and asset specificity. Thus, TCE attempts to provide a behavioural perspective on Coase's concept of transaction cost.

Four core assumptions form the basis of the TCE theory, these are:

- *Bounded rationality*. Because managers are limited in their available time, the (cognitive) perception of situations, access to relevant information and capability to process it, they cannot accurately evaluate all feasible alternatives. Consequently, their decisions will not be perfectly rational.
- *Asset specificity*. Transaction specific investments have limited value in alternative applications, which may result in *small numbers bargaining* (decrease in the number of alternative suppliers or customers) or even to 'bilateral monopoly', which occurs if both the supplier and the buyer are locked into the transaction.
- *Potential for opportunism*. Asset specificity often causes the party that has not invested in relevant resources to have leverage in the relationship.
- *Alternative modes of governance*. In order to mitigate the risk of opportunism, parties strive to implement the most suitable governance structures. These arrangements may vary from occasional highly standardised purchases, which require a minimum amount of governance, to long-term contracts with penalty or shared revenue clauses, equity investments or even vertical integration. According to TCE, trust between the parties is not equal to personal trust between individuals, but purely based on 'calculated risk' (Williamson, 1979).

Mentions of TCE in relation to Financial SCM (Hofmann and Locker, 2009; van der Vliet et al., 2015) usually does not lead to theoretical frameworks. Similarly, Liebl et al. (2016) state that a theoretical framework is missing in their case study and suggest that the relationship between buyers, suppliers and banks could have been analysed through a TCE lens. The only study by Wuttke et al. (2013b) that bases its framework on TCE and argues that its key concepts help understanding the implementation and use of SCF. Furthermore, they state that friction within financial flows in supply chains exist and are an important component of transaction costs; thus, appropriate SCF strategies can lead to more efficient supply chains. That only four studies relate transaction cost economics in one way or another to SCF, either indicates that either transaction cost economics is inadequate or confirms the lack of theoretical conceptualisation for SCF.

Agency Theory

This raises the question whether the same is the case for the second theoretical conception: agency theory. In a principal-agent relationship, the agent works for the principal and therefore

both parties are engaged in a cooperation. However, the principal and the agent have different attitudes towards risk and different goals (Eisenhardt, 1989; Jensen and Meckling, 1976). The so-called agency problem arises when there are competing goals and when there is information asymmetry (Whipple and Roh, 2010). Goal conflicts and information asymmetry stimulate opportunistic behaviour and can lead to moral hazard, a lack of effort by the agent and adverse selection, when the agent falsely describes its capabilities (Eisenhardt, 1989). Agency costs exist when there is a deviation from the principal's interest by the agent. The principal can try to reduce agency costs by incentivising and monitoring the agent's behaviour. The focus of the theory is on the determination of the most suitable contract: a behaviour-based contract or an outcome-based contract (Eisenhardt, 1989). AT is relevant for buyer-supplier relationships, since information asymmetry and goal conflicts are present in these relationships (Fayezi et al., 2012; Zsidisin and Ellram, 2003).

Among the studies that link AT with SCF, Wandfluh et al. (2015) link AT to buyer-supplier relationships in the financial supply chain. They take the principal-agent perspective to see how purchasing and finance departments (two principals) can improve cooperation with suppliers (agents) and how this influences the overall financial performance. Gomm (2010) mentions banks as principles and the companies that need the capital as agents. He mentions information asymmetry: banks are outside of the supply chain and therefore have less information than the companies in the supply chain. Pfohl and Gomm (2009) adopt the principal-agent theory to compare an internally financed supply chain with an externally financed supply chain, and mention monitoring and long-term commitment as methods to reduce agency costs. (Liebl et al., 2016) state that '*alternatively principal agent theory can be applied in order to investigate information flows as well as different intentions of the collaborating supply chain partners'*. These four examples show there are conceptualisations using AT for the financial supply chain; however, no decisive modelling has emerged neither has the potential of AT been fully exploited.

Network Theory

With agency theory having found a foothold into SCF, the question is whether network theory as third theoretical perspective offers an explanatory framework. NT defines a network as two or more of organizations ('nodes') that are connected via relationships ('links') that develop through interactions (Thorelli, 1986) (albeit that this writing on a strategic perspective). Such interactions comprise exchange processes, consisting of transactions, social exchange and information exchange in addition to adaption processes, where parties mutually influence and adapt to each other technically, logistically, and administratively (Johanson and Mattsson, 1987). This means supply chains are not only simple linear systems that exchange goods, information and money, but complex adaptive systems that continuously adopting (e.g. Choi et al., 2001; Surana et al., 2005). In terms of complex systems, interactions are seen as dynamic with regard to collaboration, inter-organisational integration and decentralisation of decision-making (Dekkers and Bennett, 2010). The existence of two different views on network theory – one as strategic, one as dynamic – implies that its application to SCF should consider which one was used.

Although from a strategic perspective network links may contain strong as well as weak ties, and both may contribute to supply chain performance, providing reliability and flexibility respectively (Ketchen and Hult, 2007), NT mainly focuses on developing long-term, trust-based relationships between supply chain members. Such positive, stable relationships contribute to joint value creation, simplify decision processes and ensure access to resources and activities. According to Thorelli (1986), power is 'the central concept in network analysis', because it offers firms a differential advantage to create or influence a network. Sources of power include size, market position, technology, expertise, trust and legitimacy. Organisations that are able to establish a more central position in the network or create stronger relationships with focal firms that are assumed to a competitive advantage related to better access to resources

and information, and more control over coordination (concept of centrality). However, this demands strong internal collaboration. Thus, effective managers are not only looking for direct savings, but also interested in building intra- and inter-organisational trustworthy long-term relationships, by sharing information and knowledge and investing in trust; thus, appropriate mechanisms for SCF should contribute to achieving these goals.

Although NT has been widely adopted in SCM literature, topics such as long-term relationship development, intra-firm coordination, information sharing and administrative adaption are implicitly considered multiple times for SCF (More and Basu, 2013; Randall and Farris II, 2009; Wandfluh et al., 2015; Wuttke et al., 2013b). However, in none an, explicit reference to NT is made. The only exception is Song et al. (2015), who base their hypothesis that information sharing can lead to improved availability of capital for SMEs on NT; however, they do not explicitly specify which network theory are using. Thus, it can be concluded that network theory has been implicitly adopted for SCF, but works do insufficiently build towards theory. This is surprising since Thorelli (1986), describes an example of adding financing facilities to existing products/services as a repositioning move to increase centrality in a network. Furthermore, Johanson and Mattsson (1988) state that financial adaption between members may reduce misfit in the relationship.

Collaborative Networks

Whether theory building has taken place from the fourth theoretical perspective – collaborative networks – is now evaluated. CN are defined as 'a distinct mode of organisation in which participant organisations work together in equity, commitment and trust exchanging information, sharing activities and resources and complimenting and enhancing one another's capacity for mutual benefit and a common purpose by sharing risks, responsibilities and rewards' (Bititci et al., 2004a). Common forms of CNs includes virtual enterprises, (dynamic) virtual organisations, extended enterprises, virtual laboratory, industry clusters, and so on (Bititci et al., 2004b; Camarinha-Matos et al., 2011). However, there is not much concordance on which entity might or not be classified as CNs, such as supply chains. For example, Bitici et al. (Bititci et al., 2004b) states that supply chains are a basic form of collaborative networks, whereas Camarinha-Matos and Afsarmanesh (2005) identifies as example of CNs 'advanced and highly integrated supply chain'. This means that conceptualisations for collaborative networks may apply to supply chains.

However, whatever perspective adopted, this strand of studies tends to focus on structure, behaviour and evolving dynamics of such entities, to understand the way in which they compete towards the achievement of pre-defined goals (Dekkers, 2009). In this sense, research on collaborative networks has clearly potential for interconnection with SCF, particularly the integration of product and information flows with financial flows in supply chains. In fact, SCF agreements often require the creation and consolidation of network relationships that go beyond the typical buyer-supplier dyad. For example, Martin and Hofmann (2016) show how reverse factoring (one of the most common SCF solutions) can be interpreted in terms of collaborative triads between buyer, supplier and financial service providers. At the same time, the authors show how the level of inter- and intra-firm collaboration plays a significant role in implementing SCF solutions, often beyond standard expectation of the traditional buyer-supplier network relationships as found in Caniato et al. (2016) and Wuttke et al. (2013b). Such evidence represents a significant overlap with CNs, as literature on the topic highlight how CNs might be organic in nature, with the potential to grow and to extend in an adaptable structure. Although evidence of CN as a theoretical background in SCF is weak, it would seem to be straightforward to theorise based on the explanatory potential of CN in relation to SCF and the integration of physical and financial flows; such interconnection may result in SCF being examined, for example, in terms of CNs' knowledge integration methods (Jayaram and Pathak,

2013), decisions models (Renna, 2013) and impact on adoption of new practices (Chong et al., 2013).

Social Exchange Theory

The final theoretical perspective – social exchange theory – assumes that interactions between organisations or groups and individuals in organisations are driven by the rewards and costs that these interactions are expected to generate, to some extent akin TCE. However, SET argues that these rewards and costs are not limited to purely economic factors, but include social aspects, such as autonomy, social approval, security and companionship. When taking decisions, companies evaluate the expected intermediate and long-term outcomes of different alternatives and choose the one that promises the best overall trade-off. The accumulation of such results determines the satisfaction with each relationship, or its 'social capital', which can vary over time. However, the standards that different interactors use to evaluate different cost (including time, effort and money) and rewards (such as status, companionship and monetary rewards) may vary across the temporal dimension and from person to person (West and Turner, 2013). This can create relative dependences, which may result in power inequalities. Due to these dynamics, relationships are not static, but develop over time. Thus, relationships can deteriorate by lack of commitment and trust as well as diverging priorities and visions (Storey et al., 2005). However, trust, open communication and informational transparency can lead to improved business performance, which in turn leads to increased trust (the 'loop model', Akkermans et al., 2004). Fynes et al. (2008) suggest that parties should strive for positive relationships as these warrant stability and beneficial outcomes, whereas negative relationships increases risk and may lead to termination. Despite being adopted in SCM literature (e.g. Griffith et al., 2006; Kwon and Suh, 2005), this lens seems not to have been used for SCF; .even though, trust is a recurring theme in SCF (e.g. Martin and Hofmann, 2015; Randall and Farris II, 2009; Wuttke et al., 2013b); because trust and commitment play a central role in social exchange theory, it seems logical to include this theory in our analysis for SCF.

Methodology

Because these five theories could provide a better understanding of motives and behaviour in financial aspects of supply chain management, albeit in quite different ways, we constructed our research design adopting a focus group methodology. Focus groups, sometimes referred to as focus group interviews, group depth interviews, or group discussions, can be traced back to the 1920s and have found broad application among practitioner researchers in for example marketing and health nutritionists (Rabiee, 2004). Nevertheless, the use of focus groups, originally designed as an academic research tool, is 'now well established as a mainstream method across the fields of social research, where they are widely used and are an extremely valuable research approach' (Ritchie and Lewis, 2014). Not only has this method been advocated for social research, already Flynn (1990) added it to the repertoire for operations management. The focus groups method aims primarily at understanding the meaning and interpretations of a select group of people regarding a specific issue or set of topics (Kitzinger, 2005; Liamputtong, 2011). Thanks to group dynamics, which are lacking in one-to-one interviews, this approach usually results in the generation of 'deeper and richer data' (Rabiee, 2004). As we want to explore and better understand the processes and intentions that drive decisions of supply chain partners regarding the management of financial flows, this interpretive method seems a good fit as interactions in the group serve the group members to better express and clarify their points of view (the 'group effect').

Study design

The focus group session was opened with a 25 minute presentation of the core concepts of financial supply chain management and SCF. This opening presentation served the purpose of aligning on terminology and provide with a basic understanding of SCF. This is especially

important: as literature in the introductory section of this paper highlights, there is general misalignment on what constitute an "SCF scheme", which leads to confusion on whether specific schemes such as Reverse Factoring or Dynamic Discounting are, in fact, subject of discussion or not. The initial presentation did not mention the five identified theories, which were by themselves not directly the subject of the focus group discussion.

Although authors differ on how many participants should partake in the focus group discussion, there seems to be consensus that the ideal group size is between four and ten persons (Liamputtong, 2011). However, smaller groups consisting of four to ten participants provide more room for each individual to contribute and interact optimally and thus explore relevant themes in more detail, hence generating more relevant data (Krueger and Casey, 2015). In line with (Kitzinger, 1994), the group was divided in three subgroups (of 5-5-6 people) each addressing a different theme. The themes of the subgroups were financial aspects, process aspects and relationship aspects. In each subgroup, a group discussion, led by a moderator and one observer (authors of this paper), lasted for 30 minutes. After each session, the participants were rotated between groups, to increase group dynamics and so minimizing the probability of dominance of certain group members. In total, three rounds of discussion were held, totalling 90 minutes. In order to stimulate exploration, check understanding and promote discussion even more, post-it sticky notes and flip charts were used.

Profile of Participants

Potential participants were invited to partake through the Centre for Engineering Education and Development of Scotland, a regional business network. In total, 16 participants, representing 8 different organisations of varying industries were present. The organizations represented were SMEs (2), mid-size (2) and large corporations (4). Thus, we applied convenience sampling based on experience and interest in the relevant subject area, which is common practice in focus groups (Liamputtong, 2011). The presence of different industries provided the right level of heterogeneity within the sample, avoiding polarisation of issues and collaboration practices towards a specific industry. Multiple industries and multiple roles within the supply chain strengthened the generalisability of results, providing a plurality of point of views within the discussion.

Data collection and analysis

The group discussions were recorded and these recordings were transcribed on a later date. Both the moderator and the observer took notes independently during the session, and special attention was paid to non-verbal and interactions between group members. Directly after the session, the post-its, flip charts and notes were collected and compared to increase reliability and internal consistence. The data was then grouped logically to identify main categories of key themes and concepts.

In the weeks following the session, the authors used the transcriptions and other data to code the findings using the categorization of the debriefing session. This coding aided in identifying matching key theoretical concepts. This coding was done by three researchers working independently and then the results were compared afterwards.

Results

In general terms, data collected from the focus group align well with the theories identified as most of the key theoretical concepts emerged during the discussions on the integration of supply chain and finance in the sub groups.

The TCE concept of bounded rationality manifested clearly in the different focus group sessions. Especially, SMEs seem to be disadvantaged as the knowledge regarding financial flows and SCF arrangements is much less matured as that of their larger counterparts in the

supply chain. In all groups, the expressed opinions quickly converge on this. Participants stated that (most) SMEs have trouble understanding financial solutions, which may lead to increased risk or excessive cautiousness on their side. One participant confessed that when a buyer offered him VMI he did not understand the scheme, nor its cash flow implications, enough and therefore made the decision on 'gut feeling'. This phenomenon leads to increased relation specific implementation cost (such as legal advice and learning cost), which may increase the 'lock in' effect and increases fear for opportunism. As one participant declared: '..this is the red light that flushes'.

AT presents, potentially, a significant explanatory power for supply chain and finance integration. As presented in the section above, it is a widely spread mean of interpretation for buyer-supplier relationships, and therefore it is suitable also for understanding issues in supply chain and finance integration. More specifically, one of the most relevant outcome of the focus group regards the competing goals, both inter- and intra-company. As one participant stated, 'the 'S' in SME stands for suspicious and sceptical', a clear reference to the conflict of goals and relative mistrust that characterise every principal-agent relationship. On the other side, several participants highlight how more transparency and clarity of communication improve the management of financial flows, for example facilitating the adoption of SCF by suppliers. Principal-agent relationships can be identified also within the same company, between different departments (in alignment with literature on SCF, e.g. Caniato et al. 2016)), for example when participants depicted the finance department as a principal, 'ruling' over purchasing (the agent) on terms and conditions of transactions. This same concept seems to be true for other departments, as one participant illustratively referred to the finance department as 'Sales Prevention'. Some buyers consider it as a sign of weakness when one of its supplier asks for early cash. This may lead to suppliers not letting buyers know their needs, which may lead to suboptimal decisions (agency cost). An interesting phenomenon that seems to be present is that, as financial flows typically move in opposite directions, there appears to be a reverse principle-agency situation in the buyer-supplier dyad, as there are conflicting goals (buyer wants to pay as late as possible, while the supplier wants the opposite), the agent (the buyer) has more information (if the invoice has been approved, if the plan is to pay within the agreed terms, etc.) and could (and frequently does) act against the principle's (supplier's) best interest by paying late. This, evidently, brings agency cost in the relationship as the supplier needs to hedge this risk with additional cash or insurance.

Overall, our findings seem to indicate that NT has much common ground with the underlying mechanisms of financial management in supply chains. Financial aspects are clearly considered as part of the original power concept in NT (Thorelli, 1986), According to NT, companies with a better financial position have more leverage to influence the network, this was confirmed by the focus group discussion ('the big party dictates'). These dominant parties could utilize their influence to optimize financial flows in the network and thus improve overall network performance. On the other hand, organizations with less power in the network, could benefit from being in an SCF scheme with important SC partner, as it may increase their centrality which facilitates access to resources such as (cheaper) capital with bank. Participants clearly indicate that they are interested in long-term cooperative relationships and that if there is enough commitment and trust present, parties are more eager to make investments in the relationship. This means that early payment may be accepted more rapidly (by buyer), or SCF agreements, like reverse factoring might be adopted easier. If, on the other hand, the relationship is weak, a request for speedier payment, may turn out in switching to another supplier.

Unlike TCE or AT, CNs presents a somehow more limited scope of application for the integration of supply chain and finance. Although collaboration has been a key topic throughout all of the three groups, limited evidence was gathered to connect SCF implementation or financial supply chain management to archetypes of CNs reported in literature. The most relevant result stemming from the focus group sessions pertains the stages of maturity of the

collaboration between buyer and supplier: long term, stable relationship facilitate collaboration and sharing of information, hinting towards the strengthening of links typical of a CNs, while less long-term and strategic relationship might result in lack of collaborative effort. As effectively put by a buyer when discussing collaborative management of financial flows: 'the supplier must be on the radar'. A second result of interest is related to the (de)centralised decision making process in large corporates. Evidence from the focus group shows that the level of centralisation plays a crucial role in mediating the ability of companies towards implementing financial supply chain management practices, even at the single company level (e.g. accepting/refusing cash discount proposals). We identify potential of interpreting this results exploiting the body of research on distributed manufacturing within CNs.

Lastly, we found that SET has strong links to the findings in the focus group conversations. Almost in every session, trust came up as a self-evident prerequisite for effective financial management in supply chains. Comments like 'trust comes first' and the barrier that a lack of trust create in exchanging crucial information speak for themselves. The discussions made clear that levels of social capital exist, not only between organizations, but also between different persons in those organizations ('people buy from people but still there is a relationship between organisations'). This may indicate that it may be sensible to let the person that has the best relationship with the supplier discuss the more sensitive topic of SCF. Additionally, different departments within organizations appear to have different paradigm on optimal interactions with supply partners: business relationship development vs. a purely transactional relationship ('a happy customer/supplier vs getting paid'), this difference is maintained as internal communication between departments is far from optimal and functional silos exist, which hampers the integration of financial and logistical flows. Finally, although large companies possess more relative power, the data from the focus group seems to indicate that SMEs have other strengths, such as higher commitment and flexibility which could be deployed to improve the quality and interdependency of the relationship.

Conclusions

In this paper we have tried to lay a stronger foundation for Supply Chain Finance by looking for alignment between SCF and theories of the firm. The view of Scottish firms shows that there are clear linkages between SCF and TCE, AT, NT and SET, and to a lesser extent between SCF and CN. There are some recent studies that already link SCF with TCE and with AT. We were able to provide further findings on these linkages. Our results show that also NT and SET provide opportunities for building the theoretical foundation for SCF. These findings are not only relevant to academia, but also to practitioners. In particular our results show implications for alignment between buyer and supplier and alignment between different company departments.

A limitation of the research is that there might be additional firm theories that have a better fit with SCF that we did not consider. The geographical context is another limitation, because there were only Scottish firms in the sample. A similar focus group could be reproduced in other countries to test our findings in a different geographical context.

Directions for future research

In terms of directions for future research, this article provides several direction of research development.

For single contributions, it highlights potential theoretical background that can provide good lenses for additional empirical or modelling pieces linking supply chain management and finance. For example, TCE or AT can be used as theoretical basis to develop case study applications further investigating the behaviour of suppliers in reverse factoring applications.

For doctoral candidates or early career researchers, there are possibility to develop contributions spanning over multiple articles, investigating theoretical areas that need further development using the integration of supply chain and finance as a potential fertile terrain for fruitful contributions. For example, while CNs and game theory are often connected (Camarinha-Matos and Afsarmanesh, 2005b; Dekkers, 2009), there is a need for further investigation. The interconnection between supply chain and finance has the potential to provide a good basis for a series of contributions in this direction: from a methodological point of view, the recent contribution by Fisher and Aguinis provides excellent guidance towards using empirical evidence in the context of SCF or supply chain an finance integration to make theoretical advancements (Fisher and Aguinis, 2017).

Finally, research groups that want to devote significant attention to the topic of SCF and – more in general – integration between supply chain and finance – might devote their effort towards consolidating the topic as a new scientific discipline, consolidating existing knowledge, clarifying its scope against existing literature and producing an effort towards the definition of a specific research agenda that would be similar to the effort product to differentiate supply chain management from logistics in the early 2000s (Mentzer et al., 2001).

Table 1: Key theoretical concepts and corresponding evidence from focus group

	Key theoretical concepts	FG1: financial aspects	FG2: relationship	FG3: processes
TCE	Bounded rationality	Purchasing has no finance knowledge	SMEs do not have supply chain perspective	Info available to supplier might be limited
	Potential for opportunism			
	Asset specificity	Assessing financial proposals would take up too much resources Technological needs are not clear		
	Ex ante/ex post transaction cost minimization			
	Alternative modes of governance			
AT	Principal-agent relationship			
	Competing goals (conflicts of interest)	Finance rules over supply chain		SMEs might show scepticism and suspiciousness
	Information Asymmetry			Communication and understanding is key Larger suppliers have knowledge about SCF
	Moral hazard			
	Agency cost		Suppliers might hinder relevant information to avoid seem weak	Supplier asking for money is a sign of weakness and damages the relationship
	Adverse selection			
	Information as commodity		Common standards of evaluation do not include finance	
	Behaviour/outcome based contracts		Right incentive can bring right focus to suppliers	
NT	Relationships ensure access to resources and activities	Only supplier with some degree of strategic relevance can access SCF	SCF has positive impact on relationship with bank (your buyer is investing in you)	
	Interdependency		Larger party dictates terms	
	Centrality		Lack of integration between departments	
	Focus on developing LT trust-base relationships			
	Information and knowledge sharing		Suppliers might hinder relevant information to avoid seem weak	
CNs	Collaborative advantage based on unified approach to value creation ('win-win-win')	Trust comes before SCF		
	Central coordination mechanism (IT as enabler)			Sales is focused on relationship management, finance on transaction
	Network as organism with adjustable structure and phase transitions	Local decisions are limited by HQ policies		
		Suppliers with cash needs are perceived differently based on maturity of relationship	Long term relationships facilitate adoption	
SET	Rewards and costs drive relationship decisions			
	Social capital			
	Power differentiation		There are differences in power btw buyer and supplier Larger suppliers more open than smaller	
	Evaluation standards vary	Ad-hoc evaluation models might be created	Culture affects willingness to discuss finance	
	Development of relationships			Relevance of interpersonal relationships between buyer and supplier
	Positive relationship ensure stability and beneficial outcomes			

A bounded rationality perspective on Reverse Factoring
Insights from Dutch SMEs

1 Windesheim University of Applied Sciences, The Netherlands
2 Politecnico di Milano, Italy

Abstract
The objective of this paper is to analyze which factors influence the small- and medium sized suppliers' decisions to accept or reject an offer for reverse factoring (RF) from their buyers. Through a multiple case-study, with the RF offer as the unit of analysis, the research attempts to identify the quantitative and qualitative factors that influence the SME's decision regarding this offer. We interview suppliers, buyers and banks, and make use of secondary data. We contribute to filling in multiple research gaps in SCF about the SME perspective and adoption of RF and provide clear managerial insights for both suppliers and buyers.

Key words: Supply Chain Finance; Reverse Factoring; SMEs.

Acknowledgements
This research was conducted in the context of the SIA-RAAK project 'Supply Chain Finance for SMEs'. SIA supports Dutch applied research with so called 'RAAK-projects' and is part of Dutch organization for scientific research NWO. With the project we won the SIA-RAAK audience award for best applied research in The Netherlands. We are thankful to SIA for giving us the opportunity to do this research and for recognizing the value of empirical research on SCF for SMEs.

Introduction
In recent years, banks have been required to increase liquid assets, resulting in increased difficulty for companies, especially SMEs, to borrow (Ivashina & Scharfstein, 2010). The resulting liquidity scarcity (Ellingsen & Vlachos, 2009) made it more difficult for companies to invest in inventories and raw materials. In this landscape, Supply Chain Finance (SCF) instruments are often presented as solutions for working capital management of both single companies and the supply chains they are part of (De Boer, Van Bergen & Steeman, 2015; Gelsomino, Mangiaracina, Perego & Tumino, 2016; Pfohl & Gomm, 2009).
Revere Factoring (RF) is the most well-known SCF instrument. With RF a large creditworthy buyer allows his suppliers to sell approved invoices to financial institutions based on the buyer's own credit rating (Dello Iacono, Reindorp & Dellaert, 2015; Wuttke, Blome, Foerstl & Henke, 2013). A recent industry survey shows that usage of SCF instruments is growing, and that RF is by far the most used instrument. The same survey shows that for buyers working capital optimization is the most important reason to do RF (Siemes, Extra, Dellermann & Gelsomino, 2017). Therefore, purchasing spend is an important characteristic when choosing suppliers whom to offer RF, and suppliers who represent a large spend might receive an RF offer first. However, since the RF market is maturing and RF is becoming a more standardized practice, onboarding costs decrease which makes it easier for buyers to also offer RF to the 'long tail' of small and medium sized (SME) suppliers. Examples of companies that already offer RF to SME suppliers are Vodafone, Puma and Jumbo (Stammers, 2016; Carlsson, 2016; Marteijn, 2015).

SMEs in the Netherlands represent more than 99,8% of all active businesses, provide 72% of all jobs and 62% of national GDP (Nederlands Comité voor Ondernemerschap en Financiering, 2017). In the Netherlands there are 47 SMEs per 1,000 inhabitants. In comparison: in France this number is 39, in UK 28 and in Germany 27 per 1,000 inhabitants (Centraal Bureau voor de Statistiek, 2015). 51% of Dutch companies have been asked to accept payment terms from their customers that are longer than they feel comfortable with (Intrum Justitia, 2017). These extended payment terms can result into liquidity problems for suppliers. In the light of these potential liquidity problems SCF solutions like RF are often portrayed as a solution for SMEs, and a win-win situation for both buyer and supplier (Klapper, 2006). The attention in both the corporate and the academic world for SCF and RF is growing, but there is a lack of attention for the supplier perspective (Wuttke, 2013a; Lekkakos & Serrano, 2016; Liebl, Hartmann & Feisel, 2016). RF is relatively new for SME suppliers, which is why there is a lack of knowledge among them about the effects (De Goeij, Onstein & Steeman, 2016). Recent research shows that often working capital optimization or reduction of purchasing prices, instead of stabilizing the supply base, are the most important reasons for buyers to introduce RF and therefore, suppliers can't just simply assume that RF will be a win-win situation (Liebl et al., 2016).
Recently the supplier perspective in RF gained some attention (Dello Iacono et al., 2015; Van der Vliet, Reindorp & Fransoo, 2015; Lekkakos & Serrano, 2016; Liebl et al., 2016; Martin, 2017). Dello Iacono et al. (2015) and Van der Vliet et al. (2015) focus mostly on quantitative factors that influence benefits and costs for suppliers in RF. Lekkakos & Serrano (2016) study the impact of RF programmes on suppliers' operational decisions and performance based on a multi-period model and numerical experiments. Only Liebl et al. (2016) and Martin (2017) use empirical data. Dello Iacono (2015) states a match between quantitative 'hard' factors and qualitative 'soft' factors is needed. According to Caniato, Gelsomino, Perego & Ronchi (2016) research should also include unsuccessful adoption cases of SCF solutions to be able to make a better analysis. Therefore, the objective of our paper is to analyze both quantitative and qualitative factors that drive an SME supplier to accept or decline an RF offer from its buyer. This is supported by empirical case study research, wherein both suppliers that accepted and suppliers that rejected an RF offer are included.

Literature review

There is a growing attention for SCF in general, and RF in particular, among academics. The field SCF is relatively new and most papers have been published after 2005. The first papers were conceptual in nature and showed the potential of a collaborative financial approach among supply chain partners (Hofmann, 2005; Pfohl & Gomm, 2009; Randall & Farris, 2009; Gomm, 2010). Later on, a stream of empirical research in SCF and RF followed, mainly focused on the perspective of the focal buyer company in the supply chain (Wuttke et al., 2013a; Wuttke, Blome & Henke, 2013b; More & Basu, 2013; Blackman, Holland & Westcott, 2013; Wandfluh, Hofmann & Schoensleben, 2016; Caniato et al., 2016). Only recently the supplier perspective has gained attention, but most of the contributions on suppliers and SMEs are non-empirical (Van der Vliet et al., 2015; Dello Iacono et al., 2015; Lekkakos & Serrano, 2016) or have only limited empirical input from suppliers (Liebl et al., 2016). An exception is the research of Martin (2017) which shows, based on a survey among 115 Swiss companies, that the supplier's commitment in participating in SCF is not only about quantitative factors, but relational factors like trust, power and dependence are also important. However, Martin (2017) states that in her research only a limited amount of suppliers is included who actually got offers for RF or other inter-organisational financing alternatives, or already implemented it. In general, important factors in the decision process that can lead to the adoption of SCF instruments are often not considered (Caniato et al.,

2016). This is especially true for the supplier perspective, since the amount of empirical data about suppliers is still very limited. Current research touches upon some important quantitative and qualitative factors, but does not show the full picture yet on how suppliers make decisions regarding RF offers. That is why case study research on SME suppliers is seen as fertile area for future research (Wandfluh et al., 2016). The literature on SCF adoption for SMEs has considered several factors, which can be grouped in the following four categories: bounded rationality, quantitative factors, buyer-supplier relationship status and the supplier's relationship with financial institutions (Hofmann & Kotzab, 2010; Van der Vliet et al., 2015; Liebl et al., 2016; Wuttke et al., 2013). In the underlying these factors will be explained in more detail.

Bounded rationality

Regarding bounded rationality, Wuttke et al. (2013a) mention that buyers experienced spending much time on explaining the concept of RF to suppliers who haven't heard of it before. Also De Goeij et al. (2016) mention supplier's unfamiliarity with RF as one of the major impediments for adopting RF. This is why Wuttke, Henke, Heese & Protopappa-Sieke (2016) state that the supplier's experience with and exposure to successful SCF business cases is important in SCF adoption. Martin (2017) shows also experience with other similar financing options like factoring, are relevant for suppliers to know how to evaluate terms and conditions in SCF. Many papers on SCF mention cross-functional collaboration within the buyer company is needed (i.e. Wandfluh et al., 2016). However, this is also important for suppliers. Wuttke et al. (2016) mention that when buyers introduce RF to suppliers they usually first talk with sales managers, but there is often an absence of explicit incentives for sales people since RF does not lead to increased prices or reduced payment terms. Therefore, it requires sales people to collaborate with internal financial people to get a better idea about company benefits. In an SCM context, Simatupang and Sridharan (2005) show the importance of information sharing for alignment on incentives and decisions. Wandfluh et al. (2016) state that information sharing between buyer and supplier, or the lack of it, is also an important success factor for SCF. De Boer et al. (2017) show in the context of SCF there can be a reverse principle-agent situation in buyer-supplier relationships, as financial flows move in opposite directions and there are conflicting goals, for example about payment terms. The buyer has more information, for example about invoice approval, but might act against the principal's (supplier's) best interest by not sharing relevant information in order to pay late. Because the supplier does not have full information, he cannot make an optimal decision regarding an SCF offer from the buyer. Martin (2017) shows that suppliers can be uncertain on future terms and conditions as well as on reasons for buyers to provide them with a financing alternative, and mentions these uncertainties can hinder rational decision making.

Quantitative factors

Pfohl & Gomm (2009) introduced the supply chain finance cube, a three-dimensional framework to assess benefits for SCF. Included are three aspects: the amount of assets (volume of financing) that needs to be financed, the duration of financing and the capital cost rate. With RF a buyer and its financier offer credit to a supplier, against the credit rating of the buyer (Demica, 2007). If the buyer has a high credit rating, the supplier enjoys low short-term financing costs. However, often when RF is introduced to a supplier, this goes together with an extension of payment terms and a discount on the invoice (Wuttke et al., 2013a; Liebl et al., 2016). Van der Vliet et al. (2015) show that a supplier needs to carefully assess if the benefits from making use of the credit rating of the buyer aren't offset by the negative financial implications of the payment term extension and the discount the supplier gives on

the invoice. Dello Iacono et al. (2015) state that ideally also the benefits and costs of competing forms of financing and training costs for getting familiar with RF should be included when assessing benefits and drawbacks of RF for suppliers, but do not include these aspects yet in their model. Regarding the latter, De Boer et al. (2017) report about suppliers who did not understand forms of SCF at first, and therefore had implementation costs such as learning costs and costs for legal advice.

Supplier-buyer relationship

Regarding supplier-buyer relationship, literature shows how a good relationship, based on shared information and trust, is an important requirement for effective supply chain management (Handfield & Bechtel, 2002; Horvath, 2001). This also applies to SCF: according to Wuttke et al. (2013a), the absence of trust reduces the supplier's willingness to adopt RF. Furthermore, power distribution, influenced by volumes, the specificity of purchased goods and intensity of competition in the market (Liebl et al., 2016) is known to influence the adoption of SCF. According to Hofmann & Kotzab (2010) an uneven distribution of power can be a big burden towards collaborative SCF approaches. In some cases the buyer has much more power than the supplier, and the buyer dictates terms in SCF contracts (Wuttke et al., 2013a). In other cases where power is more equally distributed or where the supplier has more power, buyers care more about the relationship, the approach towards suppliers is more customized and the main goal of the buyer is not extension of payment terms or reduction of purchasing prices (Liebl et al., 2016). Caniato et al. (2016) show that RF can have a collaborative function and can be used as a risk management tool for buyers, to secure the supply base. For suppliers, a long-term collaboration can be a requirement for adopting RF. However, there are also suppliers that consider RF as an instrument that increases their dependency on the buyer, which may lead to a worsened negotiation position for discussing prices (Liebl et al., 2016).

Supplier – banks relationship

Finally, some papers mention the role of the relationship between the buyer's bank and the supplier in adopting RF (Liebl et al., 2016; Wuttke et al., 2013). Wuttke et al. (2013) report on suppliers that expect "there is *a catch to SCF, as they did not trust an external bank they are currently not doing business with*". This shows that, for suppliers, it can be unclear what the consequences of RF are when buyers enlist a different bank. RF operations always involve the bank of the buyer, while often the supplier might have a pre-existing relationship with a different bank. Access to other types of financing, like bank loans or factoring, influences the willingness of a supplier to participate in an RF program (Lekkakos & Serrano, 2016; Martin, 2017). Consequently, the approach of a supplier towards RF can be affected by the pre-existing relationship with its own bank. But, as far as we know, there is no research yet about the effects of this relationship.

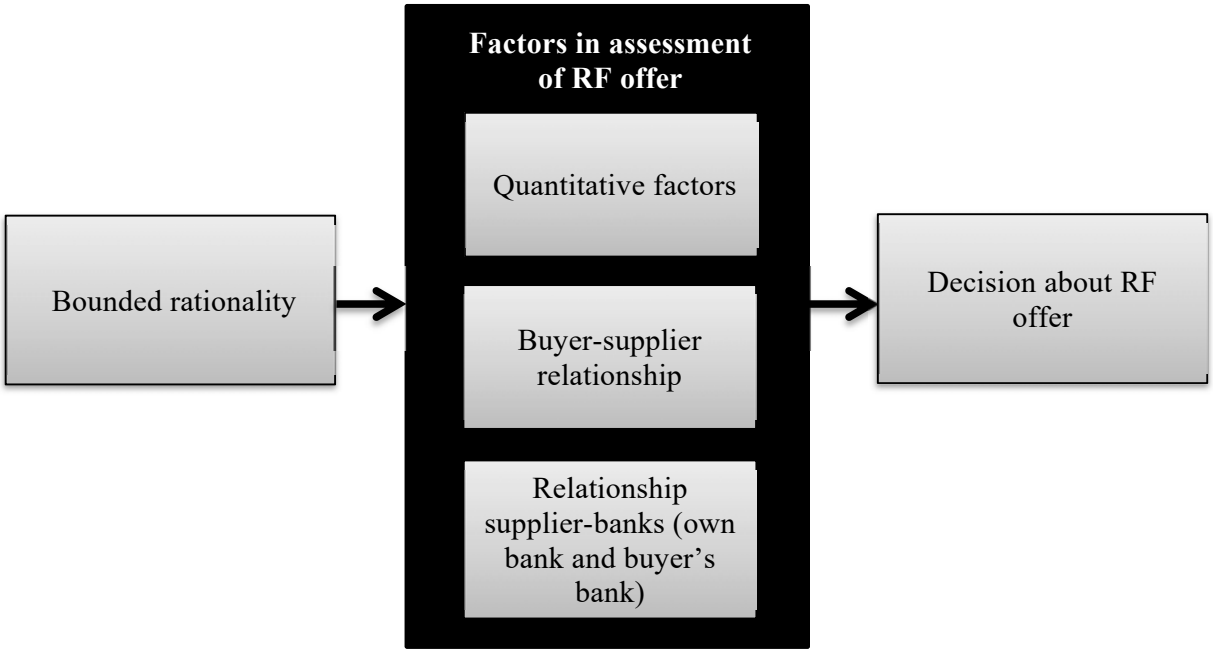
Figure 1 shows a conceptual supplier decision making framework, that consists of the constructs in Table 1 The direct factors influencing the decision for a supplier to accept or reject an RF offer from a buyer are quantitative factors, the buyer-supplier relationship and the relationship with both the own bank and the buyer's bank. Bounded rationality influences the supplier's assessment of the three previously mentioned factors. For example the lack of knowledge of suppliers about RF, reported on by Wuttke et al. (2013a) and De Goeij et al. (2016), can result into suppliers not being able to do a good assessment of quantitative effects of RF or of the effects of RF on relationships, with both buyers and banks.

Figure 1: Conceptual RF supplier decision making framework



The framework leads to the following two research questions:

RQ1: How do quantitative factors, the buyer-supplier relationship and the relationship between suppliers and banks influence a supplier's decision about a buyer's RF offer?

RQ2: To what extent does bounded rationality influence the supplier's assessment of the effects of the buyer's RF offer on quantitative factors, the buyer-supplier relationship status and the relationship between suppliers and banks?

Methodology

The methodology includes 8 case studies, wherein the Reverse Factoring offer is the unit of analysis. Case study methodology is suitable, because of the exploratory nature of this research (Yin, 2003). When the preceding theoretical foundation is not strong yet, case studies can offer an advantage (Edmondson & McManus, 2007).

Case selection

The case studies comprised 8 offers of RF, with 5 suppliers and 6 buyers involved in these offers (see table 2). The suppliers in the sample are in transportation or in food industry. There are buyers involved which are bike producers, retailers and furthermore logistics service providers working with subcontractors for transportation. There are two suppliers included who got more than one offer from different buyers. Also, there are three suppliers included who got an RF offer all from the same buyer. These three suppliers were all subcontractors, doing transportation for this buyer which is a larger LSP. All of the 5 suppliers are SMEs with a yearly turnover ranging from €2,5m - €30m. All of the 6 buyers are large companies with a yearly turnover ranging from €600m - €17,2bn. The case sample includes cases in which the supplier accepted the RF offer, but as suggested by Caniato et al. (2016) also takes unsuccessful adoption into account, by including cases in which suppliers rejected the RF offer.

Table 2: Characteristics of all 8 RF offers

RF Offer	Supplier	Industry	Buyer	Industry	Supplier decision	Data collection
RFO1	S1	Transportation	B1	Bikes	Y(es)	Interviews with S1 and B1, secondary data
RFO2	S2	Food	B2	Retail	Y	Interviews with S2 and B2, secondary data
RFO3	S2	Food	B3	Retail	N(o)	Interviews with S2 and B3, secondary data
RFO4	S2	Food	B4	Retail	N	Interviews with S2 and B4, secondary data
RFO5	S3	Transportation	B5	Logistics	Y	Interviews with S3 and B5, secondary data
RFO6	S4	Transportation	B5	Logistics	Y	Interviews with S4 and B5
RFO7	S5	Transportation	B5	Logistics	Y	Interviews with S5 and B5
RFO8	S5	Transportation	B6	Logistics	N	Interview with S5

Data collection

We chose a dyadic approach, by doing interviews with both the suppliers and buyers. Semi-structured interviews were conducted, because they provide flexibility for exploring phenomena that have not been studied extensively yet (Da Mota Pedrosa, 2012). Triangulation took place, mainly because of the usage of lots of secondary data. For most cases we were able to see the actual RF contract that the buyer proposed to the supplier. Other sources of secondary data are contracts between suppliers and banks, contracts between suppliers and credit insurers, calculation models of suppliers, internal financial reports, invoicing data and information coming from e-mail communication between suppliers, buyers and banks. Furthermore triangulation took place, because not only buyers and suppliers were interviewed, but also two banks who were involved in multiple RF offers. Interviews were conducted with key personnel involved with the RF offer. In most cases more than one department was included in the interview(s). On the supplier side these interviews were done with sales managers, financial managers or controllers and in the case of S3, S4 and S5 the directors/owners of the company. The employees interviewed from buying companies were procurement and financing managers or controllers.

Coding and data analysis

After collection of the data we started with open coding. Our strategy for coding was first to allow researchers involved to code the data independently, as suggested by Baxter and Jack (2008). All the involved researchers have then met to come to a consensus on categories and groups. We then matched patterns among cases. In this phase both interview reports and secondary data were used. The first results were reviewed by researchers and other participants in the research project, thus decreasing the likelihood of false reporting (Yin, 2003). The data collected from the different sources were related to existing literature on SCF, according to our research framework represented in Figure 1, to help us analyze which factors and linkages are related to existing literature and which ones are new. After that a

cross-case analysis was performed by comparing the various cases along each factor, in order to identify groups of cases with similar outcomes.

Results

This section will first of all provide an overview of how the four factors appear in the 8 RF offers via Table 3. After that RQ 1 and 2 will be answered, by analyzing the linkages between the decision of the supplier and the quantitative factors, the supplier-buyer relationship and the supplier-banks relationship, and finally the linkage between bounded rationality and the supplier's assessment of the three assessment factors.

Table 3: Prevalence of relevant factors in the RF offers

Factor → RFO	**Bounded rationality**	**Quantitative factors**	**Supplier-buyer relationship**	**Supplier-banks relationship**
RFO 1	No prior experience with RF for S1. S1 at first did not know how to assess quantitative effects RF. S1 is insecure about what the effect of doing RF with the buyer's bank will be on the relationship with the own bank.	In terms of financing costs RF shows very slight improvement in comparison with old situation. B1 represents large volume, difference in invoice approval after i.e. 5,10 or 15 days is big. Very important B1 can approve invoice fast. Accepting RF means losing 'cashflow flexibility' in comparison to factoring wherein they got money after 2/3 days.	This is the largest customer of S1, S1 fears rejection of the offer will harm the relationship. B1 included S1 as one of the first suppliers in their pilot RF programme. S1 thinks accepting the offer is 'giving something to the buyer', and can be beneficial in the future to 'get something back for it when discussing terms'.	S1 had factoring solution in place with own bank before RF with the buyer's bank was introduced. Accepting RF means the own bank will lose a large volume in their factoring portfolio. S1 fears this will have negative consequences in the future when discussing terms with the own bank.
RFO 2	First RFO for S2. Supplier at first did not know how to assess quantitative effects RF, in particular the effect of the discount rate was largely underestimated. Sales is main department involved, not familiar with typical financial matters. Not much collaboration sales and finance dept.	In terms of financing costs RF shows a very small improvement in comparison with old situation.	Lack of trust was the main reason for S2 to reject the RF offer. They felt main reason for doing RF for B2 was payment term extension. Furthermore, B2 couldn't answer S2's 'what if' questions. For example, what if banks step out of contract, what if Euribor goes up etc. B2 stated explicitly that accepting RF would not be a strategic benefit for S2 in comparison to supplier who would reject.	S2 is owned by a private equity group, who is supplying S2 with loans. RF would replace this loans partially, which S2 describes as not feasible for the private equity group. S2 thought that involved buyer bank could was generic, and not detailed enough about RF explanation.
RFO 3	Second RF offer for S2, came very soon after RFO2. Sales main department involved, not familiar with typical financial matters. Not much collaboration sales and finance dept.	In terms of financing costs RF shows a very small improvement in comparison with old situation.	Just like with B2, the supplier felt a lack of trust regarding the RF offer of B3 and felt that B3 could not take away their doubts well enough	S2 is owned by a private equity group, who is supplying S2 with loans. RF would replace this loans partially, which S2 describes as not feasible for the private equity group.
RFO 4	Third RF offer for S2. S2 had calculation models in place for assessing quantitative effects and gained much background info about qualitative factors.	In terms of financing costs RF shows a very small improvement in comparison with old situation.	Trust in B4 was the main reason why S2 accepted the offer. They felt B4 had a collaborative approach, and that B4 was very open and honest about the reasons of introducing an RF programme.	S2 is owned by a private equity group, who is supplying S2 with loans. RF would replace this loans partially, which S2 describes as not feasible for the private equity group.
RFO 5	First RF offer for S3, no prior experience. S3 did extensive calculations of possible quantitative effects RF and also overthought effects in terms of relation with buyer. Did not understand motives of buyer.	In terms of financing costs RF shows slightly negative effects. B5 told S3 that costs of RF could be neutralized by making sales price higher.	Buyer is most important customer. This is main reason why S3 accepted the offer. Trust was not immediately there, since S3 felt this was mainly a way to extend payment terms. S3 felt that for B5 it was of strategic importance as many suppliers as possible accepted RF.	S3 finances itself with equity and almost never needs bank finance. S3 felt explanation by the bank of the buyer was very generic at first, and did not go into depth about possible risks and long-term effects.
RFO 6	No prior experience. Learned about RF from a business contact in other company (director of S3).	Expected effects by S4 were positive, since 'it could make use of much better credit rating of B5'. However, no calculations to back this up.	Buyer is most important customer, represents large part of sales volume. Owner of S4 has long history	"Buyer's bank is large, well-known bank which makes me think this RF contract will be not much to worry about."

	S4 did not spend much time on calculating effects or overthinking other effects. Accepted the offer quickly based on trust in buyer.	B5 told S4 that costs of RF could be neutralized by making sales price higher. Cashflow effect allows for flexibility: having money available quickly is important.	with owners of B5. Therefore, he has a lot of trust in B5, which is the main reason for accepting the offer.	S4 finances itself with equity and only occasionally needs bank finance, via making use of overdraft facility.
RFO 7	Prior experience, RFO 8 was first experience. Just like S4, S5 also learned about RF effects via business contact which was director of S3.	In terms of financing costs RF shows slightly negative effects. B5 told S5 costs of RF could be neutralized by making sales price higher. This was crucial for S5 before accepting the offer.	In terms of sales volume B5 is not a large customer for S5, S5 has a diverse base of clients.	S5 finances itself with equity, almost never needs bank finance. Relation with buyer's bank or own bank was not considered a factor in the decision making.
RFO 8	No prior experience.	In terms of financing costs RF shows slightly negative effects. S5 wanted costs of RF to be neutralized by making sales price higher. This was not possible, which is an important reason why S5 rejected the offer.	S5 has a diverse base of customers, even though B6 is the largest customer, it doesn't represent a large percentage of total sales volume for S5.	S5 finances itself with equity, almost never needs bank finance. Relation with buyer's bank or own bank was not considered a factor in the decision making.

In answering *RQ 1*, what becomes clear from the 8 cases is that quantitative factors have an impact on the supplier's decision, but not always a decisive one. There are RFO's rejected by suppliers which showed positive quantitative effects (i.e. RFO 2 and 3) and RFO's accepted by suppliers with negative quantitative effects (i.e. RFO 5). The quantitative factors which play the most important role are, as expected, mainly related to volume, duration (and length of extension of payment terms) and the discount on the invoice. Implementation costs are mainly there in the form of time spent figuring out the RF offer, but in none of the cases play a decisive role for the decision making. In the cases of RFO 1 and RFO 2,3 and 4 alternative forms of financing play a role in decision making, especially in RFO1 wherein S1 had a factoring solution in place before RF. Furthermore, the effects of RF on direct cashflow and flexibility in terms of future spending are considered by especially S1 and S4. For S1 RF is seen as negative for cashflow flexibility, since they had a factoring solution before which allowed them to get their money after day 2 or 3, and with RF they have no guarantee for invoice approval time and will maybe have to wait 15 days. S4 sees RF as a positive influence on cashflow, since it provides them more quickly with money in comparison with the situation before RF, and therefore with the flexibility of doing investments quicker.

The buyer-supplier relationship is often the most important for the decision making of the supplier. As mentioned before RFO 2 and 3 showed small positive quantitative effects, however S2 did not feel enough trust to accept the offers. RFO 6 shows that trust can also be a positive motivator for decision making, the supplier involved knows the buyer for a long time and accepted the offer without much hesitation. In other cases power distribution is decisive, for example for S1 and S3 the strategic importance of the customer was an important reason to accept the RF offer. S5 is an example of a supplier who felt comfortable to reject an RF offer, because B6 was not seen as a company which had enough buying power in this relationship to demand acceptance of the offer.

Furthermore, the cases also show the importance of supplier-banks relationship as a factor. This was most striking in RFO 1 where S1 had factoring in place with the own bank. Changing from factoring to RF meant the own bank lost a large volume in factoring. Therefore, S1 fears there will be negative effects when future terms are discussed with the own bank. S2 is owned by a private equity group, which usually provides them with financing. RF would replace this loans partially, which S2 describes as not feasible for the private equity group. When suppliers finance themselves using equity and barely using bank

credit (RFO 6 and 8), the relationship with the own bank is not important for the decision making. Furthermore, there are suppliers describing that they expected more or a better explanation from the buyer's bank about the RF offer (RFO 2 and 5), and that this was a reason for them to be skeptic about the offer.

To answer *RQ2* we start with the role of prior experience and exposure to other SCF cases, as reported by Wuttke et al. (2016), in decision making, since it plays an important role in the assessment of factors. For example, in RFO 4, for S2 it was easy to calculate quantitative effects since they had a model in place after two earlier RFO's, and were able to ask more precise questions regarding possible effects. For both S4 and S5 RF was new, but the owners of both companies learned about the effects of RF from the director of S3, a mutual business contact. Both S4 and S5 explained this helped them a lot in understanding RF. No prior experience usually means that decision makers need to gain financial advice within the company. RFO 2 and 3 show that this can be difficult, since for S2 it was the sales manager who was involved in the discussions, who did not have much internal incentives related to finance and a lack of financial knowledge. Because the relevant financial employees from the company were working in a different office, in a different country, with different KPIs, the sales-finance collaboration regarding RF was a challenge. In RFO 2,3 and RFO 5, both S2 and S3 questioned the motives for B2,3 and 5 to do RF and thought they did not get full information from these buyers and the banks of the buyers involved. This shows lack of information sharing, and reveals an agency problem. RFO 6 stood out in these 8 cases, S4 explicitly mentioned not having much knowledge about RF but still accepted the offer without spending much time reviewing the effects, since S4 trusted both the buyer and the buyer's bank. Also supplier-banks relationship is a factor influenced by bounded rationality. This was most prevalent in RFO 1 wherein S1 was unsure about what doing RF with the bank of the buyer would mean for the relationship with the own bank, since their own bank would lose a significant piece of their factoring volume.

Conclusion

With this empirical research we aim to contribute to filling in the research gap in SCF literature about the SME supplier perspective. By building on recent studies – e.g. (Dello Iacono et al., 2015; Van der Vliet et al., 2015; Lekkakos & Serrano, 2016; Liebl et al., 2016; Martin, 2017) – we provide further findings on the adoption of SCF by suppliers. By taking both qualitative and quantitative factors into account and showing how they relate to each other, we aim at giving a new perspective on the topic of the supplier decision to accept or reject an RF offer. Our research shows that in terms of quantitative factors an RF offer might have negative consequences for an SME supplier, but the supplier might still accept that same offer because of qualitative factors. Also, an RF offer might be beneficial for an SME supplier in terms of quantitative factors, but the supplier might still reject the offer because of qualitative factors.

This shows some clear managerial insights, for both suppliers and buyers. First of all, for suppliers it shows that in the decision they also have to take qualitative factors into account. There can be expected positive effects in terms of financing costs, but unclarity in terms of both quantitative effects and relationship effects. For example, unclarity about approval time of invoices, about what RF will mean in terms of financial dependence on the buyer or what RF will mean for the relationship with the own bank when it replaces and old form of financing. Suppliers which expect more than one RF offer from buyers will benefit from making use of calculation models to make a good assessment of effects. For buyers, it becomes clear that suppliers can be skeptic when they feel the main reason for buyers to do RF is payment term extension. Especially, suppliers seemed to be more skeptic about RF in

cases wherein the buyer's bank, and not buyers themselves, took a leading role in approaching the supplier.

Limitations of this paper are first of all the focus on only Dutch SMEs, and second the focus on mainly two sectors (retail and logistics). Future research might benefit from taking place in other countries and other sectors. The research is exploratory with theory-building as the main goal, but theory-testing is an important next step. Furthermore, there is now an amount of papers about initiation and adoption of RF, but there are no papers yet about the phase *after adoption* of RF. It is interesting to see what the real benefits for SMEs are after RF is adopted, since our research shows SMEs do not always get full clarity on the buyer's offer during the initiation or adoption phase. This also shows us that more research on the agency problem in SCF is needed, since information sharing is an important success factor in SCF. Lastly, research on SCF will benefit from looking at other, more innovative, ways of doing SCF that gradually appear in industry, for example with a pre-shipment focus instead of a post-shipment focus.

(1) Politecnico di Milano, School of Management, Piazza Leonardo da Vinci 32, 20133 Milano (Italy)

Supply chain resilience has acquired relevance through the last decades as the primary capability for facing disruptive events. This work aims to shed lights on how resilience is pursued within the supply chain by investigating the relationships across stages and the changes brought due to the occurrence of disruption. Three supply chain stages (focal companies, first and second tier suppliers) in the Italian Biomedical industry have been involved in the analysis. Findings suggest how resilience is approached differently across tiers, but the importance of coordination is highlighted as the main driver for improving the mitigating capacity of the whole chain.

Keywords: Supply chain resilience, disruptions, Biomedical industry

Submission category*:* Competitive paper

Introduction

The ability to face disruptive events and recover from them has become a crucial capability in today's business scenario. Over the last decades, companies have proven themselves through unpredictable events that have challenged their ability to fulfil business objectives. Indeed, the frequency of disruptive events is exaggerated by the global partnerships established for achieving better products at the lowest cost. This trend exposed companies and their supply chains to a higher level of complexity and vulnerability due to a dense interconnection of companies worldwide (Christopher & Peck, 2004; Knemeyer et al., 2009; Hohenstein et al., 2015; Tukamuhabwa et al., 2015). Indeed, once a disruption occurred in a single node, can jeopardise the ability of the entire network to fulfil its requirements by affecting the capacity to tied up the elements that constitute the system (e.g. domino effect).

Resilience is the capability that academics coined for describing the ability to absorb and bounce back from such disruptive events. Over the years, resilience has gained consistency in the academic landscape as a peculiar characteristic to be designed into organisations and supply chains for driving the ability to survive in complex and vulnerable business scenarios (Hohenstein et al., 2015; Kamalahmadi & Parast, 2016). As Ponomarov and Holcomb (2009) detailed highlights in their work, the concept of resilience has changed according to the field in which has been applied (e.g. ecological, social, psychological and economic). In the management one, the term refers to the adaptive capacity of a system to face problems and recover from them by maintaining some level of control and stability (Weick et al., 2008). To this extent, a supply chain can be seen as a system in which the ability to deal with disruptions and bounce back from them is essential for avoiding interruption in the flow of information and materials.

This work aims to provide insights on the changes in the resilience approach in the supply chain brought by the disruptions occurrence from a multi-stage perspective. Specifically, a deep investigation of the strategies applied in three phases of the disruption curve (before, during and after) is provided. Coupled with an analysis of how resilience is influenced within the supply chain. Hence, the purpose becomes unveiling the relationships across supply chain stages when resilience must be pursued. To achieve the research objectives, we targeted the Italian Biomedical industry as the area experienced two huge earthquakes in 2012 that have tested the ability of such companies to face unpredictable events. Specifically, we were able to involve ten companies in three different supply chain stages: focal companies, first tier suppliers and second tier suppliers. The structure of the paper is the following. First, we provide the conceptual background required for understanding the elements analysed in this work. Second, we explained the research design regarding research background and research questions formulated. Then, we moved to describe the methodology on which this work is based. Finally, findings and discussion of them are provided. The paper concludes by outlining limitations and suggestions for further research.

Conceptual Background

Disruptions are severely affecting companies all around the world in today's business environment. Simply, disruptions are “unplanned and unexpected events that interrupt the flow of materials and products within a supply chain” (Hendricks & Singhal, 2005). To this extent, a certain degree of unpredictability into supply chains is brought due to a highly interconnected network of companies that lead disruptions spread across supply chains (Fiksel et al., 2015).

For counteracting the detrimental effects of such disruptive events, the concept of supply chain resilience was coined as the crucial capability that must be designed into supply chains. Supply chain resilience is defined as “the adaptive capability of a supply chain to prepare for unexpected events, respond to disruptions, and recover from them by maintaining continuity of operations at the desired level of connectedness and control over structure and function”

(Ponomarov & Holcomb, 2009). As noticed in the early theoretical contributions in the field of supply chain resilience, the concept of resilience is multidisciplinary one that has found several applications in heterogeneous fields (Ponomarov & Holcomb, 2009).

Supply chain resilience entails a broader perspective of how companies must improve their ability to bounce back from disruptions at the supply chain level rather than company one. Indeed, once a disruption occurs, the negative outcomes tend to spread even outside the boundaries of company level up to the supply chain (Craighead et al., 2007; Stonebraker et al., 2009). Besides, the globalisation has even worsened the situation due to the possibility that those detrimental outcomes can spread at network level since supply chains are always more related. Given the Ponomarov & Holcomb (2009) definition, supply chain resilience can be operationalised through three phases: readiness, response and recovery.

The first phase entails what companies do before a disruption occurs. So, strategies that are applied proactively having in mind how it is important to improve capacity to face problems in advance, in order to be ready once a disruption happens. Response entails the mitigate power of companies to treat the problems. In this phase, the disruption already occurs, and its detrimental outcomes are fully revealed. So, it is vital being able to deployed strategies aimed to counteract such negative effects. Finally, but not less important, the recovery phase in which the goal is going back to the original performance level (e.g. before being disrupted).

So far, supply chain resilience can be ensured by creating the concept of capability. Indeed, according to previous supply chain resilience works, companies by combining tangible and intangible resources aims to foster resilience in the supply chain.

As pointed out in the systematic literature review by Tukamuhabwa et al., (2015), works published in the last decades have focused on enriching the list of potential practices and relative capabilities that can lead to resilience. To this extent, the most refer one are flexibility, redundancy, collaboration, visibility and risk management culture.

Flexibility embraces the view of changing quickly to balance unpredictable changes in the environment. To this extent, flexibility improves resilience as a consequence of the improved company's ability to quickly adapt (Fiksel, 2006). Redundancy has been previously defined as the cornerstone of resilience. Indeed, the trigger works on resilience (e.g. Rice & Caniato, 2003 or Christopher & Peck, 2004) built their argument built around of concept of redundancy. Indeed, having extra capacity and inventory become a strategic move especially during disruptions occurrence (Tukamuhabwa et al., 2015). As redundancy can guarantee the ability to deal with both expected and unexpected peaks in demand that can cause shortages (Christopher & Peck, 2004). Collaboration entails two or more people working together towards a common goal. Within the resilience domain, that goal is the ability to deal with disruptions and recovery from them. Collaboration becomes an essential capability needed since resilience can only be achieved through cooperation in the supply chain. Aligned with the collaboration concept, it is possible to introduce the idea of visibility which is grounded on the possibility to observe and capture variations within the supply chain. Visibility can be defined as “the ability to see from one end of the pipeline to the other” (Christopher & Peck, 2004). As previous works have shown, visibility improve transparency that in turn, improves resilience by reducing the misalignment among actors in the chain. In this way, actions and effort worthless are reduced, and resilience is fostered (Christopher & Lee, 2004; van der Vorst & Beulens, 2002).

Finally, Rice and Caniato (2003) introduced how companies should foster an internal ability to highlights risks whatever it takes. To this extent, the concept of risk management culture embraces the idea that each employee should prioritise the identification of risks and their sources on a daily basis. Indeed, people have the power to anticipate disruptions consideration before disruption happened improving resilience.

Research Design

Research Objectives and Questions

Supply Chain Resilience has shown the importance both in academics and practitioners landscape. Given its importance, supply chain resilience is yet a complex and difficult phenomenon to be disentangled (Hohenstein et al., 2015; Tukamuhabwa et al., 2015). So far, scholars have worked on conceptualising resilience by identifying what companies can do for improving resilience (e.g. what kind of practices, which capabilities to foster within organisations) but few works have deeper the analyses by targeting a real disruptive event occurred, understanding how the supply chain responded and recovered from such event (Latour, 2001; Leat & Revoredo-Giha, 2013).

Besides, there is a lack of knowledge regarding the dynamic nature of resilience in which the overall resilience achieved in the supply chain is grounded on a relational link between stages. Indeed, the resilience approach pursued in one supply chain stage may influence the one achieved in others, or it may be driven by choices upstream and downstream in the supply chain. This work aims a twofold goal. First, we want to understand how companies shape their resilience approach in the face of the occurrence of a disruption event. To this extent, we aimed to characterise what companies did for overcoming such disruptive event within the three phases (readiness, response and recovery) through which resilience is created from a multi-stage perspective in order to provide a real understanding of how resilience is fostered within the supply chain. Second, we aimed to shed light on the dynamic nature of supply chain resilience by investigating the relationships among supply chain stages concerning the resilience approach deployed. The research questions to be addressed are:

RQ 1: How is supply chain resilience affected by disruptions?
RQ 2: How is supply chain resilience dynamically shaped across various stages of the supply chain?

In order to answer the research questions, this study focuses on the Medical Device Supply Chain in Italy as a context of study given the two earthquakes that affected the northeast area in Italy in 2012. Furthermore, we involved in the analysis companies belonging to three supply chain stages: focal companies, first tier suppliers and second tier suppliers.

The research question 1 (RQ 1) is intended to be answered per supply chain stage, that is, to identify the resilience practices applied at each stage of the supply chain. Instead, the second research question (RQ 2) is to be answered at the supply chain level for capturing how the resilience approach of one stage brings changes elsewhere upstream and downstream.

Research Question 1: resilience approach changes due to the disruption event

The first research question (RQ 1) intends to characterise how the disruption events affected the resilient approach of companies. To this extent, the resilience approach depends on a set of practices adopted and the relative capabilities shaped. Doing so, we aim to provide insights on how the resilience approach in the supply chain depends on the occurrence of a disruptive event since such disruption might change the perception of the strategies required within the supply chain.

Specifically, we analysed the resilience practices put in place before, during and after the earthquakes (Figure I).

Table I shows the taxonomy adopted for identifying the practices and relative capabilities created. To this extent, we combined different theoretical contributions (e.g. Rice & Caniato, 2003 and Jüttner & Maklan, 2011). First, we started from the most common proposed capabilities in the SCRES literature such as flexibility, redundancy, visibility, collaboration and risk management culture. Then, we focused on the list of practices that contribute to creating

the capability. Finally, we enriched the list of practices in each capability by drawing from different contributions (Pettit et al., 2010; Hohenstein et al., 2015; Tukamuhabwa et al., 2015).

Research Question 2: relationships among supply chain stages
The second research question (RQ2) provides a wider and deeper sense of supply chain resilience. Indeed, the objective is to provide insights on how resilience within the supply chain is dynamically shaped. Companies working in different supply chain stages may influence the way through which companies achieved resilience. Specifically, the relationships between stages may define the overall resilience of the supply chain since the practices applied by one tier may have consequences in those applied elsewhere.

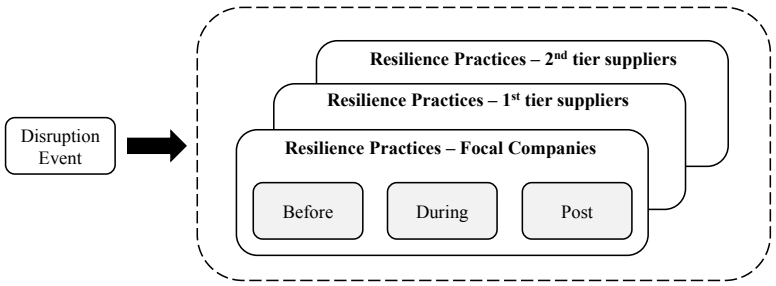

Figure I - Research framework developed for RQ 1

By considering resilience as a multitude of capabilities, such capabilities achieved in one stage of the chain may reinforce with others in different supply chain stages. Thus, answering the second research question will provide useful insights on the in interdependencies across supply chain actors that drive SCRES.

Theoretical Background
Resource dependence theory (RDT) embraces the idea that companies create a dense network for reducing uncertainty and dependency between supply chain partners (Pfeffer & Salancik, 1978). Specifically, RDT proposes how relationships must be managed effectively since, in today's globalised world, companies rely on others for acquiring resources (e.g. goods, materials) needed to match customer demand (Pfeffer & Salancik, 1978).
RDT has been applied in the supply chain field for describing how companies can easily become dependent on each other as a consequence of the fact that they work towards a common goal. To this extent, even if the dependency is increased, some companies increase their power within the boundaries of the supply chain (Crook & Combs, 2007). Such the interdependencies created within the supply chain are constraints that can be overcome through collaboration. To this extent, RDT shares the idea that such collaboration can reduce uncertainty in the supply chain (Pfeffer & Salancik, 1978). Thus, RDT will be applied in this work for disentangling how resilience is dynamically influenced by what companies do at the different levels of the supply chain. Specifically, RDT highlights the inter-organisational relationships between supply chain actors that will be investigated as the key lens for explaining resilience at the supply chain level (Pfeffer & Salancik, 1978).

Research Methodology
This work entails a case study methodology applied for investigating phenomena in the real world (Eisenhardt, 1989; Voss et al., 2002; Eisenhardt & Graebner, 2007; Yin, 2013). As

suggested in the Operation Management (OM) field, we followed an inductive research approach that aims to build theory (Barratt et al., 2011).
Besides, the Critical Incident Technique (CIT) has been deployed for targeting the scope of the analysis on specific events occurred in the past and facilitating the enquiry of interviewees (Flanagan, 1954). Indeed, as suggested in the seminal paper of Flanagan (1954), the main objective of CIT is to target an incident as the scenario for conducting research. Thus, the outcome becomes a deep analysis of any variations that can explain the subject under investigation (e.g. resilience).
CIT becomes essential for analysing the disruption events that affected the Italian Biomedical industry as we embraced a retrospective nature. To this extent, the CIT method helps to guide respondents by focusing on a specific event for gathering further details regarding what companies did for facing such devastating events (Chell, 1998) having in mind the scenario under inquiry.

Table I - List of resilience practices and relative capabilities (adapted from Pettit et al., 2010)

Capability	**Practices**
Flexibility	Postponement; Modularity and interchangeability; Process Redesign; Supplier contract flexibility; Product differentiation; Portfolio diversification and Input commonality
Redundancy	Reserve Capacity (Safety stock, Multiple sourcing, Extra-production capacity); Distributed capacity & assets; Insurance and Financial reserves
Visibility	Business intelligence; Information exchange; Tracking and tracing programs
Collaboration	Collaborative forecasting; Operational collaboration (Consignment Stock - CS, Vendor Managed Inventory -VMI, Resource Sharing and Dedicated Assets); Technological collaboration (Co-Design); Risk sharing with partners; Mutual knowledge creation
Risk Management Culture	Business continuity planning (BCP); Teamwork, Cross-training of workers; Responsibility, accountability & empowerment; Appropriate supplier selection & control; Learning, benchmarking and feedback

Sampling
We followed the procedure suggested by Voss et al., (2002) and Eisenhardt & Graebner (2007) for collecting cases among the supply chain. Besides, this work is based on the Italian Biomedical Industry which is specialised and leader in Europe in the production of disposable medical products, cardio surgery and dialysis equipment. Considering that the industry is confined to a small area in the north-east of Italy named Mirandola and Medolla, it is quite surprising how is capable of employing more than 3500 employees with about 300 companies active (Osservatorio Nazionale Distretti Italiani, 2014).
The choice of focusing the analysis in this specific industry was driven by peculiar internal and external characteristics that have made companies vulnerable to potential disruptions (e.g. highly regulated market due to patient's blood presence, products which high level of complexity and high-quality standard required and a small and limited supplier base). Moreover, last but not least, the area of Mirandola and Medolla was hit by two earthquakes and one flood in 2012 that have undermined the survival of companies. Research boundaries have been established within the work for controlling the complexity of the phenomenon under investigation. Three supply chain stages (focal companies, 1st tier suppliers and 2nd tier suppliers), as depicted in Figure II, have been considered in the analysis aiming to recognise patterns and relationships between variables (Voss et al., 2002; Eisenhardt & Graebner, 2007; Yin, 2013). As the main objective is to investigate resilience from a real supply chain perspective, three supply chain stages helped us in controlling the length and complexity of the chain and, at the same time, to move from the buyer-supplier perspective toward a better proxy

of the supply chain (Bhakoo & Choi, 2013). Besides, for ensuring that all cases belong to the same supply chain, we targeted a specific area of specialisation, which is the dialysis and companies specialised in the production of a specific product named filter for dialysis procedures. In this way, we were able to rebuild the supply chains involved in the analysis ensuring that companies belong to specific chains.

Data Collection and Data Analysis

Data was collected by means of semi-structured interviews according to an interview protocol specifically designed for capturing relevant insights needed for answering the research questions. First, we contacted the focal companies, and once they were willing to participate in the project, the interview was carried out. Besides, at the end of each interview with the focal companies, they provided a list of their suppliers. In this way, we were able to shape the supply chain up to the second-tier suppliers. Once again, targeting a specific product ensured that all companies proposed belonged to the same supply chain.

The protocol was crafted according to the supply chain stage in which the company operates.

The interviews have been conducted from February 2017 to July 2017 via telephone by two researchers with the top managers (e.g. supply chain managers, CEO). The interviews performed had a duration between 60 and 120 minutes. Furthermore, as suggested by Yin (2013), we collected information from web sites, industry and official reports for ensuring triangulation of data and achieving reliability. Besides, in case the information collected during the interview was not clear, we proceeded with a second contact by e-mail or telephone for ensuring data validity.

The final sample entails ten companies in three tiers within the supply chain as shown in Table II (data concerning companies' turnover and the number of employees refer to 2015).

Findings

Data have been analysed in the following way. First, we conducted a within case analyses. Then, we moved to a cross-case analysis per stage in which we focused on companies belonging to the same supply chain stage and finally, we performed a cross-stage analysis for identifying the resilience approach applied for dealing with the disruption (pre, during and post the earthquakes) in the three supply chain stages identified.

Resilience approach changes due to the disruption event

The first research question aims to identify how companies approach resilience for facing the disruptive events by focusing on the three phases: before being disrupted, during the disruption and after that. Resilience practices were tabulated according to the Table I. Specifically, we identified which practices were adopted and at which moment. Table III shows the cross-stage results in which we differentiated the resilience practices (and the relative capabilities to which they belong to) adopted in the three phases according to the supply chain stages targeted, where the X represents the number of occurrences of a specific practice (e.g. three X means that three companies at that supply chain stage applied that practice). We chose to report single case answers only in the second-tier suppliers stage. Findings show how resilience practices differ across the supply chain stages even though some of them are shared among them. Besides, we found how some practices were designed in advance for dealing with the disruptive events (e.g. Business Continuity Plan). While others practices have been added to the portfolio of resilience practices after being hit by the events. Indeed, results suggest how the resilient approach changed in the face of the disruptions occurred. To this extent, different practices were reinforced (e.g. having multiple suppliers) or even designed for the first time as a consequence of the disruption events outcomes. Focusing on providing a bigger picture of how resilience is achieved within the supply chains, we will describe what companies did proactively before

being disrupted and how the supply chain improved its resilience as a consequence of the deep awareness of the importance of improving the ability to mitigate such events driven by the earthquakes. As findings suggest, some practices have a supply chain nature while others are more focused on the company level. For instance, we noticed a strong level of collaboration among different entities in the supply chain. Both operational collaboration and technological collaboration was found.

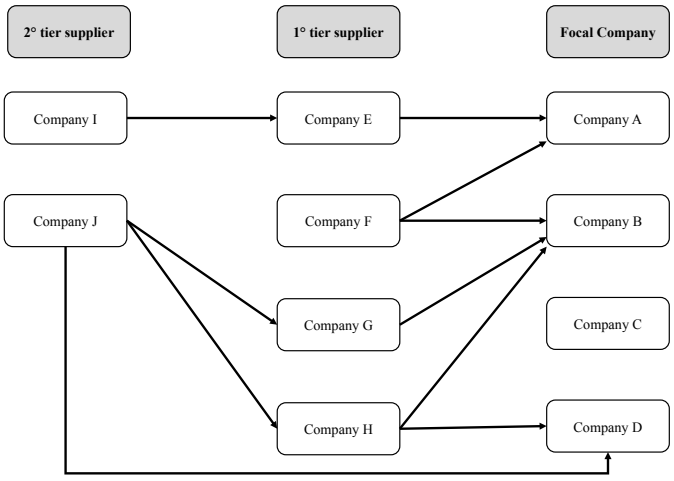

Figure II - Companies distribution across supply chain stages

To this extent, collaboration seems to be a requirement of the industry as it was originally fostered as a tool for achieving greater performance and foster innovation rather than improving resilience, as Company A stated, "*with a selected pool of suppliers (we) engaged in actual innovation projects, integrating them within our development procedure*". Despite this, the strong level of collaborative activities helped the supply chain in facing the events by increasing resources and information shared across supply chain members. Instead, other practices deployed fostered resilience at the company level. To this extent, we noticed how focal companies had already a BCP that helped in guiding the companies during the crisis. Moreover, companies defined safety stock in case of needed, and they validated alternative suppliers as back-up. Besides, we found out how companies emphasised the relevance of selecting suppliers taking into account risk and resilience considerations. Meaning, by evaluating and choosing suppliers according to their ability to face problems. Improving redundancy and risk management culture have proven to be essential for increasing resilience not just at the company level but rather to share the importance of having resources and keep in mind how problems can affect seriously operations across supply chain stages, as the disruptive events showed in 2012.

Finally, we focused our attention on how such disruptive events changed the resilience approach of companies in different stages of the supply chain. Indeed, findings confirm how the earthquakes brought relevant changes in the resilience practices.

An increased focus on flexibility was found. Indeed, all supply chain stages noticed how being flexible would have helped them in quickly adapt to deviations in the business environment. Besides, we noticed how focal companies and second tier suppliers decided to design products differently for increasing input commonality that can guarantee continuity in supplying. Furthermore, both focal companies and second tier suppliers sought to enlarge their supplier base in order to have at least a second supplier for each component (when it is possible).

The events themselves changed the sensibility towards disruptions completely. To this extent, Company A stated: "*after recovering from the event, we decided to include additional risk*

sources in our risk register". Indeed, companies fostered the risk management culture through the importance of team working and feedback strategies for reflecting and learn from what happened in the past. Aligned with the idea of creating a risk management culture, findings suggested how focal companies reinforced their business continuity plan. This advanced strategy for dealing with disruptions was already deployed by focal companies before the events in 2012, but it was felt more as a theoretical exercise rather than the first step towards an effective, resilient strategy. During the earthquakes, companies experienced the importance of having a plan for dealing with such a crisis and this helped in improving resilience proactively.

Table II - General information of the sample

Case	Industry Sub-sector/Product	Supply Chain Stage	Revenue (million €)	Number of Employees
A	Products for dialysis, enteral, parenteral nutrition, infusion and extracorporeal blood treatment.	Focal Company	61	213
B	Artificial kidneys; dialyzers; haemodialysis solutions; blood lines and dialysis filters	Focal Company	32	323
C	Filters for leucocyte removal from blood components	Focal Company	28	173
D	Dialysis equipment and disposables devices	Focal Company	232	906
E	Design of disposable devices, production and assembly of electro-medical devices	1st tier supplier	4	20
F	Dialysis line products and components, including tubes, junctions, blood lines.	1st tier supplier	40	46
G	Customized medical products for intensive care, haemodialysis and hemofiltration	1st tier supplier	2	23
H	Products for dialysis systems (dialyzers, filters, blood lines) and electro-medical equipment	1st tier supplier	25	50
I	Design and R&D of highly detailed stamps.	2nd tier supplier	8	40
J	Third party assembler of biomedical devices and bags for parental and enteral nutrition	2nd tier supplier	5	69

For instance, Company B stated "*since the disruption changed our life; we decided to create a crisis unit which is constituted by almost 40 people, in order to start working on business continuity*" while "*following the events we understood that we had to better organize our strategy by adopting a contingency plan*" was said by Company A. The following table (Table IV) summarises the improvement in resilience in the three stages brought by the events. Specifically, we put emphasises on the main investments done in practices.

Relational aspects of supply chain stages

Findings, at this stage, provide a step forward in defining how resilience is dynamically influenced among stages in the supply chain. We noticed both how decisions took in one stage of the chain creates effects downstream in the supply chain and how others stage in the supply chain proactively deployed strategies for helping customers/suppliers in dealing with problems. Results suggest how the focal companies had the power to lead the organisational changes in the resilience approach and such organisational changes drive resilience in the adjacent layers. So, in order to provide evidence on the supply chain nature of the resilience concept, we targeted two supply chains as the unit of analysis, engaging companies operating as first and second tier suppliers. Doing so, we were able to analyse how modified strategies outlined at the focal companies' stage drove an improvement in resilience in the overall supply chain.

Indeed, focal companies challenged their suppliers due to their reinforced engagement in practices for improving the risk management culture, such as BCP, appropriate supplier selection and control, team working and benchmarking. The improved awareness of the focal companies of the importance of having a supply base resilient, coupled with the strong collaboration that characterised the industry, forced suppliers to review their approach towards resilience.

For instance, it was clear how a higher flexibility was needed. Thus, focal companies demanded contractual modification for embracing a new attention to flexibility. Thus, one supplier during the event was able to provide production capacity. Besides, this was coupled with a demand of redundancy from the focal companies. Indeed, they learned how the first-tier suppliers could act as an important buffer. Furthermore, the importance of improving visibility between business partners was highlighted by the focal companies. Indeed, visibility was demanding by focal companies regarding operational activities (e.g. forecasting, process design, quality tests) and second tier suppliers' validation for improving the relationships between companies within the supply chain. Besides, practices like information sharing were crucial for understanding the current damages during the disruption and guarantee transparency in the supply chain. From a supply chain perspective, the requirements coming from the focal companies generated a domino effect upstream. Specifically, the first-tier suppliers engaged their suppliers in improving the information sharing among them, in order to provide a higher visibility at the focal companies' level as well. Besides, they asked for a greater degree of redundancy needed to guarantee a continuous availability of resources. To cope with these requirements, second tier suppliers improved safety stocks and started scanning possible new suppliers. Besides, they redesigned their operations in order to guarantee the possibility of having an extra production capacity to be dedicated in case of problems. Figure III shows the relational perspective of resilience across the stages. Specifically, highlights how resilience capabilities were modified within the supply chains, generating effects at the supply chain level (upstream and downstream). To this regard, the black arrows emphasise the overall improvement in resilience at the supply chain level due to the modification of resilient capabilities between stages while the coloured arrows describe the resilience capabilities modification driven by one supply chain stage on another.

The figure helps in shedding light on the supply chain nature of resilience. Indeed, results suggest how focal companies had the responsibility to drive a better risk attention within the supply chain. This responsibility had the consequence of improving the resilience of the whole supply chain by acting in each stage of the chain.

Discussion

This work is one of the first that investigates resilience from a broader perspective by disentangling a real supply chain.

Findings have proven how resilience is shaped differently within the supply chain. Companies operating at different tiers tend to manage risk by implementing practices that not always are aligned among partners. Focusing on what companies did proactively for facing disruptions, few practices were deployed specifically designed to create resilience (e.g. business continuity planning, multiple suppliers). Moreover, companies seemed to operate as silos without having in mind a real supply chain strategy. Despite this, companies have proven to be able to manage problems that in turn, fostered resilience within the all supply chain. Instead, after being affected by the earthquakes, companies developed a deeper understanding of the importance of being able to manage such events through a coordinated approach. Specifically, we noticed how such experience brought focal companies to push resilience within the all supply chain. Indeed, they focused their attention in modifying the internal capabilities needed for creating resilience and what is more important, they fostered a risk management culture upstream in the chain.

Table III - Cross stages analysis of the resilient practices deployed

		Focal Companies			1° tier suppliers			2° tier suppliers		
Capability	**Practices**	**Pre**	**During**	**Post**	**Pre**	**During**	**Post**	**Pre**	**During**	**Post**

Table IV - Summary of the resilience practices adopted after the disruption

Focal Company	First Tier	Second Tier
• Focus on Flexibility (e.g. multiple suppliers, suppliers contract flexibility); • Strengthen of the adoption of Business Continuity Plans (BCP) in order to increase the Risk Management Culture; • Increased requirements demanded upstream in the supply chain into contractual terms. Focus on flexibility and redundancy (e.g. safety stock, extra production capacity) of suppliers.	• Focus on improving their production capacity and the suppliers base; • Reinforced the collaborative approach both concerning operational and technological collaboration; • Enhanced the practice of information sharing for improving Visibility • Worked internally to increased awareness of the Risk Management Culture	• Fostered the level of Redundancy and Flexibility for improving reaction capacity within the supply chain; • Improved the role of Collaboration with downstream stages and Risk Management initiatives; • Embraced deeper level of information sharing for improving the overall Visibility in the chain

Due to the strong collaboration level of the industry, coupled with the bargaining power and the primary role in driving innovation, focal companies took the responsibility in driving a reshaping of the resilient approach. This is in line with the RDT's concepts, in which larger companies, as the focal companies considered in this work are, play a central role in reducing uncertainties by setting up guidelines for their suppliers, or by sharing information of the importance to gain resilience. To this extent, they acted in improving the idea that resilience is achieved by investing in practices that are applied in a day-to-day context. Thus, practices that were already applied frequently, like information sharing, supplier evaluation, multiple sourcing, could have assumed a different connotation under the umbrella of resilience. As they started to be applied having in mind a double goal: improving performance under stable conditions and, on the other side, mitigating problems under disruption occurrence.

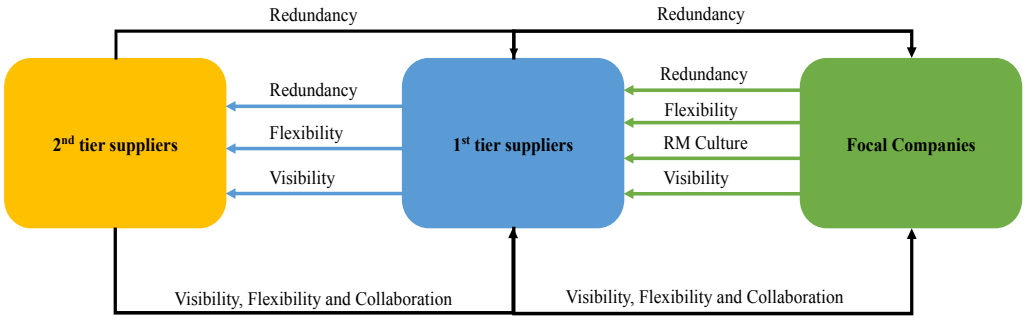

Figure III - Relational perspective of resilience capabilities within the supply chain

Doing a step forward, findings suggest how the behaviour of the focal companies in demanding more robust strategies with their suppliers, lead to dynamic improvements in the whole supply chain. Hence, focal companies understood how improving the resilient approach upstream, in turn, would have enabled them to increase their resilience as well. Going upstream in the supply chain, members recognised the importance of adapting their resilient strategies for complying on what focal companies demanded. An explanation can be provided using the Resource Dependence Theory. Indeed, from the RDT point of view, focal companies exploit their leading role in the collaborative relationship as the first tier and second tier suppliers are not able to

increase power in the relationships even though they play a crucial role in the production of the final products. It is worthwhile highlighting how resilience is influenced dynamically within the supply chain as the resilient strategy applied in one stage of the chain lead to consequences elsewhere. For instance, focal companies started including redundancy requirements in legal term with their suppliers. Thus, from a supply chain perspective, this leads to a cascade effect upstream because first and second tiers suppliers had to improve their redundancy capabilities. Hence, companies must rely on each other if they want to have a real resilient supply chain. In fact, RDT proposes how supply chain partners depend on each other for providing resources that are essential for creating resilience as even suggested by Ponomarov, (2012). Furthermore, according to the RDT principles, the collaborative nature of the Italian Biomedical industry can be used as a further element for explaining how resilience is achieved within the tiers. Indeed, companies aim at gaining beneficial outcomes in their business activities through collaboration, but such level of collaborative practices can foster a greater level of resilience as well by improving the effort developed during the crisis (e.g. prompt communication between companies, awareness of the current level of stock, production capacity).

Conclusion

Supply chain resilience aims in improving the ability of the supply chain to deal with problems. During the last years, academics and practitioners have engaged with the concept, but the full theoretical knowledge of how resilience is enhanced within the supply chain is far from being achieved (Tukamuhabwa et al., 2015; Hohenstein et al., 2015). This work has a twofold goal. First, we aimed to provide insights on how supply chain resilience is affected by disruptions. To this regard, we applied the Critical Incident Technique (CIT) to target a specific disruption that affected the Italian Biomedical Industry in 2012. Thus, we were able to understand what companies did before being disrupted, during the disruptions and what changes brought the event. Secondly, we decided to push forward the idea of how resilience is dynamically shaped within the supply chain. To this extent, we aimed to understand how resilience is influenced by choices adopted by supply chain actors elsewhere within the chain.

Implications for theory

This work leads to significant theoretical contributions. As far as our knowledge, few works have analysed supply chain resilience beyond the dyad relationships. Doing so, we provided clear evidence on how focal companies can drive the resilience of the whole supply chain. Indeed, after being affected by the earthquakes, focal companies understood the importance of increasing a risk management culture within the supply chain by coordinating resources, synchronizing efforts and demanding an increased deployment of resilience capabilities. Second, we noticed the importance of having visibility upstream in the supply chain, helped to reduce the ripple effect across tiers. Results are aligned with the contributions provided by Harland et al., (2003) and Brandon Jones et al., (2014), who highlighted how supply chain visibility affect resilience positively. Third, our findings showed how companies in different tiers of the supply chain contributed to resilience through a different portfolio of resilience capabilities. Specifically, focal companies achieved resilience by exploiting risk management culture (e.g. business continuity planning), visibility with upstream partners and by guiding the collaboration. Instead, first and second tiers suppliers contributed to resilience mainly through flexibility and redundancy. To this extent, we foster the idea how resilience can be achieved in the supply chain by deploying different resilience capabilities that might be not aligned within the supply chain. Specifically, focal companies achieved resilience by exploiting risk management culture (e.g. business continuity planning), visibility with upstream partners and by guiding the collaboration. Instead, first and second tiers suppliers contributed to resilience mainly through flexibility and redundancy. To this extent, we promote the idea of how

resilience can be achieved by deploying different capabilities that might be not aligned within the supply chain. Doing so, companies aim to improve their survivability ability by improving resilience at the supply chain level, as the ability to face disruptions requires to shift from a company perspective to a supply chain one (Rice & Hoppe, 2001). Fourth, this work is one of the first that shed light on the dynamic nature of resilience. Indeed, the interdependencies at the different levels of the supply chain (e.g. upstream and downstream) lead to variations on how resilience is achieved across stages. Last but not less important, this work contributes to the literature by applying the Resource Dependence Theory (RDT) (Pfeffer & Salancik, 1978) as the theoretical lens for understanding how the collaborative nature of the Biomedical industry foster resilience. According to RDT, companies implement a strong degree of collaboration for reducing uncertainty in the chain. To this extent, we showed how the focal companies, due to the power of such collaboration, inspired a better awareness of the importance of being able to handle problems within the chain through investments in resilience capabilities done by their suppliers.

Implications for practitioners

Managerial implications are provided as well. The primary managerial consideration is the supply chain nature of resilience that goes beyond the boundaries of the single company. Managers should work closely with their supply chain partners for understanding the improvement areas and how resilience can be fostered within their supply chain. Second, our findings suggested that resilience is achieved through practices applied in a day-to-day context, but such practices can be crucial for creating resilience during a crisis. For instance, practices like information sharing, multiple sourcing and supplier selection and control are applied on a daily basis for improving effectiveness and efficiency. To this extent, we provide evidence on how such practices are relevant for fostering supply chain resilience in both small and larger companies.

Future research

Future research is encouraged for deepening the supply chain nature of resilience. Specifically, we suggest to analysis the role of collaboration on resilience. Indeed, our work has proven how collaboration can help in dealing with disruption events as it was one of the key capability that helped companies to mitigate and recover from the disruption occurred. However, the nature of collaboration and the different degree through which collaboration is enabled were not part of the analysis, so we encourage scholars to provide further studies on it. Further supply chain stages or different products could be explored since the Italian Biomedical industry has shown a real network feature and the complexity of products are a potential driver toward an increased vulnerability. Besides, a contingent analysis should be carried out for understanding the role of variables such as firm size and product typology in the resilient approach of companies.

Supplier base dynamics. A case study of a buying firm during five decades

Anna Dubois and Lars-Erik Gadde
Technology Management and Economics
Chalmers University of Technology
SE-412 96 Gothenburg, Sweden

Abstract
This paper reports a longitudinal study of the development of the supplier base of a firm between 1964 and 2015. The results show that the supplier base changes considerably over time, while few changes are observed from one year to the next. The changes are explained by factors related to purchasing policy, relationship effects and technical modifications. Conclusions regard supplier base dynamics, as well as some methodological implications.

Keywords: Purchasing, supplier relationships, supply base

Introduction

The relationships with business partners are claimed to be the most strategic assets of a firm (Ford et al., 2011). Several authors point out the significance of suppliers by acknowledging contributions related to innovation, manufacturing, logistics, and product development (e.g. Håkansson and Snehota, 1995; Liker and Choi, 2004; Johnsen 2009). Therefore, specific attention has been directed to the strategic impact of the whole constellation of the supplier network in which the buying firm resides (e.g. Bensaou, 1998; Dyer et al., 1998; Gadde and Håkansson, 2001; Holmen et al. 2007; Håkansson et al., 2009). Following Bygballe and Persson (2015), we discuss this constellation in terms of the supplier base of the buying firm.

A common conclusion in studies of business relationships is that potential benefits arise over time, implying that effective business relationships feature longevity. However, only seldom are such assertions supported by data confirming these conditions. One exception is Håkansson (1982) who provided information about the length of almost one thousand business relationships at one point in time. The dynamics of the relationships in the supplier base were studied by Sundhof and Pietsch (1964). However, the insights in the development of these business relationships are limited since the time series embraced no more than three years. Kamp (2005) investigated the features of the supplier bases of two US plants for car assembly, and the changes during seven and eleven years respectively. The two cases differed with regard to dynamics – one was characterized by change, the other by stability. Hence, more research is motivated to increase the understanding of the long-term development of the business relationships in buying firms' supplier bases.

This paper reports a study of the dynamics of a subset of the supplier base of a fork-lift manufacturer over more than half a century (1964 – 2015). This period spans almost the entire life of the company that was founded in 1958. The overall objective of the study is to identify, describe, and analyse the dynamics of the supplier base over time. Such longitudinal research has been recommended as an important complement to the more common cross-sectional studies (Buvik and Halskau, 2000; Pfeiffer, 2010).

Theoretical anchoring of the study

It is a common view that external partnerships are established in order to acquire critical resources (e.g. Pfeffer and Salancik, 1978; Håkansson and Snehota, 1995). From a resource orchestration perspective, Sirmon et al. (2011) concluded that the needs of a buying firm change over its life cycle. In the growth phase, ambitions to secure adequate production capacity are central, as well as developing skills for the further relationship-building with suppliers. In the mature phase, efforts to acquire and integrate various sources of knowledge into the firm's operations and resources become increasingly important in order to create capabilities that can contribute to improved performance. Other authors pointing out the significance of organizational life cycles in relation to purchasing and supply management are, for example, Fox and Rink, (1978), Jap and Anderson (2007), Vanpoucke et al. (2014).

The above conditions affect what supplier features are most useful for a buying firm in various situations and result in changes of business partners over time. In turn, these replacements of individual suppliers cause the dynamics in the supplier base. Understanding supplier base dynamics thus require understanding of supplier switching patterns. However, Bygballe (2017, p. 40) concluded that "supplier switching remains largely unexplored". Similar claims were made by Pfeiffer (2010) who found that research tends to present snapshots of these phenomena rather than capturing their dynamics. Moreover, Vanpoucke et al. (2014) argue that although it is widely accepted in the literature that relationships develop over time, most research only looks at a single point in time in a relationship. This conclusion is shared by Jap and Anderson (2007), which leads to our first research question: What characterizes the development of the supplier base with respect to continuity and change of individual supplier relationships?

Pick (2010) analysed the length of relationships and the reasons for supplier switching. She concluded that certain factors were related to suppliers in terms of their lacking commitment and the buyer's dissatisfaction with their performance. Other factors concerned the situations of buying firms with regard to changes in the supply they required. In both cases the existence and quality of alternative suppliers was a critical determinant, which was pointed out also by Gadde and Håkansson (2001). Ferguson and Johnston (2011) found that the relationship length and the number of suppliers varied among purchased items with regard to the type of purchase in terms of novelty, complexity and importance. Bygballe (2017) added the buyer's strive for independence and ambitions to reduce costs as potential reasons for switching suppliers. Cost reduction as a main reason for changing suppliers was pointed out also by Quayle (1998) and Wathne et al. (2001). Accordingly, the second research question of the study is formulated as: What are the reasons for switching suppliers?

Entrance of a new supplier is not necessarily accompanied by ending of the relationship with an existing supplier. Pick (2010) claimed that termination of a relationship can be complete or partial. Partial termination implies that the old supplier will be kept in a dual (or multiple) sourcing setting. Moreover, Friedl and Wagner (2012) argued that an alternative to switching supplier for reasons of dissatisfaction would be supplier development, echoing the categorization of Hirschman (1970): exit, voice and loyalty. Finally, a supplier once replaced by another one may come back later. According to Bygballe (2017, p. 42) few studies have addressed the "self-return process initiated by the customer". This conclusion was shared by Pick (2010) who asked for more research "on the duration of the second or third relationship with a former business partner". Thus, our third research question deals with two sub-issues related to termination of relationships:

- To what extent is supplier switching partial or complete?

- To what extent do suppliers in terminated relationships come back, and how long are they then able to remain in the supplier base?

In the third section of the paper below we present some details regarding the empirical study; what was covered and how data were collected. This is followed in section four by description and analysis of the changes in the supplier base in four time periods (RQ1). Section five provides an account of the reasons for supplier switching (RQ2), while the features of the supplier switching patterns (RQ3) are analysed in section six. This is followed by discussion of the results in section seven and concluding remarks.

About the study

The study reports the development of the supplier base of a fork-lift manufacturer between 1964 and 2015. Initially, the research project covered eleven components featuring variety in terms of economic importance, technical complexity, supplier markets and whether the component was customized or standardized. When the study began, these components accounted for about one third of the total purchasing costs of the buyer. This share has been reduced slightly over time owing to integration of additional technologies. The suppliers used by the buying firm for the eleven components are reported in Appendix 1, which shows that there are some missing data in the beginning. Moreover, three of the components are no longer purchased since they became part of a system, for which both component sourcing and assembly was outsourced. The components, their main features, the observation periods and the number of suppliers used for each component are shown in Table 1.

Component	*#*	*Product features*	*Economic importance*	*Number of years*	*Suppliers used*
Mast profiles	1	Customized	Medium	52	4
Small-sized engines	2	Standardized	Medium	52	3
Batteries	3	Standardized	High	52	6
Fork carriages	4	Customized	Medium	52	9
Large-sized engines	5	Customized	Medium	48	4
Needle bearings	6	Standardized	Low	52	5
Forged forks	7	Customized	Low	52	6
Castings	8	Customized	Low	40	5
Ball bearings	9	Standardized	Low	51	8
Cog-wheels	10	Customized	Low	40	8
Spiral cog-wheels	11	Standardized	Low	21	6

Table 1. Characteristics of the sample of components

Four phases featured by differences in sourcing patterns were identified. This diversity was best illustrated when the time series was divided into four phases of equal length (1964-1976; 1977-1989; 1990-2002; 2003-2015). In the following section we describe the developments of the supplier base in the four phases.

Supplier base development 1964-2015

Phase 1 – 1964-1976

In this establishment and expansion phase the features of the fork lift were in continuous development with frequent design changes. During the 1960s the supplier base was quite stable, while the first half of the 1970s featured considerable dynamics. There are several reasons for the stability in the first part of the period. The buying firm used the suppliers they

had identified and tried from the beginning. Owing to lacking knowledge of alternative suppliers, the buyer mainly stayed with these established sources. Moreover, because of the limited volumes required, the buyer was not recognized as an interesting business partner. Finally, by focussing on a limited number of suppliers, the buying firm could reduce the supplier handling costs. The number of suppliers for the eleven components was reduced from 15 initially to 11 in 1971. This year, all but one component was single sourced.

From 1970 these conditions began to change. The firm was expanding substantially with a yearly average growth rate of almost 50 percent during the coming fifteen years. Since many of the initial suppliers were small they were not able to keep up with this expansion. Therefore, additional suppliers were required to secure supply. In 1976 the number of suppliers had increased to 22 and for seven of the ten previously single-sourced components more than one supplier was now used. Two other factors contributed to the expansion of the supplier base. Firstly, although still a small buyer, the growing size of the firm enabled splitting of the purchasing volume on two suppliers to stimulate price competition. Secondly, some customers had their particular requirements regarding fork lift features to which the buyer had to adjust by using different sources. The supplier base grew partly from increasing knowledge of supplier markets and partly from returning to some suppliers that had been abandoned in the previous ambition of promoting single sourcing. One organizational modification affecting these conditions was the appointment of a new purchasing manager.

Phase 2 – 1977-1989

From the end of the 1970s the buyer started to consolidate the supplier base. The expansive phase with increasing numbers of suppliers can be seen as a test period. Some new suppliers lived up to the expectations and were able to secure an established position in the supplier base. Others failed in this respect owing to quality and/or delivery problems or unsatisfactory price levels. Ten of the seventeen suppliers that had been introduced in the middle of the 1970s were no longer used at the end of the 1980s. The majority of these changes concerned two components that accounted for limited economic importance, and supplier markets featuring price competition.

1988 was the last year when all eleven components were purchased. At that time the number of suppliers had been reduced to 16 to be compared with 22 in 1976. The number of single sourced components had been more than doubled – from three to seven. For the other four components the buyer used more than one supplier. The dual/multiple sourcing approaches were explained by quite different reasons. For one of the components the technology was changing and the current supplier was successively replaced by a new entrant. In another case the component had developed into two distinct types which were now delivered by two specialized suppliers. For the third component, two suppliers were used to secure the volumes required. Finally, the multiple sourcing applied for batteries was due to customer requirements for specific brands.

The overall consolidation of the supplier base was affected by three main factors. First, the previous expansion caused problems in handling the large supplier base. Second, the firm's growth began to make the buying firm an interesting customer, thus enabling the opportunity to settle favourable economic agreements. Third, a change from forecast planning to order-based control called for long term agreements and joint planning with suppliers.

Phase 3 – 1990-2002

In the beginning of this phase, the buying firm was inspired by general trends in purchasing management in terms of outsourcing and system sourcing. Influenced by such thoughts the buyer began considering sourcing of systems rather than components. These plans required time to materialize, but successively affected the component structure of this study. One reason for the interest in system sourcing was that at the end of the previous phase, customer adaptations had become increasingly important. This approach required modular product design, which called for enhanced cooperation between purchasing, production and design. The change to modular designs increased the number of variants substantially. To handle these conditions, product development became increasingly driven by cost reduction ambitions. The opportunities residing in such efforts are illustrated by the fact that changing from four to three variants of one type of fork-lift reduced costs with about 15 percent.

At the end of phase 3, the size of the supplier base was almost the same as at the end of the previous phase – 15 suppliers were used in 2002 for 10 components to be compared with 16 when 11 components were purchased. Despite these seemingly stable conditions, several changes were observed. For four of the single sourced components in the beginning of phase 3, the previous suppliers were substituted by other single sources. In one case, the supplier no longer manufactured the component. Another supplier had problems with its own suppliers which caused substantial problems for the buying firm that had to find a new business partner. For one of the standardized components, price reductions were obtained by switching to a new suppler. Finally, for the fourth component, several reasons explain the change. The supplier in the beginning of the period caused lots of problems for the buyer with regard to quality and delivery. Furthermore, the price level of this foreign supplier became unfavourable owing to changing currency rates. Finally, the new supplier was able to provide specialized components to support the variety required by the vehicle manufacturer.

Regarding two previously dual-sourced components, one became subject to single sourcing, while in the other case the two suppliers used in the beginning of the period were replaced by two others. Regarding batteries, two suppliers were added because of customer requirements.

Phase 4 – 2003-2015

A major change in this phase was that the buying firm in 2007 was acquired by a Japanese Automotive Group (henceforth referred to as JAG). The ownership connection to this corporate group enabled increasing economies of scale through realization of potential synergies. However, the various business units within JAG are free to select the suppliers they prefer; there is no centralised decision-making in this respect. What is offered by JAG is a common strategic perspective and some tools for supply analysis, such as item categorization related to the Kraljic matrix. These changes have made it more difficult for a supplier to enter since potential partners are evaluated and tested more thoroughly than before. In the beginning of this period, the purchasing manager appointed in the middle of the 1970s resigned. The new manager was then substituted in 2010, and at the end of this study also this one had been replaced.

In this final phase, components 8 and 10 had become part of a system and were no longer purchased. At the end of the period the remaining eight components were supplied by 11 suppliers, compared with 14 in the beginning of the period. This change involved a reduction of the suppliers of batteries from five to two, which is explained by modifications in the

supplier market in terms of mergers and acquisitions. Three of the components (1, 2, 9) were supplied in exactly the same way during the entire period. For three of the single sourced components in the beginning of the period (5, 6, 7) the suppliers were substituted by other single sources. Regarding component 5 the supplier used in 2003 had entered the supplier base in 1999 because of technical modifications – the previous source had not been able to adjust to this change. In turn, this new supplier lost its position in a second shift of technology in 2008 and was replaced by a supplier used for another component. The change of supplier for component 6 is again explained by price conditions and implied a come-back of the supplier that had been replaced in the previous phase. In the last year of the observation period, the relationship with the supplier of component 7 was terminated. This change was due to coordinated decision-making within the JAG Group. Finally, the remaining component (4) was dual sourced in 2002 and remained so in 2015. However, the two suppliers used in 2002 were replaced by two others for several years, but at the end of the period one of the former ones re-entered.

In phase 4, the previous focus on reducing the number of product variants was modified. Instead, increasing variety was motivated by enhanced orientation in relation to the diverse requirements of customers. Moreover, in the beginning of the fourth phase, sourcing from low-cost countries was at the top of the purchasing management agenda in general. For the focal firm of this study, however, this approach did not turn out as favourable owing to long lead times featuring this supply alternative.

Relationship dynamics

Table 2 illustrates the variety in the relationship dynamics by describing the length of the relationships with the 64 suppliers used during the 52 years. One supplier has been used each year, and three others have supplied for more than forty years. Three of these four were still used in 2015, which illustrates the longevity of some buyer-supplier relationships. On the other hand, some relationships are quite short-term. 24 suppliers (38%) have been used less than five years. The average duration of the supplier relationships amounts to 12.5 years.

Number of years as supplier	1-4	5-9	-14	-19	-24	-29	-34	-39	-44	-49	-52
Frequency of suppliers	24	11	8	5	6	3	3	0	1	2	1
Suppliers remaining in 2015	1	1	1		4		1		1	1	1

Table 2. Duration of the supplier relationships

The main finding of the study is the confirmation of the short-term stability of supplier relationships. Many researchers have claimed that this stability exists, but limited empirical support has been provided. To investigate these conditions in the current study the changes from one year to the next were analyzed. The total number of decisions regarding supplier selection was 501 (52 years for eleven components, minus missing data). Each decision represented a potential change in terms of entering and/or terminating relationships with suppliers. The analysis revealed that 416 (83%) of these decisions implied that the same supplier(s) was used from one year to the next. The buying firm thus made changes of the supplier base at 85 occasions during the period between 1964 and 2015. The proportion of years without changes in the supplier base increased over time from 74% in the first phase, via 82% in the second and 88% in the third to 91% in the final phase. These figures can be compared with findings in a Japanese study containing information about business exchange among 500.000 firms during five years. The results showed that the proportion of the

relationships that continued from one year to the next amounted to 92 percent on average (Mizuno et al., 2014).

In a longer time perspective, however, the supplier base changed considerably. Of the fifteen initial suppliers, eight remained at the end of the second phase. Four of these relationships were terminated during the third phase, and at the end of the fourth phase only one of the original suppliers was still used. In the above discussion we argued that phases one and three featured substantial dynamics while the second and the fourth were characterized by striving for stabilization. This claim is supported by the fact that the number of new suppliers introduced in the four phases amounted to: 26, 7, 12 and 4, respectively.

Changes of the supplier base and drivers of change

We reported above that the total number of changes from one year to the next amounted to 85. These changes demonstrate no clear differentiation between the frequency of changes for standardized and customized components, which was somewhat surprising. Four of the components together accounted for half the number of changes, two of which were standardized and two customized. Another interesting finding was that one of the standardized components accounted for the least frequent changes (5%).

The drivers behind the 85 changes in the supplier base were discussed in the interviews with informants. Although some changes resulted from the combined effects of several factors we classified each change as a consequence of the most important factor. The analysis showed that the changes could be explained by the impact of eight main factors, six of which matched the ones identified in the literature review. In the analysis we grouped the eight factors into three categories. Two of them represent changes of purchasing policy and relationship effects, which include the six factors from the literature review. The third group, involving technical modifications, represent new factors identified in the study.

The impact of purchasing policy

The single most important driver of dynamics was the ambition to reduce cost – accounting for more than one third of the total changes (35%). Cost was the most important factor behind supplier replacements for seven of the components – three of which were standardized and four customized. Also for the four other components the buying firm strived to reduce cost, but in these cases other factors were more important. The results indicate that price reduction is less important for items that are economically significant. Three standardized components together represent one third of the changes related to cost reduction. In these cases switching costs were low in the absence of adaptations. These conditions make it easy for new suppliers to enter. At the same time, however, they are easily replaced, indicated by the fact that many of the suppliers that entered on a low-price basis were used only a few years.

‘Avoiding dependence’ and ‘consolidation of purchases’ were the main reasons for almost ten percent each of the changes. Avoiding dependence on specific suppliers is often used as a means to stimulate price competition. Sometimes, suppliers were added to reduce the perceived dependency related to transaction uncertainty in single sourcing settings. However, these attempts were not very successful owing to suppliers’ performance failures, and some of these relationships were terminated quite soon. ‘Consolidation of purchases’ has become increasingly applied in the fourth phase after JAG’s acquisition of the buying firm. The

underlying motivation regarding benefits from this approach is related to increasing volumes in relation to individual suppliers and thus reduction of administrative costs.

Relationship effects

Problem with supplier performance was the second most important driver of changes, representing 17 percent of the total changes. All these modifications of the supplier base related to six of the components – all of them customized. A plausible interpretation of this finding is that inadequate performance of a supplier delivering an important customer specific solution leads to termination of the relationship. However, termination of the relationships was not always the outcome. In some situations, quality and delivery problems were solved jointly with the suppliers, rather than by replacing the business partner. Furthermore, the buyer used some suppliers for a long time despite dissatisfaction with their performance. Since the firm is relatively small in relation to most of its suppliers there were problems in engaging large and powerful suppliers in activities aiming at adaptations and customization.

Customer requirements have driven changes with substantial consequences for the supplier base. Foreign sales subsidiaries tend to request local components in some cases, especially for batteries. Such demands are expressed as reflecting the perceptions and preferences of fork-lift users. For this reason the buyer relied on 3-5 suppliers of batteries between 1971 and 2009. This approach led to considerable costs for handling and administration of both suppliers and transactions. Moreover, the buying power of the vehicle manufacturer was reduced which impacted negatively on price negotiations.

Almost ten percent of the changes originated from suppliers. In two cases the relationships ended because of bankruptcy of the business partner. Moreover, two suppliers shifted the production of the components to other firms belonging to the same corporate groups, which did not work out well for the buyer. One supplier of a customised product closed down the production of this component. The supplier perceived the volume demanded by the vehicle manufacturer to be too marginal and decided to concentrate on other products and customers. Furthermore, a global supplier delivered a low volume component used by a diminishing range of customers. To enable elimination of this component the supplier doubled the price. Since the component was standardised, other suppliers were available for the buying firm.

The impact of technical modifications

Technical changes related to design and manufacturing was the third most important of the drivers, representing ten percent of the total changes. Design modifications impact on production technologies and may call for replacement of suppliers. Four customized components have been affected by such technical adjustments. Changes from one technology to another typically require that the prevailing and the new technology are used in parallel for some time. Therefore, technical modification processes normally cover a couple of years.

The second driver related to technical modifications regards the launch of new models and product variants, which sometimes require changes in the supplier base. Such changes are reported for two customized components. However, many of the technical challenges were handled in ongoing supplier relationships. For example, one of the customized components was affected by two major technical changes. In the early 1980s the manufacturing operations of the buyer demanded a change from extrusion to rolling, a requirement the existing supplier was unable to handle. The new supplier of rolled materials was added as a complement to the

supplier of extruded materials for two years. Then the relationship with the first supplier was terminated and the new one was still used in 2015. The second change was conducted in the 1990s within the relationship to the supplier of rolling materials and regarded modifications of production technologies to reduce costs for the substantial range of product variants. Through the joint activities of the two parties some production steps could be eliminated and some activities were outsourced to the supplier.

Supplier switching patterns

The third research question dealing with supplier switching patterns involves two issues. The first regards the situation when new suppliers enter and established suppliers lose positions. Entrance of a new supplier may occur through direct substitution in relation to an existing one. In this case the old relationship is terminated. In other cases the new supplier is added as a complement to the current one. The old supplier is then kept but has obviously lost position. This change is classified as partial switching from the previous supplier's point of view. Finally, complete switching occurs when a supplier relationship is terminated without entrance of a new one. This is the situation when one relationship is terminated in dual or multiple sourcing arrangements. Table 3 illustrates the frequency of these supplier switching patterns in the 85 changes of the supplier base.

Switching pattern	*Number and percent*	
Direct substitution of supplier. Old relationship terminated.	39	46%
Complete switching. Existing relationship terminated. No new supplier.	23	27%
Partial switching. New supplier in – the old supplier continues	23	27%

Table 3. Frequency of supplier switching patterns

The second sub-issue regarded to what extent suppliers in terminated relationships are able to re-enter the supplier base. As shown in Table 3, the total number of terminated relationships amounted to 62 (39+23). 14 of these suppliers managed to come back after the relationship was terminated. This means that 23 percent of these suppliers re-entered the supplier base. 11 of them re-entered once, while two came back twice. One of the suppliers of a standardized component featuring substantial price competition re-entered no less than four times.

Table 4 presents the details of the 14 re-entering suppliers regarding the years they supplied the buying firm and the years they were not supplying. These figures provide also information regarding how long time the suppliers remained in the supplier base after re-entrance.

Supplier	1	2	3	4	5	6	7	8	9	10	11	12	13	14
# of supply years - first entry	10	10	5	9	5	15	1	1	7	7	3	3	1	13
# of years with no supply	17	3	6	2	12	7	5	4	2	2	3	2	5	8
Supply years at second entry	*13*	*1*	5	*11*	*7*	4	22	1	1	1	2	2	3	*8*
# of years with no supply											2	3	2	
Supply years at third entry											4	1	13	
# of years with no supply											1			
Supply years at fourth entry											2			
# of years with no supply											2			
Supply years at fifth entry											2			

Table 4. Fourteen suppliers that re-entered after termination of the relationship (Italics indicate that this supplier was still used in 2015)

Four of the suppliers had delivered for more than ten years when the relationship was terminated for the first time, while seven of them had been involved five years or less as suppliers. Eight of the fourteen suppliers then re-entered within five years. Two suppliers had to wait longer for their comeback – 12 and 17 years respectively. In most cases, the re-entering suppliers did not stay long – nine of them were dropped again after five years or less. On the other hand, three relationships continued for more than ten years and two of them were still ongoing in 2015. One of the suppliers (13) entered a third time and managed to keep the position in the supplier base for thirteen years. Suppliers 11 and 12 represent the most frequent changes. Both suppliers deliver standardized components where a multitude of alternatives are available, thus making switching less complicated.

Discussion

In this section we discuss the results from the study with regard to the supplier base dynamics, the variety of the features of the business relationships, and the interplay between change and continuity.

Supplier base dynamics

The study revealed substantial dynamics of the supplier base over time. Clear differences were observed in the four phases with regard to purchasing behavior and supply chain management. These finding support the argument in previous research that purchasing behaviour changes across the various phases of corporate life cycles. For example, Fox and Rink (1978) pointed out the problems that may occur in the growth phase when the initial suppliers may lack capacity to supply the buying firm. Adding supplementary suppliers is a means of handling these conditions but leads to increasing relationship costs. In this situation, the tendency is similar to what was found in this study, that "procurement shifts to suppliers with large capacity" and that buying firms consider the "feasibility of long terms contracts with fewer sources" (Fox and Rink, 1978, p. 190).

In previous research there is an ongoing debate whether life-cycle dynamics follow a linear or a cyclical pattern (Vanpoucke et al., 2014). Our study supports the argument of Ring and van de Ven (1994) that the dynamics tend to be cyclical. There was no steady trend in the increases, decreases, and other changes of the supplier base. Instead there were movements back and forth, depending on various conditions. Some of these changes were generated from the inside of the buying firm while others were initiated by the business partners. The most significant driver of change was internal: ambitions to reduce cost, which is well in line with findings in previous research (e.g. Quayle, 1998; Wathne et al. 2001). The second most important driver concerned poor supplier performance, which is supported by Keaveney (1995) who found that service failure was the most frequent reason to switch to new suppliers. In some cases, suppliers initiated termination of the relationship since they decided to prioritize other customers, an approach identified also in Gadde and Håkansson (2001). Finally, the significance of technical factors for changes in the supplier base have been observed in several other studies (e.g. Dubois and Araujo, 2006).

Another external impact on sourcing behavior and the supplier base was related to the general development within the practice of purchasing and supply chain management. During the

fifty years, this field has undergone major changes (e.g. Trent and Monczka, 1998; Araujo et al., 2016). Some of these changes were clearly observable in the case study, such as outsourcing, system buying and increasing involvement with some suppliers. Most of these modifications originated in the vehicle industry and affected many of the suppliers of the fork-lift manufacturer, and thus impacted both directly and indirectly on the buying firm in this study.

The variety in the supplier base

There was considerable diversity with regard to the length of the relationships in the supplier base. The study confirms common claims regarding the existence of long-term relationships. The longevity is explained by various causes identified also in other studies. One reason stems from adaptations in relation to suppliers (Gadde and Håkansson, 2001) and the switching costs associated with these investments (e.g. Wathne et al. 2001). Moreover, by staying with the same supplier, buying firms can reduce the costs related to finding a new source, identified also by Zajac and Olsen (1993). Finally, in some situations it might be difficult to find alternative suppliers. Similarly, Jarvis and Wilcox (1977) concluded that repetitive purchasing behavior sometimes originated in perceived absence of other suppliers.

Another feature of variety regards the economic importance of the various suppliers. One source of variety is caused by the respective components they supply. Furthermore, there is substantial variety with regard to the dependence to the various suppliers since the level of involvement differs. Exploiting and maintaining such diversity in the supplier base has been recommended as a means of developing effective approaches to purchasing and supply management (Bensaou, 1999). Moreover, there is considerable diversity between the suppliers of the same component. For dual-sourced components, one of the suppliers is normally the main source, accounting for the larger share of the total volume.

Some features of the supplier relationships were not in accordance with contemporary perspectives of effective purchasing. For example, the buying firm applied single sourcing in supplier markets where many alternative suppliers were available and no relation-specific adaptations were required. In these situations, mainstream literature at the time recommended buyers to rely on multiple sourcing to stimulate competition between suppliers. However, later on the approach applied by the buying firm was legitimized by Quayle (1998) who advocated single sourcing even in a buyer's market, since switching to another supplier would be easy in case of supplier failure. Moreover, some of the long-term relationships were not very close in relational terms, which also contrasted prevailing assumptions in the literature. However, over time 'this durable arm's-length' approach was identified as a useful means of routinizing operations (Dyer et al, 1998; Gadde and Håkansson, 2001; Jap and Anderson, 2007).

An interesting observation was that the buying firm continued to buy from some suppliers although they were frustrated with regard to their performance. Similar conditions were identified by Backhaus and Buschken (1999), Jap and Anderson (2007), as well as by Håkansson et al. (2009) who claimed that buying firms in some situations tend to use suppliers they neither like, nor trust, simply because they represent the best offerings.

Change and continuity – an interesting interplay

The dynamics of the supplier base have been analyzed in terms of the frequency of relationship changes from one year to the next. This approach offers a simplistic perspective on the actual supplier base dynamics. As exemplified above, some of the supply problems were handled within the ongoing relationships. Even if these relationships continued, the modifications undertaken also represent dynamics, since changes were made with regard to, for example, component design, planning and delivery conditions, as well as the level of interaction between buyer and supplier.

There is also another change in the supplier base that passes unnoticed with the approach applied in this study. In cases of dual or multiple sourcing, the buying firm sometimes shifted the suppliers' share of the total purchases in order to stimulate competition or express disappointment with supplier performance. This approach has also been used in the phasing-out and phasing-in of suppliers in accordance with what Pick (2010) identified as partial switching. Such changes are also aspects of supplier base dynamics since they impact on the strength and position of the various suppliers. Finally, over a long time period the relative importance of the components changes, for example through increasing significance of electronics. When some components become more important, the suppliers of these components improve their relative positions in the supplier base.

Concluding discussion

The main contribution of the study is the detailed examination of the long-term development of a subset of the supplier base of a company. The description and analysis, related to the first research question, provides knowledge regarding the longevity and dynamics of buyer-supplier relationships. Our findings are based on systematic observations over fifty years resulting in a unique data-set, while previous research often tends to be based on what McMillan and Farmer (1979) characterized as anecdotal data or biased samples involving the most important suppliers. As indicated by Table 2, many relationships are quite short-term, which might support the argument of McMillan and Farmer (1979).

In response to the second research question, the changes from year to year were explained by the impact of purchasing policy, the effects of relationships with customers and suppliers, and the role of technical modifications. Finally, the supplier switching patterns related to the third research question contribute knowledge that other researchers have called for.

In this final section we reflect on the impact of time in longitudinal studies like this one. There are certain implications of time for both research methodology and theoretical framing. Based on our findings in this study, we agree with Pettigrew (1990, p. 1) in his argument that "time sets a frame of reference for what changes can be seen and how these changes are explained".

Regarding methodological implications, the differences between the dynamics in the four phases indicate the importance of timing. It would be unusual for a 'normal' study to cover even one of these phases. The impact of time can be exemplified with two results from this research. First, a study covering phase 1 only, would most likely conclude that the supplier base for two of the components (9 and 10) features substantial change since no less than fifteen suppliers were used in this phase. Someone studying only phase 3 would arrive at another conclusion since for the same components only three suppliers were used. Similarly, a study of component 4 in phases 1 and 2 would characterize the supply of this component to feature strong continuity – only two suppliers were used for the 25 years between 1964 and

1989. During the following 22 years, however, eight suppliers were used. Therefore, we find it reasonable to believe that the differences in terms of supplier stability and change in the two cases studied by Kamp (2005) can be explained partly by the time factor.

In relation to the theoretical context, this study was initiated at a time when research on buyer-supplier relationships was in its infancy. Over time, we have learnt a lot about buyer-supplier interaction and the content of business relationships, as well as their connectedness. In today's research landscape, the importance of understanding how individual relationships are embedded in networks of other relationships have become central in inter-organisational research. Therefore, in view of the current theoretical context, the data based on the dyadic and buyer-oriented perspective applied in the study is somewhat problematic today. First, the study does not include the suppliers' perspectives on the relationships and their interpretations of the reasons for the changes. Second, the study does not capture the whole supply base of the company, but rather an arbitrary sub-set of its supplier relationships. Third, the interaction between the buyer and its suppliers has not been captured in the study. The latter is particularly problematic since what has been interpreted as 'continuity' may indeed contain a lot of interesting changes regarding the content of the relationships.

Hence, the longitudinal approach has revealed some interesting and important findings regarding the dynamics of the supplier base and supplier switching, as well as some of the main reasons for these changes. However, more complete understanding of these phenomena requires further studies. Such studies should also take the supplier perspective into consideration, as well as both firms' interpretation of their interaction. They also need to go deeper into the analysis of the processes underlying the situations we have classified as change and continuity. The understanding of these processes requires a network perspective since what can be achieved in the relationship between a buyer and a supplier is dependent on their relationships with other business partners.

A (or AB) represents the initial suppliers for each component.
Added suppliers are labelled B, C, D, etc. as they enter the supplier base.

Malicious Supply Chain Risk: A Literature Review and Future Directions

ABSTRACT

Supply chain risk management faces a myriad of challenges. Perhaps the most understudied of which deals with intentional disruptions; that is, those disruptions arising from deliberate actions that can negatively affect supply chain operations and performance. This paper focuses on suppliers intentionally undermining the operations of a supply chain through opportunistic behavior such as: deception, product fraud and contract/trust breeches. Such behavior engenders relational failure and leads to a type of risk that extant models of risk management have neglected. Accordingly, proactively managing this type of risk requires a substantially different management approach. The following presents a review of the innovative work in this domain and subsequently advances a framework for aiding managerial decision making for proactively managing and coping with such intentional risk in a supply chain. This framework encapsulates a three-pronged approach centered on avoiding & detecting, mitigating the impact of and recovering from this unique type of supply chain risk.

INTRODUCTION

Supply chain risk, as an academic body of work, has explored much in terms of how to effectively manage risks which are from inadvertent causes such as weather-based disruptions or accidental supply failures through a variety of process-focused research. However, much opportunity remains to explore the role of relational risk associated with other companies or individuals in the supply chain engaging in malicious behaviors that can lead to disruptions. We introduce the term malicious risks to discuss these types of risk which are relatively unexplored including opportunism, supply chain fraud, counterfeit manufacturing, digital security threats, IP theft, etc.

Managing supply chain risk is an important component of supply chain management. Risks can vary from major disruptions due to natural disasters, supplier bankruptcy, quality failures, fraud, etc. In order for firms to develop a resilient supply chain, it is important that they are able to correctly interpret supply chain risk and adapt operations to meet those risks (Ambulkar, Blackhurst, & Grawe, 2015; Pettit et al., 2016). With that in mind, it is important that researchers recognize a type of risk which has received limited attention in the literature, which we identify as malicious supply chain risk. We define malicious supply chain risk as the risk a firm has as a result of an individual or organization making a deliberate decision that can lead to harmful outcomes on the firm and its extended supply chain.

LITERATURE REVIEW

We note that this area of research on risks associated with malicious behavior is increasing over the past years. The evidence suggests that companies are increasingly facing crises from product harm that results in a product recall (Liu, Shankar, & Yun, 2017). Despite these increases, there is limited research which explores the motivation to engage in fraudulent actions at an organizational level (Arnold, Neubauer, & Schoenherr, 2012).

Recent research has explored aspects of disruption risk related to intentional behavior in some way, including threats from theft, piracy, terrorism, contamination, counterfeiting and product tampering. (McGreevy & Harrop, 2015), preparing a supply chain for premeditated attacks on facilities (Parajuli, Kuzgunkaya, & Vidyarthi, 2017), how to monitor fraud risks in the supply chain. (Vollmer, 2015), or issues related from profiting from product-harm crises in competitive markets (Rubel, 2018), among others. While much of the research in this area explores specific threats/risks, there is some research which suggests strategies for managing these types of risk. DuHadway, Carnovale, and Hazen (2017) explore key differences in how to

manage intentional disruptions (similar to the concept of malicious risks used in this paper) as opposed to traditional disruptions, suggesting that mitigating intentional disruptions requires relationship based approaches, while recovering from disruptions requires the ability to restructure a supply chain. Other research suggests that manufacturers must build forms of relational governance to safeguard against the relational risk of partners (Cheng & Chen, 2016).

Research which identifies the antecedents of similar disruptions or opportunistic events have found that power asymmetry/imbalance, culture can lead to malicious risks (Villena & Craighead, 2016; Madichie & Yamoah, 2017).

Perhaps the most closely connected literature stream to malicious risks is that which explores opportunism, or 'self-interest seeking with guile' (Williamson, 1985). Using opportunism as a basis, we can identify many different types of behaviors which fit with malicious risk that have seen some exposure in the literature.

EXAMPLES OF MALICIOUS RISKS

Consider two major automotive recalls of Takata airbags and the Volkswagen emissions scandal. The Takata airbag recall, which was the largest automotive recall in history occurred because Takata switched their production to using ammonium nitrate instead of tetrazole in their airbag design to cut costs and then lied to their customers regarding the safety of the new compound being used. Takata "routinely manipulated results of air-bag inflator tests" (Trudell & Fisk, 2016). Data indicating the risk of the airbags was deleted and customers were unaware of the risks that Takata knew and understood. Takata engaged in malicious behavior to advance their own interests at the expense of their supply chain partners.

Volkswagen engaged in deceptive practices which ultimately led to a recall for their vehicles which used software to deliberately cheat emissions testing, causing an estimated 59 premature deaths (Barrett et al., 2015), and a financial settlement of over $15 billion in the United States (Fisk et al., 2016). Interestingly, in both of these cases safeguards were in place (air-bag inflator tests to verify safety and emissions testing procedures) were in place to prevent problematic behavior, yet the firms intentionally circumvented such process controls and engaged in malicious behavior for their own self-interest.

In 2013, it was found that beef lasagna contained horsemeat of varying percentages, but with some of them containing 100% horsemeat (Brown, 2013). It is absurd to think that the introduction of horsemeat into the beef supply chain occurred through some inadvertent or accidental measure given that we normally learn the skill to differentiate between a horse and cow as a toddler. At some point in the supply chain, someone made the decision to substitute a horse for a cow and sell it as beef and did so intentionally, likely because it saved them money. Even though beef and horsemeat might be reasonably comparable, the act of deception in the supply chain is what serves to motivate the exploration into malicious risks. If our supplier says, "This is beef" – should we not be able to rely on that statement? And if we do decide that we aren't ready to trust our supplier, how can we protect ourselves from when suppliers decide to deliberately deceive us, or when our suppliers themselves have been duped? The issue of product deception and fraud very quickly becomes a supply chain issue, because the ramifications of deceptive behavior have very far reaching effects on all members in the supply chain.

There are examples of firms who have taken the appropriate quality control measures to protect their supply chain who have been impacted by deliberate deception of a supplier. The lead-based paint toy recalls from 2007 which Mattel experienced are notable because Mattel

established and paid for a testing facility to test often take what would normally be appropriate measure to ensure that the materials coming into the supplier's facility were of appropriate quality. However, their supplier intentionally went around the testing facility (Woo, 2008). Accordingly, we need to rethink the way we manage a supply chain to limit our exposure to malicious risks. Traditional process-based approaches can be ignored or circumvented.

Malicious risks can take a variety of different forms, including falsifying data, supply chain fraud, counterfeit manufacturing, digital security threats, intellectual property theft, contract breach, etc. A 2012 study found that 33% of the 1215 fish samples collected at restaurants, sushi vendors, and grocery stores were labeled incorrectly (Warner et al., 2013). Supply chain fraud has been identified as the "single most exposed area" of fraud (Bhide, 2012, p. 16). Counterfeit Manufacturing has become a large problem in the automotive supply chain, and examples of their impact on manufacturers and consumers are not difficult to find. Daimler seized 1.6 million counterfeit products in a single year (Daimler, 2017). Mislabelled counterfeit plastic parts in Aston Martin vehicles have led to major recalls (Wowak & Boone, 2015; DuHadway, Carnovale, & Hazen, 2017).

If we are relying on process based controls, we are inherently relying on trust as a protection mechanism to ensure that such procedures are followed. While trust can be good, consider the dark side of trust as well.

To highlight this dark side of trust, consider the example provided in the book *Turtles of the World* (Bonin, Devaux, & Dupré, 2006). The authors explore a number of different species of tortoises, finding that in some species an interesting symbiotic relationship emerges between the turtles and some local finches. The finches eat the small bugs and parasites that live on the turtles, particularly in hard to reach places such as under the head and neck of the turtle. This

behavior involves a turtle signaling to the bird by raising up on its front legs and letting the bird crawl underneath him to eat the insects. However, some of the turtles have tasted the dark side and learned that by suddenly dropping itself onto the bird, it can catch the bird under its shell, crushing it and providing a good source of nourishment in the form of newly tenderized protein. Although this example is quite extreme, trust in relationships is exhibited in similar ways. It slowly develops over time as expected behaviors emerge which can form mutually beneficial relationships. Yet if one party decides to start playing unfairly, it can have dramatic consequences on the other involved parties.

MANAGING MALICIOUS RISKS

We explore three traditional approaches for managing risk which include detection/avoidance, mitigation, and recovery. These three phases of risk management represent before, during, and after a disruptive event has occurred.

Detection can serve as an early warning system, or can help to dodge a disruption completely. If the disruption is unavoidable, it can ensure that good plans are in place to manage the disruption once it occurs. For example, the price of bitcoin has been very volatile.. This has led to shortages of video cards and incredibly high prices, as one of the ways that bitcoins can be gathered is through electronic mining which is most efficient using high-end graphics cards. However, due to the fluctuation of prices of bitcoins, the demand is highly uncertain and difficult to predict. Being able to observe early market trends can help firms avoid under-producing or over-producing products leading to either a disruption, or a surplus of product that needs to be liquidated at a lower price.

A number of detection and avoidance mechanisms exist, including quality management (Lee & Whang, 2005), information sharing (Sheffi, 2001; Kleindorfer & Saad, 2005), supplier

audits and supplier development (Giunipero & Aly Eltantawy, 2004), and security assessment and management practices (Finch, 2004) among others. Even though there are many different mechanisms for detection, effective detection which comes from information sharing, supply chain visibility, and supplier integration can detect or prevent a variety of disruptions (DuHadway, Carnovale, & Hazen, 2017).

Mitigation can limit the potential impact of a disruption occurring. This is critical for minimizing the harm to a supply chain from a disruption. Some research suggests that structural approaches can help to mitigate damage, such as modularity and diversification (Kleindorfer & Saad, 2005). Other more traditional approaches might include inventory (Chopra & Sodhi, 2004; Tomlin, 2006). These strategies are important to recognize, because it is possible that these strategies exacerbate the risks of malicious disruptions rather than limiting them. For example, consider the impact of high levels of inventory when the disruption is due to supply chain fraud such as lead-based paint in children's toys. Higher levels of inventory would then need to be discarded in addition to the carrying costs of maintaining higher levels of inventory. Modularity has been argued to generally limit exposure to opportunism (Lippman & Rumelt, 1982; Pil & Cohen, 2006), but if the modular system is compromised through intellectual property theft or counterfeiting, the issue could be further exacerbated because the entire system is now compromised.

Recovery is another aspect of risk management that requires a completely different approach. One of the most common approaches for risk recovery is to develop a resilient supply chain, or one that is quickly able to return to it's previous state after a disruption (Christopher & Lee, 2004). However, this approach is counter-intuitive when the disruption is caused by malicious risk. When the disruption is caused by malicious risk (such finding out that your supplier has

been selling you a counterfeit product) there is no value in returning to the previous state, so resilience based recovery approaches are insufficient. Using an analogy of a human immune system, we can liken resilience to being able to recover from injury (generally an external cause, sharp/immediate pain, which heals over time). However, disruptions from malicious risks would be more likened to that of an infectious disease (occurs from inside, the spread/impact is not immediately visible, and can significantly worsen if not treated in some way). This requires a different strategy to resolve, focusing generally on internal treatment. In extreme situations, the appropriate strategy for managing an infection might be to cut out the infected part. The approach that should be taken when a supplier has a product quality failure due to some accidental cause should be substantially different than when a supplier intentionally deceives or lies about product quality and intentionally substitutes an inferior product to make money.

DRIVERS OF MALICIOUS RISKS

Although research on malicious risks is relatively limited, we identify three areas which can provide potentially interesting directions for future research. These include: structural causes, network exposure, and behavioral drivers.

- ***Structural causes*** for malicious risk can include risks associated with the general trends in with regards to the changing environmental conditions surrounding supply chain management in a modern era. These include the increasing reliance on digital manufacturing, high levels of modularity, data security processes, the world becoming increasingly connected, emergent cultural differences through a more connected world, etc.
- ***Network exposure*** can explore how the different network structures that firms find themselves in can change their exposure to malicious risks. For example, highly central

firms or firms with a high degree of connectivity to various firms might experience more exposure to malicious behavior. In addition, the influence of opportunistic behavior on a network could exhibit transitive properties such that malicious risks can spread throughout a network. The increasing role of Internet of Things and the connectivity across many different systems can also have implications on malicious risks.

- Lastly, ***behavioral drivers*** can lead to malicious behaviors. Dependence asymmetry, trust and relational governance, transitive trust, cultural norms and values, business ethics, etc. can provide interesting insight in terms of how can we limit malicious supply chain risks.

Critical factors have been identified in the literature affecting sustainability of multi-tier suppliers. This study aims to explore the use of different governance mechanisms to influence the environmental sustainability compliance of suppliers and multi-tier suppliers. Mediating and non-mediating power will be investigated in a global supply chain setting.

Keywords: Environmental sustainability; Multi-tier suppliers; Governance Mechanisms

Introduction

Organizations nowadays exert so much time, efforts resources in developing, sustaining and enhancing their supply chain relationships as such relationships have clear outcomes in terms of operational and financial performance. According to literature there are two main types of governance in buyer supplier relationships formal and informal governance. Formal governance, focuses mainly on the importance of mediating power use and explicit contracts between firms to prevent any opportunism and conflicts. On the other hand, the informal governance highlights the non-mediating power use to avoid potential risks accompanied with uncertainty and transaction-specific investments (Noordewier et al., 1990; Uzzi, 1997) and coordinate buyer supplier relationships (Dyer and Singh, 1998; Heide and John, 1992; Macneil, 1980)

As firms can use both formal and informal governance to manage their relationships with their suppliers, the relation between formal and informal governance in buyer supplier relationship has been an important study topic in operations and supply chain management (Lumineau and Henderson, 2012) it's a subject of matter also in other areas such as marketing (Cannon et al., 2000; Yang et al., 2012), strategy (Li et al., 2010a; Poppo and Zenger, 2002), entrepreneurship (Chen et al., 2013; Strätling et al., 2012), and international business (Zhou and Xu, 2012) for more than a decade.

Poppo and Zenger (2002), were the first to shed the light on this particular issue, since then it has gained increasing attention. However, knowledge on the relation between formal and informal and their applicability in the buyer supplier relationship specifically in the multi-tier environmen-

tal sustainable supply chain governance has not been discussed. (Puranam and Vanneste, 2009; Schepker et al., 2014). Current literature is mainly divided into two groups. One group claims that the two types of governance substitute each other; which means the use of one type of governance decreases the benefits of using the other one (Huber et al., 2013; Li et al., 2010c; Lui and Ngo, 2004). There is a claim by some authors that Formal governance may hinder the existence of the informal one, as it's unusual to find buyers or suppliers eager to go for long-term collaborative relationships (Cox et al., 2003; Ramsay, 1996; Sanderson, 2008).

On the other hand, another group argued that the two types of governance may be complementing each other's which means that the use of one strengthen the use of the other one (Liu et al., 2009; Poppo and Zenger, 2002). A clarification of the way in which these governance mechanisms work best to affect environmental sustainability or even influencing suppliers applicability to certain activities will definitely guide practitioners to decide their suitable way to govern the relationship with their partners whether it is formal, informal or both. In particular, investigation of the possible moderating effects on the formal-informal governance interaction may inform managerial practice by highlighting significant contextual factors.

Therefore, to choose the suitable governance mechanisms to influence a firm's multi-tier suppliers' applicability of environmental sustainability, a focal firm needs to periodically assess its interdependence and power position relative to their suppliers and customers (Dyer & Singh, 1998; Lazzarini, Claro, & Mesquita, 2008; Poppo & Zenger, 2002). It was argued that organizations need to have a positive evaluation of their partner's performance in order to justify involvement in collaborative initiatives (Wang, Kayande, and Jap, 2010). Meaning that, there has to be some performance advantages in order for organizations to be involved in the potentially risky and time-intensive collaboration (Johnson et al., 1993).

Buyer supplier governance and sustainability

As previously mentioned governance is the relations through which partners in buyer supplier relationship create, sustain, and reshape network activities (Raynolds, 2004). Consequently governance mechanisms refer to any type of practices used by firms to handle relationships with their suppliers for the sake of enhancing their performance in general. Yet in this paper we will be focusing on enhancing multi-tier supplier's environmental sustainability. As the increasing expectations of corporate conduct in line with the ever-growing enlargement of global supply chains, Firms have to respond by integrating environmental concerns into their supply chain agendas.

As the competition increases the pressure to minimize costs has motivated suppliers, especially those of the less developed countries, to break the sustainability standards in order to avoid costly changes and loss of competitiveness, leading to lower quality and sustainability violation, in addition to losing partners and stakeholders' trust and opportunities for long- term value creation. Thus the focal firm has to consider the whole supply chain sustainability as focusing only on the direct supplier's sustainable performance definitely is not enough. There are lots of efforts that has to be conducted by every firm to encourage their multi-tier suppliers as well to comply with sustainability standards. (Lim and Phillips, 2008; Maloni and Brown, 2006).

Past literature on governance mechanisms to influence sustainability of multi-tier suppliers reveals that some studies have concentrated on how much suppliers abide by codes of conduct and assessment (e.g., Krueger 2008; Mueller et al. 2009; Preuss 2009; Van Tulder et al. 2009; Yu 2008); other papers have reevaluated the key assessment and market governance mechanisms in the light of proposals for long term collaboration (e.g., Lim and Phillips 2008; Park-Poaps and Rees 2010; Spence and Bourlakis 2009; Vachon and Klassen 2006; Vurro et al. 2009), and a few made a comparison among the influence of different mechanisms (e.g., Keating et al. 2008; Jiang 2009a, b; Klassen and Vachon 2003; Lee and Klassen 2008; Reuter et al. 2010; Large and Gimenez Thomsen 2011).

It has been also noticeable that among these past studies, certain papers have studied the effects of these mechanisms from the buying firm's point of view (e.g., Keating et al. 2008; Large and Gimenez Thomsen 2011; Lee and Klassen 2008; Reuter et al. 2010), while others have analyzed them from the perspective of the supplier (e.g., Jiang 2009a, b; Klassen and Vachon 2003). So basically, papers that study the governance of sustainable processes throughout the whole supply chain agree that the better sustainable performance a firm achieve the better ability to build and sustain integrated techniques toward supply chain management, based on long-term cooperation, shared knowledge, and joint development of competence both upstream and downstream (Maignan et al., 2002; Shepherd and Gunter, 2005; Strand, 2009). Nevertheless, there is still a difference between firms in terms of both the extent of these collaborative techniques along the supply chain and to which degree sustainability issues are addressed to the advantage of all partners involved (Jiang, 2009; Perez-Aleman and Sandi- lands, 2008; Roberts, 2003).

Formal governance and environmental sustainability

Formal governance in buyer supplier relationship context indicates the extent to which the supply chain is governed by explicit rules, procedures, and norms that authorize the rights and duties of the individual firms that establish it (Choi & Hong, 2002). Other definition to formal governance mechanisms is the structural arrangements formed to control the behavior of supply chain partners in an explicit way (Blome, Schoenherr & Kaesser, 2013; Huang, Cheng & Tseng, 2014). They consist of command structures, incentive systems, standard operating procedures, and documented dispute resolution procedures (Alvarez et al., 2010), and often depend on hierarchical controls (Gulati & Singh, 1998).

There is an obvious increase in interest showed by consumers and NGOs in adherence to environmental sustainability standards, which can barely be captured in the product itself but have become a critical matter of contractual commitments owed by the supplier to the buyer. As these contracts are clearly stating expected roles, responsibilities, processes, and output standards (Huang et al., 2014). Particularly, formal governance of environmental management activities may be recognized through environmental standards, audit procedures, codes of conduct, formalized processes, or a list of restricted materials (Miemczyk, Johnsen & Macquet, 2012; Pilbeam, Alvarez & Wilson, 2012). Even though they are mainly monitoring activities, they may also involve some collaborative activities, for instance, a supplier visit followed by an action plan.

Formalization works better to enhance supplier's environmental performance in the case of high uncertainty (Alvarez et al., 2010) because some suppliers may commit unethical or illegal actions that consequently oblige the focal firm to use costly monitoring techniques (Simpson and Power 2005; Carter and Rogers 2008). Uncertainties about the assessment of environmental performance and the critical points among the many lower tier suppliers can become barriers environmental sustainability implementation. Taking Nike as an example on this issue, the firm set environmental performance baselines and sustainability improvement targets for Asian suppliers via a formal environmental management initiative (Plambeck, Lee & Yatsko,2012), Wal-Mart as well followed a formal assessment approach globally with a 15-question survey to allocate business and choose suppliers to engage at a more strategic level based on their environmental performance (Plambeck & Denend, 2011).

If buyers and suppliers follow the same rules and procedures, eventually the transaction costs will reduce and information flows will be more efficient (Choi, Doolety & Rungtusanatham, 2001). Moreover, formal governance tends to reduce coordination needs, especially when it comes to higher technological components, anticipated coordination costs or interdependence (Gulati & Singh, 1998). This sort of relationship usually acts as a form of normative pressure in the buyer supplier relationship (Di Maggio & Powell, 1983). These pressures exist when there is a strong desire to professionalize organizational practices and enhance environmental performance through mechanisms such as industry standards. Getting back to the Wal-Mart example, formal chain-of-custody certification systems are enabling Wal-Mart to map its supply network and make the supply network practices more visible, allowing for redesigning the network with the goal of cutting environmental footprints (Plambeck, 2012).

Yet, formal governance mechanisms have some disadvantages. Designing, implementing, and imposing formal control criterion waste important organizational resources (Schmoltzi & Wallenburg, 2012). In other words, if there is a high level of formal control this will imply that there are high ex-ante contractual costs and ex-postmonitoring and enforcement costs (Huang et al., 2014). In addition to all of these costs, still using formal governance excessively will not prevent opportunistic behavior and will definitely have negative influence on buyer–supplier cooperation (Huang et al., 2014). What is make the situation worse is the existence of the commoditization of auditing systems and widespread corruption will by default make the violations of environmental standards tolerable (Lee et al., 2012). Consequently, suppliers may learn to cover up all their environmental violations by associating with indigenous consulting services (Plambeck et al., 2012). Therefore, informal, trust-based governance mechanisms (e.g., information sharing, values, culture, and norms) are essential in such cases.

Informal and environmental sustainability

As mention in the previous section, formal contracts will often be incomplete and have some critical drawbacks (Williamson, 1981) and accordingly require informal mechanisms to minimize ex-posttransaction costs of monitoring and coordination (Kale & Singh, 2007) as it involves the idea of collaborative planning and solution finding among firms. Informal governance mecha-

nisms could be presented in many forms such as peer-to-peer learning, noncompetitive supplier working groups, NGO partnerships, interactive websites, supplier/industry forums, incentives to self-reporting, and informal supervision through environmental databases (Plambeck et al., 2012). Informal governance has gained attention recently for many reasons. First, increasing transparency and inspection from NGOs make social control easier rather than bureaucratic system (Lee et al., 2012). Therefore informal governance is the best substitute to the formal one, when monitoring and formal controls are difficult and costly (McEvily, Perrone & Zaheer, 2003).

Back to Nike again, the company trains its suppliers to supervise their own suppliers using NGO guidelines. It encourages the culture of self-reporting, creating reward plans for suppliers who detect any sustainability violations and come up with solutions instead of just punishing any noncompliance (Lee et al., 2012). This is considered to be another sort of informal governance which is called "self-regulation" that depends mainly on the moral perspectives (Schmoltzi & Wallenburg, 2012). To encourage suppliers to apply the idea of self-regulation some industry initiatives such as the Leather Working Group are industry forums that give suppliers the opportunity to share their environmental practices (Lee et al., 2012).

Not only Nike but also Wal-Mart uses to reward its noncompetitive supplier working groups in collaboration with NGOs to motivate suppliers' green innovation (Plambeck & Denend, 2011). This strengthen the idea that non-mediated power are creating ties between organizations can serve as social mechanisms of control (Jones et al., 1997). In these cases, rather than applying a court-enforced contract, firms may involve relational governance (Baker, Gibbons & Murphy, 2002).

Before going into more details on the informal or collaborative approach we should explain the in between type of environmental governance which is environmental monitoring. If we classified buyer supplier governance into two mechanisms, environmental monitoring is considered to be in the gray area between both mechanisms. Monitoring may be required by the supplier himself to enhance his compliance of code of practice or public standard. Even more, these standards are included in the assessment criterion of suppliers (Walton et al., 1998). The most common international standard nowadays is ISO 14001 certification which is a voluntary standard that companies can certify in order to undertake its framework, rather than establishing environmental performance requirements.

Yet, each focal firm has the freedom to choose the suitable environmental procedure that can be imposed on suppliers. Therefore, as the customer requires certain quality specifications for parts and components, as certification of suppliers' environment management systems become yet another condition. Otherwise, environmental performance standards can be directly required mentioned previously. Taking a simple example of suppliers who are forced to follow strict environmental standards is the commercial printer who supplies packages to an environmentally-conscious consumer-product producer, such as The Body Shop, can be obliged to stick to a minimum level of recycled fibers in the paperboard supplied by the paper mill.

On the other hand, for the focal firm to monitor environmental collaboration it has to devote certain resources to develop cooperative practices to integrate environmental issues in the supply chain (internalization dimension). These practices tend to capture the added value that can be resulted from a collaborative buyer-supplier relationship to minimize the environmental footprints as much as possible. For instance, in chemical management services, a supplier of chemicals is helping his customers in their own facilities to minimize their use of chemicals. Moving from environmental monitoring to environmental collaboration which is totally opposite as it doesn't focus on the direct outcome of the suppliers' environmental efforts (e.g. compliance to existing regulations); instead it focuses on the process used by these suppliers to achieve more environmentally-sound operations or product.

This sort of relationship helps to develop trust and a better understanding of buyers expectations, especially when it comes to non-economic elements of performance that eventually improve environmental sustainability. Stating it differently, when there is a high level of uncertainty, trust is essential, and this trust will not exist if there is not a sort of informal interactions between partners (Galaskiewicz, 2011). Back to environmental collaboration, the sharing of tacit knowledge is definitely a critical factor to strengthen the technological integration (Grant, 1996). Thus, this technological integration within a supply chain is expected to have a positive impact on cooperative activities associated with environmental issues.
Beside the technological integration there are also two important characteristics of the supply chain structure which have a significant effect on the environmental cooperative activities. The size of the supply network, both upstream and downstream, as it potentially influences the importance of the formal governance and willingness to collaborate (Geffen and Rothenberg, 2000; Krut and Karasin, 1999). For suppliers, extensive environmental monitoring aims to ensure conformance with government regulations and establishing systems to minimize uncertainty related to environmental issues (Min and Galle, 2001). This uncertainty is not just legal or financial, but also operational. For example if a supplier is obliged to terminate his business because of an illegal material use or because it faces a regulatory liability to clean up contaminated soil, the focal firm might suffer from an immediate shortage of a critical part or material.

On the other hand, environmentally-conscious customers might decide to boycott the company's products or services because of supplier-based environmental violations (most probably supported by non-government organizations (NGOs)). Furthermore, the firms which depend mainly on a large supplier base are more likely to have one or more suppliers who violate environmental regulations (e.g. emissions standards). Therefore, firms can reduce risks or respond promptly to environmental issues through greater monitoring of both suppliers and their sub-suppliers. In contrast, there are firms which are mainly relying on a small number of suppliers. The parties are more likely to move from pure transaction-based to more relational interactions. A high level of trust permits management to reduce their scarce resources consumption on environmental monitoring (with relatively little value added) and focus on other more critical aspects instead, such as improvement.

Otherwise, concentration can raise the probability of disruption risk; therefore it requires an increased monitoring of suppliers. Moreover, the costs of monitoring are expected to be reducing in the case of a small supply base, also encouraging more active monitoring. While the benefits of supplier base reduction is still debatable from an organization' perspective (Cousins, 1999), it can be argued, that a larger supplier base makes it harder to develop long-term relationships and integration (Trent and Monczka, 1999). The reduced likelihood of a long-term relationship is likely to hinder the initiation of environmental collaboration. Likewise, a firm that has multiple customers will not likely invest in environmental activities with specific customers – except they account for a large fraction of revenue or can be transferred to most customers (vachon2006)

Multi-tier suppliers' governance and environmental sustainability

The most critical environmental issues in the supply chain are mainly created by suppliers located in the second tier or further upstream, which also referred to as multi-tier suppliers, or sub-suppliers. There is an estimation that up to 90 per cent of greenhouse gases emissions could be generated by lower-tier suppliers. This makes us doubt the actual impact of "low emission" objectives and other sustainability initiatives taken recently by many firms. However, multi-tier suppliers have some characteristics that make it complicated for focal firms to govern their sustainability. First, focal firms cannot easily have a full knowledge and information about their multi-tier suppliers. Second, focal firms do not have enough control over multi-tier suppliers. Third, lower-tier suppliers are not suffering from environmental pressure from their society, as they are often small and medium enterprises (SMEs), not well-known to the general public, and located in developing countries where environmental regulations are less demanding.

Finally, multi-tier suppliers are more likely to have unstable relationship with the rest of the supply chain, as they can be changed easily (Tachizawa and Yew Wong, 2014).To influence multi-tier suppliers' sustainability the firm has to choose the suitable type of governance to reach a whole sustainable supply chain. There are certain practices that have been previously identified, used by the focal firm to govern multi-tier relationships with suppliers. Not all of these practices are specifically developed for addressing sustainability, as some are used to manage other issues (e.g. cost). However, sustainability is one of the main objectives for multi-tier practices. These practices can be grouped in four basic approaches: "Direct", "Indirect", "Work with third parties" and "Don't bother".

Direct: In this approach, lead firms have a direct access to lower-tier suppliers. They can by-pass first-tier suppliers and establish a direct contact with lower-tier suppliers, to monitor, govern and collaborate with them to improve their environmental or social performance. Here the firm is using typical formal governance with its multi-tier supplier.

Indirect: This approach contact with lower-tier suppliers is performed indirectly through another supplier. It is difficult for a single company to manage compliance within the entire supply chain, thus cross-tier collaboration is essential. Therefore Standards are a major indirect mechanism of coordination of lower-tier suppliers. This sort of relationship is mainly depending on the direct

supplier, so the focal firm is using formal governance and asking for strict standards compliance that leads the direct supplier to force their sub-suppliers to follow these sustainability standards.

Work with third parties: Focal firms collaborate or delegate responsibilities to other organizations (e.g. NGOs, competitors, firms from the same industry, standards institutions, etc.) to enhance sustainability standards; apply industry self-regulations or voluntary standards ideas which are previously mentioned, monitor suppliers using third-party sustainability databases, etc. Even though companies can delegate some responsibilities to the third parties such as certification bodies, it is important for focal firms to give input to such third parties and even oversight their effectiveness. Here the focal firm is using complete informal governance with both their suppliers and multi-tier suppliers.

Don't bother: In this approach firms focus on first-tier suppliers and have neither information about lower-tier suppliers nor intention to influence them. This approach may be more applied to less complex supply chains (e.g. less tiers), or firms with less visibility to the final customer. (Tachizawa and Yew Wong, 2014).

Abstract

Rush orders are handled by the supplier to meet customer requirements in a limited timeframe. Rather than considering rush orders as a deterministic planning problem in a reductionist analytical framework, a contingency-sensitive complex systems perspective highlights emergent and systemic networked interactions between the supplier and customers through this single case study of an advanced sanitary product supplier. A detailed case narrative describes and in brief reflects upon causes, effects, and solutions to rush orders. This provides grounds for describing how to conceptually model rush orders at the studied company using soft systems methodology to facilitate continuous innovation.

Keywords: *Rush orders, Networking, Soft systems methodology.*

Introduction

Rush orders are characterized by time constraints and organizational priority, managed to secure customer value. Supplier-relationship management, often termed sourcing, includes how to strategically handle orders that are often relatively unplanned due to degrees of demand uncertainty. The purpose of this paper is to empirically ground considering rush orders as a complex system. This research represents a stepping stone to more automated processing of rush orders through crafting first a conceptual model of rush orders. Such models provide foundation for modelling computer software application, linking at the operational level information technology with organization science. In this paper the foundations for such modelling of rush orders as an organizational processes following soft systems methodology (Checkland and Scholes 1991) are provided. Such modelling and future simulations applications are envisioned organised by the company as continuous innovations; a form of "Kaizen", of element of "lean" purchasing and customer services. Here we, however, do not dwell on considerations of applying lean to such administrative purchases, rather focus is directed how to design and organize this was to carry out the administrative process of handling rush orders. Since rush orders are handled through business relationships, this implies that this study concerns both a customer services (the supplier) and purchasing (the customer) perspectives. This implies a balanced view of these administrative processes in line with industrial network thinking (Gadde et al. 2010). In practical terms, sales and purchasing functionality are not prioritized at an operational level when constructing the frame of reference through the literature review.

The literature review considers in brief the following topics following an introduction on conceptualizing "rush orders": (1) customer services and planning, (2) uncertainty and managerial anxiety following rush orders, (3) economies of documentation and exchange, (4) product criticality and the customer voice, (5) uncertainty and prioritizing operations, (6) networked product complexity, (7) order process complexity. Following a statement of applied method, findings are provided as briefly commented descriptions of (1) causes, effects, and solutions to rush orders. This is followed by concluding applying soft systems methodology (Checkland and Scholes 1991) as direction for further research involving continuous modelling, simulation and developing interdependent administrative and logistics operations simultaneously using information technology (IT). This represents the core of a forthcoming full paper on how to manage rush orders *in* the complexities of a supply chain.

Literature review

Rush orders

Rush orders are received by the supplier, with time constraints as the main defining factor. The limited timeframe indicates a need to adapt to manage this form of supply. Wang and Chen (2008) provide a systemic framework from a single-firm perspective. It applies a neo fuzzy-based forecasting approach that describes how to manage rush orders by pointing out various causes and corresponding methods, including: Implicit customer's priority; concern for extra returns, outlays, or usuries; special orders authorized by higher-ups; and production disturbances. The classification indicates that rush orders, from the viewpoint of the focal firm managing downstream logistics to its customers, is not limited to only technical discrepancies. Rush orders may well be caused by marketing or managerial factors. Wang and Chen (2008) also describe three methods to solve the rush-order problem: (1) demand improvement of forecast accuracy; (2) approaches to control and receive rush orders; and (3) a mechanism to reserve capacity to improve suppliers' rush-order handling.

Customer services and planning

Svensson and Barfod (2002) argue that getting the right material at the right time is one main reason why rush orders are placed. If the general order has not been correctly filled, a rush order is needed to follow up on this. When material is missing, planned orders are delayed. Svensson and Barfod (2002) refer to this as a simple, but common problem that leads to delays in most cases. From the supplier's perspective, such problems must primarily be managed by the customer service function. Gourdin (2006) argues that a firm's customer service strategy is built around five key concepts: dependability, time, convenience, communications, and honesty, to achieve customer-responsive supply relationships to secure trust, which is expressed as loyalty in a business relationship. Wang and Chen (2008) seek to use advanced forecasting programs to help solve the rush order planning problem. In this paper this view is scrutinized based on empirical as well as theoretical considerations.

Uncertainty and managerial anxiety following rush orders

Since the rush order is a special order requiring special handling, a prioritized, ad-hoc form of organization is required when the rush order is filled (Yao & Lin, 2009). Rush orders are always at least to some degree unique supply chain events; uncertainty being a source of managerial anxiety. If such project-type of organizing is not planned, it must be developed as the order is received and filled. Chen (2010) also argues that prioritizing rush orders may provoke delays in scheduling standard orders. Kim and Duffie (2004) mention how an increase in unplanned orders such as a rush orders caused fluctuation in general lead times, significantly increased order backlogs, and greater variability in material quality, due to poor

fabrication coordination. Along this line, Ehteshami et al. (1992) argue that rush orders decrease the service level on standard orders, and increase inventory and supply delays, and the unpredictability of the production system. This leads to a higher share of rush orders tying up logistics, which may result in not enough customer-service resources devoted to standard orders. When a rush order appears, all customer-service hands are concerned with these orders hampering normal supply activities. This implies concern about balancing organizational resources between special and general orders. This also indicates that rush orders exist in a context of some managerial concern. Rush orders simply imply increased administrative workload.

Economies of documentation and exchange

From a supply chain management (SCM) perspective, considering rush orders as an exchange economy (Hammervoll 2014) directs attention to administrative process efficiencies, not only their output-focused effectiveness. Likewise as production, administration is considered here as operations. In these rush order handling processes the resources used and handled differ from production; it is in these cases of managing important to have the right documentation at the right time, to keep the flow of information going smoothly. According to Yan-Hai et al. (2005), the result of missing documentation causes planning problems, as well as poor logistics quality. This underpins the importance of having quality information that must be shared in the supply chain to execute the vital logistics of rush orders. This also implies a form of reciprocal interdependency in managing rush orders entailing need for mutual adjustments (Thompson 1967). Since these are special orders, it cannot be taken for granted that the supplier instantly understands the concept of the order, including how it is to be transported. The order may include a range of factors, such as goods, location, transport, payment and service options. All these factors can be negotiated. The more special the supplier perceives the order to be, the more mutual adjustment may be needed to get the order right. This indicates the importance of developed business relationships in such cases of hectic, because they are time-constrained, logistics operations to smoothly handle such complex interactions cost-efficiently.

Product criticality and the customer voice

Rush orders should also be evaluated in relation to the customer's perception of their criticality. This implies a value-orientation. According to Huiskonen (2001), criticality is divided into process criticality and control criticality. Process criticality is related to the consequences of a failure in which replacement is not readily available. The cost of production downtime is a major part of process criticality. Control criticality deals with possibilities to control production. This involves features of forecasting error, goods availability, lead times, and an array of logistical concerns. Criticality is associated with customer perceptions of lack of supply control or the consequences for production. When a rush order is received, a customer-responsive supplier will heed its customer's concerns by seeking to comply with its needs and deliver the goods in accordance with rush-order specifications. Lack of goods specificity affects complexity, since goods must be defined through interaction prior to supply. Demand patterns are associated with the degree of order uncertainty. Important features such as goods types, frequency, and volume. The customer voice explicitly or in a more subtle manner conveys a degree of criticality, affecting how the supplier should prioritize this order in a setting of numerous rush orders and general orders.

Uncertainty and prioritizing operations

Rush orders are also intertwined with uncertainty, since they suddenly may preoccupy the supplier's organization. According to Angkiriwang, et al. (2014), demand uncertainty is: "The

probabilistic nature of demand quantity, types, timing, and locations. Demand uncertainty could be in the form of errors in the demand forecast, changes in customer orders, uncertainty about the product specification/mix that the customers will order, and competitor actions regarding marketing promotion." However, this uncertainty is also associated with when the rush order manifests for the supplier and how it organizes this goods handling. This latter uncertainty concerns the entire organization. This implies that the organization must be able to quickly coordinate to handle the goods that are demanded by rush orders. Uncertainty must be handled for the supplier to find a viable mode of goods supply. Different solutions have been proposed to improve handling rush orders. Simangunsong et al. (2011) provide a list of strategies to cope with demand uncertainty that is typical of rush-order situations (1) postponement, (2) information sharing with downstream partners, (3) information and communication technology use, (4) use of strategic buffer stocks and lead-time management. Postponement may not intuitively seem to be a good fit for handling rush orders. However, negotiated timing of supplies becomes an issue in cases when goods are out of stock. These different factors are complementary and used to varying degrees. These all involve strategic investment, variation, and value that may be analysed through considering supply operations costs and benefits (i.e. "customer value"). Wang and Chen (2008) mention buffering inventory as a viable solution, but include that the supplier could reserve some of its production capacity to handle rush orders. The supplier should also develop specific criteria to handle incoming rush orders, such as the size of the customer, amount of the product ordered, or the profit it would create. Yan-Hai et al. (2005) state that rescheduling the manufacturing system may help support the on-time execution of rush orders, which also applies for standard orders. Tryzna et al. (2012) argue that work-in-progress inventory must be at an acceptable level, so both rush and standard orders may be fabricated in a balanced manner when there is a large amount of orders. Rush orders also represent a fabrication-planning problem that should be taken seriously in advance, due to the delivery time, change in inventory level, and lack of capacity or need for it be re-arranged. Finally, this understanding of fabrication planning includes taking into consideration the impact rush orders have on current and potential customer relationships. The criticality of an order may vary, and a high degree of criticality usually implies that a rush order is needed to be carried out. The causality between uncertainty and the use of rush orders is more unclear, but unexpected orders, when they occur, may imply that this is a rush order. This needs, however to negotiated with the customer.

Networked product complexity

Closs et al. (2008) define product complexity as "from a multiplicity of elements, as well as from relationship among the elements," meaning that it can be organizationally challenging to keep track of all production system elements. Blackenfelt (2001) describes product complexity as the number of parts and relationships between the parts, but complexity can also be related to the issues of product variety, since it directly affects complexity. As part of a supply-chain flow domino effect, the more complex a product is, the greater the risk of more sub-suppliers rendering fabrication coordination more challenging. A complex product is potentially embedded in a more complex supply network. According to Svensson and Barfod (2002), the traditional way of producing a complex, highly customized product has shifted from material processing to competence in managing product information. Closs et al. (2008) argue that market diversity creates higher complexity due to increasing product variations. To handle product complexity Closs et al. (2008) note that managers may seek to limit requirements by balancing this with customer demands for supply adaptation. It is difficult to optimize any level of product complexity to ensure the right amount of cost and revenue. Blackenfelt (2001) mentions modularization as a compromise, ensuring customer

responsiveness and cost efficiency. Product design and information exchange are ways to handle product complexity in cases of relatively severely time-constrained supply. Rush orders are often associated with deliveries of spare parts. According to Fortuin and Martin (1999), companies may have a catalogue consisting of 100,000 spare parts, but only have 50,000 actually in stock. The remaining spare parts can be ordered, but would then need to be manufactured. This implies a need for supply postponement, a strategy that seems to not be a good fit for rush orders. Fortuin and Martin (1999) argue that there is a need for categorization to know which parts to stock. Huiskonen (2001) specifies a classification system, involving only four control characteristics: (1) criticality, (2) specificity, (3) demand pattern, and (4) parts value. This implies differentiating spare parts supplies in relation to these criteria in regard to the effects they have to supply quality.

Order process complexity

In addition to product complexities, it is also vital to consider rush order process complexity. In a supply system, complexity must be defined different from product complexity. In this case, a product is a type of good associated with physical distribution, which is a static artefact. However, the system is dynamic. From a process viewpoint, complexity is defined as: "A property of an open system that consists of a large number of diverse, partially autonomous, richly interconnected components, often called agents, has no centralized control and whose behaviour emerges from the intricate interaction of agents and is therefore uncertain without being random" (Rzevski & Skobelev, 2014, p.5). Fundamental to this view is that conceptually enhancing complexity is the foundation for developing a complexity-sensitive way to manage rush orders can be developed, supported by IT software. Rezevski and Skobelev (2014) point out that the key features of complexity are openness, diversity, partial autonomy and interconnectedness of agents, lack of centralized control, and emergence. This component interlinking entails interdependence. Management must consider how to handle processes in which components continually change regarding not only time, place and form, but also how they are interconnected (pooled) and perceived. In a complex system, not only is service transformed in production, but how it is evaluated may also change over time, affecting production. Interaction, matching uncertain demand with anxieties of supplier management can be solved through using flexible resources.

Methodological considerations

A single case study of rush orders was carried out, based on the general ideographic stance taken in this research. The study began Jan. 19, 2017 when a semi-structured group interview was conducted in Norwegian with six employees at the firm's main office. Two persons from the research team took part in this visit. Our contact person was present throughout the whole interview. The corporate manager was present during the first hour and 25 minutes, while the rest were interviewed during the remaining hour and 35 minutes. Interviews were not conducted alone with each employee because of their busy schedules. Since this was a group interview, the interviewees complemented each other during the interview. They filled in information for each other, and discussed various perceptions of rush orders often associated with handling different types of orders and customers. Another positive result from the group interview was that, through careful guidance by the research team, the interviewees did not repeat themselves or overlap their responses. Group interview mediation was the responsibility of the two moderators from the research team. It provided an overview of the company functions and the firms with which it works in the supply chains. A list of potential informants among their customers was also provided.

After the interview, our contact person took us to the production and warehouse department, where we observed how the production was performed. Our contact person also showed us some of the products that were discussed during the interview so that we could get a clearer picture of what they had been talking about. Supplementary brief interviews were carried out with customers, represented by either domestic dealerships or representatives abroad. An adapted customer interview guide for dealers and representatives was created. This interview guide was sent in the same form by email to these customers, and request was made to carry out an interview using Skype. All the asked customer informants agreed to take part in the study. However, they preferred to respond to our questions by email, rather than by Skype. These customers were partially motivated by the fact that this research could help improve the handling of rush orders. The interviewees included four domestic retailers and three international representatives.

This paper highlights the emergent networked time-constrained interactions to supply spare parts between Jets AS, a Norwegian supplier of advanced sanitary systems that limit water usage to its network of domestic and international customers. First, analysis seeks to evoke the empirical state of (1) causes, (2) effects, and (3) solutions related to rush orders. Empirical raw data, other than a brief introduction of the company and its rush order handling challenge, a case narrative including quotes of the informants, are not provided in this paper due to its limited text length. This will be included in a future full paper version.

Brief empirical overview

The sanitary product supplier operates in two market segments organized as departments: (1) ship & offshore; and (2) land & transport. The difference between a traditional sanitary product that uses gravity and a vacuum sanitary product is that the latter product uses air instead of water to handle human waste. Only a small amount of water is used to clean the bowl in a vacuum system. The supplier has a network of domestic retailers and global representatives. Some of the foreign representatives support both ship & offshore, and land & transportation segments. There are 87 domestic dealerships, 85 of which only deal with systems for the cabin-home segment. The other two deal with both the cabin-home and the larger building segment. These dealerships are usually stores that carry sanitary systems and plumbing equipment for cabins. The supplier does not have a formal, explicit definition of what they classify as a "rush order". It perceives rush orders as one of many services it provides to its customers, without giving it much analytical thought. Still, it has a conception of supply timing, based on the lead time the within which orders need to be filled. The customers that place these rush orders usually contact the sales or aftersales department when they place such orders. These types of orders demand a maximum of 48 hours to answer the customer inquiry in case delivery is impossible the same day. Out of 8,506 orders in 2016, 682 of these orders were ad-hoc classified as rush orders, or approximately 8 percent of all orders. The rush-order invoice amount was 3.8 million NOK, out of a total invoice amount in 2016 of 246 million NOK. Out of the 682 rush orders, 507 were delivered in Norway, and the remaining 175 rush orders were delivered to other countries. Some orders delivered in Norway were addressed to airports and be shipped outside of Norway.

Findings - abstract

Causes
It is almost impossible to plan rush orders, which makes the time threshold difficult to predict, as well as how it will affect normal operations. Rush orders represent an everyday reality of

production at the studied company. The company also has no clear concept of rush orders and has not classified what defines a rush order. It is simply a service they provide to their customers. It is also difficult to define a rush order, since there are different degrees of order urgency, compared to other orders. Classifying a rush order is related to a continuum regarding time constraints. The distinction of what defines a rush order in the supply chain becomes increasingly unclear when considering when orders must be fabricated. Such orders must be produced in the factory, which takes time. Through exchange perceptions of urgency are manipulated. In production, rush orders are prioritized before standard orders, implying that they not follow the standard time guidelines as applied to in-stock spare parts. In fact, it is the limited conceptual understanding regarding what this actually constitutes "rush orders" and what differentiates this type of order from standard orders also hampers understating root causes of rush orders. Rush orders are, regarding its organizational symptoms (what is immediately perceived), intertwined with uncertainty, both regarding their occurrence and their managerial interpretation. Customers have a more clear understanding of the causes of rush orders, which were described in the customer interviews. They are more close to its root cause. Many of the incoming rush orders were a direct consequence of their dealers and representatives not keeping stock of the most important parts. If they kept stock of the most crucial parts, it might help reduce the demand uncertainty. In 2016, the supplier had approximately 8 percent of their orders as rush orders, which disturbs the normal production line and might cause delays. The ship-&-offshore segment has greater uncertainty, due to the fact that most products for that segment are made to fit a custom-designed installation. On the other hand, the land-&-transportation segment, in which five to six standard products are used, has a lower uncertainty level.

Effects

The supplier has no clear set of standards that explicit tells which service level they are providing to their customers. The supplier sets the ideal service level at “100 percent.” This is clearly more a motivating objective than a realistic practicality. It also seems that the supplier has not been able to handle the transition to being an innovator in the sanitary system market, going from only a few customers, to now possibly having too many. Providing excellent service to a few customers is manageable. Complexity increases as the supply system grows, rendering it increasingly difficult to plan and manage, in accordance with pre-set supply processes. The empirical findings show that the dealers and representatives express that they are very satisfied with the supplier’s service. They get quick response when they need help with something. A technical issue with an installed sanitary system is a common cause for a rush order. The supplier then responds with a willingness to fill their customers’ need for quick service. This might be one of the underlying reasons why the supplier has a problem with rush orders. They seem to push the rush-order service. They agree to rush orders that could have been sent as standard orders. This also implies organizational consequences. Resources could have been more economically used if an order that was not critical could have been shipped by standard ordering procedures. Some representatives or dealers also tend to send requisitions too late and a rush order becomes an emergency through such exchange process timing. This causes an enormous stress on the supplier’s production system. Sharing information regarding production and delivery time could have stopped the rush order, since customers might then state their spare-parts needs earlier on. Withholding the right information at the right time seems to be a problem for both the supplier, and their representatives and dealers, which makes them unable to create a responsive supply chain. This is an example of discrepancies associated with the exchange economy (Hammervoll, 2014).

Solutions

Since supply uncertainty, especially in the ship-&-offshore segment is high, is not likely to eliminate all rush orders from occurring. The uncertainty is supply chain-contingent environmental characteristic the supplier has limited influence upon. Some influence may be used to change how customers order their spare paper as indicated in the preceding section. From our empirical findings, there are some solutions already in place, but also some potential for more solutions. The retailers and foreign representatives provided some solutions. Davis (1993), and Wang and Chen (2008) argue that using inventory can be a solution to both prevent rush orders and smooth out variation due to supply and demand. Some retailers and representatives have inventories with spare parts. Our findings show that inventories with finished products/systems are organizationally challenging, due to order variation and lack of standardization. The resources are only weakly integrated, so are difficult to pool. Customers have some finished products in the land-&-transportation segment, but there is great variation in the ship-&-offshore segment. Wang and Chen (2008) also argue that if suppliers reserve management and production capacity, it could help cope with rush orders. The supplier attempted to do this and stated that employees will work overtime, if needed. The risk of having inventory and reserving capacity is that they will not be used, and money will be wasted (Wang and Chen, 2008).

Solutions to cope with demand uncertainty include postponement, information sharing, buffer stocks, and lead-time management. Postponement incurs accepting delays, which would mean a negotiated acceptance by the customer to accept waiting for an order that may be critical by an agreed-upon time. Variation of demand is uncertain, so it is difficult to predict rendering and planning. It is possible to have extra inventory (buffering) to keep rush orders under control. The supplier never knows when unexpected repairs shows up, so buffer stocks would safeguard against a meltdown in the system. The customers also experiences intermediaries, so demand is volatile and often unexpected.

Lead-time management is, expressed by the company, that it could help handle the level of uncertainty by controlling their representatives and dealers to create a space between the actual time it takes and what their customer knows. This would help the supplier keep rush orders handled within a reasonable time. Unplanned orders, such as rush orders, would be a direct cause of how lead times vary as the backlog increases and work in progress goes up and down (Kim and Duffie, 2004). Lead-time management means using flexible organizational and technical resources to cut down the time of delivery of unplanned orders. Focus should be directed toward developing production flexibility to reduce lead time in urgent situations. This includes both logistical and fabrication flexibility. It also involves developing efficient processes to manage production (logistics and fabrication) flexibility. This demands effective information systems. A key to this development is the use of product and information standards in unison to facilitate efficient, effective resource pooling.

The supplier's idea of introducing a rush-order fee was discussed with the customers. Unsurprisingly, the customers' immediate thought was that the fee was to cover some of the costs for having a high service level, which was starting to cost a substantial amount of money. In a manner, such a fee would elevate organizational awareness of the rush order and motivate customers to avoid rush orders. The interviews with customers showed clearly that improved interaction between the suppliers and their customers could help reduce supply uncertainty, as well as create orders in a standardized information format, easing interpretation and further ordering. Introducing a fee could be helpful in terms of eliminate some rush orders that actually were not that urgent. A rush-order fee could also solve the issue

of all orders being communicated as rush orders, even though they aren't. The findings from the interviews with the retailers and the representatives did not provide a clear indication of whether or not the amount of rush orders would decrease if an order fee was imposed. The majority of the customers were negative toward introducing such a fee. It could therefore also have negative effects on relationships with the supplier.

Concluding remarks

Since uncertainty is one of the prime features of customer relationships, forecasting systems are limited in detecting emerging issues of both supply demand and its technical provision, although they provide valuable management indicators directing supply-related activities,. The main limitation regarding Wang and Chen's (2008) approach is that it implies a deterministic single-firm focus.

This study attempts to understand supply-process coordination as a complex system embedded in SCM. This implies a fundamental view of rush orders as an inter-organizational problem. In addition, this study ultimately seeks to consider how such rush orders can be a complex phenomenon in this SCM context. Being conceptually grounded in SCM implies that the analytical focus is directed toward features of supply-chain integration and collaboration to coordinate rush orders as supply *processes*, rather than directed toward IS technicality.

When viewed as complex entities, the term "supply chains" (a supply system) implies a fundamental view that management should normatively-speaking be more preoccupied with achieving integration; connectivity and sufficient resource capacity (people, tools and facilities) for adaptation founded on resource flexibility characteristics, rather than in a deterministic fashion planning the organization away from the perceived managerial threat of rush-order problems. This represents theoretically a movement away from a reductionist view of management with process planning to developing organizational sensitivity of emerging processes needed to navigate in complex supply networks (Rzevski & Skobelev, 2014). This complexity may to a degree be automated using complex systems software including system agents as artificial intelligence resources.

Solving the problem of rush orders is in this research therefore, as stated, not considered as a planning problem following a deterministic line of thought. Instead, following a complex systems line of thought, process emergence associated with always unique combining of resources following industrial network thinking (Ford et al. 2017). The paper confronts the complexity rush order handling and seeks in the upcoming research to model, and thus help point out how to manage in a network characterised by this complexity of rush order handling found in the real business world. The upcoming paper will then discuss information system development; alternative IT-enabled designs of exchange processes supporting the revealed complexities and time constraints of rush orders. Future research involves developing a conceptual model following soft systems methodology applied in an organizational context seeking continuous improvement of rush order handling.

Summary

This study examines the extent to which technical capabilities and the locus of initiative in product development collaborations influence knowledge integration activities with customers. Based on a survey of 216 Swedish manufacturing firms, we find empirical support for the importance of the locus of initiative, technical capabilities of firms as well as their customers to enhance knowledge integration. In addition, firms with high technical capability that work with customers that have a similarly high technical capability tend to collaborate based on a higher degree of knowledge integration activities than when the firm's technical capability of customer is low.

Keywords: Knowledge Integration, Customer Collaboration, Product Development, Technical Capability, Locus of Initiative

Introduction

Studies in the field of innovation have identified customers as one of the key collaboration partners of manufacturing firms (Un, Cuervo-Cazurra and Asakawa, 2010; Laursen and Salter, 2006; Homburg and Kuehnl., 2014). Firms that collaborate with their customers during product development are better able to interpret market trends, understand customer demands, develop customized products, and reduce risks related to design that lead to poor functionality (e.g., Blazevic and Lievens, 2008; von Hippel, 1986; Lin, Chen and Kuan-Shun Chiu, 2010; Lau, 2011). Thus, firms increasingly collaborate with their customers when carrying out product development activities to capture customers' knowledge about possible future products.

In fact, in collaborative relationship with customer, manufacturing firms do not only contribute with their knowledge, but they also use the advantage from a systematic knowledge exchange with customers (Mahr, Lievens, and Blazevic., 2014; Cui and Wu, 2016; Eslami and Lakemond, 2016). The majority of the studies in this field of supply chain management and purchasing are performed from a customer's perspective, while studies conducted from the manufacturing firm's perspective are less common with some exceptions (Aarikka-Stenroos and Jaakkola, 2012; Laage-Hellman., Lind and

Perna, 2014). Hence, it is necessary to understand the conditions when firms face integrating customer knowledge into their product development process.

Nevertheless, many firms find it challenging to understand how to reap the maximum benefit from knowledge integration with customers. In fact, the growing importance of this systematic knowledge exchange between firms and customers require an understanding of the conditions and factors under which firms integrate the knowledge of their customers in their new product development process. For instance, a wide range of factors can affect customer collaboration in product development, such as a lack of partner commitment (e.g., Krause, Handfield and Tyler, 2007), a lack of internal integration (e.g., Mishra and Shah, 2009), and the customer's low level of technical capability (e.g., Wagner and Hoegl, 2006; Wagner, 2010; Wynstra, Von Corswant and Wetzels, 2010). Moreover, firms wishing to integrate knowledge with customers must have the requisite technical capabilities that allow sharing and combining this knowledge in product development activities (cf. Grant and Baden-Fuller, 2004; Eslami and Lakemond, 2016). In addition, the success of collaborative development is contingent on the customer's ability to contribute to knowledge integration (cf. Peled and Dvir, 2012), while the commitment of customers seems to play a role. When customers are reluctant to commit to a relationship, they are unlikely to be willing to invest resources in collaborative product development (Krause, Handfield and Tyler, 2007).

Despite growing attention paid to the need to integrate customer knowledge, empirical evidence of the role of technical capability and customer initiative in knowledge integration activities in product development is scarce. Indeed, a detailed analysis of the relationships among a manufacturing firm's capabilities, its customers' capabilities, customer initiative, and knowledge integration activities is lacking. Based on this gap in the body of knowledge on this topic, this study investigates the extent to which the above-mentioned factors affect knowledge integration activities with customers. By deriving data from a cross-sectional survey of 216 Swedish manufacturing firms, we elucidate how technical capability and the locus of initiative influence knowledge integration and how matching degrees of capabilities influence the use of knowledge integration activities.

The remainder of this paper is organized as follows. Section 2 presents the theoretical framework of this study, taking the knowledge-based view (KBV) of the firm as a starting point. This is followed by the development of the hypotheses, before presenting the study methodology and data collection procedures in Section 3. Finally, after discussing the study findings in Section 4, the work concludes with suggestions for future research in this field in Section 5.

Theoretical framework and hypothesis development

Knowledge integration with customers in collaborative product development

In the context of this study, and building on a knowledge-based perspective, collaborative product development with customers relates to the joint acquisition of knowledge and skills by firms and their key customers with the aim of developing a new product (Rindfleisch and Moorman, 2001; Wagner and Hoegl, 2006; Homburg and Kuehnl, 2014). The outcome of this collaboration is value creation, which is maximized by using distributed knowledge (Emden, Calantone and Droge, 2006). As a consequence, and in line with the growing awareness that firms must rely on external knowledge (e.g., Chesbrough, 2003; Grant and Baden-Fuller, 2004), knowledge integration is crucial to capturing the benefits of customer collaboration.

This study adopted the theoretical lens of the knowledge-based view (KBV) of the firm, which recognizes knowledge as a critical source of firm value (Grant, 1996). This lens suggests that firms must be considered to be social communities in which knowledge is combined and synthesized into economically valuable products (Kogut and Zander, 1992). According to the KBV, it is more efficient to integrate the internal knowledge of individuals into an organization than to attain external knowledge and combine it with internal knowledge (Kogut and Zander, 1992). However, there is growing awareness that not all relevant knowledge resides within the boundaries of a firm and that firms may need to rely on external knowledge (e.g., Chesbrough, 2003, Grant and Baden-Fuller, 2004). Therefore, firms are required to collaborate with external partners such as customers, as their input helps apply internal knowledge more effectively (e.g., Lukas and Ferrell, 2000). Firms that implement this approach can not only increase their knowledge but also create new avenues for other business opportunities (Cohen and Levinthal, 1990). Hence, the KBV has been extended to inter-firm collaborations (e.g., Grant and Baden-Fuller, 1994; Dyer and Singh, 1998), arguing that firms can achieve competitive advantage through external knowledge integration. Based on this perspective, an understanding of collaborative product development requires an understanding of the knowledge integration activities that firms carry out together with customers, including the prerequisites for these activities to take place.

Previous studies have demonstrated that customers are one of the main sources of knowledge when it comes to product characteristics and customer needs (Nambisan, 2002; Blazevic and Lievens, 2008). Integrating customer knowledge can therefore help firms better address the challenges of product development. In particular, firms that collaborate with their customers are better able to understand the design challenges, which in turn results in products that better serve the expectations of current and future markets (Veryzer and Borja de Mozota, 2005).

Collaboration with customers in product development necessitates that firms share and combine internal and external knowledge in order to create new knowledge (cf. Tasi, 2001). Such knowledge integration is an interactive process, where specialized

knowledge residing in manufacturing firms and customers is shared and combined into new knowledge (cf. Okhuysen and Eisenhardt, 2002; Tiwana and Mclean, 2005). This process of knowledge integration can be challenging, however. For instance, an incongruence or lack of common knowledge between firms and their customers might exist. To mitigate this problem, technical capability allows firms to achieve better knowledge integration (LaBahn and Krapfel, 2000).

Hypothesis development

Firm technical capability

Technologically competent firms gain an advantage when collaborating with customers in product development (Schiele, 2006; Wagner, 2010). Collaboration with customers is especially appropriate when a close link between a firm's technical capabilities, which comprise a combination of knowledge and skills (Teece, 1998), and a customer's needs exists. Technical capabilities represent the type of knowledge that may allow a firm to create value, which is embodied by an individual's knowledge and skills and embedded in technical systems (Johnsen and Ford, 2006). In this work, firms' technical capabilities refer to knowledge-based engineering proficiency with new technologies that can be used to react to emerging technologies during collaborative product development (LaBahn and Krapfel, 2000).

A firm's technical capability influences its ability to absorb the technical knowledge of its customers (Lin and Huang, 2013; Eslami and Lakemond, 2016). When a firm's technical capability is insufficient, it will have difficulties realizing a technology's potential, discovering the complementarities of internal and external knowledge, and integrating this complementary knowledge during collaborative activities. Indeed, firms that have a high degree of capability are best able to pursue knowledge integration with customers. Consequently, we formulate the following hypothesis:

H1. A firm's technical capability has a positive effect on knowledge integration between firms and customers in collaborative product development.

Customer technical capability

Customer technical capability refers to the degree to which the customer understands the product that needs to be developed. For example, a customer that can validate the product's architectural choices and formulate design requests is deemed capable to positively contribute to the collaborative effort (cf. Peled and Dvir, 2012). Customers with a high degree of technical capability can help design new product and production processes, which may prevent potential failures because of poor design and product functionality. Therefore, the technical knowledge of customers facilitates knowledge integration in product development.

There is a positive link between a customer's knowledge and the value of its contribution to a firm's activities (Athaide and Klink, 2009; Smals and Smits, 2012).

Athaide and Klink (2009) reported that the contribution of customers with high technical capability helps firms adapt customer needs and mitigate environmental uncertainty. Likewise, Smals and Smits (2012) stated that collaboration with capable customers increases the likelihood of creating value. In fact, some level of technical capability is required for the customer to contribute and integrate knowledge with the firm (cf. Brusoni, Prencipe and Pavitt, 2001). Consequently, we formulate the following hypothesis:

H2. A customer's technical capability has a positive effect on knowledge integration between firms and customers in collaborative product development.

Congruence of firm and customer technical capabilities

Although both firms and customers technical capabilities are important factors in collaborative activities, these have, to our knowledge, not thus far been addressed simultaneously. The combined effect of a high degree of firms and customers technical capability is expected to bolster the possibilities of conducting knowledge integration activities. Consequently, we formulate the following hypothesis:

H3. Simultaneously high degrees of firms and customers technical capabilities are associated with higher levels of knowledge integration activities than when one or both have a low degree of technical capability.

Role of the locus of initiative

Collaborating intensively with customers to enhance innovation outcomes during product development requires commitment from both parties (Gadde and Snehota, 2000). According to Muthusamy, Hur, and Palanisamy (2008), commitment based on personnel and technology can improve knowledge integration between firms and customers and thus allow them to create new knowledge. Research has shown that customers are more willing to collaborate with manufacturing firms that are more proficient in collaborating with customers in product development (e.g., Walter, 2003). Firms can become proficient in collaborating with customers by understanding their business environments and profit opportunities. In many cases, this is reciprocated by the customer's willingness to contribute to the product development process. When firms and customers commit their resources and the relationship is driven by a learning intent, the outcome is more integrative (Lagrosen, 2005; Huang and Newell, 2003). Consequently, a customer's commitment of resources and willingness to contribute can increase the degree of knowledge integration.

According to Eslami and Lakemond (2016), commitment and willingness to collaborate are related to the locus of initiative. Customers that actively take the initiative for the project tend to adopt a more active role and are more willing to integrate their knowledge. A similar finding was reported by Brockhoff (2003), who argued that if the customer takes the initiative, firms can expect to receive feedback and suggestions on product characteristics. In this situation, the goal of knowledge integration with

customers shifts from obtaining expectations and technical requirements to product feasibility and evaluating the optimization of the physical product (Lin and Huang, 2013). Hence, based on the limited available evidence, we propose the following hypothesis:

H4. The locus of initiative residing on the customer side has a positive effect on knowledge integration between firms and customers in collaborative product development.

Research Design

Data collection

The data were gathered through a cross-sectional survey of firms operating in the Swedish manufacturing industry. The population included all Swedish manufacturing firms (codes 10–32 NACE Rev. 2) having more than 50 employees. Data collection was based on a randomized representative sample of 1730 manufacturing firms. 700 manufacturing firms have randomly drawn from the target population. The data were collected via questionnaires distributed by emails to the respondents of randomized 700 manufacturing firms. Respondents were mainly R&D managers and other employees involved in collaboration with customers related to product development activities. The overall time to respond the survey was about 20 to 30 minutes. At the beginning of the process of data collection, each potential respondent was contacted by phone and we have informed about the aim and content of the study. In case that the respondent could not contribute in the survey (e.g., due to heavy workload or low interest), we were asked to suggest another possible person who could provide insights of value for the research study.

To increase the response rate, the initial invitation was followed up by three reminders, resulting in 216 valid questionnaires. The survey questionnaire was evaluated before the main study in a pilot test in which knowledgeable academic/practitioner colleagues and targeted respondents from selected firms took part. Their feedback helped refine the data collection instrument. The questionnaire was administrated through an online survey instrument. The links to the survey were sent by email to all identified individuals. The unit of analysis was the relation between manufacturing firms and their key customers in collaborative product development.

Measurement

The questionnaire items pertaining to both the independent and the independent variables were based on responses on a five-point Likert-type scale, ranging from 1 (strongly disagree) to 5 (strongly agree). The dependent variable, knowledge integration, was operationalized by three questionnaire items aiming to elucidate the extent to which employees and their customers jointly discuss errors and failures and talk about new programs and activities in order to develop new products and concepts (Akgün et al., 2007).

Firms and customer technical capabilities as well as the locus of initiative on the customer side served as the independent variables. We have measured both firms and customer technical capabilities using five items: engineer's proficiency with the latest technology, engineer's skills at creating technological innovation, capability of incorporating external technology into a new product, offering engineering support, and responding quickly to technological changes (LaBahn and Krapfel, 2000). In fact we have asked representatives on their firms technical capability and their perception of their customers. The third independent variable, the locus of initiative on the customer side, was assessed by two items: (1) customers present ideas and suggestions for new product function and (2) customers present ideas and suggestions for new materials used to create products (Freng Svendsen et al., 2011). Table 1 reports the descriptive statistics of the items of the main constructs.

Table 1. Descriptive statistics for the main constructs

Items	Number	Mean	Standard deviation	Median
Firm Technical Capability (FTC)				
Proficient with the latest technology	216	3.157	.842	3.0
Skilled at creating technological innovations	216	3.491	.846	4.0
Incorporate external technology into a new product	216	3.094	.979	3.0
Offer high degree of engineer support to customers	216	3.708	.999	4.0
Respond quickly to technological changes	216	3.474	1.001	3.0
External Technical Capability (CTC)				
Proficient with the latest technology	216	2.966	.9067	3.0
Skilled at creating technological innovations	216	2.938	.9052	3.0
Incorporate external technology into a new product	216	2.928	.8838	3.0
Offer high degree of engineer support to customers	216	2.976	.9273	3.0
Respond quickly to technological changes	216	2.818	.8687	3.0
Knowledge Integration (KI)	216			3.0
Discuss and analyze errors and failures with customers	216	3.625	1.057	4.0
Discuss new ideas and activities with customers	216	3.130	1.092	3.0
Develop new product development concepts together with customers	216	2.762	1.114	3.0
Locus of initiative on the customer side (LIC)				
Customers present ideas for new product features	216	3.349	1.067	3.0
Customers present ideas and suggestions for new materials and product production	216	2.374	1.069	2.0

Technological uncertainty and product uncertainty were used as control variables, which capture the external and internal contexts of customer involvement. To define technological uncertainty, respondents were asked to rate the level of technological innovation, product complexity, pace of technological changes, and opportunities for technological changes in their industry (Song and Montoya-Weiss, 2001). Product uncertainty was measured by asking respondents to rate the product complexity, degree of product development, maturity of technology processes, pace of technology changes, and degree of the engineering content of products (Koufteros, Vonderembse and Jayaram, 2005).

As the distribution between industries is skewed, and sometimes few firms only represented some industries, we split the firms into four clusters. Therefore, We included industry as a control variable, with low tech industry as the baseline. Based on NACE Rev. 2, participating firms were grouped into low tech, medium-low tech, medium-high tech, and high tech firms, following the approach applied by Eurostat and Statistics Sweden (SCB, 2014), which uses technological intensity as a selection parameter. 65 firms related to codes 10–19 and 31–32 were categorized as low tech (e.g., furniture, food). 56 firms related to codes 19 and 22–25 medium-low tech (e.g., petroleum, plastics) were identified. 80 firms related to codes 20 and 27–30 were categorized as medium-high tech (automotive and electric products). And 15 firms related to codes 21 and 26 are identified as high tech (e.g., pharmaceutical, electronics,

computer, and optical products). Finally, firm size and turnover (in natural logarithms) were obtained from a national database and applied as additional control variables. Table 2 shows the factors and factor loadings, while Table 3 presents the descriptive statistics of the variables and their correlations.

Table 2: Factors and factor loadings

Data analysis

The descriptive statistics in Table 3 show that firms seem to evaluate their own technical capabilities as marginally higher than those of their customers. Furthermore, firms discuss and analyze failures with customers more often than they discuss new ideas, carry our activities, or develop product concepts together. Related to the locus of initiative on the customer side, customers present new ideas for product features more commonly than offer suggestions for new materials or advice related to production.

To test the presented hypotheses, we performed a regression analysis on the complete dataset (see Table 4). Since our dependent variable is continuous, we employed ordinary least squares estimations. Model 1 contained the control variables only, while Models 2 and 3 included the effects of firm and customer technical capabilities, respectively. The regression in Model 4 included the effect of the locus of initiative on the customer side on the outcome of knowledge integration with customers. This approach helped compare the models and allowed us to predict the outcome variable (Field, 2013).

To analyze the importance of the congruency between manufacturing firms' technical capability and customers' technical capability, we performed a two-step cluster analysis, resulting in three clusters (see Table 4). Cluster 1 includes firms that rate their customers' technical capability as well as their own technical capability above the mean. We label this cluster as high/high. Cluster 2 contains firms that evaluate their external technical capability as marginally higher than the mean of all firms, but their own as lower than the mean of all firms (high/low). Cluster 3 represents firms that evaluate their customers' technical capability as well as their technical capability as low (low/low).

Table 4: Clusters for the categories of technical capability

	Mean customer technical capability	Mean firm technical capability	Label
Cluster 1	0.61	0.91	High/high
Cluster 2	0.21	-0.51	High/low
Cluster 3	-1.41	-0.64	Low/low

As our research design includes self-reported data obtained by using one instrument, there is a risk that the results are affected by common method variance. To investigate if this was a potential problem, we performed a single-factor test by using exploratory factor analysis, including all the variables. This strategy resulted in seven factors, each of which had an eigenvalue greater than 1. Moreover, the factor with the greatest loading did not account for a significant percentage of variance (14%), indicating that common method variance is not an issue in this study (Podsakoff et al., 2003). In addition, to estimate the extent of multicollinearity in our data, we evaluated the variance inflation factors, which were well below the threshold value of 10 (Belsley, Kuh and Welsch, 1980). Therefore, it seems that multicollinearity was not an issue in

our study.

Results

The regression analysis results presented in Table 5 show that the analysis supports Hypotheses 1, 2, and 4. More specifically, Model 4 shows that firm technical capability, customer technical capability, and the locus of initiative on the customer side all have a significant effect on knowledge integration ($p>0.001$). Furthermore, when comparing the different models, the explanatory value increases, indicating that the three independent variables have a complementary effect on knowledge integration activities. With respect to the effect of the control variables, the findings show that firm size, turnover, and technological uncertainty have no significant impact, whereas product uncertainty has a negative but non-significant effect on knowledge integration with customers.

To investigate the extent to which the congruency between firm's and customer's technical capabilities affects knowledge integration (Hypothesis 3), we performed a one-way ANOVA. In particular, we examined whether there was a statistically significant difference among the three clusters of firms in relation to knowledge integration with customers. The results of the one-way ANOVA test (Table 6) revealed that all three clusters were significantly different from each other ($F(2, 213) = 41.844$, $p>0.001$; post-hoc Scheffe test). Firms that have a high degree of technical capability and collaborate with customers that also have high degree of technical capability have a significantly higher degree of knowledge integration with customers (mean=0.597) than firms in Cluster 2 (mean=-0.137) and Cluster 3 (mean=-0.775). Hence, the congruence of high technical capabilities for both the manufacturing firms and customers results in a higher degree of knowledge integration, supporting Hypothesis 3. In addition, Cluster 2 firms report a significantly higher degree of knowledge integration than when both the firm and the customer have a low degree of technical capabilities (Cluster 3).

Table 6: Descriptive statistics of knowledge integration by cluster

Dependent variable: Knowledge Integration	N	Mean	Std. Dev.	Std. Error	Lower Bound	Upper Bound	Minimum	Maximum
Cluster 1	83	.597	.820	(.090)	.417	.776	-1.30	2.061
Cluster 2	84	-.137	.846	(.092)	-.321	.046	-2.07	2.061
Cluster 3	49	-.775	.908	(.129)	-1.03	-.514	-2.42	.950
Total	216	.000	1.000	(.068)	-.134	.134	-2.42	2.061

Discussion and conclusion

This study aimed to understand the effect of situational factors on knowledge integration with customers in product development projects. Few studies have thus far provided a theoretical foundation for examining the extent to which different factors influence knowledge integration with customers. In addition, existing research tends to adopt a procedural approach to the integration of external knowledge, primarily investigating the mechanisms used to integrate external knowledge (Schmickl and Kieser, 2008; Zirpoli and Camuffo, 2009). Complementing such approaches, our research contributes to the existing knowledge in the field by examining those factors that can enhance organizational procedures and improve the resulting knowledge from the KBV perspective.

To extend previous insights into customer collaboration in innovation activities, we hypothesized that various situational factors play an essential role in knowledge integration. We surveyed the representatives of 216 Swedish manufacturing firms to elucidate the manner in which two specific factors—technical capability and the locus of initiative—influence the contribution of customer knowledge. The empirical results offered support for all four hypotheses.

These findings suggest that technical capability, as embodied by employee knowledge and skills, is a key factor for reacting to emerging technologies (Johnsen and Ford, 2006). However, the technical capability of firms alone is insufficient for facilitating knowledge integration. A

customer's technical capability must also be exploited to improve new product design and production processes (Eslami and Lakemond, 2016). Therefore, we conclude that knowledge integration with customers requires a combination of firms and customers technical capabilities to overcome issues such as design and technical errors throughout the product development process.

In addition, the success of collaborative product development is affected by other factors that contribute to knowledge integration (see also Ritter and Walter, 2003), confirming that initiatives behind customer collaboration can play an important role in the success of knowledge integration. We found that the locus of initiative on the customer side has a strong positive effect on knowledge integration with customers, consistent with the findings reported by Eslami and Lakemond (2016), who suggested that if customers take the initiative, they play an active role and are willing to contribute knowledge in product development projects. Similarly, Brockhoff (2003) suggested that when a customer takes the initiative, collaboration is unsolicited. In this type of collaboration, customers are therefore more willing to provide their inputs about product characteristics, which could be valuable source of information for developers.

In sum, the present study sheds new light on the effect of contingencies on the outcome of knowledge integration. In particular, our findings reveal that while both firms' and customers' technical capabilities are prerequisites for managing customer knowledge in product development, initiative can also be instrumental in increasing the motivation and willingness of both parties to collaborate. Our study also has important implications for managers in charge of customer collaboration. Firms must understand the types of situations in which they can extract the most benefits from knowledge integration with customers. For instance, the most likely situation in which firms integrate knowledge is when they collaborate with technically capable customers and when the initiative of the project is on the customer's side. Further, recognizing these different situations could be more valuable for large firms willing to collaborate with innovative customers to increase their innovation capabilities, as it would allow them to understand in which situations they can integrate knowledge with potential customers.

This study has several limitations. First, it did not include the outcome of the effect of contingency factors on knowledge integration such as degree of innovation (incremental, radical). Future study could thus examine if contingency factors, besides affecting knowledge integration, might also influence firm performance as well as investigate how a series of mechanisms under the influence of different contingency factors could improve product quality and reduce time to market and innovation risk. Second, this study focused on collaborative product development with customers, thereby overlooking relationships with other actors such as business partners and suppliers. Third, the degree of innovation deserves further investigation. Finally, it would be helpful to study the process of knowledge integration not just in relation to product development, but also in other contexts such as service and solution innovation.

Appendix – Survey questions and items

Approximately how many employees does our company have (answer in integer equivalence)?

- 0-250
- 251-500
- 500-1000
- More than 1000

Approximately how large was the turnover of your company the last fiscal year? (in thousands of kroners)

Which of the following best describes your job title?

How long have you been work in the current company?

Does your company have a formal organisation for research and development R&D? (yes/no)
(if yes) – How many employees work in the R&D department?

Knowledge integration

Please indicate the extent to which you agree with the following on customer interaction in new product development	1 (not at all)-5 (to a great extent)
- Errors and failures are discussed and analyzed with key customers, on all levels - Our employees have the chance to talk with the customers' employees about new ideas, programs and activities that might be of use to the firm - Our employees and customer's employees develop new product development concepts together	

Locus of initiative at customer

Please indicate the degree to which your key customers contribute to the following:	1 (not at all)-5 (to a great extent)
- Key customers present ideas/ suggestions for new product features - Key customer present ideas about new materials, which can be used to produce the product.	

Firm's technical capability

Please indicate your agreement with each of the following statements with respect to your firm's technical capability	1 (not at all)-5 (to a great extent)
- Compared to our competitors, our engineers are proficient with the latest technology - Compared to our competitors, our engineers are skilled at creating technological innovations. - Compared to our competitors, we do incorporate the external technology in our new products. - Compared to our competitors, we do offer a high degree of engineering support to our customers. - Compared to our competitors, we are able to respond quickly to technological changes.	

Customer technical capability

Please indicate your agreement with each of the following statements with respect to your key customer's technical capability	1 (not at all)-5 (to a great extent)
- Compare to their competitors, our key customers are proficient with the latest technology - Compare to their competitors, our key customers are skilled at creating technological innovations - Compare to their competitors, our key customers do contribute with the latest technology in our new products - Compare to their competitors, our key customers do offer a high degree of engineering support to our customers - Compare to their competitors, our ley customers are able to respond quickly to technological changes	

Product uncertainty

Please indicate the extent to which you agree with the following on customer interaction in new product development	1 (not at all)-5 (to a great extent)
- We produce complex products rather than simple products - Our new products have a high degree of innovation - Product development has a high degree of engineering content - Our products are based on technologies that changing fast	

Technological uncertainty

Please indicate your agreement with each of the following statements with respect to technological uncertainty in your industry?	1 (not at all)-5 (to a great extent)
- There is a high level of technological innovation in our industry. - More complex products are provided in our industry. - The technology in our industry is changing rapidly. - Technological changes provide big opportunities in our industry.	

Corporate Responses to the UK Modern Slavery Act

Anthony Flynn and Helen Walker

Telephone: +44 (0)2920 874674. Fax: +44 (0)2920 874419

Abstract

The UK Modern Slavery Act 2015 imposes a legal requirement on large firms to publish an annual statement that describes their policies and practices for combating modern slavery. Our research explores how firms are responding to this institutional pressure. We first describe the Act and then explain why institutional theory serves an appropriate theoretical lens for examining firms' responses to it. Next we set out our research methodology, which involves systematic content analysis of anti-slavery statements published by FTSE 350 firms. Provisional results show that there is a high level of compliance with the minimum requirements of the Act.

Keywords: Social; modern slavery; sustainable; operations; supply chain

Introduction

Organisations are under increasing pressure internationally to demonstrate that they are socially responsible in their operations and supply chain management (SCM). This pressure can come from government policy and legislation, but other stakeholders such as shareholders, customers and the media can also influence organisations to act. This increasing attention to socially responsible corporate activity is reflected by a surge in socially sustainable SCM research which has tended to lag behind environmental SCM research (Ashby, Leat and Hudson-Smith, 2012; Miemczyk, Johnsen and Macquet, 2012). Some researchers have sought to investigate how organisations are reporting on their corporate social responsibility and sustainable SCM activities (Lozano and Huisingh, 2011; Tate, Ellram and Kirchoff, 2010; Turker and Altuntas, 2014). In this study we adopt a similar approach by scrutinizing organizational responses to the UK Modern Slavery Act as published on their websites. We investigate organisational responses from an institutional theory perspective (DiMaggio and Powell, 1983). We first introduce the UK Modern Slavery Act below.

The UK Modern Slavery Act 2015

The Modern Slavery Act, which passed into UK law in 2015, represents among the most far-reaching pieces of national legislation yet enacted in the international fight against slavery, servitude, forced labour and human trafficking. It consolidates existing slavery offences into a single Act, strengthens the power of UK law enforcement agencies to investigate and prosecute reported instances of modern slavery, increases the length of sentences for slavery-related crimes and enhances protections for its victims (HM Government, 2015). Since its adoption a number of high profile cases have been successfully prosecuted (Churchill, 2017), which attests to the effectiveness of the Act and the determination of law enforcement agencies to use it in the fight against organised crime.

Modern slavery is a term used to capture two offence categories under the Act (HM Government, 2015, p.18-19). The first offence category is slavery, servitude and forced or compulsory labour. Slavery is "the status or condition of a person over whom all or any of the powers attaching to the right of ownership are exercised". Servitude is "the obligation to provide services that is imposed by the use of coercion". Forced or compulsory labour is "work that is enacted from any person under the menace of any penalty and for which the person has not offered him/her self voluntarily". The second offence category, human trafficking, refers to

"arranging or facilitating the travel of another person with a view to that person being exploited".

As well as establishing new slavery-related offences and issuing sentencing guidelines, the Act addresses slavery in a corporate context. In particular, Section 54 of the Act imposes a legal obligation on all firms with a "demonstrable business presence" in the UK and with turnover in excess of £36 million to report annually on the steps they are taking to prevent against modern slavery in their operations and supply chains (HM Government, 2015). Firms do not have to be domiciled in the UK to come under the remit of the Act. That they are carrying on a business or part of a business in the UK is sufficient. In this way, the Act has extra-territorial reach. The revenue threshold of £36 million means, in effect, that only large firms are legally obliged to prepare and publish a Modern Slavery statement. Less than one per cent of firms operating in the UK are classed as large in size (Office for National Statistics, 2014).

The purpose of Section 54 of the Act is unmistakeably about forcing corporations to be more transparent over their approach to addressing modern slavery. While the Act does not require firms to guarantee that their supply chains are slavery free, it does require them to annually report on the actions they are taking to safeguard against modern slavery. There is both an internal (operations) and external (supply chain) aspect to firms' obligations under the Act. Stakeholders, be they shareholders, employees, investors, regulators, legislators, suppliers, unions, customers, communities or non-governmental organisations (NGOs), get to see what, if anything, the firm is doing to de-risk its operations and supply chains from the effects of modern slavery. Such visibility is intended to create a "race to the top" in supply chain standards (HM Government, 2014, p. 5), as firms seek to satisfy stakeholder expectations and match competitors' actions.

The Act imposes a number of specific reporting obligations on firms. The first of these is to produce a modern slavery statement for each financial year of the organisation. The statement must describe the actions the firm has taken or is in the process of taking to tackle modern slavery. While there is no precise reporting format for Modern Slavery statements, firms are recommended to include information about a number of fields (see Table 1).

Table 1 Main Reporting Fields for Anti-Slavery Statements

Field	Indicative information
Business operations and supply chains	Nature of the firm's business operations and details on its supply chain
Policies	Corporate policies/codes/charters/standards relevant to modern slavery
Risk assessment	Actions that firm undertakes to risk assess its operations and supply chains for modern slavery
Due diligence	Actions that firms undertakes to screen potential suppliers, employees and customers in relation to modern slavery
Risk management	Practices designed to manage the risk of modern slavery in the firm's operations and supply chains
Key Performance Indicators (KPIs)	Metrics relevant to the firm's effectiveness in combating modern slavery
Training	Programmes to inform and train staff and/or business partners on modern slavery issues

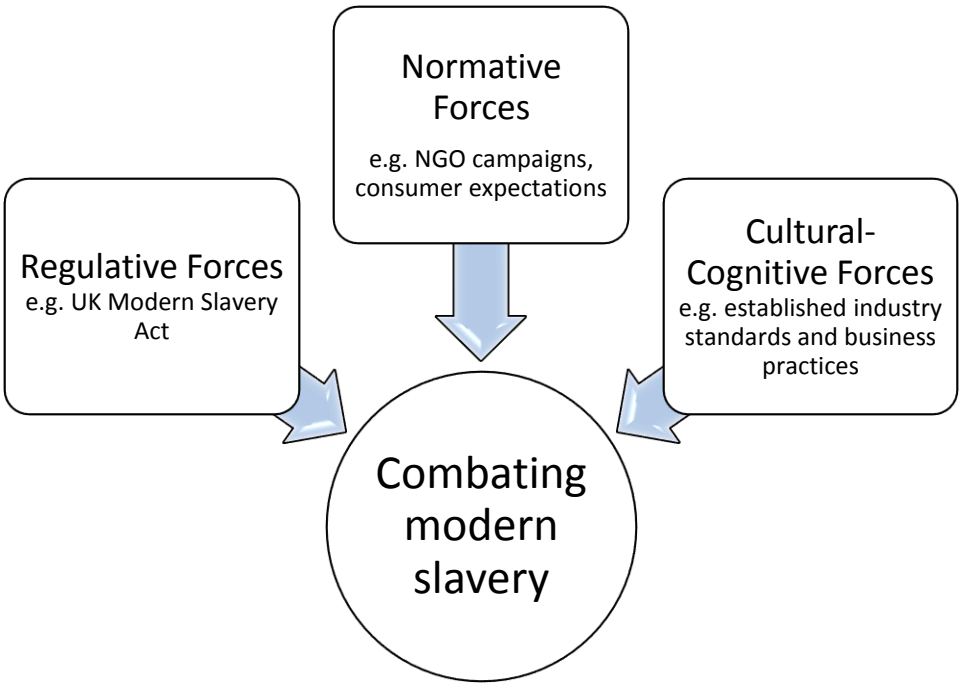
These fields include: business background, policies, risk assessment, due diligence, risk management, key performance indicators (KPIs) and training for staff and/or business partners.

The finalised statement must be formally approved by the board of directors and authorised by a company director or equivalent. Firms are then obliged to publish a link to their statement on the homepage of their website (ibid). This last step is designed to ensure ease of access to the statement, thereby increasing transparency of firms' operations and supply chain practices.

An Institutional Theory Perspective

The Modern Slavery Act represents an institutional pressure bearing on firms. It emanates from the institutional (political) environment, and so constitutes an institutional pressure on the firm as opposed to a competitive or marketplace pressure (Meyer and Rowan, 1977; Scott, 1987). The requirement to publish an annual modern slavery report is imposed on firms from the single most powerful institutional actor in any environment – government. Firms are not publishing modern slavery statements of their own volition. Rather, they are doing so in direct response to a government regulation. They are, as DiMaggio and Powell (1983) describe it, being legally coerced into adopting a new reporting practice. As with many so many aspects of organisational structure and behaviour, it is institutional forces that are determining how firms manage concerns over modern slavery in their operations and supply chains.

Fig. 1 Institutional Pressures for Combating Modern Slavery



Importantly, the Modern Slavery Act is not the only institutional pressure that firms face in relation to ethics and human rights in supply chain management (see Fig.1); nor is it the first. For some time large corporations have been under pressure from NGOs, international bodies such as the UN and wider society to improve standards of employment throughout their supply chains, support fair trade in their country of operations and work to protect the natural environment (Preuss and Brown, 2012; Svensson, 2009). This amounts to a normative institutional pressure on the firm; that is, a pressure that is morally sanctioned rather than legally governed (DiMaggio and Powell, 1983; Scott, 1987). At the same time ideas around corporate social responsibility, stakeholder management and sustainability have entered into mainstream management thinking and education (Ferrell et al., 2013). This equates to a cultural-cognitive pressure on firms as such ideas and beliefs become taken-for-granted across industries (DiMaggio and Powell, 1983).

From an institutional perspective, firms are expected to comply with the requirements of the Modern Slavery Act in order to safeguard their social legitimacy. Not complying with prevailing institutional standards undermines social legitimacy, with potential consequences for the firm in terms of reputational damage, customer dissatisfaction, investor concerns, difficulties in accessing resources and problems securing regulatory approval (Dowling and Pfeffer, 1975). Interestingly, the UK government is alive to this dynamic. In its guidance for firms on how to comply with the Act, it reminds them that modern slavery provisions not only protect workers but also encourage firms to develop a reputation for integrity and social responsibility among their internal and external stakeholders (HM Government, p.4). Conversely, failure to demonstrate compliance "may damage the reputation of the business" (HM Government, p.6).

The power of institutional pressures to determine organisational structure and practices notwithstanding, compliance is not always a given. Depending on the institutional pressure, organisations can exercise a degree of agency and seek to insulate their core operations from external demands (Oliver, 1991). In some cases organisations may seek to avoid or even openly defy prevailing institutional expectations (Oliver, 1991). In other cases organisations may give the appearance of compliance without substantively changing their practices in response to institutional pressures. Meyer and Rowan (1977) labelled this phenomena "ceremonial conformity", by which they meant that institutional conformity can be distinctly ceremonial or symbolic in form. The possibility that firms will engage in a form of ceremonial conformity with the Modern Slavery Act and its reporting requirements cannot be discounted. For whatever reason, they may be unable or unwilling to give full effect to its obligations.

Sustainable SCM studies adopting institutional theory

A number of different studies have adopted an institutional theory perspective to investigate CSR and sustainable SCM (Touboulic and Walker, 2015). Some conceptual papers have adopted institutional theory (as well as others) as the basis for developing sustainable SCM frameworks (Grob and Benn 2014, Varsei et al. 2014, Moxham and Kauppi 2014). The following table summarizes studies adopting an institutional theory perspective to investigate sustainable procurement, purchasing, SCM and practices.

Table 2: Studies adopting an institutional theory perspective on sustainable SCM

Main finding	Countries	Authors
Government influence, institutional mechanisms and senior management commitment minimise barriers to the adoption of sustainable practices.	South Africa	(Dos Santos, Svensson, and Padin 2013)
Applied Institutional Theory to explore the role of supermarkets in the development of legitimate sustainable practices across the dairy supply chains	UK	(Glover et al. 2014)
Develop a framework which explores links between management, measurement and performance through decoupling as articulated by institutional theory	UK	(Grosvold, Hoejmose, and Roehrich 2014)
Employ agency and institutional theory arguments to explore the conditions under which first-tier suppliers will act as agents who fulfil the lead firm's sustainability requirements	Multi	(Wilhelm et al. 2016)
Institutional context affects not only the overall CSR behaviour of the company, but also its institutionalization into a specific function	Germany and Italy	(Ferri et al. 2016)

Sustainable purchasing priorities viewed from institutional perspective, amongst others	US	(Pullman and Wikoff 2017)
Explores the conditions that lead an organization to engage and prioritize sustainable procurement practices, develops model that includes institutional theory	US	(Roman 2017)
Explore the impact of institutional pressures, institutional logics and institutional complexity on sustainable SCM	UK	(Sayed, Hendry, and Bell 2017)
Institutional pressures to adopt sustainable SCM at an industrial park level	China	(Zeng et al. 2017)

It can be seen that institutional theory has proved valuable for understanding the pressures to adopt sustainable SCM. In our study we adopt it to explore an aspect of socially sustainable SCM that to date has received little attention due to the recency of the legislation, that being organisational responses to the UK Modern Slavery Act (2015).

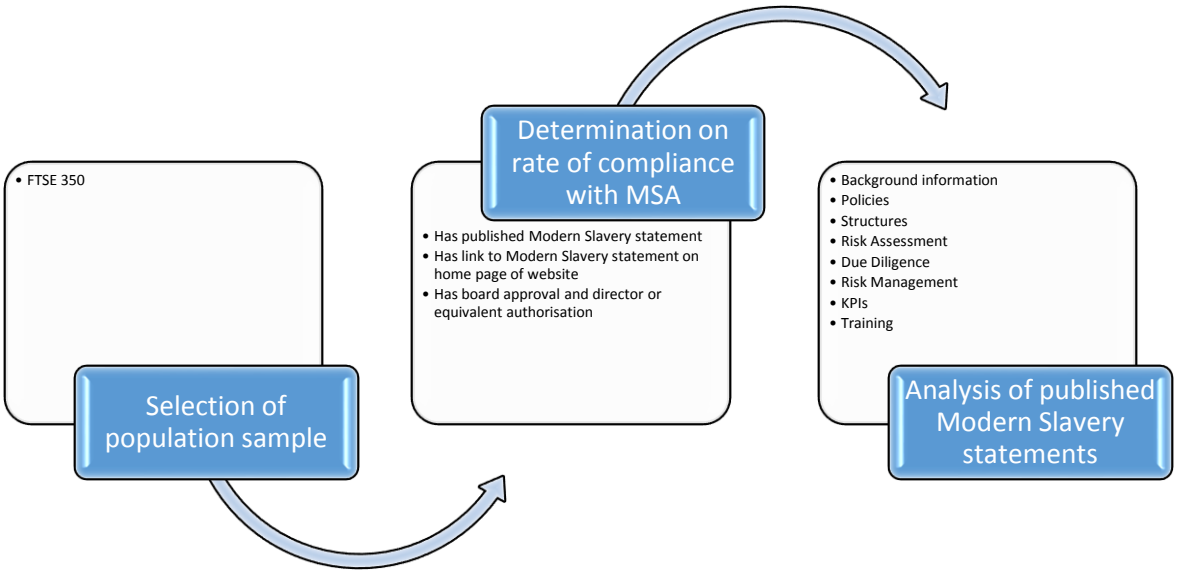
Research Design

Our interest in the Modern Slavery Act is driven by two research questions. These can be stated thus:

> *RQ1: To what extent are firms complying with their legal obligations under the Modern Slavery Act?*
>
> *RQ2: What structures, policies and practices are firms using to combat the risk of modern slavery in their operations and supply chains?*

In seeking to answer the research questions we proceeded as follows (see Fig. 2).

Fig 2. Research Process



First, we identified the FTSE 350 as the most appropriate population sample. The FTSE 350 consists of the 350 largest publicly listed firms on the London Stock Exchange. Second, we examined each firm from the FTSE 350 list against their compliance with the provisions of the Modern Slavery Act. Three sub-questions we asked as part of this process (1) has the firm published a Modern Slavery statement? (2) has the firm created a link on the homepage of their website to their Modern Slavery statement? (3) has the Modern Slavery statement received

board approval and is it signed by a director or equivalent role? Third, we performed a systematic content analysis on all available Modern Slavery statements. This constitutes the most substantial component of the research and was still ongoing at the time of writing this paper. Further information on the development and application of the coding protocol is given in the sub-section below.

Development of coding protocol

Our approach to coding Modern Slavery statements is informed by institutional theory. Institutional theory predicts that firms will adopt particular structures, policies and practices in direct response to regulative, normative and cultural-cognitive pressures. We are interested in discovering what structural features, organisational policies and practices firms have adopted as a result of institutional pressures to combat modern slavery. What does this mean in coding terms? For structural attributes, it means searching for evidence of chains of command for managing anti-slavery, anti-slavery steering committees, working groups, etc. For policies, it means searching for organisational policies/charters/codes linked to slavery and human rights. Moreover, it includes international standards and accords that influence organisational policy e.g. U.N. Declaration of Human Rights, Ethical Trading Principles, etc. For practices, it means identifying actions that firms are taking to mitigate the likelihood of slavery and trafficking in their operations and supply chains.

The coding is proceeding as follows. We started by breaking down the overarching categories of structure, policies and practices into a number of sub-categories. For instance, in relation to anti-slavery practices we sought evidence in the Modern Slavery statements of firms auditing suppliers, imposing contractual obligations on suppliers to adhere to minimum ethical standards, remediating problems in supply chains, terminating relationships with problematic suppliers, etc (see Table 3). To uphold reliability we operationalised each concept. By way of example, imposing contractual obligations on suppliers was operationalised by reference to words/phrases such as "clauses" and "terms and conditions", terminating problematic relationships was operationalised by reference to words/phrases such as "terminate" and "cease working with", etc (see Table 3).

The selection of concepts happened in an iterative fashion. We expected some concepts to feature strongly in the Modern Slavery statements based on our knowledge of industry practices and what previous academic studies have found in respect of structures, policies and practices for promoting ethics in supply chain management. During our initial screening of statements we also observed practices that were appearing with regularity but which we did not anticipate e.g. firms requesting their Tier 1 suppliers to hold Tier 2 suppliers to Modern Slavery Act standards. These unanticipated concepts were subsequently incorporated into our coding protocol. Only when we were satisfied that our protocol was comprehensive did we begin to code in earnest. Our preferred approach was to code by category. Hence, we coded structural attributes relevant to modern slavery first across all 287 statements. When this was complete we proceeded to code policies relevant to modern slavery across all 287 statements, and so on.

Table 3 Coding Protocol

Concept	**Definition**	**Operationalisation [Keywords]**
Practices		
Declaration of Compliance (Suppliers)	Requirement for suppliers and contractors to sign up to or assent to the buyer's code of conduct.	"sign up", "agree in writing", "confirm adherence", "declare compliance", "attest", "certify"

Declaration of Compliance (Employees)	Requirement for managers/employees to sign up to or assent to the company code of conduct.	"sign code", "acknowledge in writing", "commit to", "confirm implementation", "complete assurance process", "certify compliance"
Contractual Obligations	Insertion of anti-slavery clauses, provisions or terms into purchase agreements and supplier contracts.	"clauses", "terms and conditions", "contractual provisions", "framework terms", "legal undertakings", "prohibitions"
Audit	Formal inspection of the organisation's own and/or suppliers' operations through onsite visits, interviews with workers, checking employee records, policy reviews, etc.	"audit", "onsite visit", "onsite assessment", "field-based assessment"
Remediation	Requirement for the organisation and/or its suppliers to take corrective action on ethical issues.	"remediate", "corrective action", "improve conditions", "improvement actions", "work together to develop a plan", "mentoring support"
Termination	Terminate a contract because of sub-standard ethical performance on the part of a supplier, customer or employee.	"terminate contract", "cease trading", "discontinue", "delist", "exit relationships", "deselection", "dismissal", "refuse to partner"
Living Wage Accreditation	Pay workers and/or contract staff at least the UK Living Wage.	"Living Wage"
Inform Suppliers	Inform suppliers of the organisation's updated stance on modern slavery and what it expects from them.	"written to our suppliers", "communicated changes", "informed by letter"
Supplier Own Slavery Policy	Requirement that suppliers have their own anti-slavery policies and procedures in place.	"equivalent policies for slavery", "have own policy and procedures on slavery", "furnish copy of slavery statement"
Supplier Own Annual Slavery Report	Requirement that suppliers prepare an annual slavery and human trafficking report.	"annual slavery report"
Avoidance/Divestment	Not sourcing commodities from a named country/Not investing in a named country.	"Named country"
Certification/Licensing	Supplies that are certified or suppliers that are licensed according to a named industry standard.	"Named initiative"

Review Meetings	Formal meetings to periodically review a supplier's performance.	"review meetings", "meet on a regular basis"
Cascading	Expectation that suppliers implement risk management procedures for their own suppliers and subcontractors.	"cascade", "flow down", "end-to-end responsibility", "one-up", "hold own suppliers to same standards", "third parties to take responsibility for controlling their own supply chain"

Provisional Results

Provisional results indicate that compliance with the provisions of the Modern Slavery Act is high among the FTSE 350 group (see Table 3). The first stipulation of the Act is that firms must publish an annual statement describing activities to combat modern slavery in their operations and supply chains. Over 80 per cent of FTSE 350 firms have published a modern slavery statement. Breaking this down, the largest 100 firms comprising the FTSE 350, known as the FTSE 100, have all published statements bar two. The rate of compliance among the other 250 firms comprising the FTSE 350, known as the FTSE 250 is lower. In their case 76 per cent of firms have published a modern slavery statement. Further analysis revealed that the majority (63 per cent) of FTSE 350 firms that have not published statements are in the Finance and Insurance industry.

The second stipulation of the Act is that firms must create a link on their website homepage to their modern slavery statements. Of the firms with modern slavery statements (n = 287), we found that 79 per cent adhered to this part of the Act. In other words, it was possible to access the firm's modern slavery statement on their home page. For the other 21 per cent of firms, it was necessary to search the company's internal library of documents and reports to locate the statement. Doing so goes against the intention of the Act, which is to increase visibility on how firms are managing modern slavery risks. It also means that the opportunity to signal to stakeholders that the firm is committed to preventing modern slavery is being lost. Again, FTSE 100 firms exhibited higher compliance than FTSE 250 firms.

The third stipulation of the Act concerns board approval and director authorisation. Here approximately 90 per cent of firms under consideration (n = 287) have ensured that their statements have been signed off by a director or a senior manager. This is important as it signals that modern slavery is on the radar of the board of directors and senior management. Moreover, by signing off modern slavery statements directors and senior management are taking ultimate responsibility for this business risk.

Table 4 Compliance with Modern Slavery Act

Compliance Aspect	**FTSE 100**	**FTSE 250**	**FTSE 350 (Total)**	**n**
Published Modern Slavery statement	98%	78.1%	83.9%	342
Link on website home page to Modern Slavery statement	84.7%	76.2%	79.1%	287
Signed off by director or executive	92.9%	89.4%	90.6%	287

Research Contribution

This paper has empirical and theoretical contributions to make. Empirically, it aims to provide among the first evidence on how firms are responding to the Modern Slavery Act. This evidence

will complement the existing body of knowledge on ethical, sustainable supply chain management (e.g. Tate et al., 2010; Walker and Jones, 2012). Our preliminary results show that compliance with the Act has been strong to date, although the FTSE 250 cohort is currently lagging the larger FTSE 100 cohort. We are currently analysing the contents of the modern slavery statements, and will make this data available in the near future. Theoretically, our research applies institutional theory to a new context; that of legislative efforts to force large firms to report on and take responsibility for modern slavery in their operations and supply chains.

Supply market orientation as a sensing and responding capability in purchasing and supply management: A dynamic capabilities view

Abstract
We conceptualize the concept of supply market orientation (SMO), discuss how it is developed and how it differs within and across firms based on multiple case studies. By elaborating the dynamic capabilities view to the SMO phenomenon, we combine empirical evidence with theoretical reasoning in its establishment as a dynamic capability. Firms that exploit supply market intelligence to assess, integrate, and reconfigure their resources in a timely and rigorous manner are projected to be more successful than those who not. However, reactive vs. proactive SMO application is contingent upon firm-level and purchasing category-level characteristics.

Keywords: Purchasing integration, Supply market orientation, Case studies

Introduction

Rising global trade and competition, demand for increased product variety, shorter product life cycles, and rapid technological change are expected to intensify in the future (Bozarth et al., 2009; Mitchell et al., 2011). In this regard, firms that are better equipped to cope with market developments and to anticipate changing conditions are expected to reap superior profitability and competitive advantage (Day, 1994). Thus, the concept of market orientation has attracted broad attention among practitioners and scholars alike. Essentially, market orientation is reflected in the activities and behaviors associated with the firm-wide generation, dissemination and responsiveness to market intelligence pertaining to current and future customer needs (Kohli & Jaworski, 1990).The strong customer focus underlying the market orientation concept has resulted in research emphasis on downstream markets. However, increased levels of outsourcing, raw materials scarcity, political and technological turbulence, and intensified competition also require firms to approach their upstream markets strategically (Kraljic, 1983; Krause et al., 2001; Liao et al., 2010). Neglecting such markets could result in the misalignment of supply and demand, compromising operational performance and risk mitigation (Handfield, 2010). As purchased goods and services typically range between 50% and 80% of the costs of goods sold for manufacturers (Johnson et al., 2011), even incremental improvements to purchasing and supply management processes impact firms' bottom-line (Azadegan et al., 2013). Moreover, firms seek supplier capabilities in engineering, design, manufacturing, and delivery (Narasimhan & Das, 2001; Petersen et al., 2005), and count on suppliers as sources of innovation (Calantone & Stanko, 2007). As a result, some suppliers also impact a buying firms' top-line performance (Zimmermann & Foerstl, 2014). For instance suppliers of semi-conductors have become an important source of innovation in passenger cars, but these suppliers cannot be considered direct suppliers to the lager automotive OEMs. Hence, companies such as BMW have developed supplier technology scouting processes to potentially integrate these seemingly unimportant, in terms of spend volume, and distant suppliers in ongoing product innovation projects.

Only a few scholars have examined market orientation in the upstream supply context. Handfield (2010) was one of the first scholars to directly address supply markets in an explo-

ration of supply market intelligence. Further steps toward an understanding of supply market orientation have been taken by research on supply chain orientation (Fawcett et al., 2007; Ellinger et al., 2012). In spite of a range of concepts addressing the challenges of direct supplier portfolio management (Kraljic, 1983) our understanding how buying firms create transparency and intelligence about the entire upstream supply network, including distant suppliers, is limited. In particular, the active management of nexus suppliers and other key lower-tier suppliers must be enabled through supply market intelligence (Yan et al., 2015). In fact, little is known about what this concept actually constitutes, how it is developed, and how it differs across buying firms and how it differs in its application across purchasing categories. Thus, we pose the following research question: *How do buying firms develop and configure sensing and responding capabilities through supply market orientation and how do they differ within and across firms?*

To answer to the question we conducted multiple case studies with embedded multiple units of analysis (Corbin & Strauss, 1990; Yin, 2009). Thereby, we first establish the theoretical background for our exploration based on the information and knowledge management literature in purchasing and supply management. As a theoretical backbone we elaborate concepts of absorptive and desorptive capacity as well as dynamic capabilities (DCV), which all stem from the family of resource-based theories. Next, we draw from the five case studies to explicate a concept and definition of supply market orientation. Reflecting our findings against the literature we elaborate on its value capture potential based on various contextual antecedents that drive its application at the purchasing category level We conclude by stating the contributions we have made to business practice and theory, and by discussing a number of promising avenues for future research.

Theoretical background

Supply market intelligence and knowledge

Assessing the purchase situation in terms of the importance of purchasing (e.g., cost of materials to total costs, value-added profile, profitability profile) and the complexity of the supply market (e.g., supply scarcity, competitive environment, pace of technological change), firms can determine the type of supply strategy required to minimize supply vulnerabilities and to exploit their potential buying power (Kraljic, 1983). However, the purchasing portfolio approach and other related frameworks are rather static and neglect the need for continuous updating of information to ensure fitting strategic choice over time as the supply environment evolves. Recently, for instance, Akhavan and Beckmann (2017) found that proactive, opportunity-oriented strategies, where suppliers and their capabilities are developed, are able to respond more effectively to the changing requirements than traditional reactive strategies. In order not only to react to upcoming information, but to proactively update information and be ahead of competition, firm-level capabilities in developing supply market intelligence and knowledge are needed. Supply market intelligence can be defined as "a process for creating competitive advantage and reducing risks through increased knowledge of supply market dynamics and supply base composition" (Handfield, 2010, p. 43-44).

Traditionally, research focusing on knowledge and knowledge-based capabilities lays its foundation on knowledge-based view of a firm (KBV). KBV sees knowledge as the most important strategic resource of a firm building the resource-based view of a firm (RBV) (Grant, 1996). RBV explains how firms create competitive advantage by accumulating and exploiting resources that are rare, valuable, non-substitutable, and difficult to imitate (Rumelt, 1984; Wernerfelt, 1984; Barney, 1991). In the purchasing and supply management arena KBV has been applied with a focus in the creation and transfer of knowledge (Blome et al., 2014), through collaboration (Zacharia et al., 2011) and its impact on firm as well as supply chain performance (Hult et al., 2006; Kristal et al., 2010).

Firm's ability to sense information concerning the business environment, turn it into

knowledge and to respond through reconfiguration of resources and capabilities is also referred to as absorptive capacity (AC). According to Cohen and Levinthal (1990, p. 128), absorptive capacity refers to "the ability of a firm to recognize the value of new external information, assimilate it and apply it to commercial end". The basic premise is that prior related knowledge is needed to assimilate and to use new knowledge. AC depends on the links between individual capabilities and can be strengthened if a firm develops a broad network of internal and external relationships (Cohen & Levinthal, 1990). In the supply management literature, AC is combined especially with buyer-supplier relationships and networks (Narasimhan & Narayanan, 2013; Sáenz et al., 2014), performance (Azadegan, 2011; Dobrzykowski et al., 2015), innovativeness (Azadegan et al., 2008; Azadegan, 2011), and value creation (Sáenz et al., 2014) but lately also with sustainable sourcing practices (Meinlschmidt et al., 2016). Kim et al. (2015) studied the concept of relative absorptive capacity in buyer-driven knowledge transfer. Azadegan et al. (2008) utilized the knowledge-based view whereas it is increasingly theorized as a dynamic capability (Sáenz et al., 2014; Volberda et al., 2010).

In addition to the absorption of knowledge also the desorption has recently been received close attention (Meinlschmidt et al., 2016; Roldán Bravo et al., 2016). The interplay of absorptive and desorptive capacity is at the core of a supply market orientation capability. Hence, the continuous calls for proactive and faster responses to supply market dynamics require more than the ability to sense assimilate and apply external information. Successful firms redeploy internal and external resources and capabilities through internal coordination and integration in their pursuit to capture value creation opportunities (Hodgkinson et al., 2012; Najafi-Tavani et al., 2016) and to attain temporal congruence with the external environment (Teece et al., 1997). Essentially, such dynamic capabilities are defined as "the firm's ability to integrate, build and reconfigure internal and external competences to address rapidly changing environments" (Teece et al., 1997, p. 516). Hence, specific processes or routines enable the combination, transformation, or renewal of the resource stock of firms into new operational processes and capabilities as markets evolve (Eisenhardt & Martin, 2000). By conceptualizing supply market orientation as such a dynamic capability, we assume an indirect link between supply market orientation and buying firm operational and financial performance (Zott, 2003; Barreto, 2010).

Market orientation in the upstream supply context

Essentially, market orientation refers to the implementation of the marketing concept. It is reflected in the diverse activities and behaviors associated with firm-wide generation, dissemination, and responsiveness to market intelligence (Kohli & Jaworski, 1990). Thereby, market intelligence embraces current and future customer needs and preferences as well as the exogenous forces (e.g., competition, technology, culture) affecting them (Jaworski & Kohli, 1993; Matsuno et al., 2000). Rooted in marketing research and practice, the market orientation concept fundamentally embraces the notion of customer focus (Kohli & Jaworski, 1990). For a comprehensive overview of the market orientation literature, we refer to Liao et al. (2011).

Few scholars have examined market orientation in the supply context. Fugate et al. (2008) emphasized the role of logistics in market orientation. Zhao and Cavusgil (2006) reported a link between suppliers' market orientation and manufacturers' trust, which in turn affects manufacturers' long-term orientation toward suppliers. Min et al. (2007) argued that market orientation drives a systems approach to consider the supply chain as a source of resources and skills, thus promoting collaborative initiatives. However, these research efforts do not explicitly take supply market peculiarities as contextual antecedents for the application of a supply market orientation capability into consideration.

The market orientation concept has influenced the domains of demand chain management (Chen et al., 2004; Jüttner et al., 2010) and supply chain segmentation (Christopher & Towill, 2002). Moreover, a step toward understanding supply market orientation has been

taken by research on supply chain orientation, which emphasizes a supply chain philosophy in the firm (e.g., Mentzer et al., 2001; Ellinger et al., 2012) and the corresponding need to manage the capacity and capabilities of suppliers to improve productivity, quality, and innovation (e.g., Lee, 2004; Fawcett et al., 2007; Ireland & Webb, 2007).

Another step towards an understanding of supply market orientation was taken by Handfield (2010), who explored a concept of supply market intelligence. However, the concept essentially mirrors the existing concept of market orientation with regard to its basic information processing aspects of market intelligence generation and dissemination. Little is yet known about how firms use supply market intelligence and what this implicates organizationally at the functional and the purchasing category level. Moreover, market intelligence is just the starting point of a market orientation (Kohli & Jaworski, 1990), which becomes ever more important for the successful seizure the established sourcing practices such as supplier evaluation and selection, supplier development, supplier certification, supply base optimization, and strategic supplier relationship management (Narasimhan & Das, 2001; Choi & Krause, 2006).

Case study methodology

Rationale and sampling

Even though existing research has provided a number of ideas on what supply market orientation could entail it was not yet clear what actually constitutes supply market orientation, how it is developed, how it differs within and across firms, and which contextual factors can explain such differences. Following our research question, we sought to explore the focal phenomenon in the context in which it occurs (Meredith, 1998), while being able to embrace existing findings and theory for a substantiation of our results (Eisenhardt, 1989; Yin, 2009). In this regard, our research approach can best be described as theory elaboration (Vaughan, 1992). In particular, we applied a qualitative, inductive research design comprising multiple case studies with embedded multiple units of analysis (Eisenhardt, 1989; Yin, 2009). This approach allowed us to identify and explore relevant constructs and interrelationships, adding description and understanding of the interactions, meanings, and processes that constitute real-life settings (Gephart, 2004). In doing so, we extended the DCV to the realm of our study, providing a theoretical rationale for our empirically derived concept and research propositions.

In selecting cases, we followed a theoretical sampling logic that allowed us to replicate and extend findings and theory by exploring and understanding important categories, properties, and interrelationships (Meredith, 1998). Thereby, cases were chosen for their potential to illuminate and extend relationships and logic among constructs, that is, for their potential contribution to theory development within the set of cases (Glaser & Strauss, 1967; Eisenhardt, 1989; Eisenhardt & Graebner, 2007). Thus, cases allowed for relational inference (Meredith, 1998) rather than representational inference from a random sample from a population (Flyvbjerg, 2006).

We restricted our initial population to large firms (turnover > $5 billion; employees > 15,000) with a large multinational supply base (suppliers > 25,000), thus constraining variation due to size differences and regional idiosyncrasies. We presumed that such large firms have an overall greater need and resource endowment towards a supply market orientation. For reasons of external validity, we deliberately attempted to build a theoretical sample comprising firms operating in different businesses, mainly manufacturing, services, and a hybrid of these two (Allred et al., 2011).

Moreover, we required variation regarding supposedly relevant contextual factors at the firm and the purchasing category level (e.g., Kraljic, 1983). Thus, our main observational unit of analysis is the firm, whereas the major purchase categories of the firm serve as an explanatory sub-unit of analysis (Wilhelm, 2011).

We first selected a manufacturing firm (ALPHA) and a service firm (ECHO), each with a

supposedly heterogeneous supply environment in terms of different purchase categories. Based on emergent findings from the first two cases, we selected incremental cases to facilitate the replication and extension of findings and theory (Eisenhardt, 1989; Yin, 2009). Thus, our sampling strategy shifted from typical cases (ALPHA, ECHO) to diverse cases (BRAVO, CHARLIE, DELTA) (Seawright & Gerring, 2008; Pratt, 2009) for a more sophisticated understanding of differences in the nature of supply market orientation and related interdependencies. Table 1 characterizes our final sample comprising the five firms.

Table 1. Sample Characteristics.

	Industry	Turnover	# Employees	#Informants	#Interviews	Functional areas involved in interview process (no exact job titles; possibly more than one informant from the same functional area)
ALPHA	Manufacturing	> $50 bn	> 100,000	10	12	Purchasing (strategy, controlling, market intelligence, category management) Liaison functions (procurement engineering, commodity engineering) Other technical functions (quality, R&D)
BRAVO	Manufacturing and services	> $50 bn	> 100,000	6	7	Purchasing (strategy, project purchasing) Liaison functions (cost engineering) Other commercial functions (customer projects) Other technical functions (engineering, R&D)
CHARLIE	Manufacturing	< $10 bn	< 50,000	8	8	Purchasing (strategy / processes, controlling, category management) Other commercial functions (marketing, sales) Other technical functions (engineering)
DELTA	Services	> $50 bn	> 100,000	8	8	Purchasing (strategy, category management) Liaison functions (procurement engineering) Other commercial functions (marketing strategy, marketing operations) Other technical functions (engineering, product innovations)
ECHO	Services	$10-50 bn	50,000-100,000	8	8	Purchasing (CPO, subunit CPO, strategy, controlling, communications) Other commercial functions (sales)

Data collection and selection of informants

To investigate the focal phenomena from different angles, tapping into a wide range of individual experiences and perspectives, we used numerous informants (Jick, 1979; Stuart et al., 2002; Eisenhardt & Graebner, 2007). We first approached purchasing managers since the purchasing function is usually the major interface to firms' upstream supply chains. Also, the inclusion of purchasing managers allowed us to better gauge supplier relationships (Frohlich & Westbrook, 2001) and integration with other internal functions. We then approached additional informants in liaison, commercial or technical non-purchasing positions. An illustration of our data collection and informant selection is provided in Table 1.

Data collection comprised in-depth interviews with informants to gain understanding of the phenomena (Pratt, 2009), including the meanings ascribed by informants to actions and settings (Gephart, 2004). We developed semi-structured interview protocols with open-ended questions to enable managers to describe events and processes, to facilitate comparability of findings, and to retain the flexibility to probe deeper into emergent themes by eliciting examples, illustrations, and other insights (Kohli & Jaworski, 1990; Fawcett et al., 2012). The interviews lasted 45 to 90 minutes and were added until we reached theoretical saturation (Glaser & Strauss, 1967; Eisenhardt, 1989).

We conducted between seven and twelve interviews per firm. All interviews were transcribed as a basis for coding analysis according to Strauss and Corbin (1998), resulting approximately 700 pages of interview transcripts in total. Out of the total of 40 informants, 28 held purchasing positions, seven held marketing and sales positions, and five held quality, engineering, or R&D positions. The initial interviews conducted at each firm were supple-

mented with a questionnaire to complement and challenge interview responses. Furthermore, we collected secondary data in the form of publicly available documents (e.g., annual reports) and internal firm documents (e.g., guidelines, process documentation, performance reports).

Data analysis

We first conducted a within-case analysis, generating single case representations in the form of detailed, descriptive write-ups (Ellram, 1996; Barratt et al., 2011). Within-case analysis results were then used as a basis for cross-case synthesis, which involved identifying, comparing, and contrasting patterns across cases in search of similarities and differences among cases and groups of cases (Eisenhardt, 1989; Yin, 2009). In doing so, we added order to the emergent conceptualization of supply market orientation by explicitly delineating patterns, thereby introducing causality (Whetten, 1989).

A manual coding process was used to reflect the diverse and nuanced answers as well as the linguistic and firm-related variety of informants' language (Fawcett et al., 2012). First, we derived first-order codes and provisional codes (Pratt, 2009) by following open coding procedures (Strauss & Corbin, 1998). Data and emergent results were then used together with the literature to derive second-order codes and to enfold theory (Pratt, 2009) by using axial and selective coding procedures (Strauss & Corbin, 1998). Thereby, we consolidated specific, but related codes into broader, more theoretical categories (Strauss & Corbin, 1998).

Results: Supply market orientation across cases

In the following section, we develop a definition of supply market orientation and discuss the concept and its elements. In doing so, we mainly build on our empirical case study observations while simultaneously reflecting the theoretical DCV perspective to underpin our results.

An empirically derived definition of a supply market orientation capability

As a basis for the following discussion, Table 2 integrates detailed information about the practices observed at our cases in generating, disseminating, and using supply market intelligence, thereby indicating differences and similarities within and across firms.

Our cases demonstrate that supply market intelligence comprises more than day-to-day information exchange between firms and their suppliers. Rather, supply market intelligence embraces multiple tiers of the upstream supply chain and the exogenous forces affecting them (e.g., regulation, technology, competition). Examples include analyses of suppliers' supply cost structures (ALPHA, BRAVO), supplier peer group analyses (DELTA), workshops with both complementary and competing part suppliers to create new technologyy ideas (ALPHA), and analyses of competitors' supply cost structures as a basis for benchmarking (ALPHA). Together with external financial analysts, DELTA conducts extensive financial supplier risk assessments. CHARLIE evaluates key commodity markets (e.g., crude oil) of relevance to its directly sourced raw materials. BRAVO and DELTA do not directly source raw materials, but analyze related markets along with internal and suppliers' cost structures to determine price trends for sourced parts and products. A purchasing executive at BRAVO stated: *"Of course, in the sense of market intelligence, we know very well how [raw material] prices develop. […] If there is a 30% rise in copper prices, we can tell quite well what that means for the final product. For this, we made assessments […] to determine the copper content […] in our [sourced and final] products."*

Moreover, supply market intelligence embraces not only current suppliers and supply markets, but also potential suppliers and supply markets. This pertains, for example, to technology and innovation screening (ALPHA, BRAVO, DELTA). ALPHA recently collaborated with a consultancy firm to evaluate supply market structures and potential suppliers for plastic parts in China. A global purchasing analysis team at BRAVO evaluates opportunities and risks in potential supply markets, including market structure and supplier analyses along with macro-economic analyses. CHARLIE evaluates opportunities and risks in raw material mar-

kets as part of its extensive supply risk management. DELTA and ECHO evaluate suppliers' technical capabilities together with product and service trends to improve their own product and service portfolios.

Table 2. Case Analysis Display Supply Market Intelligence Generation, Dissemination, and Use

	Supply market intelligence generation	Supply market intelligence dissemination	Supply market intelligence use
ALPHA	***Intra-functional (purchasing central):*** Macroeconomics, firm-wide markets/suppliers (e.g. raw material markets), competitors (e.g. global sourcing/cost structures) ***Intra-functional (purchasing local):*** Specific/ad-hoc analyses (e.g. regional markets/suppliers), bundling potentials, cost benchmarking, technology screening ***Cross-functional (commodity / procurement engineering):*** Technical market/supplier analyses (e.g. cost structures, processes, quality), technology/innovation scouting, joint analyses with suppliers (e.g. process optimization/innovation workshops) ***External (market researchers / consulting):*** Macroeconomics, raw material/commodity markets (e.g. price indices), specific ad-hoc analyses (e.g. plastics markets in China)	***Intra-functional (purchasing central and local):*** (De-)centralized regular and ad-hoc collection/dissemination ***Cross-functional:*** Meetings/discussions (e.g. strategy review, technology council) Teams (e.g. material strategy teams: purchasing, R&D, quality) Processes (e.g. quality monitoring/management, contract design) Projects (e.g. product lifecycle management, cost optimization) Liaison functions (commodity/procurement engineering) Ad-hoc to technical functions such as R&D and quality (e.g. technology/innovation roadmaps, preferred suppliers/materials) Very little active ad-hoc to sales (e.g. preferred suppliers)	***Intra-functional (purchasing central and local):*** Strategy formulation (e.g. supply base development, global sourcing, cost optimization, technology roadmaps), risk management (e.g. currency/commodity hedging, availability / quality assurance), negotiation, supplier management and development, target setting, performance evaluation, budgeting, reporting ***Cross-functional:*** Strategy formulation (e.g. outsourcing initiatives, cost analyses in business strategy, technical supplier analyses in strategies of R&D/quality), product lifecycle management, value engineering, product development, budgeting, planning (price, quality, capacity), reporting
BRAVO	***Intra-functional (purchasing central):*** Macroeconomics, supply base (e.g. competitive/cost structure, wages, skill levels), market potentials and risks, early indicators ***Intra-functional (purchasing local):*** Specific/ad-hoc analyses (e.g. regional markets/suppliers with respect to quality, technology, opportunities and risks) ***Cross-functional (cost engineering):*** Technical market/supplier analyses (e.g. cost structures, processes), supplier benchmarks (incl. competitors), technical support of specific/ad-hoc analyses (e.g. market opportunities/risks) ***External (market researchers):*** Macroeconomics, raw material/commodity markets	***Intra-functional (purchasing central and local):*** (De-)centralized regular and ad-hoc collection/dissemination ***Cross-functional:*** Regular standard analyses (e.g. price, availability) Ad-hoc analyses (e.g. new market evaluations/potentials/risks) *In-house development / manufacturing context:* Projects (active/on-demand) / little active ad-hoc dissemination Liaison functions (cost engineering) *Customer service / integrated solutions context:* Projects (on-demand) / very little active ad-hoc dissemination	***Intra-functional (purchasing central and local):*** Strategy formulation (e.g. supply base development, cost reduction roadmaps with key suppliers), risk management (existing and new markets), product cost structure analyses, price benchmarks, negotiation, supplier management and development, target setting, performance evaluation, budgeting, reporting ***Cross-functional:*** Projects (e.g. supplier selection, evaluation, development), sourced innovation and utilization of suppliers' technical capabilities in the context of in-house product/service development, planning
CHARLIE	***Intra-functional (purchasing central):*** Macroeconomics, broad market/supply base analyses ***Intra-functional (purchasing local):*** Specific/ad-hoc analyses (e.g.regional markets/suppliers with respect to price, delivery, quality, technology), regular/ad-hoc raw material market analyses (e.g. market overview/potentials/risks, competitor benchmarks, price forecasts/variance analyses) ***External (market researchers):*** Macroeconomics, raw material/commodity markets (e.g. crude oil, steel, plastics) to complement extensive internal efforts	***Intra-functional (purchasing central and local):*** (De-)centralized regular and ad-hoc collection/dissemination ***Cross-functional:*** Regular IT-based dissemination of raw material analyses/reports Limited additional active dissemination to marketing and sales (e.g. ad-hoc analyses in case of unforeseen events/crises) Meetings (e.g. budgeting, strategy, pricing/engineering councils) Projects in technical equipment and machinery (largely commercial analyses by purchasing on-demand of other functions)	***Intra-functional (purchasing central and local):*** Strategy formulation (e.g. raw material strategies), risk management, negotiation, supplier management and development (technical equipment and machinery), target setting, performance evaluation, reporting ***Cross-functional:*** Strategy formulation (e.g. business unit strategies based on raw material/product structure analyses), negotiation support for sales (raw material analyses), customer contract design (price escalation clauses)
DELTA	***Intra-functional (purchasing central):*** Macroeconomics, broad market supply base analyses, competitors (incl. peer groups), suppliers (e.g. market shares, financials), raw material/commodity labor markets, product trends ***Intra-functional (purchasing local):*** Specific/ad-hoc analyses (e.g. regional markets/suppliers, detailed analyses of price/product developments and trends) ***Cross-functional (procurement engineering):*** Technical supplier analyses (e.g. cost structures/processes) ***External (market researchers / financial analysts):*** Financials (Bloomberg), specialized market research platforms	***Intra-functional (purchasing central and local):*** (De-)centralized regular and ad-hoc collection/dissemination ***Cross-functional:*** Supply market reports (developments/trends in major categories) Supplier books (consolidated intelligence on strategic suppliers) Meetings (e.g. budgeting, planning, strategy) Liaison functions (procurement engineering) Projects (mostly on-demand, for example firm-wide cost optimization projects, mobile/fixed line network construction projects)	***Intra-functional (purchasing central and local):*** Strategy formulation (e.g. supply base development), cost/price benchmarking, risk management (operational/financial), negotiation, supplier management and development, budgeting, target setting, reporting ***Cross-functional:*** Cost-benefit analyses, business case calculation (cost/price aspects), supplier evaluation and selection, technical cost optimization initiatives, product/service portfolio management, strategic firm-wide cost optimization projects, budgeting, planning
ECHO	***Intra-functional (purchasing central):*** Macroeconomics (very limited), few broad market analyses ***Intra-functional (purchasing local):*** Specific/ad-hoc analyses (e.g. regional markets/suppliers), product / service innovations/technology trends (limited scope) ***External (market researchers):*** Macroeconomics, standard raw material/commodity markets (e.g. steel, copper, wood, plastics, crude oil, fuel)	***Intra-functional (purchasing central and local):*** Little centralized collection/dissemination (broad overviews) Ad-hoc dissemination at subgroup level (diverse efforts) ***Cross-functional:*** Meetings (e.g. status/market reports delivered by purchasing) Ad-hoc management reports (e.g. board, subgroup management) Projects (largely restricted to standard issues: price, availability)	***Intra-functional (purchasing central and local):*** Strategy formulation (e.g. supply base development, spend / category management, insourcing), risk management, basic supplier management and development ***Cross-functional:*** Business case calculation, quotation costing, tender preparation, supplier evaluation/selection, reciprocal business deals (suppliers' portfolio/earning power)

Our case observations show that the purchasing function plays a critical role in the generation and, in particular, the dissemination of supply market intelligence, due to its strong interface to supply markets and its boundary-spanning role inside the buying firm. This is reflected in the statement by a senior purchasing executive at ECHO: *"People identify us [purchasing] as an information pool in any situation. We are often the contact persons for all sorts of things. […] Through the permanent dialog, we are always some kind of catalyst: we pass on information, place it appropriately, establish contacts, communicate, facilitate… that's also part of our job."*

However, supply market intelligence is not the sole responsibility of the purchasing function. In fact, its highly interdisciplinary nature (e.g., macroeconomic, technical, and financial analyses) requires integration with other functions, including liaison functions. Even though the case firms differ in their specific efforts, most of them use supply market intelligence in strategy formulation, risk management, supplier management, and performance management. Thereby, firms develop abilities to create valuable knowledge emanating from the dispersed and specialist supply market intelligence and to beneficially embed this knowledge into practices, processes, and organizational routines. Here, we refer to knowledge as information and know-how (Kogut and Zander, 1992), which includes, for instance, market research know-how (ALPHA, BRAVO, CHARLIE), forecasting know-how (ALPHA, CHARLIE), and cost and process analysis know-how (BRAVO).

Our observations suggest that exploiting supply market intelligence allows firms to project whether certain resources (or combinations thereof) will be more or less beneficial. Resource complementarities can provide advantages in that multiplicative effects surpass the gains from deploying resources individually (Siggelkow, 2002; Das et al., 2006). At ALPHA and CHARLIE, exploiting supply market intelligence improves supply risk management and enables fast and flexible response to supply market changes. Exploiting supply market intelligence improves supplier management, strategy formulation, quality management, and the development of new products at ALPHA, BRAVO, and DELTA. At ALPHA, it also enables the timely development of alternative technologies and new suppliers. Thus, exploiting supply market intelligence enables firms to deploy their resources in purchasing and supply management more effectively.

The DCV provides valuable insight into the capability development process (Eisenhardt & Martin, 2000). Specifically, the DCV provides understanding of the process by which firms transform the dispersed resources available in purchasing and supply management into the distinctive capability of supply market orientation. Thereby, supply market orientation can be disaggregated into the capacity to sense opportunities and threats through supply market intelligence, and to exploit this intelligence to seize opportunities and to enhance, combine, and reconfigure available resources in purchasing and supply management (Teece, 2007). A similar notion has been put forward by Menguc and Auh (2006), who suggested that a customer market orientation is transformed into a dynamic capability when complemented by reconfigurational capabilities. Moreover, scholars have attributed an important role to learning mechanisms in the development of dynamic capabilities (Zollo & Winter, 2002), thus emphasizing the role of knowledge in the conceptualization of supply market orientation.

Based on our case firm observations and our theoretical arguments, we are now able to articulate the following definition of supply market orientation: *Supply market orientation refers to the capability of a firm to exploit supply market intelligence to assess, integrate, and reconfigure the heterogeneously dispersed resources in purchasing and supply management in a way that best reflects the peculiarities of the firm's supply environment.*

This definition recognizes the concept of supply market intelligence and thus reflects the basic information procedural aspects of extant conceptualizations of market orientation. However, it explicitly addresses the beneficial exploitation of supply market intelligence. Second, the definition recognizes the diverse practices in purchasing and supply management that

have been adopted individually by firms to tackle the challenges of their particular supply environment. However, dynamic and responsive markets require firms to manage their upstream supply chain more strategically (Liao et al., 2010). Thus, our definition builds on the DCV to incorporate the notion that firms not only accumulate dispersed information and knowledge as resources, but rather assess, integrate, and reconfigure internal resources as a result of the generated intelligence in a way that best fits their supply environment.

Elements of supply market orientation

Our cases provide evidence for the existence of different elements of supply market orientation, which is in line with research suggesting that dynamic capabilities exhibit common features, but are idiosyncratic in their details (Eisenhardt & Martin, 2000). First, the elements of supply market orientation can differ with regard to their organizational level. While firm-level elements span different purchase categories, category-level elements are specific to a certain purchase category. Category-level elements comprise, for instance, efforts of individual category managers to conduct specific analyses of materials, parts, and suppliers. Firm-level elements comprise, for example, a corporate supply market intelligence department at ALPHA, a global purchasing analysis team at BRAVO, a market research team in purchasing strategy at DELTA, as well as category-spanning market intelligence generation and dissemination processes. As individual category managers' efforts are inevitably limited in scope and sophistication, such firm-level elements of supply market orientation are of utmost importance to complement category-level efforts.

The elements of supply market orientation can furthermore differ with regard to their temporal focus. Reactive elements reflect a defensive stance, and are often related to specific customer market-related demands by internal stakeholders. A category manager at CHARLIE noted as follows: *"When a business unit would like to advance a new product […], then it's our task to evaluate: Which are the right raw material sources? Where are they? Which [raw material] specifications are necessary to arrive at the final product?"* A customer service manager at BRAVO critically appraised the reactive element: *"The information may be available, or may be obtainable, but it's not push information. […] Purchasing does not provide quarterly overviews, for example of certain markets. […] If we have a specific project, or a potential customer, or if we have entered the tendering stage, and we place specific requests, then purchasing is absolutely capable of delivering the information. But it's not delivered proactively."* This process is illustrated in the bottom part of Figure 1.

On the other hand, proactive elements reflect a preventive stance and an endeavor to delve into uncharted territory. As such, they often relate to risk and innovation, with the aim of proactively pushing supply market opportunities and risks into the firm. Hence, supply market intelligence is generated in anticipation of its value, as opposed to the reactive case (top part of Figure 1). A purchasing manager at CHARLIE remarked: *"Through market intelligence, that is, an understanding of supply markets and their dynamics, we try to be faster than our competitors to understand in which direction markets are moving. […] Anticipating market developments can be advantageous for the firm."* A purchasing executive at ECHO noted as follows: *"As we are close to the markets, to the industry, to manufacturers, to large retailers, we are quite close to new products, innovations and trends. […] For this, we have to identify market novelties and innovations as fast as possible, evaluate their relevance for our business and, of course, position them accordingly [in the firm] and place them in our offers."* A senior purchasing executive at BRAVO stated: *"Purchasing needs to be ahead in terms of knowledge. It should not happen that development approaches with a supplier or a technology that purchasing does not know about yet."* Essentially, proactive elements of supply market orientation reflect the notion that performance benefits through dynamic capabilities lie not only in the firm's ability to transform and reconfigure extant resources, but also in doing this in a rapid and timely manner, ahead of competitors (Eisenhardt & Martin, 2000;

Teece, 2007). Figure 1 illustrates both elements of supply market orientation.

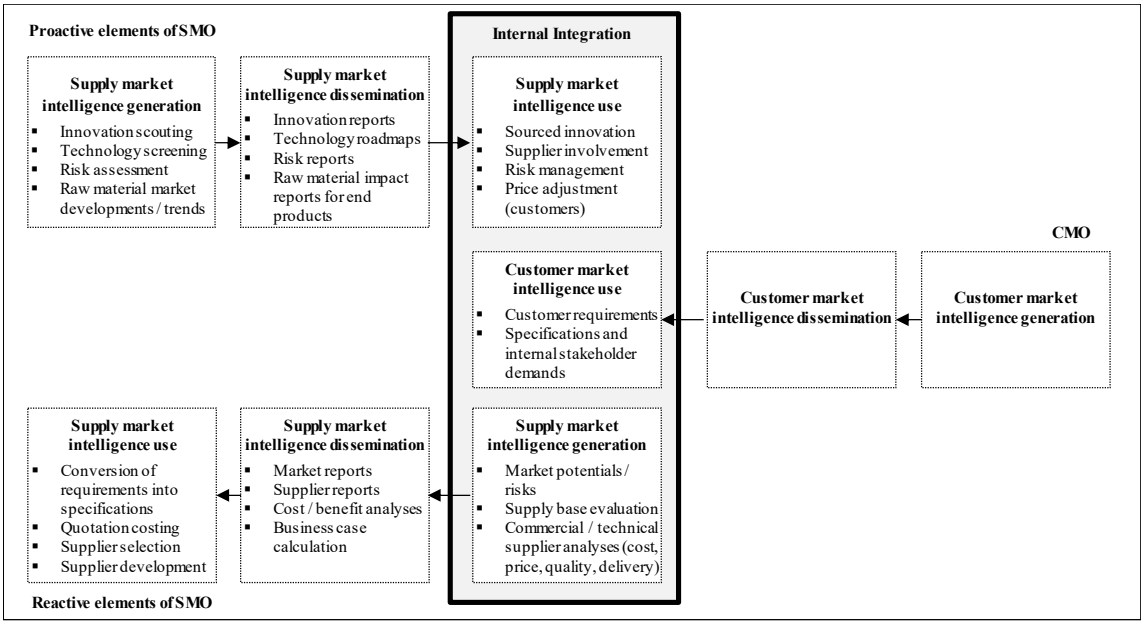

Figure 1: Proactive and Reactive Elements of Supply Market Orientation

Contributions, limitations and future research

Contributions to theory

We conceptualized and defined supply market orientation, thereby discussing how it is developed and how it differs within and across different firms (Table 2; Figure 1). We reflected our empirical observations against the background of the literature and the DCV for a more focused exploration and stronger substantiation of the results. Throughout the study, we provided empirical evidence and theoretical reasoning to endorse supply market orientation as a valuable dynamic capability

Our concept of supply market orientation recognized existing research in that it embraced the concept of supply market intelligence and the diverse concepts in purchasing and supply management that have often been adopted individually by firms to tackle the challenges of their particular supply environment. However, the concept of supply market orientation addressed the beneficial exploitation of supply market intelligence in the firm's various practices, processes, and organizational routines more directly, thus extending previous research in this area. In particular, we found that exploiting supply market intelligence allows firms to better observe the peculiarities of their supply environment and to then decide whether certain resources available in purchasing and supply management (or combinations thereof) will be more or less beneficial.

Furthermore, our concept of supply market orientation emphasized that firms not only accumulate and deploy dispersed resources, but rather integrate and reconfigure those resources in a way that best reflects their supply environment. Thereby, we found that firms can pursue their strategies more effectively through supply market orientation, as they sharpen their strategic focus, and thus channel efforts and investments into the most relevant resources and practices. Our results suggest different elements and configurations of supply market orientation. While firm-level elements span different purchase categories, category-level elements are specific to a certain purchase category. Moreover, reactive elements reflect a defensive stance, whereas proactive elements reflect a preventive stance and an endeavor to delve into uncharted territory.

Our results furthermore demonstrate that firms with advanced supply market orientation

are expected to exhibit more effective supplier integration and internal integration. Specifically, supply market orientation enables firms to make more informed integration decisions and to implement chosen integration practices more effectively, making the resulting integration more effective. In line with the DCV, we argue that the mere existence of dispersed resources in purchasing and supply management may not be critical for integration success. What is more important is how firms combine and reconfigure those resources to reflect their supply environment. Thereby, we emphasize that supply market orientation may well result in less integration, for example, for purchase categories sourced in a market situation where the firm is simply a price-taker.

Contributions to practice

Our results support the notion that uncertain and erratic business environments create the need for firms to build resources and capabilities to learn and adapt to new market conditions. In this regard, we provide valuable guidance for managers as to how supply market orientation may support them to cope with the challenges of an increasingly dynamic and complex global supply environment. Thereby, we support the notion that there is substantial benefit in actively generating and exploiting supply market intelligence in anticipation of its value rather than being reactively to customer market matters and internal stakeholder demands.

Since different configurations of supply market orientation are not equally useful in all possible situations, managers should place differing degrees of emphasis on the activities associated with generating, disseminating, and exploiting supply market intelligence. Thereby, our results show that the scope and focus of supply market orientation may well differ within the same firm, depending on the different purchase categories the firm sources, and the associated supply market environments. Furthermore, it is a first step to enable firms to more effectively utilize the value-adding potential of their integration practices. Supplier and internal integration can be the cause or the result of supply market intelligence generation and dissemination. More generally, supply market orientation helps managers assess how much integration is justified in which supply environment. This is particularly valuable for managers because, internal and supplier integration consume resources, pose risks and require investments in terms of money and time (Christopher, 2000; Koufteros et al., 2007; Schoenherr & Swink, 2012). In this regard, supply market orientation may prevent managers from misallocating valuable internal resources.

Limitations and future research

As with any inductive case-based research, our study lacks generalizability to some extent, even though we pursued a methodologically rigorous research approach. Thus, the next research step would be to deductively test constructs and relationships in a survey of multiple firms in diverse supply chains and industries. Thereby, future research could enlighten why some firms excel at effectively translating their dispersed resources into successful processes and capabilities while others do not. For example, there may be further critical differences between manufacturing and service firms, requiring future attention.

Incorporating supply market orientation as a potential intervening variable in empirical tests of the relationships between dimensions of supply chain integration and dimensions of operational performance and business performance may further contribute to the understanding of underlying relationships. Thereby, our results motivate future research to empirically test performance implications of supply market orientation at the firm and purchasing category level. In addition, the environmental uncertainty types might differ across industries or across different modes of production.

Our results indicate that supply market orientation may enable firms to better balance the supply chain and the demand chain. Schoenherr and Swink (2012) suggested that firms might accomplish synergies from the possession of superior capabilities with respect to opportuni-

ties and boundary conditions in both customer markets and supply markets. Thus, future research could investigate the role of supply and customer market orientation to attain supply chain fit and to effectively match demand and supply (Wagner et al., 2012).

Goals, Conflict, Politics and Performance of Cross-Functional Sourcing Teams

Abstract

Strategic sourcing decisions are carried out in cross-functional teams to improve decision quality. Yet, cross-functionality also introduces behavioral challenges such as conflict and politics among team members. Based on data gathered in a social team experiments, we find a mediated effect of goal misalignment on politics via two types of inter-personal conflict. Perceptions of politics in turn obstruct rational team sourcing decisions. This study contributes to the scholarly understanding of the challenges that cross-functional sourcing teams face and enables PSM executives to reduce conflict and politics in sourcing teams and to ultimately enhance their decision outcomes.

Submission category: competitive paper

Keywords: global sourcing; teams; organizational politics;

Introduction

As a result of the outsourcing waves of recent decades, international and global sourcing have become integral elements of firm strategies and operations (Carter and Narasimhan, 1996; Trent and Monczka, 2003). In order to make effective sourcing decisions, various functions such as purchasing, logistics, R&D, production management, or marketing have to align and integrate (Mentzer et al., 2008; Trent and Monczka, 1994). Thus, these functions are interdependent in Purchasing and Supply Management (PSM) decision making processes, requiring functional representatives to exchange and jointly process information and combine their expertise in sourcing teams (Moses and Åhlström, 2008; Thompson, 1967). Such teams are temporarily formed and mandated to perform the vendor selection based on their diverse functional expertise (Foerstl et al., 2015).

It is well-established that cross-functional integration contributes to firm performance and supply chain effectiveness (e.g., Flynn et al., 2010), yet such diverse teams also face challenges from functional misalignment and conflicting motives that potentially interfere with rational decision making processes (Kaufmann et al., 2012; Moses and Åhlström, 2008). These challenges of cross-functional sourcing team integration have hitherto received little scholarly attention. Today, especially inter-personal conflict, self-serving politics, and their relationship in PSM team decision making remain underrepresented yet impactful phenomena (Bai et al., 2016; Thornton et al., 2016). Considering these research gaps, we pose the following research questions: (1) How do (mis)aligned goals affect conflict and politics in cross-functional sourcing teams and how are both related to each other? (2) What are the performance implications of conflict and politics in cross-functional sourcing teams?

This paper contributes to the yet emerging literature on conflict and politics in sourcing teams (e.g., Kaufmann et al., 2010; Kaufmann et al., 2012). Furthermore, we follow the call for more 'people-focused' PSM research, which is the primary underestimated PSM research theme today (Wieland et al., 2016). In our pursuit, we provide empirical evidence on political decision making processes within sourcing at the team level of analysis. Such political team processes are seldom observed even in general management and the organizational behavior domain outside PSM outlets (Vigoda-Gadot and Vashdi, 2012). Finally, this research enlightens us on which types of conflict should be prevented and which should be tolerated by firm leaders to serve team decision making and decision quality.

The remainder of the paper is structured as follows: First we reviews the emerging PSM team research and define our concepts of interest. Next, we develop our hypotheses based on

PSM and general management insight, present our methodology, and channel our results into a discussion of findings. We end with the implications of our research and future research opportunities that may fill the limitations that we accepted in this study.

Theoretical Grounding and Literature Review of Behavioral Research in Sourcing Teams

Cross-functional sourcing teams are regularly formed to make strategic decision about the upstream supply chain (Driedonks et al., 2010; Flynn et al., 2010). Functional representatives come from diverse backgrounds such as production, purchasing, marketing, or research and development and usually have divergent goals, expertise, or decision making styles (Kaufmann and Wagner, 2017; Moses and Åhlström, 2008). Cross-functional sourcing teams are examples of task-based functional integration that serves to solve a particular sourcing task through temporal rather than permanent integration (Foerstl et al., 2015; Miller and Dröge, 1986). Hence, such a team can be defined as a temporal collection of individuals from different functional units who have a common purpose of enhancing performance of a particular supplier selection (Mohsen and Eng, 2016).

Organizational buying behavior (OBB) literature has established that corporate buying is a multi-dimension, multi-person, and thus multi-perspective process, laying grounds for behavioral research in sourcing teams (Sheth, 1973; Webster Jr and Wind, 1972). Interestingly, original OBB models do account for conflict, negotiation, bargaining, and politicking as irrational sources of inefficiency (Johnston and Lewin, 1996; Sheth, 1973), yet we lack empirical evidence on such challenges of buying processes. For many years, this research stream has not been fully exploited(Sheth, 1996), particularly as it relates to global sourcing teams. It has been suspected that conflict and political dynamics affect PSM decisions (Moses and Åhlström, 2008; Stank et al., 2001), yet behavioral operations literature has hitherto not focused much on behavioral issues in teams. Building on the OBB tradition, we extend the research on behavioral sourcing that we present in the following.

Studies have begun transferring insights from OBB's process models to the sourcing team as unit of analysis, for instance in studies on uncertainty in sourcing decisions (Kaufmann et al., 2012; Kaufmann et al., 2014; Riedl et al., 2013). Accordingly, sourcing team research has added meaningful insights into decision making biases (Kaufmann et al., 2010), rationality (Kaufmann et al., 2014; Riedl et al., 2013), and team cohesion (Kaufmann and Wagner, 2017) in sourcing teams. Even more recently, initial findings on conflict and politics as specific challenges to sourcing teams have been published (Marshall et al., 2015; Stanczyk et al., 2015).

Exploratory inquiry into problems during cross-functional sourcing decisions detect that conflict as well as politics are significant challenges to PSM teams (Moses and Åhlström, 2008). Further studies show that the established types of conflict have different effects on PSM teams and that emotions are usually unproductive in conflict situations (Andre, 1995; Ehie, 2010). Such conflict can best be resolved by open and collaborative conflict resolution strategies (Oliva and Watson, 2011). Yet, qualitative observations indicate that collaboration can be obstructed for instance by power imbalance among team members as well as functional goal misalignment and political agendas of individual members (Stanczyk et al., 2015). Other observations add that effects of political agendas can vary depending on the underlying political goals of individuals in outsourcing projects (Marshall et al., 2015).

Overall, it can be concluded that "there is relatively little knowledge about the politics in and around teams" (Vigoda-Gadot and Vashdi, 2012, p. 287) and that "conflict and politics have traditionally been treated as separate literatures, and the link to connect both is understudied"

(Bai et al., 2016, p. 96). Thus, we develop hypotheses around goals, conflict, politics, and team performance to inform both PSM and general management research.

Hypotheses development

The proposed research model is shown in Figure 1, comprising six constructs and the relationships among them. Table 1 defines the six constructs. Our hypotheses around conflict are supported by extant literature[1] and serve validating purposes in the sourcing team context. In our model we focus on the 'conflict–politics link' and on the performance implications of politics in concordance with the research questions of this study.

Table 1: Construct Definitions

Name	Construct Definitions	Based on
Goal misalignment	Differences in the goals, interests, or priorities such as price, quality, security of supply, etc.	Stanczyk et al. (2015)
Task conflict	Disagreements among group members about the content of the tasks being performed	Jehn (1995)
Relationship conflict	Interpersonal incompatibilities among group members, which typically includes tension, animosity, and annoyance	Jehn (1995)
Perceptions of politics	Factors that contribute to employees perceiving a work environment as backstabbing, self-interest pursuing and unequally appraising.	Ferris and Kacmar (1992)
Procedural rationality	The extent to which the decision-making process reflects a desire to make the best decision possible under the circumstances.	Dean and Sharfman (1993a)
Team member satisfaction	The general state of joy, happiness, and satisfaction during and after the team work.	Jehn et al. (2010)

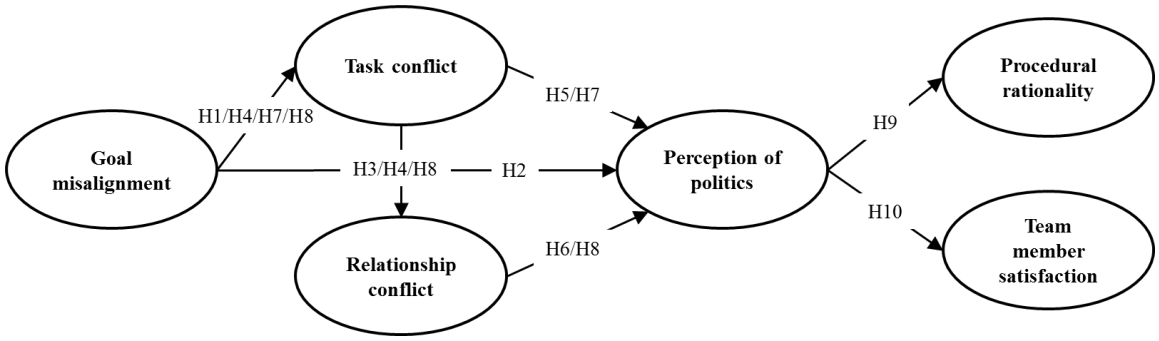

Figure 1: Research model (control variables omitted)

The effect of goal misalignment on conflict in cross-functional sourcing teams

Dissimilar goals lie at the heart of task conflict although conflict does neither in its conceptualization nor in its measurement instrument encompass misaligned goals as an explicit part of conflict (Jehn, 1995, 1997). The misalignment of functional goals in sourcing teams should still naturally drive task conflict among its members. Thus, we posit.

H1: Goal misalignment positively affects task conflict in cross-functional sourcing teams.

Extant research has indicated that misaligned goals create several problems in sourcing teams (e.g., Moses and Åhlström, 2008), yet PSM and organizational research remain unclear on whether misalignment alone can create the perception of politics in teams. POP may emerge under misaligned goals in a sourcing team based on a dual process: One alternative may be an

[1] This study in informed by a previous review of 165 publications on conflict and politics literature in and beyond teams outside the scope of PSM/SCM journals. We omit a review of this literature due to space limitations.

unjustified anticipation of politics. Functional managers realize goal misalignment during the team work if the misalignment was not anyhow clear ex-ante. Hence, team members may perceive politics based on the anticipation of self-serving or opportunistic intentions of their fellow team members solely due to mutually exclusive goals. Hence, they expect politics and experience POP since they are aware that others are incentivized to reach their functional targets as they are themselves.

H2: Goal misalignment positively affects POP in cross-functional sourcing teams.

Another alternative may be that managers are given justified evidence to support POP as soon as problems emerge in the team. For this path, however, we first need to establish connections between conflict types (H3, H3, H4) as well as between conflict and POP (H5, H6).

Several studies including longitudinal designs have hypothesized and successfully tested a positive causal effect of task conflict on relationship conflict, while the inverse claim remains unsupported (e.g., De Wit et al., 2012; Peterson and Behfar, 2003). Studies argue that intensive task conflict eventually leads to interpersonal annoyance and animosity, which are elementary parts of relationship conflict (Jehn, 1997). Therefore, we expect to replicate the driving effect of task conflict on relationship conflict at the team level.

H3: Task conflict positively affects relationship conflict in cross-functional sourcing teams.

Relationship conflict, however, is not naturally driven by the misalignment of goals per se but can depend on several contextual variables such as the team task, diverse cultural dimensions, or team familiarity (De Wit et al., 2012). Especially the latter has proven to be impactful because relationship conflict can be path dependent as past relationship conflict can trigger more relationship conflict (Peterson and Behfar, 2003). Yet, our study assumes a so called 'task-based' functional integration as sourcing teams being composed specifically for a discrete sourcing task rather than being permanently installed (Foerstl et al., 2015; Miller and Dröge, 1986). This assumption is in line with the strategic nature of supplier selection decisions, which are not part of regular day-to-day business. Members in temporary task-based sourcing teams usually have comparably little experience with one another due to their heterogeneous functional origins and hence should not suffer from path-dependent relationship conflict.

Still, extant studies have established mediation of task conflict's effect on team outcomes through relationship conflict. This rationale is based on a sequential escalation logic of slow or unproductive task conflict subsequently creating dissent on the emotional level, which then reduces performance outcomes (Camelo-Ordaz et al., 2015). Drawing on this argumentation, we hypothesize a mediation effect.

H4: Task conflict mediates the link between goal misalignment and relationship conflict in cross-functional sourcing teams.

The effect of conflict on POP in cross-functional sourcing teams

The functions in sourcing teams are interdependent meaning that they need to exchange resources such as information and documents through internal integration processes (Moses and Åhlström, 2008). In fact, they are reciprocally interdependent, meaning that one function's output is necessary as other functions' input and vice versa while making the global best decision for the firm as well as for finding local optima to serve misaligned functional interests (Stanczyk et al., 2015; Thompson, 1967). Conflicts restrict resource access as functional managers become hesitant to share information that may oppose one's own interests. Task and relationship conflicts

are hence resource constraining problems and consequently managers seek ways to work around them in order to still achieve their individual functional goals.

Political tactics can ease resource access in relations suffering from conflict (Gargiulo, 1993). Tactics that help ease resource access are, for instance, ingratiation towards important owners of information, coalition formation to overrule constraints, or selective information sharing to serve functional needs (Stanczyk et al., 2015). Such behavior in turns contributes to factors that contribute to employees perceiving a work environment as political in nature – that is POP. We expect both task conflict and relationship conflict to trigger POP in sourcing teams since both types of conflict obstruct individual resource access and can result in politics as coping strategy. Task conflict obstructs exchange processes based on rational incompatibilities of task-focused goals while relationship conflict obstructs exchange primarily based on irrational personal incompatibilities.

H5: Task conflict positively affects POP in cross-functional sourcing teams.

H6: Relationship conflict positively affects POP in cross-functional sourcing teams.

Moreover, when obstacles such as task or relationship conflict do emerge based on goal misalignment (H2, H3, H4), functional mangers experience even more POP than reasoned in H2. The mere anticipation of politics is now amplified by the immediate need to acquire resources through politics. We hence expect to find a mediating role of task conflict between goal misalignment and POP building on H1 or even a sequential double-mediation of both types of conflict towards POP. Thus, building on H2 and H4 we hypothesize.

H7: Task conflict mediates the link between goal misalignment and POP in cross-functional sourcing teams.

H8: Task conflict and relationship conflict double-mediate the link between goal misalignment and POP in cross-functional sourcing teams.

The effect of POP on performance outcomes of cross-functional sourcing teams

As derived above, functional managers need to retrieve information and specific knowledge from other functions to perform their analysis and contribute to effective decision outcomes in cross-functional sourcing teams (Moses and Åhlström, 2008). Ideally, all team members focus their attention at the multi-lateral retrieval processes that are necessary to integrate interdependent task information on complex decisions (Mell et al., 2014). Organizational research, however, suggests that when the environment is charged with POP, the dominant response strategies chosen by employees are either to withdraw in order to protect oneself from negative emotional and psychological consequences of POP or to engage in politics more intensively to win the political game (Hsiung et al., 2012; Wiltshire et al., 2014). Since individuals in teams rather than broader organizations tend to refrain from withdrawing (Maslyn and Fedor, 1998), team members are only left with playing along to win. This means that POP not only obstructs integration and retrieval processes based on misaligned goals, but shifts team members' attention to exerting political influence, rather than combining interdependent task information (Kaufmann et al., 2010). Managers hence focus more on managing their resource constraining counter-parts via political tactics rather than making use of the information necessary to make the best decision (Dean and Sharfman, 1993a, 1996; Eisenhardt and Bourgeois, 1988). Hence, we expect that this obstruction reduces reduce the rationality of the decision making process.

H9: POP negatively affects procedural rationality in cross-functional sourcing teams.

Several studies have supported that POP in organizations reduces satisfaction of employees with their job (Miller et al., 2008). However, studies have shown that allegedly

straightforward and well-researched links, such as POP and withdrawal from the job, can be challenged in the team context (Maslyn and Fedor, 1998) (see H9). Thus, we seek to trace the effect of POP on our second performance outcome dimension, team member satisfaction.

POP reflects that inter-personal relations rather than individual effort determine personal goal achievement in organizational research (Ferris and Kacmar, 1992). Similarly in sourcing teams, political conditions weaken the impact of individual analytical scrutiny on goal achievement and elevate the ability to retrieve information and other resources via political tactics as success factor. Altering the individual 'effort-outcome function' by introducing political exchange standards contradicts the ideology of fair treatment and rewards (cf. Andrews et al., 2003). Hence, under these unfair conditions, individual rewards and appreciation by functional peers become more uncertain as increasing POP further reduces the effect of effort on personal outcomes. Such uncertainty reduces the satisfaction with the team-work overall since a clear estimation of expected individual rewards cannot be made. We formulate our final hypothesis.

> **H10:** POP negatively affects team member satisfaction in cross-functional sourcing teams.

Research Methods

We choose a social experiment at the team level in order to effectively control extraneous influences and extract solid inferences about our dependent variables. We selected, the vignette-based experiment method which has become well-accepted in behavioral operations (Bachrach and Bendoly, 2011; Croson et al., 2013) and sourcing research (Knemeyer and Naylor, 2011). Subsequently, we describe our experimental design, its variables and measures, as well as our treatment of possible biases.

Experimental Design and Data Collection

Our experimental design follows the methodological guidelines for vignettes (Bachrach and Bendoly, 2011) and a recent example of a complex team experiment (Mell et al., 2014). We chose to conduct an on-site experiment including real team interaction (event technique) on a sourcing task to foster perceived realism (Koschate-Fischer and Schandelmeier, 2014). The vignettes were generated through iterative discussions with researchers and professionals following the guidelines by Rungtusanatham et al. (2011). The baseline-situation describes a hypothetical manufacturing firm Bronson Inc. facing a selection of an important supplier. In order to continue serving the market with motorcycles, the sourcing team needs to successfully select a new engine supplier. We randomly assigned participants into teams of three and likewise randomly assigned the teams to one of the two experimental conditions (see next section). Due to space constraints the baseline scenario and the vignettes are not presented in the paper. The full material is available from the authors upon personal request.

All participants received a general briefing about the process, individual rewards, and the study's rules before individual instruction emails were sent out. After completing an online survey tool on several control variables, team members were instructed to read their individualized instruction email that framed each participant into an upcoming supplier selection meeting for a strategic sourcing item (motorcycle engine) and an individual functional background (purchasing, marketing & sales, or R&D) along with explicit functional goals (e.g., supplier flexibility). All instruction e-mails contained an individualized document with information items on four possible suppliers and a spreadsheet that would assist participants in their pre-meeting analysis. After 30 minutes of individual analysis, participants were asked to

perform manipulation checks and to select their current preferred supplier in an online survey tool.

Next, the individuals formed a cross-functional sourcing team (as earlier randomized) and were given up to 60 minutes to come up with a supplier selection as the outcome of their self-guided group discussion. During the discussion, participants had to retrieve relevant information from fellow team members to find their preferred supplier reflecting high functional interdependency (Moses and Åhlström, 2008; Thompson, 1967). Teams were seated at a table in closed meeting rooms. After a decision had been made, all participants individually filled out an online survey tool on all mediating and endogenous variables of our model. Finally, we thanked and de-briefed the participants and handed over their rewards.

Experimental Conditions and Manipulation

Participants were either instructed to maximize benefits and minimize costs in their choice according to a set of identical indicators (goal alignment) or a function-specific set of indicators (goal misalignment). Hence, the newly developed experimental design is based on two different conditions of goal misalignment. This instruction was explicitly coupled to the performance-based rewards while participants were not aware of other function's goals initially.

Literature is ambiguous whether experiment subjects should be incentivized. We incentivized our participant because previous performance-based pay-outs have shown several positive effects such as increased data quality (Hertwig and Ortmann, 2001). We sampled professionals enrolled in part-time graduate programs. They were incentivized with both fixed and performance-based course credit where possible (10-15% of their grade) or monetary incentives where course credit was infeasible (5€ for attendance and 5€ performance-based) (Koschate-Fischer and Schandelmeier, 2014). We found no significant difference between the two types of incentives in terms of engagement as a measure of participants motivation (7-point scale) (mean cash=5.3; mean course credit=5.5; p=0.25, not significant). The rewards are small enough for participants to perceive them as small 'thank you' and not compare them to their opportunity costs of participation (Koschate-Fischer and Schandelmeier, 2014).

Sample characteristics

We recruited full-time employed participants only and distribute our sampling across several sub-groups to ensure validity of our findings (Knemeyer and Naylor, 2011). The participants are part-time graduate students and executive MBA students (214 in total) who are all fully employed as sustainability, procurement, and commercial or technical supply chain agents or other departments such as sales and marketing, to mirror the cross-functionality of PSM teams. Overall, 85 female and 129 male individuals have participated. The sample is on average 26.3 years old, has 4.5 years of work experience predominantly in manufacturing (25%), services (13%), and finance (13%) industries (first-level SIC) and is familiar with team work (5.6) as well as engaged in the experimental task (5.5) on a seven-point Likert scale.

Variables and Measurement

We vary the independent variable goal misalignment on two levels by giving out aligned and misaligned goals in the sourcing teams and verifying the manipulation ex-post based on the 'goal similarity' scale (Jehn, 1995). Our dependent variables are task conflict, relationship conflict, POP, procedural rationality, and team member satisfaction. We operationalized task conflict and relationship conflict with the widely used scale items in Jehn (1995) and used parts of the Kacmar and Carlson (1997) instrument for POP. Adjustments to the POP scale were necessary such as replacing the term 'organization' with 'committee' and excluding items that are

not applicable to the team context. We further used 'committee' instead of 'team' to avoid significant bias towards cooperation detected in extensive pre-tests. Adjustments are in accordance with extant PSM and organizational literature (Bai et al., 2016; Maslyn and Fedor, 1998). Finally, we assess team performance with procedural rationality drawing on Dean and Sharfman (1993a) and measure team member satisfaction using a scale instrument used in Jehn et al. (2010). We chose to proxy team performance with rationality and satisfaction as suggested by extant studies (Jehn et al., 2010; Riedl et al., 2013).

Regardless of their assigned group, all participants read the same baseline-scenario that provided information about the company, industry, firm size, sourcing item, decision importance etc. Thus, we are controlling for factors that are commonly known to influence strategic decision making processes (Dean and Sharfman, 1993b). We also captured respondents' age, gender, work experience, industry, familiarity with teamwork, perceived realism of the setting, and engagement. Most are omitted in the following analysis since only engagement had a significant influence on our dependent variables. We slightly adapted engagement items to the focus on the 'task' instead of on the 'job' (Rich et al., 2010).

Table 2: Measurement Model Properties and Loadings

Construct (alpha; CR; AVE) *Original Item*	Item Code	PLS loading	AMOS loading
Engagement (alpha .917; CR .932; AVE .705) (Rich et al., 2010)			
I worked with intensity on the task.	Eng1	.857	.824
I tried my hardest to perform well on the task.	Eng2	.815	.750
I exerted my full effort to the task.	Eng3	.877	.855
I exerted a lot of energy on the task.	Eng4	.814	.795
I strived as hard as I can to complete the task.	Eng5	.827	.781
I devoted a lot of energy to the task.	Eng6	.848	.831
Goal misalignment (alpha .794; CR .878; AVE .706) (Jehn, 1995)			
As a committee we have similar goals (reversed).	GoalMis1	.850	.843
The main goals of my committee are the same for all members in my committee (reversed).	GoalMis2	.854	.826
We (my committee) all agree on what is important to our committee (reversed).	GoalMis3	.816	.629
Perceptions of politics (alpha .861; CR .902; AVE .643) (Kacmar and Carlson, 1997)			
People spend too much time sucking up to those who can help them.	Pop1	.783	.710
People are working behind the scenes to ensure that they get their piece of the pie.	Pop3	.819	.752
Individuals are stabbing each other in the back to look good in front of others.	Pop4	.789	.697
People do what's best for them, not what's best for the committee.	Pop5	.748	.706
There is a lot of self-serving behavior going on.	Pop6	.868	.855
Procedural rationality (alpha .712; CR .828; AVE .634) (Dean and Sharfman, 1993a)			
How extensively did the committee look for information in making this decision?	ProcRat1	.748	.614
In general how effective was the committee at focusing its attention on crucial information and ignoring irrelevant information?	ProcRat3	.792	.668
How extensively did the committee analyze relevant information before making a decision?	ProcRat4	.846	.745
Relationship conflict (alpha .890; CR .924; AVE .752) (Jehn, 1995)			
How much emotional conflict is there among members in your team?	Rc1	.882	.853
How much are personality conflicts evident in your committee?	Rc2	.8881	.818
How much interpersonal tension is there among members in your committee?	Rc3	.874	.823
How much friction is there among members in your committee?	Rc4	.830	.784
Task conflict (alpha .868; CR .910; AVE .718) (Jehn, 1995)			
To what extent are there differences of opinion in your committee?	Tc1	.756	.653
How frequently are there conflicts about ideas in your committee?	Tc2	.875	.842
How much conflict about the work you do is there in your committee?	Tc3	.871	.830
How often do people in your committee disagree about opinions regarding the work?	Tc4	.881	.831
Team member satisfaction (alpha .927; CR .910; AVE .718) (Jehn et al., 2010)			
I was very satisfied working with this committee.	Satis1	.939	.914
I was happy working with this group.	Satis2	.946	.933

PLS measurement model properties; Model fit of comparative AMOS analysis: χ^2=866.8; χ^2/df=2.21; CFI=.890; RMSEA=.075

Validity assessment and Measurement Model

As recommended by Anderson and Gerbing (1988), the following analyses were conducted to assess construct validity and reliability. Previously validated scales, a thorough literature review, and a pre-test were used to ensure content validity (Forza, 2002). Several rounds of pre-tests with practitioners and scholars resulted in several major revisions of the material. We improved other and length of the material until no further progress could be made.

Confirmatory factor analysis (CFA) in AMOS was used to assess convergent validity. The results indicated to narrow down items for POP and procedural rationality. We only accepted items above the recommended cut-off value (Nunnally, 2010). Scale reliability was assessed based on Cronbach's alphas and composite reliability for each scale. Finally, all variance inflation factors range below 5 (most below 3), indicating that multicollinearity was negligible (Kock and Lynn, 2012). All details on our variables are summarized in Table 2.

Furthermore, the comparison of the square root of the AVE for each construct and the corresponding correlation coefficient (see Table 3) supported discriminant validity (Fornell and Larcker, 1981).

Table 3: Construct Correlation Matrix

	EN	GM	POP	PR	RC	TC	TMS
Engagement (EN)	.804						
Goal misalignment (GM)	-.421**	.840					
Perception of politics (POP)	-.322**	.550**	.808				
Procedural rationality (PR)	.399**	-.428**	-.504**	.796			
Relationship conflict (RC)	-.290**	.504**	.759**	-.418**	.867		
Task conflict (TC)	-.238**	.592**	.639**	-.382**	.746**	.847	
Team member satisfaction (TMS)	.586**	-.595**	-.589**	.509**	-.550**	-.493**	.876

* $p < 0.05$; ** $p < .01$; diagonal shows square root of AVE (Fornell and Larcker, 1981)

Manipulation Checks and Bias Treatment

Several steps were taken to reduce concerns on manipulation failure, realism of the study, common method bias, social desirability, and bias via incentives. To check the effectiveness of the manipulation, we perform a qualitative manipulation check to verify the coupling of goal indicators to the performance-based rewards right after the analysis of the vignette material and additionally measure goal misalignment in the final ex-post survey instrument (Perdue and Summers, 1986). 89% performed the qualitative manipulation check correctly, while a two-sample t-test on goal misalignment survey responses shows a significant difference of means between the conditions at the 0.01 significance level.

Experiments are criticized for lack of realism (e.g., Bachrach and Bendoly, 2011), however research shows that the perception of realism matters to participants instead of the actual embeddedness into a real firm context (Koschate-Fischer and Schandelmeier, 2014). Participants rate the experiment as relatively realistic (4.4). Overall, 113 participants have rated the experiment realistic (>4), which can be considered a good result given the challenge to convey a realistic lab experiment.

Common method bias (CMB) was assessed by applying Harman's single-factor test (Harman, 1976). The principal component analysis revealed the first factor accounted for only 39.2% of the total variance and 5 additional factors with eigenvalue greater 1 were identified. CFA revealed that the single-factor model did not fit our data well across all samples (χ^2=2967.33; χ^2/df=3.45; CFI=.481; RMSEA=.121) (Korsgaard and Roberson, 1995). Therefore, we conclude that CMB did not significantly impact our structural model estimations.

Measurement of social desirability bias did not yield significant influence on our results. Moreover, given the team setting social desirability of an individual is less of an issue. We followed the experimental and survey design recommendations to limit the influence of CMB and social desirability bias (Bachrach and Bendoly, 2011; Rungtusanatham et al., 2011).

Results

We tested our hypotheses using structural equation modelling. Please see Figure 2 for a summary of estimations of the structural model and the hypotheses tests, which are subsequently summarized per hypothesis. Our results show that goal misalignment created task conflict among the cross-functional sourcing team (H1; β=.595, p<.01; see Table 4) and that misaligned goals also create POP based on an anticipation of politics (H2; β=.214, p<.01). Thus, we accept H1 and H2. Furthermore, the model supports the direct link between task and relationship conflict (H3; β=.718, p<.01). Furthermore, we test whether task conflict mediates the link between goal misalignment and relationship conflict (H4). Since both H1 and H3 are supported, a mediation effect is theoretically feasible. The Sobel-test statistic for H4 is 119.5 exceeding the ±1.96 cutoff at p<.01 (two-tailed) (Sobel, 1982).

Figure 2: Research Model Results

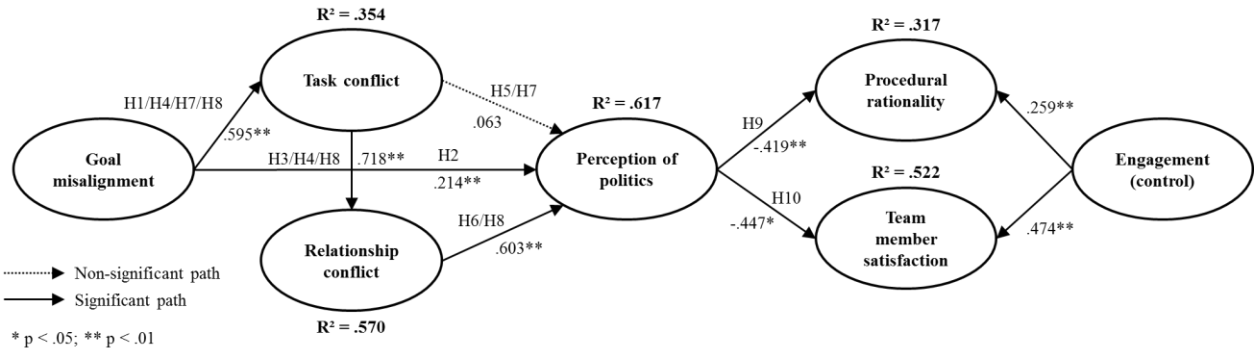

Table 4: Path Coefficients and Total Effects

Substantive relations	Path coeff. (stdev)	Total effect (stdev)	Hypothesis
Goal misalignment →Task conflict	.595 (0.045)**	.595 (0.045)**	H1 (accept)
Goal misalignment →POP	.214 (0.047)**	.509 (0.048)**	H2 (accept)
Task conflict →Relationship conflict	.718 (0.041)**	.718 (0.041)**	H3 (accept)
Task conflict →POP	.063 (0.064)	.063 (0.064)	H5 (reject)
Relationship conflict →POP	.603 (0.064)**	.603 (0.064)**	H6 (accept)
POP →Procedural rationality	-.419 (0.058)**	-.419 (0.058)**	H9 (accept)
POP →Team member satisfaction	-.447 (0.061)**	-.447 (0.061)**	H10 (accept)
Mediation	Specific indirect effect		
GM → TC → RC	.427 (.046)**	-	H4 (accept)
GM → TC → POP	.037 (.041)	-	H7 (reject)
GM → TC → RC → POP	.258 (.036)**	-	H8 (accept)

p-Values calculated using bootstrapping method; * p < 0.05; ** p <.01

Additionally, we tested for mediation using bootstrapping. Supporting H4, we found an indirect effect of goal misalignment through task conflict on relationship conflict of .427 at p<.01 (Table 4). Since task conflict does not show a direct effect on POP (β=.063, p=.35), we reject H5. Relationship conflict, however, does show the hypothesized positive effect on POP (β=.603, p<.01) to support H6. H7 found no support because a necessary link between parts of the mediation model was not found significant (H5). Moreover, Preacher and Hayes (2008) recommend using bootstrapping to assess multiple mediation. The specific indirect effect of goal

misalignment through both types of conflict (β=.258) was found significant at p<.01, supporting H8 (see Table 4 bottom). Finally, we tested whether POP affects procedural rationality and satisfaction and found support for its detrimental effect on rationality (β=-.419, p<.01) and on team members satisfaction (β=-.447, p<.01). Hence, we accepted H9 and H10.

Discussion

Theoretical implications and future research

While our results indicate a single mediation path from goal misalignment to POP apparently sourcing teams perceive politics when functional representatives need to use politics to overcome relationship conflicts (H5, H6).Only relationship conflict serves as sufficient trigger for representatives to give up rational negotiation and engage in political influence tactics that cause POP (H6). Task conflict does not drive POP, which indicates that managers do not need to counter-act task conflict in sourcing teams, which can even have positive effects (De Wit et al., 2012). In this study, task conflict does not show its rationalizing effect, possibly because participants were either way focused on discussing the provided data during the experiment. This could or could not be a limitation of this research given that task conflict's effect are highly context specific (De Wit et al., 2012). Future research could substantiate the merits or danger of task conflict in sourcing teams.

Second, this study observes the inter-relation of conflict and politics in teams. Extant studies have taken the perspective of politics causing conflict but treated goals and politics as aggregate: "Teams of this [political] sort usually have low goal compatibility as everyone in the team pursues different goals. According to the structural perspective, competition and conflict arises" (Bai et al., 2016). We have disentangled the relation of goals, conflict, and politics in this study. Future research could dive deeper into the mutual relation of conflict and politics and include the actor-based political behavior perspective (Allen et al., 1979) to test a circular relationship between conflict and the two dimensions of politics, POP and political behavior. Assessing coalition formation, lobbying, control of agendas, and strategic use of information is certainly a methodological challenge (Eisenhardt and Zbaracki, 1992), but can be expected to unveil potential counter measures to prevent negative effects on sourcing team effectiveness.

The final main theoretical implication of this research is that we have identified a chain of problems in cross-functional teams building on earlier collection of success factors and possible pitfalls (Moses and Åhlström, 2008; Trent and Monczka, 1994). The identified complex mediation path mirrors OBB in that it shows a complex process of sequentially emerging problems in a multi-person and multi-perspective team (Webster Jr and Wind, 1972). Future research's task is to trace the right point in time to intervene. Longitudinal research may be able to more closely track the emergence of conflict, politics, or other behavioral challenges in sourcing teams and observe shifts from functional to dysfunctional effects. Here we would like to stress that task conflict has proven to have positive effects in other research contexts (De Wit et al., 2012). Hence, we advise future research to substantiate our outcomes for other cross-functional sourcing team settings. An inductive finding of this research remains that the double-mediated 'goal misalignment-POP link' (H8) could be extended to both procedural rationality (-.108, p<.01) and team member satisfaction (-.115, p<0.01). Despite the complexity of the mediation path, they account for 50.7% and 50.4% of the total effect, respectively. Task conflict might be a leverage point to team value creation either causing relationship conflict and subsequent problems (H8) or inhibiting negative consequences.

Managerial implications

Our study reminds managers that cross-functional sourcing team processes are charged with behavioral challenges that analytical decision tools cannot overcome or manage. We show how misaligned goals subsequently lead to conflict and politics in sourcing teams to finally reduce the rationality of decision outcomes and overall decision performance (Riedl et al., 2013). Similar to organizational buying overall (Sheth, 1973), problems in sourcing teams emerge in a step-wise escalation process: misaligned goals lead to conflicts, which lead to politics and further negative outcomes. Goals and incentive structures are hard to change and should not even be aligned in case they support procedural rationality. Research has supported that task conflict (i.e., controversial discussion about the task) has rationalizing effects for decision outcomes (De Wit et al., 2012). Our results indicate that if managers and team leaders achieve to reduce emotionality in conflict situations, not only detrimental relationship conflict but also politics and further negative performance implications such as low rationality and satisfaction will not manifest.

Conclusion

In responding to the initial research questions, we found that misaligned goals create task conflict and that task conflict subsequently drives emotional relationship conflict in sourcing teams. Our main contribution is evidence for two extensions of this mediation. Relationship conflict further leads to perceptions of politics, which in turn reduces team member satisfaction and procedural rationality along with the overall performance of the sourcing decision (Riedl et al., 2013). Hence, this study has shown that problems in cross-functional sourcing teams emerge as step-wise escalation process, in accordance with the procedural perspective taken in OBB theory. We hope to motivate future research to investigate sourcing teams in general and particularly team conflict, team politics, their mutual relation, and suitable mitigation strategies to avoid negative outcomes while making use of the positive aspects of cross-functional integration (De Wit et al., 2012; Stanczyk et al., 2015).

Abstract
Many firms are exposed to price volatility from commodity purchases, which poses a financial risk to their firms. We investigate how organizations acquire, analyze, and disseminate information when assessing commodity price risk from an Information Processing Theory (IPT) perspective. The results of 12 case studies with companies in Germany, Italy, and the U.S. show varied approaches for acquiring, integrating, distributing, and creating shared meaning. Market indices, external service providers, informal discussions, and formal market research are primary sources of commodity price volatility information when assessing price risk exposure, and is a key precursor for mitigating this form of risk.

Key Words: commodity risk assessment, information processing

1. Introduction

For organizations purchasing raw materials, energy products or components with a high level of raw material content, uncertainty in commodity prices is a serious challenge. Prices for commodities, such as agricultural crops, crude oil, and metals are driven by the market's perceptions of underlying factors influencing supply and demand, and thus are constantly changing. Managers must make decisions about product innovation and design, purchase timing and quantities, budgeting, pricing, and risk mitigation strategies without knowing exactly what commodity prices will be in the future. As highlighted by Matook *et al.* (2009), the entire commodity portfolio should be managed using a risk management process. Further, in most cases, actions by individual organizations within the market structure will not influence

prices. Thus, supply chain managers must develop strategies for mitigating their organization's exposure to price risk (Gaudenzi *et al*., 2017; Zsidisin and Hartley, 2012).

Commodity price risk has been ranked as one of the top 10 risks faced by organizations (BDO, 2016; World Economic Forum, 2015; Deloitte University Press, 2015; Dobbs *et al*., 2013). Commodity price risk has a significant impact on an organization's short-term and long-term financial performance, for example the cash-to-cash cycle, value of purchases, and value of inventories (Rampini *et al*., 2014; Arezki *et al*., 2014; Kalari and Power, 2013; Jacks *et al*., 2009). Commodity prices may also be related to economic-political decisions, such as in the case of fuel trade and price strategies (Davarzani *et al*., 2015), and to stock prices (Gaudenzi and Bucciol, 2016; Wen *et al*., 2014; Bandaly *et al*., 2013; Creti *et al*., 2013; Vivian and Whoar, 2012; Henriques and Sadorsky, 2011). However, empirical investigations on the commodity price risk assessment process from a supply chain perspective are limited (Fischl *et al*., 2014).

Our research aims to address this gap in the literature by investigating how organizations acquire, analyze, and disseminate information when assessing commodity price risk, the important first step in the process for mitigating commodity price risk. Using case studies, we examine how manufacturing companies in different industries assess commodity price risk for their direct purchases and those made by first tier suppliers. We identify factors that may explain the choice of assessment approaches and suggest effective practices, using information processing as the theoretical lens (Wiengarten *et al*., 2017; Tazelaar and Snijders, 2012; Tushman and Nadler, 1978; Galbraith, 1973, 1974). Risk assessment is a process that involves gathering, analyzing, and using information to determine the probability of a risk occurring and its effect on the organization (Zsidisin *et al*., 2004; Harland *et al*, 2003). Although several studies have examined various types of supply chain risk management processes from an information processing perspective (Fan *et al*., 2017; Fan *et al*., 2016; Kauppi *et al*., 2016; Bode *et al*., 2011; Hult *et al*., 2004), the process used to *assess* supply chain risk, and commodity price risk in particular, has received scant attention. The majority of previous studies highlight the importance of information processing, focusing on disruption risk or supply chain risk as a whole (Revilla and Saenz, 2017). However, we are not aware of any studies exploring how the assessment process is developed, or studies specifically analyzing commodity price risk assessment processes. Our results contribute to theory and practice by providing guidance on how firms assess commodity price risk.

The next section provides a background of commodity price risk, and Information Processing Theory (IPT) is then discussed within the context of supply chain risk management research. We describe the grounded-theory approach (Pinnington *et al*., 2016; Denk *et al*., 2012; Manuj and Pohlen, 2012; Strauss and Corbin, 1998; Strauss, 1987) used to gather and analyze data from case studies of 12 manufacturing companies located in United States, Italy, and Germany. Results and managerial implications are described. Conclusions, limitations and opportunities for future research are then provided.

2. Information processing theory and commodity price risk assessment

Commodity price risk management is a process that requires assessing price risk and then deciding which are the most effective and efficient mitigation strategies for assuring a good mix of risk control and risk financing (ISO Guide 31.000, 2009; Faisal *et al*., 2007). Information processing is needed to address uncertainty and equivocality and facilitate organizational decision-making (Wiengarten *et al*., 2017; Daft and Lengel, 1986; Tushman and Nadler, 1978; Galbraith, 1973) when assessing commodity price risk. An organization's

information processing capabilities should fit with its information processing needs (Daft and Lengel, 1986; Tushman and Nadler, 1978), playing a potential moderating role in the complexity-performance relationship (Wiengarten *et al*., 2017). Information processing theory suggests as uncertainty increases, organizations must develop the capability to process more information or reduce the need for information through the use of slack resources, with the fit between information processing capability and processing needs affecting performance (Tushman and Nadler, 1978; Galbraith, 1974).

Empirical studies have applied IPT to the management of supply chain risk (Kauppi *et al*., 2016; Fan *et al*., 2017; Fan *et al*., 2016; Bode *et al*., 2011). Bode *et al*. (2011) suggest that firms gather and process information to determine if and how to respond to supply chain disruptions but do not examine assessment approaches in their study. Kauppi *et al*. (2016) suggest that customer and supplier integration increases information processing capabilities and find higher levels of integration are related to greater use of risk management practices which encompass prevention, dectection, response, and recovery. Revilla and Saenz (2017) highlight the need to share risk information externally with other supply chain partners. Fan *et al*. (2016) find the positive relationship between information sharing in the supply chain and information analysis with operational performance is enhanced when products are customized, or when there is technological or market turblence. Risk information sharing and risk assessment are both positively related to risk sharing in the supply chain (Fan *et al*., 2017). Thus, although research suggests information processing is essential for risk assessment, the process used to assess commodity price volatility and risk has not be explored. Therefore, in this research, we examine the processes supply chain managers use to assess commodity price risk. IPT suggests that companies facing greater uncertainty, for example the highly servitized firms (Benedettini *et al*., 2015) and those where commodity purchases account for a large percentage of purchases or purchases commodities in which market data are not readily available would need to develop more information processing capabilities (Fan *et al*., 2017).

Researchers have conceptualized information processing steps in different ways. Tushman and Nadler (1978) conceptualize information processing as involving the steps of gathering, interpreting, and synthezing information. Gathering involves collecting relevant information, interpreting involves assigning importance and significance to information, and synthezing involves understanding the relationships among elements (Turner and Makhija, 2012). In a final step, to support decision-making, information must be shared within the organization (Tushman and Nadler, 1978). Daft and Weick (1984) suggest that organizations gather data, interprete the data, and then take action. Building upon organizational learning (Huber 1991), Hult *et al*. (2004) conceptualize information processing to develop knowledge in a supply chain context as consisting of knowledge acquisition, information distribution, and shared meaning. Further, Huber (1991) states developing a common understanding about data results in the development of shared meaning. Information processing theory has been also applied to the management of complexity and uncertainty in supply chain networks (Wiengarten *et al*., 2017; Li *et al*., 2014).

In a supply chain risk management context, researchers have not adopted a consistent model of information processing for risk assessment. For example, Fan *et al*., 2017 conceptualize three steps in the process, risk information sharing, risk analysis and assessment. Several studies use two steps for information processing during risk assessment, information gathering and information dissemination (Fugate *et al*., 2009; Carr and Lopez, 2007; Hult *et al*., 2004; Conduit and Mavondo, 2001). Khan and Burnes (2007) distinguished the phases of collecting, processing and applying supply chain risk information. In this research, we examine

information processing for commodity price risk assessment, applying the steps proposed by Hult *et al*. (2004) of 1) acquiring information, 2) interpreting information, 3) distributing information and 4) creating shared meaning.

3. Methodology

The research methodology consists of gathering and analyzing qualitative data from 12 firms headquartered in the United States, Italy, and Germany. We used a grounded theory approach (Strauss and Corbin, 1998; Strauss, 1987) to gain an in-depth understanding of the risk assessment process for commodity price risk, to apply and expand upon on existing theories about commodity price risk mitigation strategies (Zsidisin and Hartley, 2012), and to build new theories about those factors influencing the risk assessment. The methodology was designed to meet the grounded theory criteria of fit, understanding, generality and control (Strauss and Corbin, 1998; Strauss, 1987). The initial idea to study commodity price risk assessment was developed based on a review of the supply chain risk management literature helping to ensure the findings fit with the substantive area of risk assessment. Further, respondents participated in providing data through interviews, reviewed the interview transcripts, and subsequently received a report of the study's findings helping to facilitate fit and understanding. To ensure generality, the semi-structured interviews lasted one hour or more and thus were long enough to ensure that respondents could provide their own diverse perspectives.

3.1 Sample and Interview Process

In this study, qualitative data were gathered from interviews with supply management and risk management professionals in 12 firms headquartered in the United States, Italy, and Germany using a grounded theory approach (Strauss and Corbin, 1998; Strauss, 1987). The sample (Table 1) was selected so differences in headquarters country, organizational size, industry and the variety of commodities purchased could be examined (Flyvbjerg, 2006). The companies were assured of anonymity and thus their actual names are not used. The sample includes five larger companies, with revenues of ten billion $/€ or more, five medium-sized companies (revenues more than one and less than ten billion $/€) and two smaller companies whose revenues are less than one billion $/€. Companies operate in the chemical, packaging, transportation, aerospace, equipment manufacturing, and food industries. A wide range of commodities were explored including wheat, coffee, cocoa, steel, aluminum, polyethylene, wood fiber, and rubber.

Table 1. Case study firm and commodity characteristics

Country	Code	Industry	Firm size*	Commodities Investigated	Commodity Characteristics
U.S.	INTG	Integrating manufacturer	Medium	Plywood, Oriented Strand Board (OSB), Steel	More than 65% of purchases is on price volatile commodities
	EQUIP	Equipment manufacturer	Large	Steel, rubber, Styrene-Butadiene Rubber (SBR: an oil derived product)	Steel accounts for approximately 25 % of total purchases
	PACK	Plastic Components	Medium	Polypropylene	About 70 % of overall spend is for polypropylene
	VEICL	Commercial vehicles	Medium	Steel, aluminum	Aluminum and steel account for a large part of total purchases
	CONS	Food Production	Large	Corn, wheat, soybeans, vegetables	Price-volatile commodities account for 50 % of the overall spend
Italy	PASTA	Food production	Medium	Common wheat and durum wheat	The cost of these commodities accounts for 45% of the cost of costs of goods sold
	FLY	Aerospace	Medium	Carbon fiber, aluminum, titanium	14% of overall spend is on key commodities
	CHEM	Chemical	Small	Ethylene, Propylene (oil derived products)	85% of overall spend is on these two commodities
Germany	CAR	Automotive	Large	Steel	20% of overall spend is on commodities, with half being steel
	CHOC	Food Production	Small	Chocolate/cocoa	20% of the overall spend is on these commodities
	ELEC	Electronics	Large	Steel	The purchasing spend is 50 % of total sales
	COFF	Food Production	Large	Coffee	Commodities are the most volatile part of costs of goods sold

*Large firms have revenues exceeding 10 billion $/€; medium firms have revenues between 1 and 10 billion $/€, small firms have revenues under 1 billion $/€.

A structured interview format was used to gather data. Open-ended questions (available upon request) were developed to examine types of purchases, risk assessment and price risk mitigation strategies. Data were gathered in face to face or phone/videoconferencing interviews which lasted about one hour each. The interview questions were shared with each respondent prior to the interview.

In each company, after gaining agreement to participate, the first step was to conduct an interview with the Chief Purchasing Officer (CPO) or Director-level or above supply management professional. As part of the interview, these respondents were asked to identify one or two knowledgeable key informants who were responsible for managing price risk for direct purchases (e.g., raw materials) or for other commodities purchased in their value chains from suppliers or other parties. The interviews were audio recorded and transcribed. Participants reviewed the transcripts and minor changes were made by four individuals (Rubin and Rubin, 2011). A report summarizing the findings was shared with all participants. We also gathered secondary information about each company before and after the interviews which provided context for the responses (Miles *et al*., 2014).

3.2 Data Analysis

The unit of analysis is the firm's methodology for assessing commodity price risk and developing price forecasts. Following the approach by Strauss and Corbin (1998), data were open coded by the researchers to confirm that the IPT processing steps 1) acquiring information, 2) interpreting information, 3) distributing information, and 4) creating shared meaning were the appropriate categories. This was followed by axial coding, grouping codes into broader, more inclusive codes (Margolis and Molinsky, 2008; Isabella, 1990). The process allowed us to identify risk assessment components and potential causal relationships. The coded interview protocols were regularly triangulated among the group of researchers to ensure inter-rater reliability (Armstrong *et al*., 1997) and there was an initial inter-coder reliability rate of 90%. The researchers discussed and resolved differences in application and interpretation of coding. In the next step, selective coding, we identified dominant themes that emerged from the data.

4. Findings

The research findings of how firms assess commodity price risk are organized along the four steps of 1) acquiring information, 2) interpreting information, 3) distributing information, and 4) creating shared meaning. A summary of evidence in each of these areas is summarized in Table 2.

Table 2. Summary of Findings

Code	Standardized Process	Acquiring Information	Interpreting Information	Distributing Information	Creating Shared Meaning	Primary Risk Mitigation Strategy
PASTA	Yes	Market indices Supply market research gathered by buyers all over the world Informal discussions with suppliers	Value at Risk Monte Carlo simulation	Internally within supply management Externally with suppliers	Determine sourcing regions Input into budgets Length and amount of financial hedging	Financial hedging
FLY	No	Market Indices External service providers	Managerial judgement	Internally within supply management Externally with suppliers and customers	Input into budgets Timing of supplier negotiations and length of contracts	Contractual agreements with customers
CHEM	No	Market indices Informal discussions with customers and suppliers around the world	Managerial judgement	Internally within supply management Cross-functional with business unit	Determine sourcing regions Determine amount of spot buys versus contract coverage	Adjusting volume under contract versus spot buys
CAR	Yes	Market indices External service providers Informal discussion with suppliers General market trends	Managerial judgement	Internally with supply management Internally with cross functional executive board	Input into budgets Long term planning	Contracts with prices tied to indices with suppliers
CHOC	No	Market indices Informal discussions with suppliers General market conditions	Quantitative pricing simulations Managerial judgement	Internally within supply management Externally with suppliers	Input into budgets Financial hedging	Financial hedging
ELEC	Yes	Market indices Formal, in-depth supply market research	Quantitative pricing model Managerial judgement	Internally within supply management and with finance	Input into budgets Timing of supplier negotiations and length of contracts	Financial hedging

		Informal discussions with suppliers				
COFF	Yes	Market indices Supply market research gathered by buyers all over the world	Managerial judgement	Internally within supply management Cross-functional with business unit and finance	Length and amount of financial hedges	Financial hedging
INTG	No	Market indices External service provider General market conditions	Managerial judgement	Internally within supply management Externally with suppliers	Contract length and timing	Contract timing and length with suppliers
EQUIP	No	Market indices Market service providers Industry conferences	Managerial judgement	Internally within supply management and with finance	Input into budget Determine contract escalation	Contracts with escalator clauses with suppliers
PACK	No	Market indices Informal discussions with suppliers	Managerial judgement	Internally with executive team Externally with customers	Input into budgets Modeling to determine pass-through prices to customers	Contracts with prices tied to indices with customers
VEICL	No	Market indices Informal discussions with suppliers	Managerial judgement	Internally within supply management	Input into budget Cost and margin analysis Determine contract escalation	Contracts with escalator clauses with suppliers
CONS	Yes	Market indices Formal in-depth supply market analysis	Fundamental analysis and econometric models	Internally within supply management Senior level executive team Externally with customers and suppliers	Length of financial position and types of trades	Financial hedging

The evidence suggests four of the companies in the study have standardized processes for assessing commodity price risk. With the exception of EQUIP, evidence suggests that standardized processes are used for commodity risk assessment by the larger companies in the study. Two of the larger companies, ELEC and CON have an established centralized supply market research group responsible for gathering and analyzing supply market data. In both of these cases, spend on commodities is 50% or more of the company's overall spend. PASTA, a medium sized company, whose commmodity purchases account for 45% of its costs, also uses a standard assessment process. However, rather than creating a centralized process, it uses a team of globally dispersed buyers to gather price risk information. The process at COFF, which did not disclose its spend ratios, is also standardized.

4.1 Acquiring Information

All the companies in our study monitor external data sources with respect to the key commodities they directly purchase. However, the level of aggregation and data sources, which include published market indices, external service providers, broad economic and market data, and informal discussions with suppliers and customers, differ by company. To assess commodtiy prices, all the companies monitor commodity prices reported by market indices relevant to their commodities on commodity exchanges such as NYMEX, LME, ICE, and CME or industry indices such as American Metal Market and ICIS (chemicals). Three companies (CAR, FLY, and INTG) report using supply market intelligence services such as IHS Global Insight and the Commodity Research Unit (CRU) to forecast prices. The supply executive of CAR explained why they used external sources rather than developing commodity forecasts internally:

> *"We rely on the data coming from service providers and (…) consolidate the forecasts of various banks e.g. and use the average for each commodity. Of course, we would have people who are capable of creating such a forecast, but they do also not have the magical crystal ball and therefore we do not spend additional energy and money to create forecast."*

However, some organizations noted that in specific sectors the data provided by these service providers may not always be accurate. This is the case of FLY, for some certified high-quality materials for avionics, or in some emergent countries. The supply manager of EQUIP for example explained:

> *"I do use some forecast services ... You can pay a lot of money to companies that will forecast crude oil for instance or even natural rubber you can buy forecasts. I've done most of my own. I've found that some of the services that we use - and the volatility that we see in the raw materials markets – the services haven't been very good."*

Seven of the companies in the study use informal discussions with suppliers to gather information to assess commodity prices: PASTA, CHEM, CAR, CHOC, ELEC, PACK, and VEICL. PACK, for example, collects and integrates information from a variety of primarily resin suppliers and incorporates this with market price data.

The CPO of CHOC explained how they use information provided by suppliers:

"They (suppliers) know the markets very well. But we never rely on the opinion of a single supplier, we take the views of all suppliers. Further, we use neutral sources. All that plus our own feeling for the markets goes into our strategy process."

VEICL relies on suppliers for information about the steel market but does not use them as a source of information about aluminum. The commodity manager of VEICL explained:

"We look for trends, look to see if there's anything we can apply. Most of the time we do try to just factor in for some percentage increase, just so that we have that forecast for material increases in our budget."

For some companies, such as INTG and COFF, collecting data about steel requires going beyond the first tier in the supply chain. This is the case of INTG, because the price for steel is influenced by what is occurring at the mills with regard to lead times, due to longer lead times serving as an early warning indicator prices may be increasing. COFF also moves beyond its first tier suppliers, collecting information from local coffee traders in the countries from which it buys coffee.

Three companies in the study (PASTA, CONS, and ELEC) acquire primary data using specialized commodity research teams and develop their own price forecasts. PASTA has buyers located in supply markets across the globe to gather data on durum wheat production and uses suppliers as a primary source of price risk information. CONS's buyers work with suppliers to understand market availability and pricing of the fresh commodity raw materials to develop these forecasts. These raw materials are not traded in exchanges so market prices are not accessible.

The direct purchases commodity manager of PASTA said:

"The market of durum wheat is complex, and we need a strong market intelligence. For this reason, we have buyers that operate all over the world in order to know what's going on in those areas and to define which is the best strategy for our needs."

The executive of ELEC said:

"Our purchasing colleagues are clearly closer to the market. The HQ-analysts deliver valuable information but in bilateral talks with the suppliers, you learn more than what you can read from the reports – the general sentiment, patterns you have seen before in this market or elsewhere in the business."

4.2 Interpreting Information

After acquiring information, data must be analyzed and processed in order to make good decisions based on data (Daft and Weick, 1984). Four of the companies, PASTA, CHOC, ELEC, and CONS develop quantitative forecasting models or simulations to assess commodity price risk using financial hedging as their primary risk mitigation approach. The only other company in the study that primarily uses financial hedging, COFF, does not use quantitative approaches for risk assessment.

PASTA has developed a price risk assessment model that is based on Monte Carlo simulation and a Value at Risk (VaR) model, integrated with an internally developed price forecasting model, statistically correlating volumes, quality, demand and stock variables within four different "budget

times." In addition, CONS's buyers develop for each major commodity a "play-book" based on the information and forecasts provided by the procurement group. These documents describe the buyer's risk assessment and mitigation strategy and are constantly updated, supporting daily communication between buyers and CONS's procurement group analysts.

The executive of ELEC stated:

> *"The individual commodity manager is responsible to gather further information for the relevant markets – that is prices but also information on individual companies. We call the result of that exercise a material group strategy."*

Interpreting information can be complex because some commodities, such as certain agricultural commodities or metals, are interlinked with each other in terms of price variations. This presents a significant level of complexity due to different factors, such as interactions with currency rate valuations, relationships with different materials and financial speculation. For example, CHOC and FLY have experienced this combination of commodity and currency risk.

Similarly, the supply manager of CONS said:

> *"In the bigger corn, wheat, soybeans, they're very interconnected and so that we know one drives another. And they're also very big exposure items for us. So we spend a lot more time and create very similar (forecast) analysis weekly or monthly about all of those."*

The CEO of CHEM also declared that fluctuations of currencies in international markets often absorb the price variations of raw materials. Many commodities are related to other raw materials in the value chain. This is the case we found in our analysis with steel (with coke and iron ore), alloy (with manganese and chrome), and propylene and ethylene (with crude oil).

Most of the companies predominately use managerial judgment to assess price risk as is the case in CHEM, COFF, INTG, EQUIP, PACK, and VEICL. When using judgement, respondents highlighted how experience is relevant when analyzing data. Dane and Pratt (2007) describe how intuition can influence judgments and their applications to managerial decision making. The results are consistent with this line of research showing the more knowledge chain members possess increases information acquisition, and the greater their awareness, in conjunction with good information processing and experience, can ultimately enhance supply chain outcomes (Hult *et al*., 2004). As Hult *et al.* (2004) states: "Members of chains that possess significant memory are aware that knowledge coordination across nodes reduces duplication, waste, and redundancy". The CEO of CHEM highlighted:

> *"We listen at what markets and suppliers say to make an analysis and to elaborate internally our strategy … but these are primarily sensations. In fact, to take good decisions we need experience."*

The supply manager of INTG said:

> *"We're doing pretty good, outguessing where the market's going. And it just comes from – I don't know – years of experience and just talking to a lot of people and just kind of taking a lot of things into account."*

Besides the use of qualitative or quantitative tools for information analysis, many respondents (PASTA, CHEM, CAR, CHOC, ELEC, INTG, PACK, CONS) adopted the word "feeling" to explain the role and effectiveness of an intuitive information processing approach (Carter *et al*., 2017; Dane and Pratt, 2007). The direct purchases director of PASTA – for example – highlighted that experience is essential to understand all the influencing factors that lead to commodity price fluctuations. For example, buyers know that the quality of the harvest, in each region, will differently influence durum wheat price dynamics.

The executive of ELEC said:

> *"The key ingredient for our perfect meal is experience or intuition. It is not one or the other, both come together and help us form an opinion."*

The level of experience increases time by time, leading to better forecasts, as explained by the purchasing director of INTG:

> *"So we're going to continually do it a better and better, more refined job at understanding what that is but also forecasting it. So I just think we're going to increase our level of sophistication in forecasting some of those key raw materials."*

Only two of our study participants, FLY and CAR, do not analyze data in the forecasting process. FLY, in fact, relies upon service providers and key players in the supply chain (large scale assemblers) for price forecasts. CAR internally collects all the data about price dynamics, particularly regarding physical supply dynamics and needs for demand reduction. Then the company requires that its suppliers report on the role and importance of each raw material group, with external service providers interpreting the data.

4.3 Distributing Information

Information about price risk can be distributed internally within the organization and externally with suppliers and customers. Consistent with previous research, all of the managers in our study regularly discuss trends and price risk within internal functions through interdepartmental meetings (Jaworski and Kohli, 1993). In the purchasing function of PASTA managers explained the information sharing across purchasing managers of different geographical areas:

> *"We usually have weekly meetings, all together, also involving the area managers of Italy, Europe and the rest of the world. We meet every week to discuss about the (price) situation in the market, and to take decisions."*

In CONS, the commodity manager highlighted the role of internal functions and meetings:

> *"we are asked to provide a long-range kind of plan or forecast to our businesses in terms of what we view to be inflation. And typically, that is done internally, around fiscal year."*

ELEC and COFF also share commodity price information with finance. The key role of Finance in cross-functional meetings is described by the commodity manager of COFF:

"For every BU, we have a monthly commodity review. This is when the commodity group presents their fundamental analysis for each commodity and gives a recommendation for coverage. On the other side of the table you have the BU, CPO, CFO and the people who actually do the negotiations and contracting. But those meetings are largely dominated by finance, as finance knows best the marginal risk and the price risk."

Also, the purchasing director of INTG said:

"There's lots of opportunities in all procurement organizations to be much more sophisticated from a financial assessment, whether it's breaking down a supplier's cost to developing forecasts to whatever it may be. I just think there's some real opportunities there."

Further, an executive in ELEC explained:

"Our Supply Market Intelligence model is really good. A key thing is that all the buyers and other colleagues (e.g. from finance), they all use the same figures. This brings consistency or alignment and more fact-based discussions. So this consistency helps us making decisions faster. By the way, we share the indicators and forecasts with our buyers and with the businesses, but not with our suppliers."

CAR, COFF and CONS typically form internal, cross-functional teams composed of procurement managers, buyers, chief procurement officers, and sometime financial officers. In those cases where results are shared within larger cross-functional groups, involving parties such as research-and-development (R&D) officers, sales managers, and operations managers, interviewers state their capability to make good forecasts represents a competitive advantage.

However, only some of the case study participants share forecasts with suppliers, such as in the food (PASTA, CHOC, INTG and CONS), manufacturing (EQUIP) and aerospace industry (FLY) in our study, where companies share their information with suppliers for validation and as part of the negotiation process for purchasing contracts.

In CONS, the Vice President of World Wide Sourcing explained:

"Those cost estimates will be shared with our customers and the divisions so that they can build their margin forecasts and manage their margins going forward. (…) – (about suppliers): we will discuss, because I mean really over time, it is our desire to have a win-win relationships."

Similarly, the supply manager of EQUIP said:

"(we share our forecasts and) they share with us their view of the market – what they are hearing from other OEM's and it is very collaborative environment. We have done that – we get a lot of positive feedback from companies because we share pretty openly and transparently how we plan our business so that they can plan their capacities."

A win-win strategy is also presented by the supply manager of INTG:

"we've done is if it's a money-saving idea and we share those savings with the supplier. So it's kind of a win-win for both parties."

Most direct and second-tier suppliers regularly run their own forecasts, which increases the general level of knowledge and quality of the bilateral talks, resulting in more competitive negotiations.

The Direct purchases manager and the CEO of CHEM highlighted that they don't share forecasts with suppliers, but:

"It is very difficult to share an (effective) forecasting model, we need to talk to the customers and suppliers around the world, listening to the big players, important managers that know very well the market, so there are not techniques, it's a feeling.

From a different perspective, CAR's raw materials manager linked a good analysis of raw material price, and cost transparency, to a (better) control of supplier relationships:

"It was all about transparency: Which price risks do we have then? Where can we use indexes? All these things helped us to get the supplier relationships back under control. We have isolated the price volatility from the normal purchasing negotiations, the supplier negotiations, the price negotiations. We have annual price negotiations that focus again and more or less only on the value creation of the supplier, the ratio potential, streamlining the production processes."

In the value chain, the visibility at the second-tier level is even more limited. The commodity manager of non-ferrous commodities in ELEC explained:

"Today, steel prices or rather the cost structures of steel are largely intransparent. But the grey zone is not 40%, no, we can pretty reliably calculate 80% of their costs, we are not totally blind."

Sharing information with customers was not discussed in the study with the exception of FLY, PACK and, partially, CONS in the case where commodity prices were passed through to the customer as part of the contract.

4.4 Creating Shared Meaning

According to Huber's (1991) definition of shared meaning, companies in our study develop a shared understanding of the available information and implications of commodity price dynamics to provide input into the budgeting process, to make sourcing decisions, to determine contract length and timing, to decide upon the amount for spot buys, and to determine hedging strategies. The results from the risk assessment process are used to derive a comprehensive purchasing strategy and for budgeting purposes. To develop a shared meaning, reconciliation frequently involves intense discussions between modelers, commodity buyers, and other officers to ultimately create a better decision-making process and ideally a better result.

For example, the purchasing director at FLY stated:

"Our goal is to respect our forecast, the budget."

The CPO of CHOC confirmed that the price risk assessment is primarily used to define the budget, and added:

"….We have a (price) risk related to the market. But once we have made our budget, we have a second risk – the risk relative to our budget! (…) How do we measure our success? Relative to our budget."

For the VEICL's commodity manager the understanding of commodity price risk dynamics is related to a cost and margin analysis:

"The base price is set through cost breakdown. We would break down the actual total cost by raw material and then the conversion and then margins and then logistics and all of that. So in order to start the process, we need to know the "cost confidence" of the product."

Also, the purchasing director of PACK linked the risk forecast to issues related to cost and budget, but adopted the extended perspective of big retailers downstream in the supply chain, saying:

"So they (big retailers) really need to understand what their cost exposure is for the year so that they can make their budget assumptions."

In CAR, the supply executive highlighted their cost-transparency orientation:

"Our focus in on cost transparency. We have hundreds of cost engineers who calculate our products. This approach of transparency in terms of the value added absolutely requires that you challenge all objectively measurable cost positions of your raw materials."

For a supply management executive at ELEC, shared understanding of price risk should primarily lead to fast decisions:

"The greatest challenge for our company when managing price risk? Being fast. Why, time is money. It is really that simple."

Time is also a key-measure for COFF, since a commodity manager stated:

"We know the delay between the time when the commodity price changes and when we can change our prices: it is nine weeks – that is what you always have to cover."

The focus on costs, from a supply chain perspective, is explained by the commodity manager of CONS:

"They (suppliers) have to share with us what the raw product cost consideration is and for – in the example I used – tomatoes – it is pretty easy because it is very transparent not only to us but to the whole industry."

At the same time, the supply chain manager of CONS takes a supply chain wide perspective by saying:

> *"We use them (forecasts) to communicate kind of exposure to the market for places that we are not hedged and what the risk and opportunity could look like in those future years. And for places that we are hedged, we use that as a benchmark to say we're favorable versus the market or unfavorable versus the market."*

5. Discussion and managerial implications

For all the organizations in our study external information acquisition is the key step in the risk assessment process, because it influences the approaches adopted for information interpretation and distribution. However, there are key differences in the type of information, which affect information interpretation and distribution. Three of the organizations (PASTA, CONS, and ELEC) have the most sophisticated information processing processes for assessing commodity price risk. They have standardized processes and gather large amounts of primary data on supply and demand and then internally analyze these data to develop a forecast using quantitative tools. COFF and CHOC appear to have the next level of information processing capabilities. COFF uses a standardized process, gathers and processes primary data but uses managerial judgement for forecasting. Information processing is not standardized at CHOC, but primary data are gathered and quantitative pricing simulations are used along with managerial judgement to develop price forecasts. Both COFF and CHOC engage in financial hedging. CAR also uses a standardized process and gathers information from both primary and secondary sources but relies on managerial judgement for forecasting and does not engage in financial hedging. The remaining companies have capabilities to assess commodity price risk, but their processes are not standardized. In addition to market indices, the other companies use external service providers, informal discussions with customers and suppliers, or general market trends for information gathering, and then use managerial judgement to interpret risk information.

What factors drive PASTA, CONS, and ELEC to have more developed information processing of commodity data than other companies in the study? According to IPT, organizations which face greater consequences from exposure to the uncertainty from commodity price risk would be expected to increase their information processing capabilities to reduce uncertainty. We examined company size, spend, and choice of risk mitigation factors for potential relationships. Company size could be a factor because larger organizations will likely have more resources to invest in commodity price risk assessment. However, although two of the companies are large (CONS and ELEC), other large companies in the study do not have the same level of information processing capabilities.

For PASTA, CONS, and ELEC, price volatile commodities account for 45% or more of spend, suggesting effectively managing commodity price risk is an opportunity for cost savings. This may be especially important for PASTA, CONS, and CHOC, who are facing increasing competition in the low margin food industry. COFF is also in the food industry, although the nature of their products and strength of their brands many not expose them to as much margin pressure. However, at INTG, CHEM, and PACK the spend percentage on commodities is similar. Further, CHEM and PACK are in low margin businesses. Thus, having a large enough spend is

likely to be a necessary, but not sufficient criterion for driving the development of information processing capabilities.

The results suggest the complexity of the primary risk mitigation strategy used by the organization may also be a factor in the development of information processing capabilities. Companies use sourcing strategies (such as supplier switching or purchasing timing), contracting strategies (such as escalator clauses or passing price increases to customers), and financing strategies (Gaudenzi *et al*., 2017) to mitigate commodity price volatility. PASTA, CONS, and ELEC extensively use financial hedging to mitigate price risk. Financial hedging is a complex process that involves making decisions not only about the physical commodity but also about the timing, volume, and types of transactions of financial trades. Financial hedging likely increases uncertainty and the need for information processing as suggested by IPT (Tazelaar and Snijders, 2012; Tushman and Nadler, 1978; Galbraith, 1973, 1974). Thus, organizations that rely heavily on financial hedging to mitigate price risk may need to invest more to process information in assessing commodity price risk. Price risk information is essential for making hedging decisions. However, COFF, which also uses financial hedging, does not employ quantitative methods in their analyses. This may be in-part because there are significant differences in the types and flavors of the coffees in the different regions of the world where they source green coffee beans making the use of quantitative modeling more difficult. CHEM and PACK can pass cost increases or decreases on to the end consumers as part of their contractual agreements; thus they only need to know actual market prices or the agreed upon index. Their customers are exposed to the uncertainty from commodity price volatility.

Assessing commodity price risk is a complex task and interpretation typically is done by teams, rather than individuals. All companies in the study use a cross-functional approach to interpret information. During interpretation, teams carefully analyze relationships among different materials, financial speculation, and other external factors to decide upon risk mitigation strategies. From our findings we observed commodity price risk should include the input from multiple business functions, using cross-functional teams to incorporate numerous perspective and create a more holistic assessment for better guiding managerial decisions. However, our findings do not allow us to deeply understand which is the optimal design and extent of a cross-functional risk assessment process.

Our results suggest that when risk assessment is based on several inputs, sophisticated interpretation models, and is shared across different teams, it leads to better decisions but may also be time consuming. In parallel, several respondents highlighted how expert analysts and decision makers use their intuition for understanding complex connections among several decision variables, and getting faster decisions. This evidence suggests that past experience and intuition are capabilities that can make sophisticated risk assessment processes faster and more effective. Thus, the sense of urgency in making decisions based that would be affected by price volatility may affect the design of the assessment process.

The amount of knowledge, experience, and familiarity with risk assessment is defined by Hult *et al.* (2004) as "achieved memory". Similar to the findings of Dane and Pratt (2007) and Carter *et al*. (2017), several respondents (PASTA, CHEM, CAR, CHOC, ELEC, INTG, PACK, CONS) have long-term experience purchasing price volatile commodities, and use intuition when

interpreting information about risk. This experience seems to lead, in the perception of the respondents, to the capability for understanding complex connections among several decision variables, and hence resulting in faster and better decisions about risk mitigation strategies. In a supply chain context rational approaches and intuition can complement each other (Carter *et al*., 2017). For example, in supplier selection, the interaction between intuition and rational decision-making is positively related to supplier performance (Kaufman *et al*., 2017). Future research can explore roles and effectiveness of intuition and analytical approaches in assessing and mitigating supply chain risk.

When there is less visibility in a commodity market, for example, when market prices are not publicly available or trusted, companies depend upon suppliers and upstream supply chain members as sources of information (Roehrich *et al*, 2014). Thus, it is likely the supplier relationships are more important for information acquisition and interpretation for some commodities than for others. Even in markets when price data are visible, companies informally use suppliers as a source of price risk information. However, in our study we found only some companies share their price forecasts with their suppliers, suggesting that even though companies profess to have close supplier relationships, the lack of trust may still be a barrier to effectively assessing and mitigating commodity price risk.

Looking downstream in the supply chain, information sharing is rarely a reality. This may be a lack of trust with how price risk information would be used by customers. When contractual agreements with customers require price adjustments, assessment information is shared. For example, this occurs in the aerospace industry, where there are several cases of customer-driven risk assessment polices that have the goal of increasing the efficiency of supply chain risk mitigation strategies, particularly in terms of contracting strategies. CHEM and PACK also share actual price data with customers as part of contractual agreements, allowing them to pass price increases or decreases directly to customers.

6. Conclusions and future research directions

Commodity price risk is a reality in today's supply chains. Commodity price risk requires firms to first thoroughly assess their exposure to price volatility before determining if and what approaches should be considered for best mitigating this threat to profitability. Our study shows companies use different approaches for assessing commodity price risk and some organizations have more developed information processing capabilities than others. The key difference appears to be in the investment in internal resources to acquire and interpret information. Three companies, PASTA, CONS, and ELEC have the greatest information processing capabilities. This is likely influenced by the reliance on financial hedging as a risk mitigation strategy by these companies. The sense of urgency in making decisions may also influence the information interpretation process. When time is critical, organizations may depend upon experienced experts rather than teams for interpreting information. Trust of appears to influence information dissemination within the supply chain, especially with customers. However, additional empirical research, such as a survey, is needed to confirm the relationship of these factors with the commodity risk assessment information process.

There are several limitations with our research. The case study approach limits our ability to confirm relationships among the constructs. A large-scale survey would allow for relationships to be confirmed. In addition, future research could investigate the role of intuitive information process management and decision-making approaches compared with analytic, rational and formalized processing (Carter *et al*., 2017; Dane and Pratt, 2007). Another limitation of our research is that we did not explore the effectiveness of the different risk assessment approaches. Future research should focus on relating performance outcomes to the commodity price risk assessment process. Further, we focused only on one phase of the price risk management process. Future research should take a holistic view of all stages of risk assessment and mitigation processes from a portfolio theory or real option perspective. Future research could also further investigate the level of sophistication, complexity and cross-functionality the information process should have in order to assure the best risk assessment outputs, at the most reasonable cost for the organization. Fuzzy set Qualitative Comparative Analysis (fsQCA) could be used for interpreting qualitative data and evaluating the potential relationships between 'predictors' (such as firm characteristics) and an outcome (such as the effective and efficient price risk assessment model).

To our knowledge, there are only a few studies explicitly examining how firms can assess and mitigate commodity price volatility from a supply chain perspective. Our exploratory research provided a starting point for future empirical studies. We believe more research is necessary for understanding the role of the supply chain function in helping firms to create greater predictability in the price paid for commodities.

Abstract

Competition between companies has evolved into competition between supply chains. Buying companies increasingly recognize the need to cultivate relationships with their suppliers. Maintaining these relationships is highly dependent on sufficient information sharing between suppliers and buyers. We investigate the influence of social capital and buyer power on information sharing. A survey of first tier suppliers in the Dutch meat processing industry was carried out. The data from 82 suppliers was analyzed using Partial Least Squares. It appears that relational social capital has a direct influence on information sharing. Both cognitive and structural social capital have a direct effect on relational social capital, while expert power has an indirect effect. Coercive power showed no influence at all. Implications are provided. Buying companies can encourage supplier information sharing by building up their own expertise and cultivating social relationships.

Key words: information sharing, social capital, expert power, coercive power

Category: competitive paper (IPSERA 2018)

1 Introduction

Recent developments such as global competition, globalization and rapid response to customer needs are redefining business as usual. One of the changes is the new focus on competition between supply chains instead of competition between firms (Hsuan, Skjøtt-Larsen, Kinra, & Kotzab, 2015). An organization is highly dependent on its connections with other organizations in a supply chain. A supply chain is a concept of closely coordinated, cooperative networks, competing with other networks (e.g. Chuang, Chen and Lin, 2016). The competitive focus has led to the requirement of new management skills in terms of developing inter-organizational relationships with strategic partners (Hsuan et al., 2015). Inter-organizational relationships will improve integration between organizations, where integration can help companies to coordinate central processes, create cost savings and improve firm performance (Flynn, Huo, & Zhao, 2010). Information sharing is a key component in these inter-organizational relationships (Carr & Kaynak, 2007).

Information sharing refers to the exchange of critical information that facilitates inter-firm collaboration among supply chain members (e.g. Zhou and Benton, 2007). Numerous benefits have been linked to information sharing (cf. Sahin and Robinson, 2002), even sizeable advantage over competitors (e.g. Liu et al., 2013). Shared information will lead to cost savings through inventory and batch size reductions (Marshall, 2015), improved forecasts and reduced inventory levels (Lee et al., 2000), improved inventory control (Costantino et al., 2014), and the mitigation of the bullwhip effect and improved inventory variance (Costantino et al., 2015). Information sharing contributes to a better performance of the logistic system in terms of time, quality and speed (e.g Hsuan et al., 2015).

Information sharing in supply management has been extensively studied for decades (for an overview, see Marshall, 2015 and Kembro, Selviaridis and Näslund, 2014). Despite the recognized benefits, many firms seem reluctant to share information with their supply chain partners (e.g. Olorunniwo and Li, 2010). A barrier to information sharing are concerns about trust and confidentiality (Li and Lin, 2006). A fear of unequal distribution of risks and returns is likely to hinder information sharing (cf. Li et al., 2014; Manatsa and McLaren, 2008). Power and dependence are generally considered important for the understanding of buyer-supplier relationships (e.g. Cox, 2001). A high dependency asymmetry may be detrimental to information sharing, while powerful companies could impose on supply chain partners which information is required (e.g Vijayasarathy, 2010; Yigitbasioglu, 2010).

Literature on information sharing recognizes the importance of social relations between buying and supplying companies (e.g. Li et al., 2014). Social capital theory has become a useful theoretical lens for examining buyer-supplier relationships (e.g. Gelderman, Semeijn and Mertschuweit, 2016). Social capital refers to the resources that are available through networks of relationships (Nahapiet and Ghoshal, 1998). Social capital is being recognized as an important concept for examining information sharing practices (cf. Matthews and Marzec, 2012; Yim and Leem, 20130). However, the impact of social capital on information sharing is hardly investigated, with Li et al. (2014) as a notable exception.

Nahapiet and Ghoshal (1998) propose three dimensions of social capital: a cognitive dimension (sharing meaning and understanding between actors), a structural dimension (the frequency of

interactions and contact between actors), and a relational dimension (referring to trust, friendship, and respect). Li et al. (2014) hypothesized that the three dimensions all directly impact the information sharing content and quality between a manufacturer and its major supplier. However, there is strong evidence that the three social capital dimensions should not be handled as independent variables (Gelderman et al., 2016). Instead, there is substructure in these dimensions in which cognitive and structural social capital are antecedents of relational social capital (e.g. Carey et al., 2011; Horn et al., 2014; Roden and Lawson, 2014). To the best of our knowledge, no previous studies have investigated the substructure of the three social capital dimension and its impact on information sharing. The main research questions of this study are: what is the direct effect of (the substructure of) social capital dimensions on information sharing? And: what is the indirect effect of (buyer) power on information sharing through these social capital dimensions?

The purpose of the study is to investigate the role and the importance of power and social capital dimensions in the context of information sharing. Our study contributes in several ways to the current body of knowledge. First, our study enhances knowledge by investigating the influence of (all three dimension of) social capital on information sharing. Second, instead of handling the three social capital dimensions as independent variables (cf. Li et al., 2104), we have developed a conceptual model which includes a substructure for the dimensions that is well-grounded in previous studies. Third, this study extends previous research by examining the role of power in the mechanisms that produce information sharing. Power is an often overlooked concept in information sharing studies. Our study investigated the interplay of power, social capital and information sharing in buyer-supplier relationships.

The remainder of this paper is structured as follows. Hypotheses and a conceptual are developed and derived from literature on social capital theory, power and information sharing. The conceptual model is empirically validated using data from a survey among the first tier suppliers of a large Dutch deli meat producer.

2 Literature review and hypotheses development

2.1 Information sharing in the supply chain

All companies need information to cope with the uncertainties in their business environment (Stern and Reve, 1980). A generic definition of information sharing is "the degree to which each party discloses information that may facilitate the other party's activities" (Heide and Miner, 1992, p. 275). Within the context of interfirm collaboration, information sharing refers to the exchange of data, information and/or knowledge between supply chain parties (Kembro and Näslund, 2014). The literature generally supports the notion that effective exchange of critical information facilitates interfirm collaboration and that it can provide a strategic advantage over competitors (e.g. Li et al., 2014). Information sharing with supply chain members includes the exchange of information on operations management (e.g. material flow, order entry, shipping, billing) as well as the exchange of forecasts and plans (Marquez, Bianchi and Gupta, 2004). Undistorted, accurate and up-to-date information is useful for making decisions on production, inventory and logistics management (Bargshady et al., 2016) which is a critical factor in the success of supply chain performance (Zhou and Benton, 2007). Many studies have provided evidence that information sharing contributes significantly to the mitigation of the well-known

bullwhip effect (e.g. Wu, Chang and Hsu., 2014; Costantino et al., 2014). Despite the many important benefits of information sharing, more skeptical views point at the downsides and the limited advantages due to complexities and costs (e.g. Tran, Childerhouse and Deakins, 2016). Risks include a loss of power and/or competitiveness (e.g Uzzi and Lancaster, 2003: Kembro and Näslund, 2014).

Studies have argued the need for advanced information technology to exchange supply chain information (e.g. Li et al., 2014). The Internet and EDI are primary vehicles that drive electronic transactions and information sharing (Marshall, 2015). Poor data quality and a lack of shared information will result in costly repercussions and operational problems (Tran et al., 2016). Confidence in the security and quality of information systems impacts the willingness and capability of companies to share confidential information (Zhang and Li, 2006). However, appropriate information technology is not a sufficient condition for companies to engage in information sharing (Li et al., 2014). Relational factors are important too in explaining the involvement of firms in the exchange of (confidential) information (e.g. Fawcett. Ellram and Ogden, 2006). A social exchange perspective appears promising for examining information sharing practices in the supply chain (Wu et al., 2014).

2.2 Social capital and information sharing

Social capital theory has its roots in sociology and political science where it describes and explains the preferential treatment and cooperation between individuals and groups (e.g. Putnam, 1955). Social capital is referred to as a valuable asset that stems from access to resources made available through social relationships (Nahapiet and Ghoshal, 1998). Social capital theory has become a useful theoretical lens for examining buyer-supplier relationships (e.g. Gelderman et al., 2016). Studies have reported the beneficial effects of social capital operational performance in terms of costs, quality, lead time, flexibility, and delivery (e.g. Cousins, Handfield and Lawson, 2006; Lawson, Tyler and Cousins, 2008; Whipple, Wiedmer and Boyer, 2015). Other studies have included strategic benefits such as product innovation, market creation, technological development (e.g. Villena et al., 2011; Sanders, 2008; Terpend et al., 2008), and information sharing (Li et al., 2014).

In their seminal paper, Nahapiet and Ghoshal (1998) proposed three dimensions of social capital: a cognitive dimension which represents shared meaning and understanding between actors, a relational dimension which refers to trust, friendship, respect, and mutuality established by regular interactions between actors, and a structural dimension which refers to the frequency of interaction, the frequency of contact between the various departments in both organizations and the number of contacts between various levels within both organizations. These different dimensions can have different effects on information sharing and other performance measures (Gelderman et al., 2016; Li et al., 2014). Additionally, we assume specific interrelationships between the dimensions: cognitive and structural social capital are considered antecedents of relational social capital (cf. Carey et al., 2011; Horn et al., 2014; Rodenand Lawson, 2014).

Cognitive embeddedness between two actors was found to be positively associated with relational embeddedness, in that alignment between beliefs and expectations reinforces trust and commitment (Simsek et al., 2003). Cognitive social capital, as shared understandings, values and beliefs, is likely to breed trust (Carey et al., 2011). If parties have little understanding for one

another, relational capital is not likely to grow (cf. Adler and Kwon, 2000). With Roden and Lawson (2014), we expect that cognitive social capital has a positive impact on relational social capital. In addition, we propose a positive relationship between structural capital and relational capital as well. Structural social capital, as social interactions, facilitates the development of trusting relationships (e.g. Carey et al., 2014). Studies have shown that trust is developed through direct experiences and interactions with each other (e.g. Granovetter, 1985). Therefore, we propose:

H_2: Cognitive social capital has a positive impact on relational social capital.

H_2: Structural social capital has a positive impact on relational social capital.

Although the concept of information sharing has received increasing attention in academic literature, few empirical studies investigate the relationship between (dimensions of) social capital and information sharing. In the study of Li et al. (2014), cognitive and relational social capital appeared to have a positive impact on information sharing. In another study, it was found that structural, relational and cognitive social capital affect knowledge sharing, which in turn influenced organizational performance (Kim et al., 2013). Carlos and Pinho (2013) reported that trusted parties showed reduced feelings of vulnerability and as a result, they did not hesitate in committing and cooperating in a long-term relationship. In a related study, Willem and Scarbough (2006) found that trust and mutual understanding constitute the basis for higher approachability and improved communication, which fosters more intensive knowledge sharing. Obviously, with a lack of trust, parties will be unwilling to exchange sensitive information (e.g. Fawcett et al., 2007). Similarly, other studies reported a positive relationship between trust and information sharing (e.g. Li and Lin, 2006; Wang, Zha and Schuh, 2014). We expect:

H_3: Relational social capital has a positive impact on information sharing.

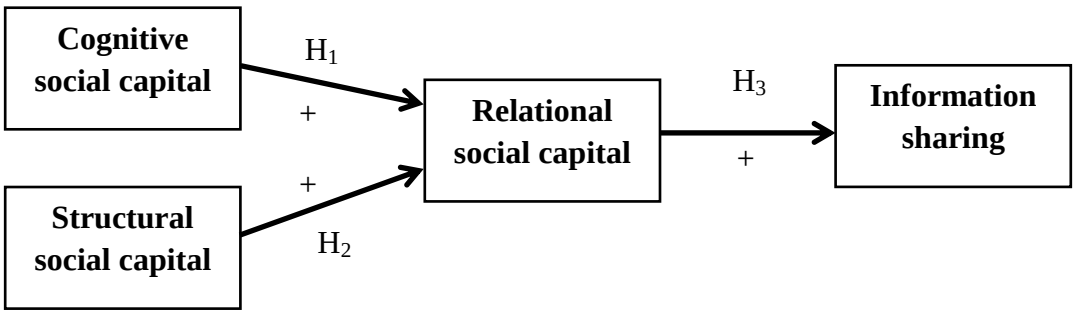

Figure 1 Social capital dimensions and information sharing

2.3 The influence of coercive and expert power

Considering the importance of social capital in buyer-supplier relationships, we need a thorough understanding of its drivers and barriers. However, little work has been done to explore the antecedents of social capital (cf. Chang & Hsu, 2016). In addition, the few studies on these antecedents focus on social capital on an individual level within organizations. An example is

Van den Hooff & Huysman (2009) who investigated the impact of organizational characteristics (e.g. organizational culture and structure) on social capital and knowledge sharing with colleagues.

The potential of including power in information sharing studies has been underplayed (cf. Kembro et al., 2014). The actual sharing of information by a weaker party is likely to be influenced by the power of the stronger party. In many industries, buying firms are able to dominate or even exploit their suppliers (Yigitbasioglu, 2010; Schleper, Blome and Wuttke, 2017). Large retail organizations initiate decisions, configure products and place orders that pull products through the supply chain (Hsuan et al., 2015). Therefore, customers and buyers are usually more powerful than the manufacturers and suppliers of goods (Huo, Wang, Zhao, and Schuh, 2016). Suppliers may be reluctant to share information due to perceived risks, costs and other downsides (e.g. Tran et al., 2016; Uzzi and Lancaster, 2003: Kembro and Näslund, 2014).

The Resource Dependence Theory has proved to be a useful perspective for understanding and studying buyer-supplier relationship. The main principle of this theory is that organizations need to get access to external resources, while trying to remain autonomous from other organizations (Pfeffer and Salancik, 1978). An often quoted definition of power is given by Dahl (1957, p. 202-203): " A has power over B to the extent that he can get B to do something that B would otherwise not do." A critical element in this definition is the ability of a party to impose his or her wills on others, to overcome resistance in achieving a desired goal or result. Resource Dependency Theory helps to explain why companies share or do not share information. A dominant company could, for instance impose on another company to share certain information (Kembro et al, 2014) or to use a certain information sharing mechanism (Yigitbasioglu, 2010).

However, there are contrasting views on the role of power in sharing information between buyers and suppliers. A dominant player can force weaker parties to share information. Buyer can use influence strategies in achieving compliance and cooperation from suppliers (e.g. Frazier and Rody, 1991). Another mechanism might be that dominated suppliers will try to refrain from sharing confidential and important information (Kembro et al., 2017). In a more positive vein, some studies found that power can provide an effective coordination of exchange relationships, promoting supply chain integration and performance (e.g. Maloni and Benton, 2000; Caniëls and Gelderman, 2010). How can we account for these paradoxical different effects?

The answer could be found in the multidimensional nature of power. Different types of power may have different effects. Dominant firms can have different power bases to influence a weaker party (French and Raven, 1959). Power types can be classified by their need for activation. Activated power types are based on intentional use, while passive power types are created by the perceptions of the other party and are hard to control directly (Reimann and Ketchen, 2017).

Superficially, it can be argued that the use power is incompatible with developing and maintaining collaborative relationships. The reality is more complex. Coercive power may only result in enforced compliance in combination with reduced levels of trust and social capital , since the impact is based on (the threat of) punishment. In contrast, expert power builds trust and could result in voluntary collaboration, (cf. Gangl, 2015). Recently, Chae, Choi & Hur (2017) found evidence for the distinct effects of coercive power and nonmediated powers, such as expert power, on supplier commitment.

Coercive power is a form of activated power. *Coercive power* includes promising rewards in case of compliance and threatening punishments in case of noncompliance (Benton and Maloni, 2005). This type of power use is based on the willingness to inflict negative consequences to noncompliance (Gundlach and Cadotte, 1994). Expert power is a typical example of a passive power type. *Expert power* is based on the appreciation of the other party's expertise (Benton and Maloni, 2005). Passive power types are likely to have beneficial effects on relationships, while activated power types can have detrimental effects (Huo, Flynn and Zhao, 2017). For instance, the threat or actual use of expert power in a supply chain increases cognitive social capital in terms of common interests as well as promoting collective goals and vision (Jonsson and Zineldin, 2003). The opposite is expected from the threat or actual use of coercive power (Chen, Zhao, Lewis, and Squire, 2015. We propose the following hypotheses:

H_4: Coercive power has a negative impact on cognitive (a) and structural social capital (b).

H_5: Expert power has a positive impact on cognitive (a) and structural social capital (b).

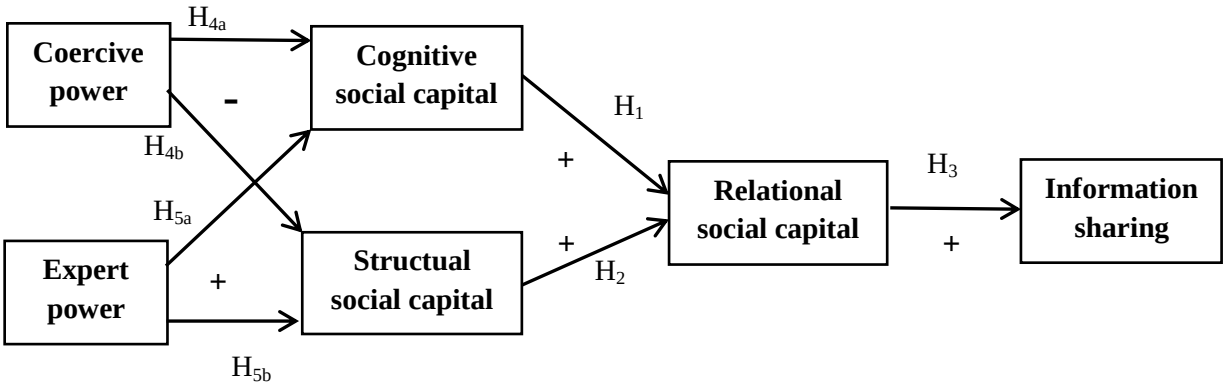

Figure 2 Conceptual model

3 Research method

Data collection took place through an electronic survey amongst a sample of managers employed at European food producing companies. To test the hypotheses, we invited suppliers of Zwanenberg Food Group to participate in the study. The Zwanenberg Food Group is one of the leading European producers and exporters of meat products and canned meat. Suppliers where selected on two criteria. The organization should be Dutch and it has to be a first tier supplier for Zwanenberg Food Group. A draft version of the questionnaire was pre-tested on a small number of respondents (pilot study).The final version of the questionnaire was administered online. After a week non-respondents received a kind reminder with the request to complete the questionnaire. The survey resulted in 82 useable responses.

To investigate the constructs, six variables were measured on 7-point Likert scales. These variables are information sharing, cognitive social capital, relational social capital, structural social capital, coercive power and expert power. To ensure that the respondent will take the time to read the questions carefully, there are questions with both positive and negative pronunciations (Saunders, Lewis, and Thornhill, 2012), which is important for the validity of questions measured

by a seven-point Likert scale (Dillman, 2000). The questions were translated into Dutch. Two translators executed the translation, one is a native speaker of the source language and one is a native speaker of the target language.

All operationalizations were derived from measurement scales used and validated in other academic studies and adapted to fit the context of this study. *Coercive power* was measured by using the four items adapted from from Brown, Lusch and Nicholson (1995). An example item is: "The major customer's personnel would somehow get back at us if we do not make changes in our research and development". *Expert power* was measured by four items adapted from Brown, Lusch and Nicholson (1995). An example item is: "Our major customer ensures changes in our research and development because we trust the customer's judgment". It should be noted that the operationalizations of the power constructs refer to the threat that emanates from the actual use of power. It is not about the actual use of power, but the imminent possibility that buyer power is exercised at the expensive of a supplier. *Structural social capital* was measured by three items derived from Villena, Revilla and Choi (2011). An example item is: "Our major customer and we do not have frequent and intensive interaction with each other" (reverse coded). *Cognitive social capital* was measured by four items derived from Li, Ye, and Sheu (2014) and Son, Kocabasoglu-Hillmer, and Roden (2016). An example item is: "Our major customer and we share the same vision". *Relational social capital* was measured by five items derived from Li, Ye and Sheu (2014) and Wu, Chuang and Hsu (2014), and Villena et al. (2011). An example item is: "Our major customer and we share confidential information with each other". *Information sharing* was measured by four items derived from Li et al. (2014) and Wu et al. (2014). An example item is: "We are willing to share our actual sales data with our major customer".

4 Results

A total number of 157 suppliers was first contacted by email, then the questionnaire was sent out electronically. After a follow up email, sent after two weeks, a total number of 82 questionnaires were completed, which results in an effective response rate of 52,3% (82/157). We included some background variables to get insight in sample characteristics. Company size was measured by questions about the number of employees and annual revenues in Euros. About 11% of the respondents were employed by companies with annual revenues less than 10 million Euros, while 39% worked at larger companies with more than 100 million Euro revenues. The majority of companies contracted fewer than 100 suppliers (64%) and employed fewer than 500 employees (66%). Respondents were asked to indicate their job title that reflects the position in their company. About 17% of the sample consisted of managing directors. Almost 59% held a position in sales (mostly account managers), while 24% was employed in another position. All respondents were involved in activities and decisions regarding the customer relationship management of their company, which suggests sufficient knowledge from the respondents to complete the questionnaire.

Partial Least Squares (PLS) analyses were performed using the plspm package in R (Sanchez, Trinchera, Russolillo, 2017). The variance-based PLS-SEM approach achieves relatively high statistical power even with small sample sizes and is the recommended method when working with reflective constructs (Hair et al., 2017). The analyses comprise two main steps: (1) in the first step, the 'outer' model is tested and (2) in the second step, the 'inner' model is tested. The

outer model maps the indicators on the latent factors and examines indicator loadings which analyses the measurement model and thus reliability and validity. The inner model maps the paths between the latent factors which analyses the structural or hypothesized model.

Eigenvalues did not indicate multidimensionality of any latent factor and Cronbach's alpha values are all well above the threshold values of 0.60 (Hair et al. 2014). All Average Variance Extracted (AVE) values are well above 0.40. The loadings of the indicators on the latent factors are all well above .40 and there were no cross-loadings on other factors (cf. Lowry, Gaskin 2014). In sum, results indicate unidimensionality of the latent factors and suggest that convergent and discriminant validity of each latent factor is acceptable and show evidence for the reliability of the constructs.

The results of the inner model are presented in Table 1. Five of the seven hypothesized paths are statistically significant. The results confirm the substructure of the social capital dimensions (H_1 and H_2). We also found support for the impact of relational structural social capital (H_3). However, no statistical support was found for the hypotheses that assumed a relationship between coercive power and cognitive social capital ($H4_a$) and structural social capital ($H4_b$). It appears that expert power, as expected, has a positive impact on these two social capital dimensions ($H5_a$ and $H5_b$). Figure 2 shows the structural model including the size and significance of path coefficients, as well as R^2 values.

Table 1: Size and significance of the Structural Model Path Coefficients

Path	Path Coefficients	*t Values*	Sign. Levels	*p* Values
Coercive Power -> Cognitive Social Capital	-0.084	-0.774	N.S.	0.441
Coercive Power -> Structural Social Capital	0.047	0.426	N.S.	0.671
Expert Power -> Cognitive Social Capital	0.395	3.640	***	0.000
Expert Power -> Structural Social Capital	0.419	3.810	***	0.000
Cognitive Social Capital -> Relational Social Capital	0.306	2.940	**	0.004
Structural Social Capital -> Relational Social Capital	0.216	2.070	*	0.042
Relational Social Capital -> Information Sharing	0.248	2.290	*	0.025

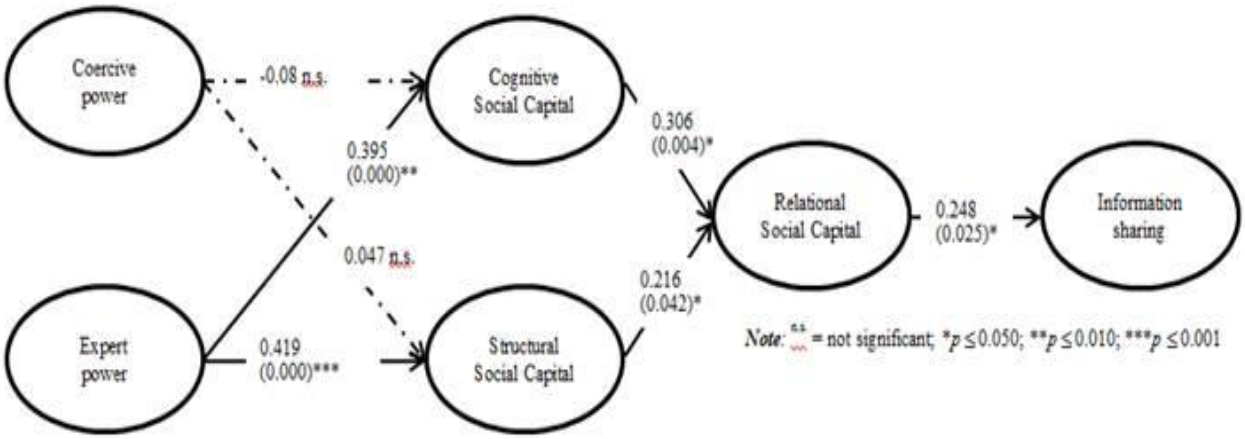

Figure 2 PLS results of the structural model

5 Conclusions and discussion

Information sharing has been extensively studied within the context of supply chain management. Literature recognizes the importance of social capital that accrues in buyer-supplier relationships. However, no studies have investigated the role of the substructure of the three social capital dimensions on information sharing. Despite the many attributed benefits, many firms seem reluctant to share important information with their supply chain partners. A high dependence asymmetry is likely to be important, although past studies seem to have overlooked the role of power in information sharing. This study was aimed at filling these gaps by investigating the interplay of power, different social capital dimensions and information sharing.

This study contributes to the body of knowledge about information sharing in buyer-supplier relationships. First, our study extends previous literature by investigating the influence of the substructure of social capital dimensions on information sharing. The results of our study confirm the theoretically based substructure of the three social capital dimensions (cf. Gelderman et al., 2016; Horn, Scheffler and Schiele, 2014; Carey, Lawson and Krause, 2011). Indeed, cognitive capital (shared meaning and understanding) and structural capital (interactions and contacts) are antecedents of relational social capital (trust, friendship, mutuality). In addition, the empirical findings support the hypothesis that links relational social capital to information sharing (cf. Li and Lin, 2006; Fawcett et al., 2007; Wang et al., 2014).

Second, although power is generally considered a key concept in understanding buyer-power relationships, dependence asymmetry appears to be an overlooked factor in information sharing studies. This study included the role of coercive and expert power for gaining additional insights in information sharing. Third, literature shows a rather inconclusive picture of the impact of power on coordination, collaborating, and information sharing in supply chains. Some studies assume a direct effect of power on information sharing (e.g. Li et al., 2014; Yigitbasioglu, 2010). In this study we have argued that power will only indirectly influence information sharing, namely through social capital. We found partial evidence for this mechanism.

Fourth, we did find a (positive) path that runs from expert power through social capital to information sharing. Suppliers appreciate the expertise of the buyer, which contributes to the a shared understanding (cognitive capital) and interactions (structural capital). However, the provision of information might not be completely mandatory. Suppliers could be forced to exchange information by the use of coercive buyer power. For this power type, we expected a negative impact on social capital which works on to information sharing. However, we did not find a statistical significant effect of coercive power on social capital. This finding is in line with the notion by some that the use of power is not always problematic and can be a positive force in supply chains, as long as the dominant party acts fairly (cf. Yigitbasioglu, 2010) and does not necessarily exploit the weaker party (cf. Pfeffer and Salancik, 1978; Caniëls and Gelderman, 2010). By distinguishing coercive and expert power, as contrasting power types, we have shed light on the complex role that power can play in information sharing between buyers and suppliers.

Also, we found a (relatively strong) negative correlation between coercive power and expert power. Apparently, these power types were employed as substitutes, not in a complementary way. In other words, a buyer that uses expert power in a supplier relation, is not likely to simultaneously use coercive power as well (and vice versa). Buyers can choose which power type to employ, depending on the supplier and the context.

6 Limitations and recommendations

This study has a number of limitations, which could induce further research. The sample was restricted to supplying companies of one buying (food producing) company. The study could be replicated in other settings, for instance by selecting less mature industries or by focusing on (innovative) startups. To get more insights into the effects of power and social capital, future research could use a dyadic approach and include the experience and views of multiple buyers and suppliers. Another limiting aspect is the cross sectional nature of this study. Experimental and longitudinal studies would be more suitable for investigating cause-effect relationships, shedding light on the interplay of the various variables under study. Case study research could be aimed at more thoroughly investigating the relationship these concepts. Another advantage of case study research is the possibility to include three or more companies from a supply chain or to include several individuals employed within different companies (cf. Kembro and Näslund, 2014).

Our research can be extended in other ways as well. Stronger parties can use influence strategies in managing their business partners (Frazier and Rody, 1991). Coercive influence strategies can produce full compliance and cooperation, although dominated parties can also show partial compliance, delayed compliance or negotiated compliance (cf. Gelderman, Semeijn and De Zoete, 2008). Future research could incorporate different types of compliance that suppliers could use in their response to requests of powerful buyers to share important information. Similarly, studies could differentiate between a willing submissiveness and a resentful submissiveness (cf. Gölgeci, Murphy and Johnston, 2017).

More and different power types could be included in research designs. Our study employed coercive power (active) and expert power (passive). The seminal typology of French and Raven

(1959) describes also reward, referent and legitimate power. Different power types can have different effects on buyer-supplier relations. The concepts of expert and coercive power in our study refer to the threat that emanates from the actual use of power. It would be interesting to investigate the effects of an actual deployment of influence strategies by powerful buyers. Future studies could also focus on the content and the quality of information shared among supply chain partners (cf. Li et al., 2014). To be more specific, research could differentiate between operational, tactical, and strategic information (cf. Wu et al., 2014). Sharing operational information on production and deliveries forms a very different context than sharing strategic information for gaining competitive value, promoting collaborative behaviors between various supply chain members.

The results of our study suggest that purchasing professionals could benefit from the finding that (the threat of using) power does not impact information sharing directly. Social relation factors do play an important intermediate role. Trust is essential for suppliers to exchange information with a more powerful customer. Buying companies should acknowledge that relational social capital (trust, respect, friendship) can be promoted by investing in cognitive social capital (shared understanding and meaning) and structural social capital (frequency of contacts and interactions) and also expert power

Buyers should think and rethink the selection and use of different power types. Expert power impacts information sharing, be it in an indirect way through high levels of social capital. The use of coercive power creates a very different situation. Although many managers might think that they can force suppliers into sharing information, our study indicated that coercive power showed no influence at all (nor positive, nor negative). Buying companies can encourage supplier information sharing by building up their own expertise and cultivating social relationships.

Appendix Measurement of variables

Variable	Items
Coercive power [a]	The major customer's personnel would somehow get back at us if we do not make changes in our research and development.
	The major customer does not withdrawn certain needed services from us if we do not make changes in our sales. (R)
	The major customer does not hint that they would take certain actions if we do not make changes in our production process. (R)
	The major customer could have made things difficult for us if we do nog agree with their suggestions about distribution.
Expert power [a]	Our major customer ensures changes in our research and development, because we trust the customer's judgment.
	Our major customer ensures changes in our sales, because they have great business expertise about sales.
	Our major customer does not ensures changes in our production, because we usually do not have good advice from the customer. (R)
	Our major customer ensures changes in our distribution, because they have specially trained people who know what had to be done.
Information sharing [b]	We are willing to share information about the available stock with our major customer.
	We are willing to share our production planning with our major customer.
	We are not willing to share our production capacity with our major customer. (R)
	We are not willing to share our actual sales data with our major customer. (R)
Relational social capital [b]	Our major customer and we are concerned about the welfare or interests of each other when making important decisions.
	Our major customer and we are willing to offer assistance and support to each other, even if the circumstance changes.
	Our major customer and we share confidential information with each other.
	Our major customer and we do not have a close personal interaction. (R)
	Our major customer and we are willing to invest in specific resources for each other, because we maintain a close relationship.
Structural social capital [c]	Our major customer and we maintain close social relationships with each other.

	Our major customer and we do not have frequent and intensive interaction with each other. (R)
	Our major customer and we did not obtain new interactions by the cooperation. (R)
Cognitive social capital [d]	Our major customer and we share the same vision.
	Our major customer and we do not share the same ambitions. (R)
	Our major customer and we share the same goals.
	Our major customer is similar to us in that we both are willing to change for the benefit of the relationship.

(R) = recoded

Abstract

Opportunistic behavior is a well-known reason for the failure of collaborative buyer-supplier relationships. Research on buyer opportunism typically focusses on leverage supplier relationships. Little is known about the actual opportunistic buyer behaviors in strategic partnerships. This study is the first to use the Critical Incident Technique to identify and describe actual occurrences op opportunistic buyer behavior, including antecedents and effects. Purchasing professionals have been interviewed about their own personal opportunistic behavior, resulting in rich descriptions of 29 critical incidents. Most commonly, multiple expressions of opportunism are used in the same incident, grouped into not honoring agreements (1), lying and cheating (2), and abusing power positions (3). Several buyers put the responsibility of opportunistic behaviors on their superiors or on the pressure for short term results. Sometimes opportunism was a reaction to perceived supplier opportunism. Buyers applied opportunism when the relation with their supplier was already deteriorating.

Keywords: buyer opportunism, strategic supplier partnerships, critical incident technique

Category: competitive paper (IPSERA 2018)

1 Introduction

Collaborative relationships with strategic suppliers are generally considered crucial for company performance and market competitiveness (e.g. Yen & Hung, 2017). Organizations increasingly outsource strategically important functions and activities, which makes supplier collaboration vital for the success and performance of companies (e.g. Raassens et al., 2012). However, governing such relationships can be problematic, resulting in failure. Opportunistic behavior by either party is considered an important reason why many collaborative relationships enter into difficulties or even fail (e.g. Bhattacharya et al., 2015; Raassens et al. 2012). Opportunism implies a choice for self-interest with malicious intentions and at the expense of the partner. Consequences can be very serious, like conflict (Barnes et al., 2010), reduction of trust, (Mysen et al., 2011), destabilisation (Anderson & Jap, 2012), reduced willingness to invest (Suh & Houston, 2010) or relationship termination (Kang et al., 2016).

Studies report contradictory findings regarding the antecedents of opportunistic behavior. Williamson (1975) states that knowledge-sharing stimulates opportunism, although Yam & Chan (2015) found the opposite. It is generally agreed that trust reduces opportunism (e.g. Liu et al., 2009), while but excessive trust (Carey, Lawson et al., 2011) as well as little trust (Vidal, 2014; Kang et al., 2016) appear to be positively related to opportunism. A long term focus is likely to reduce opportunism (Choi et al., 2015; El Rahman, 2015), although Hawkins, Wittmann et al (2008) found that the contract span stimulates opportunism. Contrasting results were also found for dependency and buyer opportunism. Crosno et al. (2008) reported a negative relation, while Joshi & Arnold (1997) found a positive impact of dependency. These contradictions call for a deeper investigation into the actual causes and motivations of opportunistic behavior.

Most commonly, research on opportunism involves studies on supplier opportunism (e.g Villena et al, 2011). The extant literature has focused on opportunistic behavior of suppliers, investigating the safeguards buyers need to put in place to protect their interests (e.g. Bhattacharya et al., 2015). Buyer opportunism is assessed by suppliers or sales representatives (e.g. Choi et al., 2015). These studies however, yield few insights into actual opportunistic behavior by purchasers, their underlining motives and effects on buyer-supplier relationships.

The few academic studies on buyer opportunism are mostly in the form of survey studies (e.g. Villena and Craighead, 2016; Bhattacharya et al., 2015; Hawkins et al., 2013; Liu et al., 2010). These studies are aimed at testing hypotheses concerning specific antecedents and consequences of opportunistic buying behavior. However, these studies provide little knowledge about the actual use of opportunistic buying behavior and the conditions that induce or stimulate the use of such negative tactics. More research is needed on the antecedents and effects of actual opportunistic buyer behavior. In contrast, our study is aimed at contributing to our understanding of buyer-supplier relationships by exploring the reasons and motives for actual buyer opportunism

Research on buyer opportunism is typically focused on leverage supplier relationships, not on strategic partnerships (e.g. Hawkins et al., 2013; Joshi & Arnold, 1997; John, 1984; Vidal, 2014; Bhattacharya et al., 2015). Despite the negative effects of opportunism, buyers still

behave opportunistically even in strategic supplier relationships (Liu et al., 2010). It remains unclear why buyers persist in the use of opportunistic tactics. This study investigates actual buyer opportunism within strategic supplier relationships, as viewed by buyers who actually engaged in such behavior. The leading research question is: what is the role of buyer opportunistic behavior in strategic supplier relations?

Our study focuses on self-observed buyer opportunism and aims to gain a deeper understanding of true motives, manifestations, and consequences of buyer opportunism. The Critical Incident Technique (CIT) was used to identify and describe actual occurrences of opportunistic behavior, antecedents and effects. Purchasing professional in the Dutch manufacturing industry were interviewed, resulting in rich descriptions of 29 critical incidents of opportunistic buyer behavior.

2 Theoretical background

2.1 Strategic supplier relationships

As companies do not have all the resources needed for competitiveness, they will seek to build relationships with supplying firms. Developing strategic relationships with innovative suppliers is a viable, well-known innovation strategy (e.g. Oke et al., 2013). Buyers aim to leverage strategic supplier relationships to gain competitive advantage. Such buyer-supplier relationships may develop into a strategic supplier partnership requiring compatible goals, coordination, planning, and problem solving efforts (e.g. Qrunfleh & Tarafdar, 2013). Strategic supplier partnerships are long-term relationships that influence the strategic and operational capabilities of individual participating companies to help them achieve significant ongoing benefits (Li et al., 2006). These relationships require direct association, mutual planning and problem solving, continuous improvement, and selection of a limited number of suppliers (e.g. Gunasekaran et al., 2001). Such partnerships enable information sharing, joint improvement activities, and integration, leading to greater responsiveness (cf. Qrunfleh & Tarafdar, 2013). Strategic, integrated relationships are characterized by high levels of commitment, conflict resolution, cooperation, and trust (cf. Maloni & Benton, 2000).

Literature suggest many differences among partnerships (e.g. Kim & Choi, 2015). In the ideal case, strategic partnerships are based on equality in which both parties have an interest in a flourishing long term relationship (e.g. Caniëls & Gelderman, 2007). These relationships are characterized by interdependencies, trust, commitment, and an open exchange of information. A very different type of relationship is a ‘locked -in partnership’, in which a company has no alternative than to maintain the currently employed relationship (Harrison et al., 2012). A locked-in relationship is most commonly due to unchosen, unfavourable conditions. The partner at a disadvantage can be trapped in the relationship and can be exposed to opportunism (Grandinetti, 2017). A buyer might be forced by patents, a monopoly position of the supplier, high switching costs or by the demands of a major customer (Gelderman & Van Weele, 2003). The buyer then could try to make the best of the situation by starting a long term relation, not entirely voluntarily and therefore probable less intense than in a real partnership. Successful alliances bring great rewards, such as higher stock exchange value, improved competitiveness and reputation (Dyer et al., 2001). When relationships fail to

achieve continuity of supply and cost reduction, partners typically face a substantial fall back in performance (Kang et al., 2016).

2.2 Buyer opportunism

Academic publications on opportunism generally use Williamson's (1975, p. 6) definition: "self-seeking interest with guile" (p. 6) "at the expense of the partner" (Kang et al., 2016 p. 240). Opportunism is often conceptualized in behavioral terms such as 'deceitful withholding of information' and 'failing to keep promises' (e.g. John, 1984). These behaviors should not be confused with normal business practice based on implicitly shared (relational) norms, such as hard bargaining, demonstrating competitive behavior, entering into necessary confrontations and constructive conflicts (Young and Wilkinson, 1997).

Hawkins et al. (2008) divide opportunism-related research in two streams. First is the Transaction Cost Analysis (TCA) approach focusing on institutional and legal aspects and rational human behavior. For instance *bounded rationality* assumes that human cognitive abilities are limited so that they will not always act rationally (and sometimes opportunistically). People will exhibit opportunistic behavior when they think this is beneficial. In contrast, the Social Exchange Theory (SET) rejects opportunism, emphasizing relational aspects of a relationship such as trust, commitment, cooperation, satisfaction, and relational standards. Hawkins et al. (2008) consider opportunism in partnerships an aggressive pursuit of self-interest without regard for others which manifests itself in forms such as theft, fraud, breach of contract, dishonesty, data manipulation, false promises, threats and withholding information. Such behaviors are morally reprehensible and legally questionable.

The extant literature discusses various types of opportunism, see Table 1. Wathne & Heide (2000) distinguish between 'blatant' and 'lawful 'opportunism. Blatant opportunism is inconsistent with contractual and other explicit agreements, for instance lying (Yam & Chan, 2015), theft, deception, guile (Williamson, 1989), threats, dishonesty, and data manipulation (Hawkins et al., 2008). Blatant opportunism is often illegal. In contrast, 'lawful' opportunism concerns behavior which is not inconsistent with agreements, but rather with common decency or other social aspects of relationships. Examples are withholding information (Williamson, 1989), using loopholes in contracts (Yam & Chan, 2015; John, 1984), indecent behavior, avoiding agreements and coming back on agreements (Wathne & Heide, 2000).

Opportunistic behavior can be further typified as 'active' or 'passive' (Wathne & Heide, 2000). Active opportunism involves expressively forbidden behaviors (Das & Kumar, 2012). Active opportunism is directly related to financial loss and involves an explicit action (Kang et al., 2016), for instance supplying low-quality products for the purpose of making higher profit margins Mpinganjira et al., 2015). Examples of passive opportunism are avoiding contact (Yam & Chan, 2015), refusal to adapt (Wathne & Heide, 2000) and withholding information (Williamson, 1989). Similarly, Hawkins et al. (2013) distinguish between 'strong' and 'weak' opportunism. In case of weak opportunism there appears no identifiable perpetrator at the time of execution, as opposed to the 'strong' variant. Weaver & Dickson (1998) divide opportunism in the categories 'objective' and 'perceived'. Objective

opportunism refers to behavior that can be expected on the basis of contracts, while perceived opportunism is about breach of social relationships.

Opportunistic behavior	Type of opportunism	Source
Withholding information	Lawful/Passive	Williamson (1989), Hawkins et al. (2008)
Withholding know-how	Passive	Kang, Han et al. (2016)
Threats	Blatant/Active/Strong/Perceived	Hawkins et al. (2008)
Deceit	Blatant/Active/Strong/Objective	Williamson (1989), Hawkins et al. (2008)
Breach	Blatant/Active/Objective	Hawkins et al. (2008)
Data manipulation	Blatant/Active/Strong/Objective	Hawkins et al. (2008)
Theft	Blatant/Active/Strong/Objective	Williamson (1989), Hawkins, Wittmann et al. (2008)
Lying	Blatant/Active/Strong	Yam & Chan (2015), Kang et al. (2016)
Use of loopholes in contract	Lawful/Perceived	Yam & Chan (2015), John (1984)
Misleading	Blatant/Active	Williamson (1989)
Dishonesty	Blatant/Perceived	Hawkins et al. (2008)
Indecent behavior	Lawful/Strong/Perceived	Wathne & Heide (2000)
Avoiding contact	Lawful/Passive	Wathne & Heide (2000)
Come back on agreements	Lawful/Active	Wathne & Heide (2000)
False promises	Blatant/Active/Strong	Hawkins et al. (2008)
Refusal to adapt	Passive	Wathne & Heide (2000)

Table 1: Types of opportunistic behavior

2.3 Consequences of opportunism within a partnership

The consequences of opportunism within a partnership can be severe. Serious cases can lead to a conflict (Barnes et al, 2010; Joshi & Arnold, 1997), and destabilization of the relationship (Anderson et al., 2012). ‘Active’ opportunism can even result in the termination of the cooperation and thus loss of "sunk costs" or depreciation of investments in the relationship (Kang et al., 2016). An opportunism-threat may even result into an increased risk of acquisition by the customer (so a customer buys a supplier) (Hawkins et al., 2008).

A major concern of opportunism is the negative effect on performance in a buyer-supplier relationship (e.g. Joshi & Arnold, 1997). Opportunism will reduce flexibility (Samaha et al., 2011), and the willingness to invest (Suh and Houston, 2010). A related issue is the undermining of trust (e.g. Barnes et al, 2010; Hawkins et al, 2008; Joshi & Arnold, 1997; Mysen et al., 2011), the reduction of commitment (Joshi & Arnold, 1997; Mysen et al., 2011; Suh and Houston, 2010), and the reduction of satisfaction (Seggie et al., 2013; Joshi & Arnold, 1997). In general, opportunism is likely to result in lower levels of social capital (Carey et al., 2011), incoherence and uncertainty (Wang et al., 2010).

Finally, opportunistic behavior may evoke opportunistic responses from the other party (e.g. Yen & Hung, 2017; Caniëls & Gelderman, 2010). A victim of opportunistic behavior could react by shirking (Handley & Benton, 2012; El Rahman, 2015) or evasion of obligations or

deliberately underperforming. A victim could also react by ‘poaching’, which can be described as deploying common resources or knowledge purely in self-interest, without the knowledge of the partner(Handley et al., 2012). Another reaction might be free riding (El Rahman, 2005), parasitizing on the relationship, and manifestations of retaliation (Vidal, 2014). Opportunism undermines the strategic partnerships by reducing output and trust.

2.4 Antecedents of opportunism

One of the aims of this study is to understand the causes of buyer opportunism in strategic supplier relationships. We will investigate opportunistic buyer behavior from three different theoretical perspectives: Transaction Cost Economics (TCE), Social Exchange Theory (SET) and Resource Dependence Theory (RDT), as depicted in Figure 1.

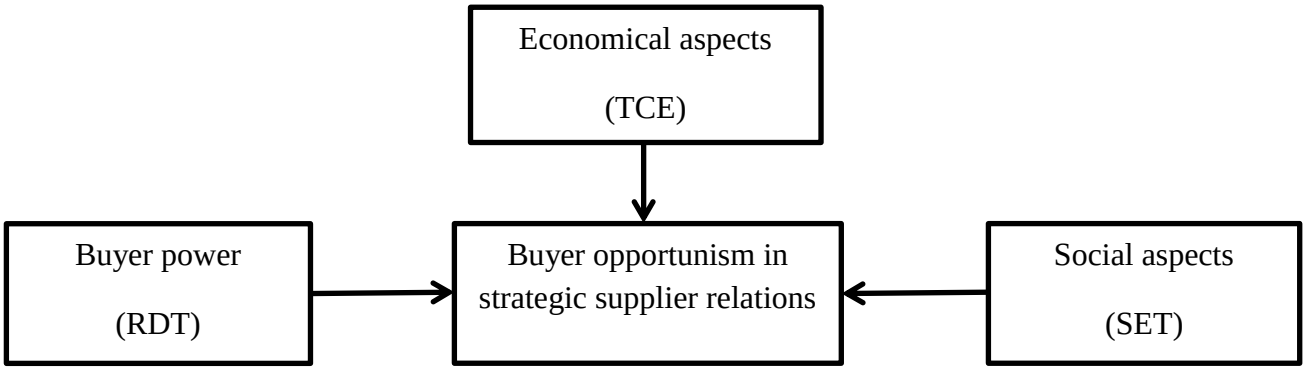

Figure 1 Theoretical antecedents of opportunism

2.4.1 Transaction Cost Economics (TCE)

TCE attempts to understand complex economic organizations by combining legal, economic and organizational theories (Williamson, 1989) and forms the basis of a large group of possible antecedents of buyer opportunism. Important in this context are the relation-specific investments (e.g. Kang et al., 2016; Choi et al., 2015). As these investments are greater, the risk of ‘sunk cost’ will increase when ending the relationship and partner opportunism will therefore be less likely.

The next important subgroup is the planning horizon of the partners. Pressure on short-term results can trigger partners into inappropriate behavior (Kang et al., 2016), while a long-term orientation of buyers suppresses this behavior (e.g. Choi et al, 2015. El Rahman, 2015). Hawkins et al. (2008) argue that there is a positive correlation between the length of a contract and opportunism. A mismatch of objectives (Hawkins et al., 2008), and inequality of profit distribution (Kang et al., 2016) are potential antecedents of opportunism.

Other antecedents relate to human limitations in the decision-making process that can lead to wrong decisions. El Rahman (2015) cites excessive self-confidence, blind spots and uneven valuation of profits and losses. John (1984) adds that the possibility of personal gain (rewards) induce blurring of standards of individuals. Finally there is economic ethnocentrism (Lee,

1998) that makes people to some extent feel that their "own" group is superior, which may lead to negative behavior towards the partner.

As the anticipated risks relating to the relationship and the shared objectives grow, the chance of ‘active’ forms of opportunism will increase (Kang et al., 2016). There are various forms of uncertainty that contribute to opportunism. Lee (1998) specifically mentions decision making uncertainty, Wang et al. (2013) adds uncertainty in behavior of the partner and Crosno et al. (2008) finally environment uncertainty, i.e. unexpected changes in circumstances. Mysen et al. (2011) points at market turbulence. Finally role conflicts and ambiguity lead to risk, which in turn leads to opportunism (Kang et al., 2016).

2.4.2 Social Exchange Theory (SET)

SET is a social psychological and sociological perspective in which human relationships are central to a business cooperation. Being based on human interactions it is clear that many antecedents of opportunism come can from this perspective. The first subgroup consist of relational norms and values. "Relational norms are expectations with regard to behavior which at least are supported by part of a group of decision-makers, which have proven to contribute to individual interactions between businesses" (Hawkins et al., 2008 p. 903). These relational norms are said to be negatively related to opportunism (e.g. Tang Pong et al., 2010; Joshi & Arnold, 1997; Caniëls & Gelderman, 2010). Hawkins et al. (2013) recognize the negative relation between opportunism and ‘corporate ethical values’ (CEV), honesty and integrity, and the positive relation between avoiding responsibilities and ‘subjective expected utility’, meaning that people tend to pick the option that seems to deliver maximum results. Furthermore, Hawkins et al. (2012) and Hawkins et al. (2013) demonstrate that subordinates follow the behavior displayed by their superiors.

Various studies have shown that differences in the culture of partners can lead to opportunism (e.g. Lee, 1998; Kang et al., 2016). Not unexpectedly, Kang et al. (2016) found that rivalry between two parties and communication problems can induce opportunism. Relationships benefit from a higher frequency of transaction (Bhattacharya et al, 2015) and contact (Hawkins et al., 2008; Wang et al., 2013). The amount of the social capital, or the value of social relationships, has a negative relationship with opportunism (Villena et al., 2011).

A major issue of opportunism within SET relates to trust. Trust is the confidence of one partner in the honesty and goodwill of the other partner (Liu et al., 2009). Generally, trust reduces opportunism (Liu et al., 2009; Hawkins et al., 2008). This effect is enforced when trust is linked to formal contracts (Liu et al., 2009). Apparently there is such a thing as an optimal level because a lack of trust stimulates opportunism (Vidal, 2014. Kang et al., 2016) as well as over-confidence (Carey et al., 2011; Granovetter, 1985). Wang et al. (2013) call ‘identification based trust’ a form of blind faith inducing opportunism. Still, literature reflects controversy about the effectiveness of contracts in mitigating opportunism (e.g. Yang et al., 2017).

2.4.3 Resource Dependency Theory (RDT)

An important tenet of the Resource Dependency Theory is that is considers the ability to acquire and maintain resources as the key to organizational survival. Every organization must transact with elements in the environment to acquire the many resources that it depends on (Pfeffer & Salancik, 1978). The dependence on resources creates power relations and problems of vulnerability for the weaker party to opportunistic behaviors (e.g. Schmitz et al., 2016). Powerful companies may behave opportunistically by exploiting the available opportunities. Due to their power within the network, there will be little to no repercussions of such opportunistic behavior (Morgan et al., 2015).

RDT examines how external sources influence the behavior of an organization. John (1984) states that a dominant power position of the supplier ('coercive power') is positively related to buyer opportunism. However, Caniëls & Gelderman (2010) conclude that a dominant power position of the vendor can have a moderating effect on buyer opportunism, provided that the power is not being used. Furthermore, it is clear that RDT related opportunism plays a particularly important role in 'locked-in partnerships' so that there is an imbalance in the balance of power. Hawkins et al. (2013) show that buyer power enforces 'strong form' opportunism, but not the 'weak form'. In line with RDT, we expect that buyers will try to decrease their dependence on suppliers and to increase the suppliers' dependence (e.g. Oke et al., 2013). Buyers might rely opportunistic behaviors in order to manage, to reduce, and to avoid dependence on suppliers (e.g. Pfeffer & Salancik, 1978).

Joshi & Arnold (1997) note that dependence is positively related to opportunism under 'low relational norms' but negative under 'high relational norms'. In general, dependence has been shown to have a negative relationship with buyer opportunism (e.g. El Rahman (2015; Crosno et al., 2008). A power-dependence relationship develops when a company becomes dependent upon another organization and has a relatively low degree of autonomy. A company might suffer from opportunistic behavior when autonomy is low due to the asymmetric dependence on a business relationship (e.g. Lee et al., 2015). However, it should be noted that RDT places dependence problems in perspective. Dependence as such is not problematic, problems arise when dealing with less dependable partners (Pfeffer and Salancik (1978).

3 Methodology

The critical incident technique (CIT) is used to investigate significant occurrences (events, incidents, processes, or issues) identified by respondents, the way they are managed and the perceived effects. A key advantage of CIT is that it asks for unprompted information, deemed to be important for respondents (e.g. Oldenburger et al., 2008). The technique is believed to be effective in explorative studies, aimed at gaining understanding of the perceived impact of incidents and ultimately at solving practical problems (Flanagan, 1954). CIT has been used in a wide range of disciplines (Gremler, 2004), notably in service encounters (e.g. Bitner et al., 1990). However, CIT is not a commonly used method in research on purchasing and supply management (Gelderman et al., 2016).

A critical incident in our study is considered any form of buyer's opportunistic behavior within a strategic supplier relationship. Prior to the interviews, each respondent was informed in writing on the purpose of the study and what was meant by certain key terms (cf. Hamlin et al., 2011). Trust, a guarantee of confidentiality, anonymity and a relaxed atmosphere are prerequisites to allow respondents to speak sincerely about their 'inappropriate' behavior.

In general, the validity of the research will increase with the number of observations, wherein saturation is the goal. Upfront it is hard to predict how many critical incidents and respondents are sufficient to achieve adequate validity. Respondents were selected from a professional purchasing network in the Dutch manufacturing industry, based on their first-hand experience with opportunistic behavior in a strategic supplier relationship. It is important that respondents have sufficient experience and authority within purchasing in order to provide valuable information, where a possible threat of respondent bias should be kept in mind. Each respondent was asked to describe their own opportunistic behavior in the course of a strategic buyer-supplier relationship.

Each interview was fully transcribed and then coded. Variables are recoded when necessary to have a positive relationship with opportunism. For example, 'relational norms' was renamed 'lack of relational norms' to indicate a positive relationship with opportunism. For the five antecedents of opportunism with contradictory academic findings both a positive and/or a negative relation to opportunism was registered. In the interviews special attention was given to the role of antecedents. Respondents were asked for each critical incident to elaborate on issues of power, opportunism-display and types of partnership. Respondents were encouraged to provide factual reports, rather than interpretations (cf. Hughes et al., 2007).

4 Results

4.1 Respondents and critical incidents

During a period of ten weeks in 2016, twelve respondents were interviewed, generating a total of 29 critical incidents. Table 2 provides an overview of the job titles and the years in which the critical incidents took place. In small companies, the roll of strategic buying with partner suppliers is often performed by the director or owner. That was the case with respondents numbers six, seven and eight. A maximum of three critical incidents per respondent was set. This has yielded a total of 584 minutes of recording, resulting in over 200 pages of transcripts. After 12 interviews is was decided to conclude the data collection process, since saturation appeared achieved.

It is striking that the majority of cases showed multiple expressions of opportunism within the same incident. These various expressions were grouped into not honoring agreements (1), lying and cheating (2), and abusing power positions (3). In almost all incidents, the buyer abuses its dominant position, mostly in combination with one or both of the other categories. Some of the literature-based opportunistic behaviors were not reported. Respondents might prefer to describe themselves in milder terms. 'Lying' and 'cheating' sounds worse than 'misleading' and 'coming back on earlier agreements'.

Resp.	Job titles of respondents	Incident 1	Incident 2	Incident 3	date
# 1	Buyer machine factory	2008	2008	2014	10/6/2016
# 2	Buyer metal machining company	2005	x	x	15/6/2016
# 3	Purchase-manager machine factory	2014	2016	x	15/6/2016
# 4	Free-lance project buyer	2003	2007	x	22/6/2016

(x): Respondent could not report on other incidents

Table 2: Job titles and years of critical incidents

4.2 Displays of buyer opportunism

It should be noted that buyer opportunism with partner suppliers does not to occur very often in Dutch industry. Several approached potential respondents could not find any occurrence of this behavior, even after the 'prompting' examples of others. More than half of the respondents who had experience with opportunism could remember fewer than three incidents even though they had been buyers for 15 years or longer.

A pattern emerged of behavior that is generally associated with leverage suppliers, such as setting competitors against each other and hard bargaining on price, i.e. a combination of exploiting buying power and focus on short-term gains. In some incidents it was even explicitly stated that the action was intended to get rid of the partner. Examples include expressions such as "*we wanted them out of the strategic box*" (incident 10.1), and "*we realized that we had become dependent and therefore we have taken action*"(incident 12.3).

4.3 Consequences of buyer opportunism

A large variety of effects of buyer opportunism was found. We found that no relationship appears able to withstand blatant opportunism. If opportunistic behavior against suppliers has become the standard, there seems to be no basis left for strategic cooperation. In a minority of cases, the buyer thought that the opportunistic act had no apparent impact on the relationship, but it is questionable whether the purchaser is always able to form a complete judgement. The hidden damage can be much greater than the buyer can estimate. However, it means that in the vast majority of cases the buyer is aware of the resulting negative consequences for the relationship. In some incidents, the relationship was even terminated, but more often it was downgraded to less cooperation and lower levels of relationship intensity. Several buyers specifically intended to downgrade a strategic partnership to a leverage relationship.

4.4 Antecedents of buyer opportunism

Hereafter, the antecedents of buyer opportunism are examined and explained by using the three theoretical perspectives.

4.4.1 Transaction Cost Economics (TCE)

Every critical incident showed at least one TCE antecedent, making it the most common category. Especially from this perspective buyers appear to get encouraged to use 'leverage' tactics. Not surprisingly "pressure on short-term results" was the most frequently mentioned argument. Buyers apparently have trouble with things they cannot predict or control. For example, the buyer of incident 6.1 blurted; "*I will make sure he can't control me* ".

Before the respondents perform opportunism it appears that they often first make an assessment of the risks of their behavior, confirmed by statements like "*even with no deal I would still be the winner*" (incident 7.3) and "*I'm confident that they won't find out. Otherwise I wouldn't have done it"* (incident 5.2).

The buyer's short-term orientation combined with leverage tactics appeared several times in the study. In this case suppliers had a long-term orientation, (incident 6.2): "*The partner wanted to be a partner, but we just wanted the best deal*." On the other hand, opportunistic suppliers sometimes intend to harvest on the short term (incident 9.3): *"We saw him as a partner, but he felt he didn't make enough money."* Sometimes the supplier has no plans at all because the customer no longer fits into the strategy. "*We may have the idea that we have a good partner, and we might not fit into their sales strategy, and they only do business because we asked and we should stop whining"* (incident 3.2).

Buyer's personal issues can easily escalate into a conflict in which the relationship incurs serious damage or is even terminated. These issues appear not very important, like a representative that is seen as too inexperienced (incident 9.3). In addition, statements are made as "*personal satisfaction*" (incident 5.1 and 5.2) and "*eye for an eye, tooth for a tooth*" (incident 9.1). Emotionally touched buyers want to deliberately inflict damage to the relationship and thereby appear to lose sight of the higher importance of strategic cooperation, as the statement "*I did it for my own satisfaction*" illustrates (incident 5.1)

A disadvantage of bonus structures is that they are often based on short-term results and they can therefore potentially stimulate opportunism. In this study, however, personal gain was only mentioned once as antecedent of opportunism and then even as a minor factor. Personal gain therefore appears not to play a significant role in buyer opportunism.

4.4.2 Social Exchange Theory (SET)

In all incidents one or more SET antecedents appear to promote opportunism. Apparently, the relationship was not ideal prior to the incident. "Dissatisfaction with the relationship" and "little trust" were mentioned most often. When the relationship seemed fine, buyer opportunism was caused by explicit orders from higher management or by a sudden deterioration of the supplier's performance. A respondent (incident 1.2) was irritated by the

many ‘back door’ visits of representatives and technicians. The vendor obtained too much knowledge and information, contributing to the buyer’s decision to become opportunistic.

Trust plays a role in half of the incidents. Although prior studies show that trust has a reducing effect, this was not observed in any of the incidents. The incidents in our study showed that both too little and too much trust can be antecedents of opportunism. When "much trust" is being embarrassed in most cases it leads to an emotional response from the buyer, leading to anger and revenge. The relationship is then beyond rescue, it gets damaged and is often terminated. Also, tust may have a ground-breaking effect. One buyer thought he would get away with opportunism because, there was a solid basis of trust (incident 12.1). Little trust in often leads to an emotional response from the purchaser repeatedly falling into retaliation. The buyer in all cases steers towards ending the collaboration.

It is striking that knowledge is seen as valuable by both parties and that both want to get the upper hand. Knowledge at the partner can apparently be seen as a threat. In this way, knowledge equals power which is sought by the buyer. In incident 10.2 it was stated that "*it is a supplier, so a third party and we should not tell everything"*.

4.4.3 Resource Dependency Theory (RDT)

In terms of power-balance almost all relations in this study were based on equivalence, or with a slight advantage to the purchasing party. Not surprisingly, therefore, only five cases of "locked-in" partnerships were registered. Most of our sample is based on equality. In cases where one of the parties is slightly more powerful only half of the cases showed RDT-type antecedents. In locked-in relationships however RDT antecedents were found significantly more often than in balanced relationships. Apparently a higher degree of dependence stimulates buyers opportunistic behavior. Dependency appears positively related to opportunism. Low dependence encouraged buyers to act with opportunism. This conclusion is confirmed by statements like *"I will get away with it because I am powerful*” (incident 8.1), "*I will easily find another supplier"* (incident .2) and "*because they wanted us real bad, I took as much as I could”* (incident 12.2).

In situations where the buyer was dependent, we found evidence for both a stimulating and an inhibiting effect on buyer opportunism. In the situation of incident 9.1 the buyer is dependent because he is bound to a particular supplier by head office contracts. The combination of centralization, formalization and dependence created a certain arrogance at the supplier and a personal aversion by the buyer. The buyer then becomes engaged in a personal vendetta, and therefore it is a case of ‘low relational norms’. In addition, we found instances where the buyer was aware of his dependence and took a rational decision not to be opportunistic. "*I need the source code, otherwise I would have played harder*” and "*I remained on speaking terms because a lawsuit was not a solution*" (incident 7.1) are clear examples of the inhibitory effect of high relational standards on buyer opportunism. When buyers were aware of their dependence they may take measures to reduce it. "*We wanted to get out of the strategic box*" (incident 10.1) and "*We realized that we were dependent and therefore we have taken preventive countermeasures*” (incident 12.3) are examples.

In general, many buyers seem to have trouble with the dependence associated with strategic supplier relationships and use their power to escape from it, not only when the balance of power is to their disadvantage.

5 Discussion

Some surprising discoveries were made in this study. It appears that 'personal gain' (or 'reward') hardly plays any role, which contradicts the conclusions by John (1984). This study also could not confirm the conclusions of Hawkins et al. (2013) that a dominant buyer power position promotes the use of 'weak form' opportunism.

A basic prerequisite for a strategic supplier relationship is a long-term orientation (Monczka et al., 1998). When indeed there was a mismatched alliance horizon, the relationship was beyond rescue, all in line with the findings of Choi et al (2015) and El Rahman (2016). It is striking that in all cases where this antecedent occurred, opportunism category "buyer abused dominant power position" was practiced. Thus, in case of mismatch of alliance horizon, the buyer easy falls back to abuse of power.

The extant literature posits that dependence may give rise to power and that power breeds opportunism (e.g. John, 1984). The results of the study provide support for this relationship, since dependency appears positively related to opportunism. This finding can be partly explained by the relational norms (Joshi & Arnold,1997), as shown by this study, but it seems that dependence (c.f. Mysen et al., 2011) also plays a role. Our study makes clear that 'satisfaction with the relationship' is negatively related with opportunism (cf. Villena et al., 2011; Wang et al., 2013), and suggests that buyers only fall into opportunism when they are not satisfied with the relationship or when they are forced by internal stakeholders cf. (Hawkins et al, 2008; Wang et al, 2013). In our study this was found several times.

In our study we did not find evidence to support Hawkins's et al. (2013) conclusion that a dominant power situation stimulates 'strong form'- but not 'weak form' buyer opportunism. 'Weak form' opportunism was only found a few times, in situations where the buyer was the powerful party. We found that a dominant power position of the supplier is positively related to buyer opportunism, which is in accordance with John (1984) and Caniëls et al. (2010), since suppliers actually abused their dominant power position in all critical incidents.

6 Conclusions and recommendations

In general the reason for using opportunism is to obtain short-term gains in spite of the possible long-term adverse effects. From the literature 16 possible opportunistic tactics were defined (Table 1). In our empirical study, 11 of these were actually observed and two new ones were added, namely 'abuse of power by exercising pressure' and 'leverage tactics with partner'. Tactics can be categorized into three groups: the buyer does not stick to agreements (1), the buyer lies and cheats (2), and the buyer abuses a dominant power position (3).

Our study indicates that buyer opportunism within strategic supplier relationships always consists of abuse of power, usually in combination with lying/cheating and/or do not honor agreements. Several buyers intended to downgrade a strategic partnership to a leverage

relationship. Usually opportunism concerns an individual action of a single buyer (= deviant personal opportunism), although in many cases it appears to be driven by top management, or is it an integral part of the company culture (= blatant opportunism). Buyers regularly act on explicit instructions from their superiors, or they feel compelled by pressure for short-term results or unworkable procedures and protocols.

Some clear patterns become visible. Buyers often only accept limited responsibility for their own behavior. Instructions from above, unworkable protocols, and corporate culture and pressure for short term results are frequently mentioned as motives for opportunistic behavior. Also, opportunism often appears a conscious choice of a buyer, based on a sound assessment of risks and consequences of opportunism. Lastly, buyers tend to lapse into power games which are more appropriate for dealing with leverage suppliers.

In the vast majority of incidents, opportunism had harmful effects on the relationship, such as insecurity, conflict, destabilization and undermining of trust. Sometimes, the relationship ended but more often it got damaged to an extent that it could no longer be called a strategic partnership. Our findings indicate that buyers only decide to act opportunistically if they felt already dissatisfied with the relationship. It is therefore unlikely that the relationship would have remained optimal even if the buyer had not taken to opportunism.

If companies have decided that strategic partnerships with suppliers are necessary and appropriate, it is also necessary to take measures to prevent, recognize and fight opportunism. The study shows that governance structures often encourage buyer opportunism although they intend to achieve the opposite. Often buyers feel that their opportunistic behavior is induced by company rules, supervisor instructions, corporate culture and pressure for short term results. Purchasing professionals could benefit from clear guidelines and accepted behavioral norms for dealing with strategic suppliers.

The study has several limitations. We felt that saturation was achieved after 29 relevant ‘critical incidents’, since no new manifestations of buyer opportunism were observed. Anonymity was promised in advance and assured. Still, the results of this study should be interpreted with caution, since the findings are based on self-reported, socially less-accepted behavior. It seems that people do not easily admit to lying or to behaving dishonestly, but rather call it “misleading” or "coming back on previous agreements”. Furthermore, a number of antecedents such as ‘blind spots’, ‘excessive self-confidence’ and ‘ethnocentrism’ are difficult to recognize by respondents. A promising avenue for future study could be a focus on the potential role of subjective perceptions, interpretations and meaning-making of the involved professionals. Future research might want to explore the justifications of purchasing professional for their unethical and opportunistic behaviors.

More in general, organizational buying behavior is most commonly considered a rational, cognitive and object process, driven by logic and not emotions. However, we agree with Kemp et al. (2018) that emotions do play an important, be it understudied, role in organizational buying. Future studies could investigate the influence of emotions on the deployment and effectiveness of opportunistic buying behavior.

Obviously there are also factors that have an inhibitory effect on buyer opportunism. Further research is needed to increase understanding and theoretical anchoring. This study was limited to Dutch industrial buyers who reported not much opportunism. We might assume that that different standards prevail in other sectors and other countries. Future research could try to shed more light on sectorial and cultural differences regarding antecedents and effects of buyer opportunism. Since we build our findings on expert interview, our results may serve as a basis for further quantitative research.

There are recommendations for practitioners too. Buyers tend to get negatively emotionally involved when it comes to trust issues, leading to a desire for revenge. Negative emotional involvement almost always encourages the buyer to break up the relationship. It is highly questionable whether a personal incident is a valid reason for a company to break a valuable partnership. If companies aim for long-term partnerships with suppliers they must ensure that buyers build a relationship on a business foundation. When the emotional bond evolves into something counterproductive, companies should assign that supplier to other buyers.

Buyers dealing with strategic suppliers (partners) require different profiles and characteristics than those dealing with leverage suppliers or suppliers of non-critical items . A partner-buyer must have sufficient emotional stability skills and act as a relationship intermediary. He should have a long term orientation, excellent communication skills and be well integrated within his own company. A leverage buyer, on the other hand, is more of a street fighter who focusses on short-term gains and frequent changes of suppliers. Opportunism is intended and required here. Is it realistic to think that one individual can excel simultaneously in both situations? Segregation of duties for strategic and tactical purchasing in this case, will improve the quality of purchasing. Because buyers often have few partner suppliers lack of experience can also play a role. Proper education and training would be a major contribution.

Abstract

In response to an increased uncertainty and financial instability of modern supply chains, companies have been leaning towards Supply Chain Finance schemes. Among these schemes, Dynamic Discounting (DD) is growing in importance. Literature on DD is exceedingly scarce and devoid of empirical evidence. The purpose of this study is to analyse the different archetypes of DD and which drivers affect buyers in choosing among them. Through 9 company interviews, 4 archetypes of DD were identified and classified in terms of actors' role and information sharing as well as main adoption drivers from the perspective of a large buyer.

Keywords: Dynamic Discounting, Supply Chain Finance, Trade Credit, Working Capital Management

Introduction

In the peak of the recent economic and financial crisis, corporate defaults were common. The substantial underestimation of default risks up to 2007 led to massive downgrades of both sovereign and corporate ratings (deHaan, 2017; Niepmann and Schmidt-Eisenlohr, 2017a) and, overall, a significant negative effect on international trade (Niepmann and Schmidt-Eisenlohr, 2017b), especially through a restriction of trade finance facilities towards more risky parties (Asmundson et al., 2011). Liquidity-scarce companies tried to compensate the contraction in bank lending through a stronger lean focus towards working capital, i.e. increasing payment terms towards suppliers and / or reducing settlement terms with customers (Klapper and Randall, 2011; Martínez-Sola et al., 2017) or even exacerbating cutbacks in inventory levels (Bendavid et al., 2017). However, trade credit in itself cannot fully compensate the contraction of bank lending stemming from the financial crisis (Love, 2011).

As a consequence, liquidity shortages hit corporates, creating chain effects: lost payments propagate from a company to its suppliers (Raddatz, 2010). Evidence shows that the propagation effects of liquidity shortages tends to stop only when it faces a large, cash-rich firm, for example a retailer with a negative cash-to-cash cycle (Boissay and Gropp, 2007). Propagation to suppliers is only one of the effects of liquidity shortages. Studies show that trade credit defaults have also a downstream propagation effect: liquidity shocks likely induce a reduction in trade credit provided to other customers, increasing default risk and involuntary payment delays (Coricelli and Masten, 2004). This context, sometimes referred to as “trade

credit default chains" (Boissay and Gropp, 2007; Coricelli and Masten, 2004) greatly contributed to the development of policies and financial schemes through which large, cash-rich, companies can facilitate access to liquidity to cash constrained, usually SMEs, suppliers (Boissay and Gropp, 2007). Most authors identify this concept as Supply Chain Finance (SCF, e.g. Pfohl and Gomm, 2009; Randall and Farris II, 2009; Seifert, 2010).

However, empirical evidence on SCF is still vastly focused on the most well-known schemes and products (most notably, Reverse Factoring, e.g. Dello Iacono et al., 2015; Lekkakos and Serrano, 2016; Liebl et al., 2016). As practitioner turn their attention to alternative schemes, such as Dynamic Discounting (DD), this raises scientific questions related to its adoption, drivers, benefits and overall relevance as a working capital management tool. Therefore, the objective of this paper is to investigate the adoption of DD solutions through a multi-case study approach involving both providers and large buyers, in order to cast a light on the existence of different archetypes of DD and provide a framework for the drivers influencing the choice of large companies regarding this SCF scheme. The remaining of the paper is organised as follow: the second section present relevant theoretical background, while the third describes objectives and methodology of this contribution. The fourth and fifth sections presents the results of this model: DD archetypes and drivers of its adoption, while the sixth and final session concludes the paper.

Literature review and research goal

Evolution of Supply Chain Finance

SCF has been defined in many ways: as a set of financial solutions (Chen and Hu, 2011), as an advanced form of Reverse Factoring (Wuttke et al., 2013b) or, more broadly, as the inter-company integration and optimisation of financial processes in the supply chain (Caniato et al., 2016; Gelsomino et al., 2016; Pfohl and Gomm, 2009). For the scope of this paper, SCF can be defined as the optimisation of the flows and allocation of financial resources in a supply chain with the aim to increase value, requiring the collaboration of at least two primary supply chain members, possibly facilitated by external service providers (de Boer et al., 2015). Literature on SCF presents two main perspectives: a financial- and a supply chain-oriented one (Gelsomino et al., 2016). The first focuses on the optimisation of account receivables and payables only (Lamoureux and Evans, 2011; Wuttke et al., 2016, 2013a), while the second, adopted in this contribution, expands such focus to a broader set of concepts related to working capital (e.g. collaborative inventory optimisation to reduce working capital needs, as in Randall and Farris II, 2009) or even fixed asset financing (Hofmann, 2005; Pfohl and Gomm, 2009).

As testified by the nature of the two perspectives, SCF is positioned at the intersection of supply chain management and finance (Hofmann, 2009, 2005; Pfohl and Gomm, 2009). While from supply chain management literature it draws concepts such as collaboration and information sharing, one of the main contribution from financial literature comes from trade credit. Trade credit is as a short term business loan from a supplier allowing its buyer to delay payments (Lee and Rhee, 2011). Contributions focused on trade credit are plentiful and long precede SCF itself (Chang et al., 2008; Seifert et al., 2013; Soni et al., 2010). It is recognised that the concept of trade credit is strictly related to SCF (Basu and Nair, 2012; Klapper and Randall, 2011). Trade credit is the most important source of short-term external finance for firms and, in its essence, it is used in two basic forms: a simple delay in payment, or a two-part term policy (also known as cash discount policy), in which the supplier allows the buyer to settle payment within a short term (e.g. 10 days) in exchange for a discount (e.g. 2%), or within standard payment terms for the total nominal value (Lee and Rhee, 2011).

Trade Credit motives

DD evolved from cash discount practices typical of trade credit. However, cash discounts translate to Annual Percentage Rate (APR) that easily exceed 40%, which is considerably higher than the average cost of debt, even for non-creditworthy suppliers (Chludek, 2011; He et al., 2010). Therefore, it has value to analyse motives behind cash discount approaches and (secondarily) trade credit itself. Among the six main suppliers motives for accepting trade credit (for more information and a detailed analysis of trade credit literature, cf.: Seifert et al., 2013), we will focus on the one that are relevant for either the typical supply chain context of DD (relative small suppliers and large buyer) or that tackle specifically on cash discount policies: capital access, product market position, credit information and non-salvageable investments. *Capital access:* large corporates have usually lower costs to access finance and might share this with smaller supply chain partners, e.g. a large supplier might accept trade credit to lower small customers financial burden (Schwartz, 1974). More recently, contributions show how trade credit is in fact a form of financing with high costs, with companies with a weaker credit position using cash discount policies to access liquidity (Hill et al., 2017). *Product market position:* small firms are usually characterised by higher costs of external financing and also by less opportunities to benefit from economies of scale. Consequently, trade credit can become an important tool for building stable relationships and capturing new businesses (Wilson and Summers, 2002). More recently, trade credit has being connected with the possibility for small firms of eliminating financially weaker competition while avoiding margin-erasing price competition (Peura et al., 2017). *Credit information:* financial institutions may find more profitable to "indirectly" lend money through trade credit, rather than direct loans (Jain, 2001). Financial institutions save in monitoring costs by exploiting a large buyer or supplier knowledge on smaller, opaque supply chain partners. Although in the context of trade credit such motive is mainly addressed from a large-supplier small-buyer perspective (Seifert et al., 2013), literature on well-known SCF solutions (such as reverse factoring) highlight this point as well (Klapper, 2006). *Non-salvageable investment:* Smith (1987) suggests that suppliers should adopt cash discount practices in order to monitor the buyer's default risk. A buyer not able to accept an early payment proposal (usually carrying a significant return on cash) can be interpreted as a sign of financial struggling and as the need of close monitoring. From a modelling point of view, cash discount policy can be introduced to reduce the risk of a supplier of incurring in bad debt (Chuang and Wu, 2017).

From the demand side, buyers' motives for trade credit requests are usually triggered by transaction pooling and/or credit rationing (Seifert et al., 2013), while cash discount policies are usually motivated (on the buyer side) by the specific return on cash that they can generate (Chuang and Wu, 2017; Luo and Zhang, 2012).

From Trade Credit to Dynamic Discounting

As discussed above, DD takes root from the cash-discount policy typical of trade credit practices and, through a proper use of a buyer-supplier integrated platform, allows the dynamic settlement of invoices (Polak, 2012). DD arises as it is recognised that 'mass application' of static discount policies precludes potential profits gained through the 'customised' application of early payment discounts (Randall and Farris II, 2009). The flexible use of cash discount policies, when buyer and supplier can agree on settle an invoice at any given time within standard payment terms in exchange for a proportional discount provide, overall, higher total benefits to companies involved (Zhou et al., 2013). According to He et al. (2010), DD can either be buyer-initiated (i.e. the buyer declare the acceptable discount rate and the supplier reacts by accepting early payments) or supplier-initiated (i.e. the supplier suggests competitive discount and the buyer accepts the proposal).

Authors agree that a proper DD application requires an IT platform (Gelsomino et al., 2015; Nienhuis et al., 2013). More specifically, DD is considered to be a "three-corner" SCF model (i.e. models that involve a buyer, a supplier and a third party, which can be a financial institution

or an IT service provider), and a common schema that lets SMEs, suppliers of an anchor buyer, fast access cash at acceptable rates (Nienhuis et al., 2013; Polak, 2012; Polak et al., 2012). As the benefits for the buyer rely on the discount realised, the supplier mitigates the cash flow-in uncertainty, as well as increases trust and cooperation among supply chain players (Templar et al., 2016). DD has received great attention from practitioners. Recent SCF market analyses devote considerable attention to this programme and to the providers offering it (BAFT et al., 2016; GBI, 2016, 2013; The Paypers, 2014). However, although the interest in the topic seems to be high, no attempts have been carried out so far to cast a light on its main application archetypes or drivers for its adoption. Thereby, the overall objective of this contribution is to address the literature gap related to the lack of knowledge and empirical evidence on the different "archetypes" of DD, as well as over drivers of adoption by large buyers. Consequently, the paper identifies two Research Questions:

RQ1. What are the characteristics of the main DD archetypes currently available in the market?
RQ2. What drivers influence a buyer choice between different archetypes?

Research methodology

Case study design

Research on Dynamic Discounting is clearly at an exploratory stage: even though the interest from the business world is remarkable, scientific contributions are scarce and focused exclusively on traditional understanding of the concept streaming from trade credit literature, with extremely limited empirical evidence and little consideration of new practices enabled by the digitalisation of the trade process. Thus, exploratory case studies are considered appropriate for this context, as the theoretical foundation is rather weak (Edmondson and Mcmanus, 2007). Even though the study is mainly based on an inductive approach, its general constructs, key variables and their relationships are still grounded in the theoretical domains that underpin the development of DD – namely, SCF and trade credit (Voss et al., 2002). More specifically, from previous literature it is possible to identify four macro-variables: actors' role, information sharing, strategic objectives, and relationship status. These four macro-variables allowed to develop a preliminary structure of the research and led to the phase of data collection. Coherently with the iterative nature of this process, the collection of data allowed to correctly identify the operationalisation of the different variables. Annex A links presents the theoretical grounding of the macro-variables, together with their operationalisation in the context of the model presented in this paper, as described in the remaining part of this section.

Data collection and analysis

A multiple case studies methodology has been adopted, where the unit of analysis selected is the DD solution: the unit of analysis was the proposed solution for technology providers and the solution adopted or under investigation for buyers. This allows to strengthen the result generalisability and to perform an exhaustive cross-case analysis of the relevant variables (Voss et al., 2002; Yin, 2009). The sample selected is heterogeneous, allowing the collection and comparison of different points of view on the same applications. Overall, nine companies have been object of interviews: six global service providers offering different archetypes of DD, one buyer with a DD solution implemented and two buyers without a DD solution in place (Gibbert et al., 2008). The sample heterogeneity allows to combine insights form providers regarding their own DD offer with the one of buyers that have decided to either adopt or not adopt DD. Characteristics of companies interviewed are reported in Table 1.

For data collection, each interview has been recorded and transcribed, as well as developed into schemes and summaries. Triangulation has been performed through secondary data sources such as internal presentation shared by the interviewees, available commercial material and other relevant pieces of information. Coding followed a two steps approach: open coding to

identify relevant categories based on the four macro-variables identified from literature, and axial coding, to identify and connect together specific constructs from data collected (Voss et al., 2009). Overall, coding generated 12 detailed variables, which are described in Annex A. The identification of those 12 variables allowed to perform cross-case analysis, with the goal of identifying cross-case patterns in the data collected through two-dimensional tables crossing the variables identified (divided per RQ) and the sample of cases. The complete cross-case analysis can be found in Annexes B and C, and are presented and discussed in the following sections of this paper.

Table 1: characteristics of the interviews carried out

Role	Name	Industry	Headquarters	Market served	Interviewee
Providers	P1	Financial services	USA	Global	Director business development
	P2	Financial services	Germany	Global	Sales manager
	P3	IT and financial services	USA	Global	Global account manager
	P4	Financial services	Finland	Nordics, Netherlands and North America	Head of financing product line; Analyst
	P5	Financial services	USA	Global	Strategic account executive
	P6	IT and financial services	USA	Global	European marketing director
Buyers	B1	Chemical	Netherlands	Netherlands	Financial administration
	B2	Chemical	Germany	Global	IMS purchasing director; Global purchasing director
	B3	Consumer electronics	Netherlands	Global	Procurement finance business partner

Archetypes of Dynamic Discounting (RQ1)

Through the cross-case analysis reported in Annex B, we answered to the first research questions. The case studies allow us to identify the main archetypes, in terms of actors involved, roles of different actors and information sharing.

All the service providers in the sample offer Dynamic Discounting solutions, which are characterised by a great level of customisation. However, all the different versions available can be traced back to four main archetypes: Standard Dynamic Discounting; Dynamic Discounting with Third Party Financier; Dynamic Discounting with SPV (Special Purpose Vehicle); Dynamic Discounting through Market Place. Table 2 is summarizing the main features of each archetype; each model is then described in the following paragraphs.

Table 2: Description of the Dynamic Discounting archetypes

		Standard DD	DD with 3PF	DD with SPV	DD through Market Place
Actors' role	Actors involved	Buyer; Supplier; Platform	Buyer; Supplier; Platform; Bank	Buyer; Supplier; Platform; SPV	Several buyers; several suppliers; platform
	Main actor	Buyer-centric	Three corner model	Three corner model	Supplier-centric
	Discount rate responsible	Buyer	Service provider	Service provider	Supplier
	Targeted return	Buyer has a targeted return	Buyer has not a targeted return	Buyer has a targeted return	Buyer has a targeted return
	Discount rate discrimination	Buyer	Service provider	Service provider	Supplier
Information sharing	Supplier awareness	Full supplier awareness	Partially aware	Not aware	Full supplier awareness

	Buyer visibility	Full visibility on single discount rate (single)	Personalized on the basis of customer requests	Visibility on the package made by several invoices (aggregated)	Visibility on the package made by several invoices (aggregated)

Standard Dynamic Discounting

The first archetype identified has been named "Standard Dynamic Discounting", because it refers to the traditional scheme, which is already possible to find in the existing SCF literature. In this first case, the DD practice is buyer-driven, thus the buyer is in charge of setting the discount rate of the programme. These rates can be either the result of a negotiation process before the on-boarding of the suppliers or they can be a pure choice made exclusively by the buyer. When a supplier agrees to be part of the programme, it can have access to the online platform and it can make a request for an early payment. Then, the buyer pays the supplier at the agreed date in exchange for a discount on the nominal value of the invoice. The discount percentage is based on a sliding scale and the specific value is calculated considering the payment date, the net terms and the discount rates defined during the on-boarding process. The reference scheme of a Standard Dynamic Discounting solution is reported in Figure 1.

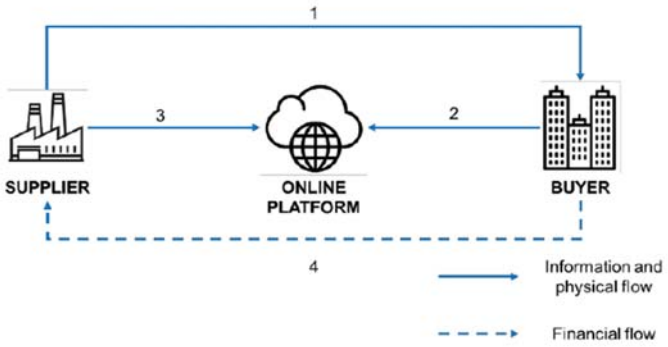

Figure 1: Standard Dynamic Discounting archetype

Step 1. After having received the Purchase Order (PO) from the buyer, the supplier sends the goods required and issues the invoice related to the specific PO.
Step 2. The buyer receives the goods and the invoice and he carries out the typical reconciliation activities in order to verify the coherence between the PO, the goods received and the invoice. When the invoice is approved, it is uploaded by the buyer on the online platform managed by the service provider (with an eInvoicing process, the invoice is already uploaded on the platform before the supplier sends it to the buyer). Finally, a notification is sent to the supplier in order to advise him that early payment is available for that specific invoice.
Step 3. After receiving the notification, the supplier is free to decide when and if to ask for early payment. On the dedicated section of the portal, the supplier can visualize all the invoices already approved and available for funding. Once the request of early financing is made, the buyer receives a notification on the platform.
Step 4. Finally, the supplier receives an amount of money equal to the nominal value of the invoice decreased by the discount provided. As stated before, this discount depends on the tariffs previously agreed during the on-boarding process and it is automatically calculated by the system, according to how many days in advance the payment is required.

Thanks to the interviews performed with the four service providers that offer this specific archetype (P2, P3, P4, and P5.1), it is possible to deepen a couple of aspects, which characterise this solution. First of all, during the process of setting the right discount rates, the buyer has the possibility to perform a supplier segmentation. According to several drivers, such as size of the

spending, location and strategic relevance of the relationship, the buyer can cluster suppliers in order to provide different rates for each different group. For example, P5.1 offers a solution called “Bucketed approach”: suppliers are grouped in different buckets, according to some distinctive drivers, and then the buyer is able to perform a “discount discrimination”, offering higher or lower rates, coherently with the bucket of origin. Secondly, this archetype allows the suppliers to choose between two ways of implementation: the programme can be on an automatic basis or on a manual one. The former approach means that when the suppliers join the platform, they sign an agreement stating the willingness of receiving early financing for all the invoices that are approved. The latter approach means that the supplier is free to choose manually, invoice per invoice, when to ask for an early payment.

Dynamic Discounting with Third Party Financier

The second archetype identified has been named “Dynamic Discounting with Third Party Financier”. The main peculiarity that distinguishes this version from the others is the source of the funding: the buyer doesn’t invest his own excess cash in the programme, but exploits the help of a third party financier (3PF). This particular archetype is provided only P6 because this service provider has a strong strategic collaboration with a preferred third party financier. In order to implement this version of DD, a trusted account needs to be set up at the buyer’s name. This account is then managed by the 3PF, who is responsible for obtaining all the capital required for running efficiently the programme. The funds can either come from banks and other institutional investors or from independent investors, which at maturity receive the return of their investment. The initial three steps are exactly the same than the previous archetype.

Step 4. The request for early payment and the relative information about the supplier and the specific invoice are then sent to the 3PF through the service provider. This phase ends with the invoice approval by the 3PF.
Step 5. The supplier receives the requested early payment from the 3PF, who previously raised enough capital from an investment fund set up at the buyer’s name. The Accounts Receivable value related to that specific invoice remains on the third party financier’s balance sheet until maturity.
Step 6. The buyer pays back the 3PF the full amount on due date. Most of the times, the buyer is able to extend payment terms with suppliers.
Step 7. Depending on the specific horizon of the investment, 3PF delivers the interests matured to the investment fund, while the invoice discount obtained is shared between the three actors involved (buyer, service provider and third party financier).

A distinctive element of this solution is the fact that the buyer has no visibility at all on the discount rates. The buyer is simply required to provide P6 with its suppliers list and with the access to a set of relevant information about them. Then, the service provider enriches these data by using some analytics and by analysing public information as well. Finally, the service provider negotiates the discount rates with all the suppliers during the on-boarding process, coherently with the analysis performed. Once a supplier has agreed to join the programme, the buyer is notified, but the discount rates related to each specific supplier are completely invisible to the buyer, since the whole financing process is managed by the 3PF. Acting in this way, the buyer can avoid appearing as the financing partner of the programme.

The buyer can be completely sure that the service provider would try to maximise the discount rates during the negotiation process with suppliers, because of the logic that stands behind the discount division. Every time that an invoice is discounted, that amount is reduced by the cost of capital from the 3PF and then, whatever is left is shared between the service provider and the buyer. Similarly to the Standard Dynamic Discounting model, also in this situation, the supplier is able to participate to two slightly different versions of the same programme: in the version called “Cash Planner”, every time an invoice is approved, it is automatically sent to the

3PF. On the other hand, even though this version is less frequent, the supplier has the possibility to pick manually the invoice to finance.

Dynamic Discounting with Special Purpose Vehicle

The third archetype is called "Dynamic Discounting with SPV". This specific version is offered only by P5.2 and it exploits the presence of a third party institution, the so-called Special Purpose Vehicle (SPV), which acts as an intermediary between the suppliers and the buyer. A Special Purpose Vehicle is defined as a subsidiary of a company, whose aim is to isolate risk from the parent company. This can be done by maintaining assets and liabilities on a completely separate balance sheet. This archetype can be seen as a combination between a Dynamic Discounting practice and a Reverse Factoring. Suppliers that agree to join this programme have no visibility on the financing source: this solution makes whoever is funding invisible to the suppliers. The first 2 steps are the same for all the archetypes; for this reason, they are not displayed in the scheme.

Step 3. After receiving the notification, the supplier is able to decide when and if to ask for early payment. On the dedicated section of the portal, the supplier can visualize all the invoices already approved and available for funding and the relative rates. Since the supplier has no visibility on the financing source, there are no differences between the rates related to a Dynamic Discounting programme and the ones related to Reverse Factoring.

Step 4. When the supplier makes a request for early payment, two different situations can arise, depending on buyer cash availability.

Step 4.A. If the buyer has personal cash to use, the specific invoice is purchased by SPV and it can be grouped into a package, called note. Each note is built taking into account the buyer and his requests: service provider receives from the buyer information about the amount of cash he wants to invest and the expected return. Then, hundreds of invoices are combined in order to build one note, which is characterised by a specific amount and a return. At the end, the provider sells the note, which has been created in order to meet buyer's expectations. In this case supplier receives the requested early payment from the buyer through SPV, which acts as an intermediary

Step 4.B. If the buyer has currently no excess cash or he is not willing to invest in such programme, or the invoice is not suitable for being included in any note, the supplier can still get the financing through a standard Reverse Factoring solution. In this case, supplier receives the financing from the external financial institution (bank) through the platform, which is involved in Reverse Factoring. In this case, according to the agreements, which characterise the Reverse Factoring solution in place, the buyer pays back the bank at due date.

This archetype is different than a traditional DD practice, because the invoices are actually bought and sold, in an aggregate way, by the service provider. Moreover, since the notes are collateralised by the AR of the supplier and all the invoices, which are part of a specific note, are taken from the supplier base of the buyer, this can be considered as a real risk-free investment. Basically, the buyer is investing his money, being aware that the riskiness of the investment itself depends on whether or not he will pay back his suppliers. Finally, one of the main big advantages of this solution is the possibility for the buyer to keep the anonymity. When suppliers access their dedicated section in the platform, they can see the list of the invoices available for early payment and the relative discount rate, which they have negotiated with Iota during the on-boarding phase. In this way, they are not aware about where the money comes from. This situation can be particularly useful when the buyer is dealing with suppliers that have the same or even bigger size, and, thus, that have a strong negotiating power.

Market Place

The fourth and last archetype is the one proposed by P1 and it is named "Market Place". The logic that stands behind this business model is the belief that a Dynamic Discounting process characterised by rates set by the buyer is an inefficient process. First of all, the buyer cannot be

completely sure about what the supplier is really willing to accept. Moreover, there is not either a traditional negotiation process, since each buyer may have thousands of suppliers and it can be time-consuming. With the intention of creating an additional evolution of Dynamic Discounting practices (which already evolved from cash discount policies), this archetype has created a dynamic real-time environment for companies, where needs of the suppliers are matched with requests of the buyer. In order to generate the appropriate market place, this archetype completely switched from traditional practices, where the buyer or the service provider were in charge of setting the discount rates of the programme, to a supplier-led solution, where the supplier is the only responsible for it.

The web-based platform is not a unique global market, but it encompasses several markets. The main reason for the presence of multiple markets is inside the concept of supply chain itself: one supplier has multiple buyers, and the platform provides one market for each of those buyers. Likewise, one buyer has many suppliers, who are willing to unlock cash for their businesses. When the supplier logs on the dedicated section of the platform, he has full visibility on all the available invoices, which have been already approved by the buyers after the usual reconciliation process. Then, supplier is able to decide the discount rate that wants to provide. The system automatically calculates the amount of the discount, considering the proposed rate, the days paid earlier and the nominal value of the invoice. If the supplier is satisfied, it can save the settings and wait until the end of the day, otherwise can still change the proposal anytime during the day. On the buyer's side, when buyer logs on his dedicated section, the parameters to set are the amount of cash buyer wants to invest and what return is willing to reach with this investment.

Then, the market place runs on a daily basis: at the end of the day, the platform, thanks to an appropriate algorithm, is able to match what the suppliers require with what the buyer is ready to invest. The following day, each supplier can decide whether to keep proposing the same discount rate (in the case it received the early payment) or to increase the rate (in the case it couldn't receive the money). However, this model is positive not just for the supplier but also for the buyer. The market place is able to create appropriate packages by combining invoices from different suppliers with the final aim of satisfying the targeted return that the buyer sets, because the algorithm works taking into consideration a "blended rate". It is possible to accelerate payments also for suppliers who are proposing rates lower than the targeted return, on condition that they are balanced by other suppliers who propose higher rates. Another advantage for the buyer is the possibility to define a targeted return on a monthly basis instead of a standard daily basis.

Drivers of adoption of Dynamic Discounting Archetypes (RQ2)

In this section, the RQ2 is investigated, to identify some possible drivers of adoption in the buyer perspective. Looking at the academic literature, it is still not clear how companies can understand which one, among the existing Dynamic Discounting archetypes, is the right version to implement. Through the case studies, we were able to better specify the main drivers identified through the literature, as well as to customize the value of those drivers for the four archetypes identified. The summary of the main drivers for each archetype is reported in Table 3, cross case analysis is reported in Annex C.

Table 3: Description of the drivers of the Dynamic Discounting archetypes

Macro-variables	Variables	*Standard*	*3Party financier*	*SPV*	*Market place*
Strategic objectives	Strategic goal	Buyer financial performance	Combination	Combination	Buyer financial performance
	Tangible benefit (discount)	2%-5% in average	2-6% in average	8-10% in average	6-7% in average
	Intangible benefits	Risk management and non salvageable investments	Improvement of DSO metrics	Expanding business tool	Improvement of DSO metrics Expanding business tools Time factor
Relationship status	Targeted suppliers	Long tail	Whole supply base	Whole supply base	Whole supply base
	Implementing and switching cost	Minor	Minor	Significative	Significative

Interviewed companies have addressed three main variables in terms of strategic objectives. First of all, the main goal to introduce DD, that might be just a new solution used by the buyer to improve its personal financial performance or it could also be a tool to strengthening the relationships along the supply chain. Considering the DD with 3PF, the main goal is to exploit as much as possible the benefits that arise from an invoice discount and from an extension of payment terms, thus the focus is more on improving his own financial performance. Similar approach was also identified for the case of Standard DD, where most of the service providers addressed that buyer is mainly focused exclusively on its personal return, trying to get the highest possible discount. In DD with SPV and Market Place configurations, the buyer tries to achieve a better financial position, but paying attention not to stress the relationship with suppliers.

The second variable mentioned by interviews pertain to the expected results, in terms of discount. This variable is mainly specific of the specific service provider, but looking at the main replies achieve through the interviews, it was possible to identify some average value for each archetype. In this sense, the most convenient solution appears the SPV, that can bring quite high level of discount return, thanks to the ability of the SPV itself to arrange and combine different options for the buyer.

The third variable mentioned in the interviews pertain to some intangible benefits, beyond the discount. In particular, interviews identified 4 main intangible benefits, with different elements of important for the four archetypes. For standard DD, the most important element pertains to risk management: two service providers stated the importance of maintaining a stable and sound relationship, especially if the supplier has made some relationship-specific investments. For the 3PF, it is particularly relevant the potential improvement of DSO metrics. As a matter of fact, some service providers as well as companies part of the research addressed that close to the end of the business year, suppliers may accept/propose discount rates, which are characterised up to 10% variance, compared to other moments of the year. This benefit was raised also by the service provider offering the market place solution, which is the approach more supplier-centric. The SPV archetype reported as additional benefit the use of the solution as a expanding business tool. In particular, the need of building or increasing the customer base is especially common for start-ups, which may be innovative and well-performing, but constrained by liquidity problems. This benefit as well was also reported by the service provider offering the market place solution. Finally, the market place archetype reported also an additional benefit, related to time factor. They especially reported the flexibility of the platform proposed and so the possibility to avoid time consuming legal agreements and thus to have quick access to financing.

Considering the relationship status, the first variable investigated pertains to target suppliers. It investigates which group of suppliers the buyer should target for the on-boarding process. Considering also the findings from the existing literature, the Standard DD is often coupled with a Reverse Factoring solution independently (not part of the DD archetype). This means that the buyer usually implements DD with the suppliers belonging to the so-called long tail, and RF with top suppliers. On the other hand, the three remaining configurations have in common the possibility for the buyer to target the whole supplier base, because Reverse Factoring is often embedded into the archetype itself.

The last variable taken into consideration pertains to expenses for the implementation of a DD solution and the effort for switching from a SCF solution to another within the same online platform. Considering the Standard DD, there are no significant costs, but just some small expenses about vendor communication, setup activities and creation of new documents and agreements. Moreover, switching from one solution to another is pretty simple, since they usually share the same service provider's platform. Also for a DD with 3P Financier, the implementing costs are quite low, since this solution just requires simple setup activities and agreements. On the other hand, the costs for putting in place a DD with SPV can be significant: they entail legal expenses and external counselling in order to setup a dedicated compartment in the SPV. Finally, the Market Place implementation costs can be considered as well to be quite significant, since this archetype is a more complicated construct and it requires more documentation than a simple one-page legal agreement typical of the first two archetypes.

Conclusions

This paper aims at investigating a key SCF solution, namely Dynamic Discounting. Through the support of a multiple case studies methodology, four DD archetypes were identified: each archetype is characterized in terms of actors' role and information sharing. Each archetype was also investigated in terms of drivers (i.e., strategic objectives and relationship status) for the adoption, with a buyer-centric perspective.

The paper presents some contributions both from a research and a practitioner perspective. For the former, literature about DD is poor, especially in terms of empirical contribution. The paper cast some lights on practical implementation of DD, illustrating the main archetypes with the support of an empirical basis. Moreover, literature is investigating DD as a stand-alone solution: the proposed archetypes show that on the one hand different models are existing under this concept and on the other hand the adoption of DD might be synergic with other SCF solutions, i.e. Reverse Factoring. For the latter, the paper provides an overview about the possible models to introduce DD into companies, helpful for managers investigating it. The identification of the main drivers for each archetype might also be a suitable tool, supporting the decision-making process.

The paper has also some limitations, that can open up opportunities for further research. First of all, most of the evidence comes from the analysis of major technology providers case: the sample should be enlarged, including also the perspective of small technology providers, reinforcing the viewpoint of big buyers and introducing the perspective of suppliers. Second limitation is that just the buyer perspective was taken into consideration for the identification of drivers: further research might aim at analysing the problem with the supplier perspective too. Thirdly, the paper just addressed the strategic objectives behind the choice: additional research will aim at quantifying potential benefits achieved through the solution. Finally, the cases hint the potential combination of DD with other SCF solutions, such as the adoption of Reverse Factoring for strategic suppliers and those of DD for the "long tail" of suppliers. Additional research might investigate the potential combination of different tools, to exploit all the value of SCF for both buyers and suppliers.

Supplier Communications during Production Ramp-up: What can Procurement do to improve Ramp-up Performance?

Claudia Gesell[1], Andreas H. Glas[2] and Michael Eßig[2]
1 Audi AG, Germany
2 Bundeswehr University Munich, Germany

Abstract
Ramp-up, defined as the period between the completion of development and a stabile serial production, is of high importance for the success of manufacturing companies. Supplier communication is repeatedly mentioned in the literature as a source for improving ramp-up performance. Therefore, the aim of this paper is to conceptualize the exchange of information between a buyer and a supplier to improve the understanding of the communication during the ramp-up process. For this purpose, a systematic review of the literature is used to analyze the status quo of existing communication concepts in ramp-up management. The paper conducts a content analysis of a sample of 86 subject-relevant articles from academic journals. Surprisingly, although communication plays a central role in ramp-up management, only a few limited and specific findings were discovered. In the ramp-up literature, communication is only mentioned but is not further expounded upon. Hence, this paper identifies research gaps in the communication literature regarding ramp-up management and proposes a novel potential direction for future research.

Keywords: communication, ramp-up management, buyer-supplier relationship

Introduction

The period between the end of product development and full capacity production is known as production ramp-up (Terwiesch and Bohn, 2001). Production ramp-up is a crucial phase for a number of reasons. Surbier et al. (2014) identify time, costs, complexity, and uncertainty as reasons, why almost every company faces problems related to new product introduction, in the short or medium term. To illustrate these issues, this work introduces the topic of supplier communication during production ramp-up with an example from the automotive industry.
In general, the automotive industry is currently characterized by increasing customer requirements with respect to the quality and individualization of products (Thiebus et al., 2006). Therefore Original Equipment Manufacturers (OEM) create new car segments, such as Sport Utility Vehicles (SUV), and enrich existing segments with more individualized possibilities (Thiebus et al., 2006). Likewise, new technology, such as the development of electro mobility during the next ten to 15 years, will increase the number of new models. Model diversity increases significantly. For example, AUDI AG, a German automotive manufacturer, had three models in 1980 but is expected to have 17 models by 2025 (Gesell 2017; Jung, 2017). Customization and new technologies increase model quantity, which leads to more frequent ramp-up processes. However, 33% of all ramp-ups today do not reach their cost targets, and 50% do not reach their technical targets (Bauer et al., 2014; Bischoff, 2007). Therefore, production ramp-up affects both successful serial operations and commercial success (Bauer et al., 2014). It can be assumed that the success of the production ramp-up affects the performance of the whole product introduction project.
Production ramp-up is also a topic in purchasing and supply management; even though the ramp-up phase affects numerous functions in a company, such as marketing, finance, and sales, the most related ones are product development, production planning and supply chain functions (Surbier et al., 2014). OEMs externalized a wide range of development and production tasks to suppliers that formerly might have been carried out in-house (Hab and Wagner, 2017; Jung,

2017). This means, that OEMs focused on their core competencies, and for other activities, they draw on the expertise of suppliers (McIvor and Humphreys, 2004). It is the task of the supply management functions of a company to coordinate with the suppliers during production ramp-up and to be the interface to the upstream market (Calabrese, 2000).

Production ramp-up has been studied by numerous researchers since the late 1990's, but the literature addresses a wide range of topics, such as planning, knowledge management, personnel management, and product change management (Surbier et al., 2014). It seems as if there was no distinct focus on the role of the procurement department and the opportunities provided by an improved buyer-supplier coordination. However, both academics and practitioners underline the importance of coordination and information sharing in buyer-supplier relationships (Baglieri et al., 2007; McLoughlin and Horan, 2000). Generally, the communication during production ramp-up is identified as an important success factor (Bauer et al., 2014; Filla and Klingebiel, 2014). The high relevance of supplier communications during production ramp-up was the starting point of this research to further investigate how the communication interface has already been analyzed.

Very few articles have been found that explicitly address the topic. A recent literature review by Surbier et al. (2014) on the status-quo of production ramp-up research mentions the aspect of "cooperation between personnel, departments, and companies," but it only cites two references (Surbier et al., 2010; Kuhn et al., 2002). This is surprising, as product introduction is a topic for almost every manufacturing company, and production ramp-up will increase in many industries due to short product life cycles and customization. It has been assumed by the authors that there must be more knowledge about the phenomena in the literature. The following guiding research question was considered by this present study.

RQ: What is the status quo of purchasing-driven supplier communications in ramp-up management?

To answer this research question, a structured review of the literature is executed with a distinct focus on buyer-supplier communications and production ramp-up. The level of analysis is dyadic and analyzes the relationship between buyers and suppliers. This article reports on this review, and the remainder of the article is organized as follows. After this introduction, an analytical framework is formulated in order to evaluate the literature according to the dimensions of that framework. Next, the methodology is outlined in section 3 and provides details of the literature review. This is followed by section 4, in which the findings of the review are presented. Finally, the results are discussed in section 5. The article ends with concluding remarks and identifies areas for future research.

Supplier communications in ramp-up management: An analysis framework

To ensure a common understanding of ramp-up management and supplier communications, the following section introduces both topics. On that basis, this chapter synthesizes both aspects and develops an analytical framework. This, structures the topic and allows for further analysis of the literature according to the dimensions of that framework.

Review of ramp-up management

The focus of this article is on the production ramp-up in which there is great coordination between buyers and suppliers. Therefore, ramp-up is a critical phase of the entire product life cycle (Surbier et al., 2014; Thiebus et al., 2006). Production ramp-up is the primary issue and has its routes and origins of discussion in the new product development literature. Indeed, ramp-up is defined as the last step of the new product development process (Surbier et al., 2014). There is a general consensus on the definition of ramp-up in the literature. The first definition given by Bohn and Terwiesch (1999) was adopted by later studies. Ramp-up refers to the period between the completion of development and full capacity utilization (Bohn and Terwiesch, 1999). Therefore, ramp-up is the linking process starting with the release for development and ending at the subsequent serial production phase (Surbier et al., 2010; Thiebus et al., 2006).

Ramp-up management can be divided into phases. The three frequently mentioned phases are the pre-series, the pilot series and the ramp-up phase (Kremsmayr et al., 2016). The pre-series phase is the only phase where series tools are not used. The objective is to identify potential spheres of action and to qualify the personnel (Bußwolder et al., 2016). In the following pilot phase, all tools, materials, and staff are the same as in the series production (Thiebus et al., 2006). Suppliers also start ramping up their parts. The last phase is the ramp-up phase during which the first products are sold to customers (Bußwolder et al., 2016; Winkler et al., 2007). Furthermore, the ramp-up phase is characterized by the demand of increasing production output from the customer side and ends at the production of a predefined volume (Kremsmayr et al., 2016; Surbier et al., 2010).

The most common characteristics of ramp-up come from Surbier et al. (2014) and, are summarized below.

- There is low initial knowledge about the product and processes (Fleischer et al., 2003; Juerging and Milling, 2006; Terwiesch and Xu, 2004). Learning gradually occurs (Terwiesch and Bohn, 2001; Terwiesch and Xu, 2004; van der Merwe, 2004) but is difficult (Haller et al., 2003; Säfsten et al., 2008).
- Low production output (Fleischer et al., 2003; Haller et al., 2003; Juerging and Milling, 2006; Terwiesch and Bohn, 2001).
- Higher cycle time (Haller et al., 2003; Terwiesch and Bohn, 2001; Terwiesch et al., 2001).
- Low production capacities (Fleischer et al., 2003; Haller et al., 2003; Juerging and Milling, 2006; Terwiesch and Bohn, 2001; Terwiesch et al., 2001).
- High demand (Haller et al., 2003; Terwiesch and Bohn, 2001; Terwiesch et al., 2001).
- High disturbance in process, supply chain or product quality (Fjällström et al., 2009; Fleischer et al., 2003; Terwiesch et al., 2001).
- Lack of planning reliability (Meier and Homuth, 2006).

One of the most important activities in ramp-up management is the discovery and removal of problems and missed opportunities (Terwiesch et al., 2001). Any interruptions or problems during ramp-up have negative impacts on efforts and costs and could turn the whole project from a success into a loss (Surbier et al., 2014). Often, ramp-up is considered as a project, such as a temporary endeavor to transform a unique product introduction into series production (Juerging and Milling, 2006). Therefore, the performance indicators are mostly derived from the classical project performance measures, such as the “magic triangle” of costs, quality and time (Surbier et al., 2014). In summation, ramp-up management covers all main activities related to planning, executing and controlling a production ramp-up, while the objective is to carry out a ramp-up within the planned time frame using high quality processes and cost compliance (Clark and Fujimoto, 1991; Surbier et al., 2010; Terwiesch et al., 2001).

Review of supplier communications

Suppliers involvement early in new product development helps to increase the operational performance of buyers and suppliers; the main benefits are an increase in the synchronization of the supply chain, a deduction of total costs, an improvement of quality and cycle time and a stronger competitive position (Monczka et al., 1998; Monczka et al., 1993; Tan, 2001; Vanpoucke et al., 2014). The topic of involving suppliers in the processes of the buyer is discussed in the literature under the topics of “supplier integration” and “supplier relationship management”. Supplier relationship management is the part of the supply chain management that addresses all aspects of the business relationship between companies and their suppliers (Das et al., 2006; Dwyer et al., 1987; Farmer, 1997; Lamming and Hampson, 1996; Morgan and Monczka, 1996).

In successful purchasing relationships, effective communications are a key factor (Ambrose et al., 2008). Numerous studies of buyer-supplier relationships have identified communication as an antecedent of trust (Morgan and Hunt, 1994) and of relationship success and satisfaction

(Human and Naudé, 2014; Mohr and Spekman, 1994; Monczka et al., 1993). Communication can be defined as "the formal as well as informal sharing of meaningful and timely information between firms" (Anderson and Narus, 1990). Therefore, communication is the process of acquiring all relevant information, interpreting this information and effectively disseminating the information to those who might need it (Crotts and Aziz, 1998). Communication is of vital importance to everyone involved in the purchasing relationship (Emmitt, 2010; Zulch, 2014). Therefore, it could be assumed that effective communication is also relevant for successful production ramp-up. That assumption is supported with some exemplary statements about the importance of communication during ramp-up (Table 1).

Table 1: Exemplary statements about communication during ramp-up

Author	**Statement**
Bauer et al., (2014)	”The start of series production is an interdisciplinary process in which **information and communication flow** play an important role.”
Filla and Klingebiel, (2014)	”Most of the pre-series sub-processes are equivalent to series processes. The main difference is **a higher effort on the communication and information flow** to ensure a new material flow for supplying the pre-series production; especially under consideration of permanently changing components in the product related bill of materials.”
Nau et al., (2012)	”**Communication** has a high weighting factor, because this is usually an important task in all ramp-up projects.”
Surbier et al., (2010)	”**Intense collaboration** and **information exchange** is needed to complete the ramp-up objectives.”

The statements in Table 1 imply that supplier communications during ramp-up may reduce development time, reduce development and product costs and improve product quality both now and in the future. For this reason, this analysis regards communication between the buyers and suppliers. Indeed, the communication (behavior) of companies during ramp-up and other phases is performed by individuals and poses several methodological challenges.
Referring to the methodological individualism, which was introduced as a methodological precept for the social sciences by Weber (1922), all explanations of social phenomena (macro level) have to be couched in terms of statements about individuals (micro level) (Hodgson, 1986). The micro level could be researched through observations or hypotheses testing, but the macro level could not be analyzed. To gain knowledge on the macro level, the insights from the micro level have to be interpreted and aggregated to reveal generalize knowledge. This research follows this reasoning, which allows us to explain social phenomena in terms of individuals and relationships between individuals (Hodgson, 2007).
To structure supplier communications for the analysis of the literature, a basic understanding of communication is used from the huge amount of literature from diverse disciplines on communication. At its most basic level, communication is described by the S-O-R-Model (stimulus-organism-response) (Woodworth, 1921). This model pictures that stimulation and human behavior (reaction, action) are linked by an organismic component (Buxbaum, 2016). This means that the human behavior is usually a complex function of interacting factors. Furthermore, Shannon and Weaver (1964) state that communication consist of the following five components.

- The information source selects a desired message out of a set of possible messages (this is a particularly important remark, which requires considerable explanation later).
- The transmitter changes this message into the signal, which is sent over the communication channel from the transmitter to the receiver.
- The channel is merely the medium used to transmit the signal from the transmitter to the receiver.

- The receiver ordinarily performs the inverse operation of that done by the transmitter to reconstruct the message from the signal.
- The destination is the person for whom the message is intended.

The communicated message flows from the sender. It is encoded through the transmission channel/medium by a verbal or non-verbal method for the receiver that decodes the message (Shannon, 1948; Shannon and Weaver, 1964). Weaver (2007) added one more component, the so-called noise. Noise exists in every communication medium and distracts the receiver from the contents of the message. To ensure effective communication, all components must function to prevent misunderstanding (Zulch, 2014). In other words, content, medium, feedback, and the frequency of communication must be aligned (Mohr and Nevin, 1990).

Analysis framework for supplier communications in ramp-up management

This chapter describes an analysis framework for supplier communications in ramp-up management. Three theories encompass this framework, including social exchange theory, role theory and principal-agent theory.

Social exchange theory states that individuals or groups attempt to interact with others with the expectation of a reward. It assumes that behaviors can be assessed by the rewards of interaction minus the costs of that interaction (Wu et al., 2014; Yang et al., 2009). Role theory focuses on the roles that receivers and senders play in social interactions, which are induced through shared expectations and associated behaviors of different parties within specific contexts (Andersen et al., 2009; Dong et al., 2016). Principal-agent theory argues that there is asymmetric information sharing between dependent actors. Wherever one individual or group depends on the action of another, an agency relationship arises. The individual taking the action is called the agent. The affected party is the principal. The challenge in the principal-agent theory arises whenever the principal cannot perfectly monitor the agent's action and information, which almost always occurs (Pratt and Zeckhauser, 1985). Thus firms in a buyer-supplier relationship can be expected to have access to and possess different information (Oosterhuis et al., 2013).

Based on the above mentioned three theories for supplier relationship management, the three process phases of production ramp-up, and the understanding of communications with the S-O-R-model, the analysis framework synthesizes those mentioned aspects.

Referring to the ramp-up management, the model (see Figure 1) refers to the three phases A to C between development and serial production (Bauer et al., 2014; Fjällström et al., 2007; Surbier et al., 2010; Thiebus et al., 2006). In this paper, serial ramp-up is defined by the three phases of (A) pre-series, (B) pilot series and (C) the ramp-up phase (Bußwolder et al., 2016; Kremsmayr et al., 2016).

Next, the model (see Figure 1) consists of six dimensions that are related to communication. The communication dimensions are classified into (1) behaviors, (2) roles, (3) channels, (4) information type, (5) quality (that in sum build the factors of success of communication), and (6) influential factors and sources of irritation.

The behavior of communication partners is characterized through trust, commitment, and their cultural background (Dwyer et al., 1987; Ireland and Webb, 2007; Large, 2005; McCarter, 2005; Mohr and Spekman, 1994; Moorman et al., 1993; Moorman et al., 1992; Morgan and Hunt, 1994; Rosenbloom and Larsen, 2003; Schurr and Ozanne, 1985). It is based on the social exchange theory and the principal-agent theory. All text in the structured literature review related to behaviors is coded to that communication dimension. Next, communication roles are distinguished and the sender and receiver roles are derived from the role theory (Andersen et al., 2009; Dong et al., 2016), as well as sub-roles (who on the buyer side communicates with who on the supplier side).

The next three communication dimensions are deduced from the model by Shannon and Weaver (1964). The information channel describes how information is exchanged. For example, the literature differs in face-to-face meetings, telephone and e-mail (Mohr and Nevin, 1990; Mohr and Spekman, 1994). The information type characterizes what information is exchanged

(Monczka et al., 1998; Noordewier et al., 1990; Richeson et al., 1995; Samaddar et al., 2006). Communication quality includes aspects such as timeliness, accuracy, reliability and relevance (Chen and Paulraj, 2004; Monczka et al., 1998; Naumann and Rolker, 2000). Finally, the influential and interference factors represent a collective dimension that comprise all other issues that could have an effect on the supplier relationship, communications and ramp-up management.

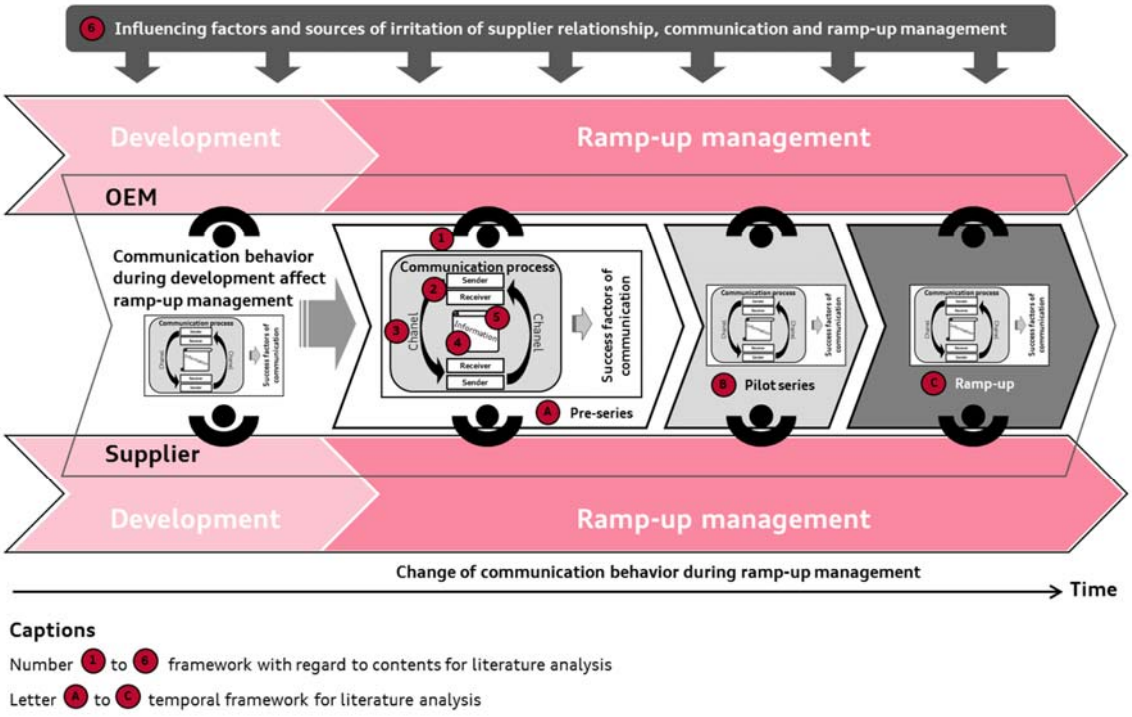

Figure 1: Analysis framework for supplier communication in ramp-up management

Methodology

This paper is based on a systematic literature review. To ensure completeness and reproducibility, it follows the typical methodology of a review (Denyer and Tranfield, 2011; Easterby-Smith et al., 2015). In addition, backward and forward snowballing was used. Snowballing refers to using the reference list of a paper or the citations to the paper to identify additional papers (Wohlin, 2004).

Table 2 gives an overview of how the review was conducted by discovering literature through Science Direct. This database was selected due to its broad coverage of journals across all fields, disciplines and research areas. The keywords for the search were the following: communicat(ion/e/ing), informat(ion/ing) in the area of communications, buyer-supplier and supply chain in the area of supplier management and ramp-up, product launch, and the start of production in the area of ramp-up management.

Table 2: Overview on methodology of literature analysis

Database	SienceDirect
Search	First round: combination of Communication and Ramp-up Management terms: For title/ keywords/ abstract Second round: combination of Communication and Supplier Management terms: For title/ keywords/ abstract exclusion fot the keyword supply chain only for title
Search terms	Combination of Communication, Ramp-up Management and Supplier Management (due to lack of consistent terminology): **Communication:** communicat*, informat* **Ramp-up Management:** ramp-up, product launch, start of production (no hits) **Supplier Management:** buyer-supplier, supply chain (only title)
Language	English
Sources	Journal papers, conference proceedings, textbooks (of all application fields/ disciplines)
Review period	-2017 (using 1997 in the search of previous years did not reveal any significant papers)
Result of analysis	297 papers identified, read and evaluated (based on abstracts and cross reading) 86 papers remained (after exclusion of non-relevant papers)

The first search round was conducted by combining the communication and ramp-up management keywords. As many articles do not have any of the ramp-up management related terms in their titles, keywords or abstracts, (the combinations with the keyword start of production resulted no hits), a second search round was conducted. It focused on the combination of communication and supplier management terms.

Findings

Identified articles

The analysis reveals the status quo of academic attention on supplier communications in ramp-up management. In total, 297 articles were identified through the search strings combining communication with supplier management or ramp-up management terms. Of these articles, 86 were included in this review. There are two main reasons for the high number of rejected and excluded articles. First, articles that solely addressed information technology and its systems were excluded. Second, papers that did not have a connection to communication between partners in the supply chain or communication during ramp-up were also excluded. The review included articles up to the first quarter of 2017 and included early stages of literature, but our analysis did not reveal any significant papers before 1997.

The research suggests that there has been increasing interest in supplier communications during the last seven years, as 60% of the articles were published in the last seven years. However, of the 86 identified articles, only six contain supplier communications in ramp-up management as a focus topic (named key articles in Figure 2). All others have differing main topics but include some scattered, often limited information on communication and information exchange in buyer-supplier relationships or rather generic statements about ramp-up management. Even this initial descriptive analysis of the sampled articles indicates that supplier communications gained scientific interest, but overall, the number of sources is very scarce.

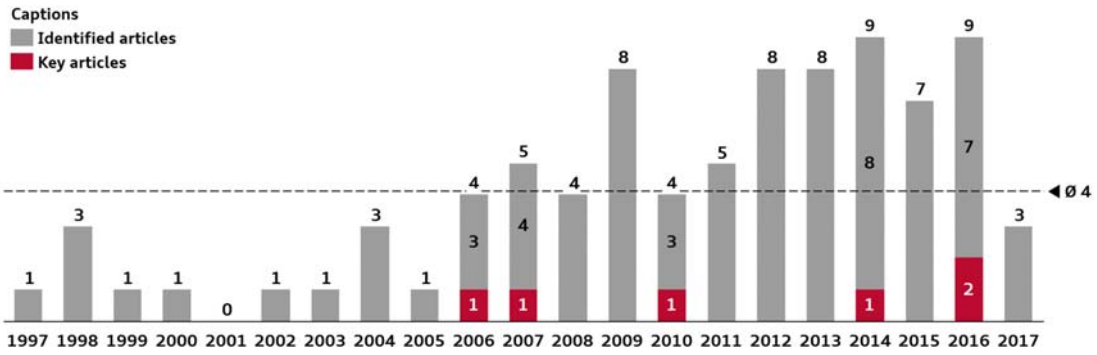

Figure 2: Articles identified as relevant for communication in ramp-up management, shown per year. The key articles are in red.

Next, the findings of the relevant articles suggest a dominance of quantitative methodological approaches. A total of 61 articles (71%) report on quantitative methods. In contrast, of the six key papers three are conceptual, two use qualitative methods and one applies survey methodology (Figure 3).

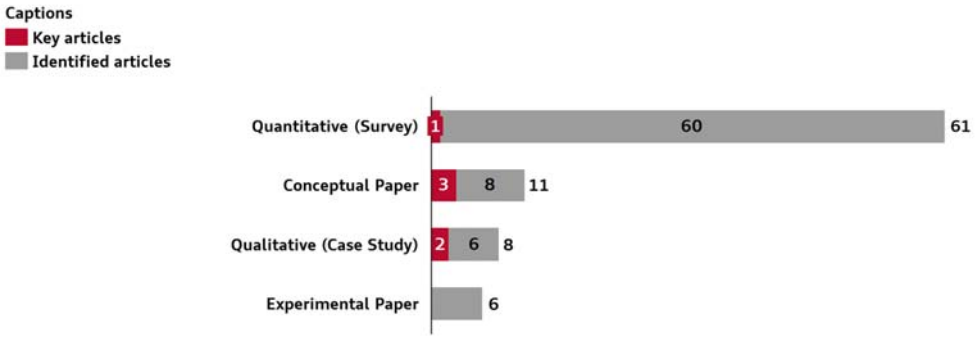

Figure 3: Relevant articles per applied methodology. The key articles are in red.

Findings concerning communication

In a few of the 86 identified articles, there are more than one communication dimension analyzed. The topics of communication behaviors and communication channels are the areas of highest interest, with 56 and 50 codings, respectively. These are by far the highest number of references per topic. Additionally, two categories (information type and communication quality) are discussed and have a significant number of codings (33 and 38). In contrast, the dimension of roles, that describe the relationship between senders and receivers is underrepresented and only addressed in side notes. Only Dong et al. (2016) examines role ambiguity and role conflict as two facets of role hazard between buyers and suppliers. All other topics are addressed, even when most contributions only touch on the topic (Figure 4).

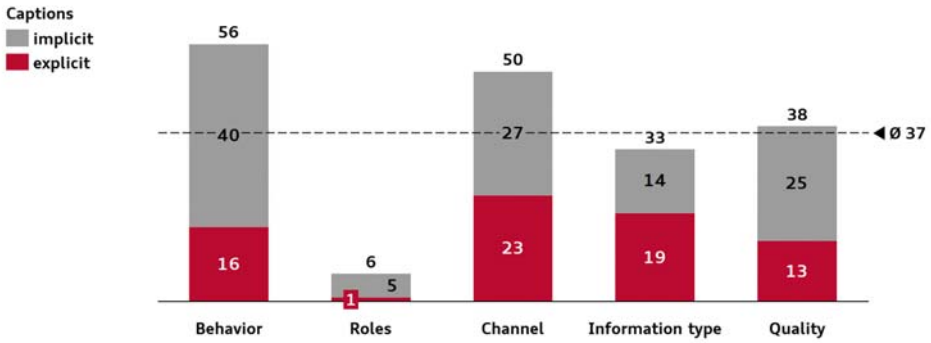

Figure 4: Relevant articles for communication shown per communication dimension. The articles with an explicit focus are in red.

Findings concerning production ramp-up management

As the second search round focused on communications in supplier relationships, many of the identified articles within this round did not contain ramp-up management content. Therefore, there are only six main articles with a focus on the integrated aspect of communication in ramp-up management. The results show that only two articles focus explicitly on communications during ramp-up (Figure 5). Furthermore, only two articles, Bußwolder et al. (2016) and Kremsmayr et al. (2016), distinguish between different phases within the production ramp-up.

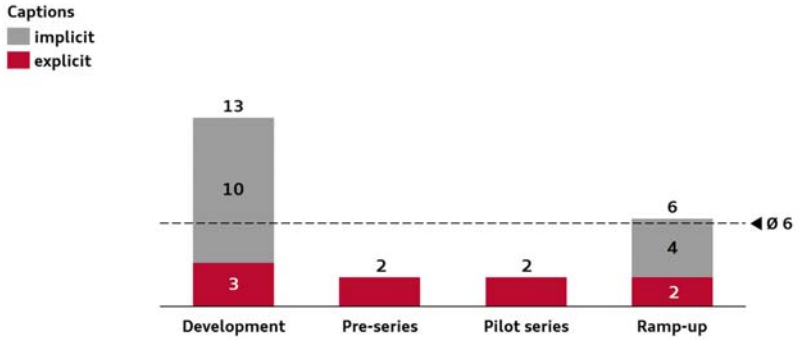

Figure 5: Relevant articles for ramp-up management shown in a timely manner. The articles with an explicit focus are in red.

Results of six key articles on supplier communications in ramp-up management

Based on the analysis in the last section, a first finding is that there is a great research gap with respect to communications in ramp-up management. Only six articles address supplier communications in ramp-up management, and five of those papers are from the intra-company perspective. Only Thiebus et al. (2006) examine knowledge management in the automotive supply chain. Thus, a research gap could be identified to analyze communications in the buyer-supplier relationship since the articles are case-based or conceptual and a statistical validation is missing. Table 3 provides an overview of the key articles, and the following section will analyze these articles in more detail.

Table 3: Overview of key articles on supplier communications in ramp-up management

Author	Title	Industry	Method	Supplier mgmt	Ramp-up mgmt	Communication
Bauer et al. (2014)	Concept of a Failures Management Assistance System for the Reaction on Unforeseeable Events during the Ramp-Up	automotive	concept	intra-company	implicit	information and communication flow/ transparency
Bußwolder et al. (2016)	Classification of Company-specific Influence Factors as Part of a Knowledge Management System for Ramp-up Projects	automotive	survey	intra-company	explicit	knowledge management/ transparency
Fjällström et al. (2007)	Differences Concerning Information when Handling Predictable and Unpredictable Events in Production Systems	automotive	case study	intra-company	implicit	types of information
Kremsmayr et al. (2016)	On the Application of Agility Principles in Ramp-up Management: Approaching the Challenges in the High-End Powder Metallurgy Industry	powder metallurgy	concept	intra-company	explicit	transparency
Surbier et al. (2010)	Interface Modeling and Analysis during Production Ramp-up	electronic	case study	intra-company	implicit	information exchange/ information quality/ information flow
Thiebus et al. (2006)	Knowledge Management for Ramp-up in the Automotive Industry	automotive	concept	supply chain	implicit	knowledge management

Bauer et al. (2014) developed a failure management assistance system to handle unpredictable events during ramp-up. Therefore, information and communication flow and transparency are two major factors for the success of the system. Bußwolder et al. (2016) only mentioned that knowledge management and transparency are very important for the success of a ramp-up project, but they give no details of how to communicate. In contrast, Fjällström et al. (2007) identified the information types required for successful production ramp-up and compared the preferred methods of information perception and information strategies. Kremsmayr et al. (2016) noted that a successful ramp-up requires the highest transparency concerning process maturity. Like Bußwolder et al. (2016) they give no further details on communication. The purpose of Surbier et al. (2010) is to design diagnosis tools to analyze and characterize the information exchange at the interface between project actors. Thiebus et al. (2006) described a new approach based on the cycle of organizational learning to improve ramp-up performance in the automotive industry. The analysis revealed that present research addresses supplier communication in ramp-up management in a rather generic and fragmented way with a low level of detail. This is in contrast to being guided from a theoretically substantiated perspective that also takes into consideration the fact that most articles only mentioned communication. Thus, there are only a few starting points about supplier communication in ramp-up management (Figure 6).

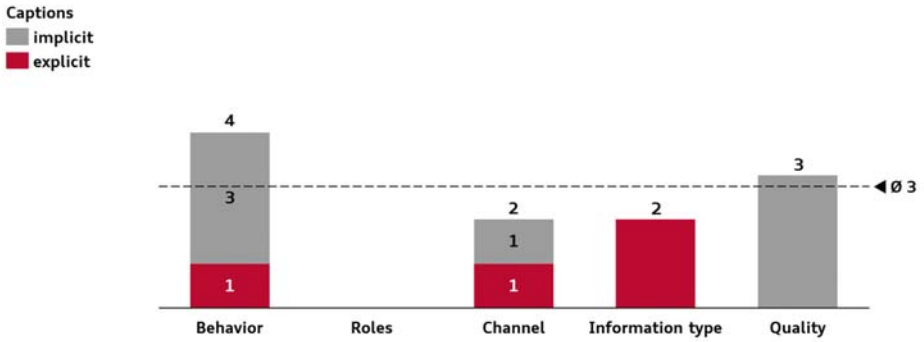

Figure 6: Key articles for supplier communications in ramp-up management shown per communication dimension. The articles with an explicit focus are in red.

In addition, an analysis of the influencing factors and sources of irritation (noise) on communication was conducted within the key articles. Table 4 provides an overview of the identified content. Two of the major influencing factors and sources of irritation are increasing (product and process) complexity and shorter product life cycles (Bauer et al., 2014; Bußwolder et al., 2016; Kremsmayr et al., 2016; Thiebus et al., 2006). Other sources of irritation are late engineering changes (Bauer et al., 2014; Fjällström et al., 2007; Surbier et al., 2010) and inexperienced or limited trained staff (Bauer et al., 2014; Fjällström et al., 2007).

Table 4: Influencing factors and sources of irritation of supplier relationship, communication and ramp-up management reviewed in the six key articles.

Author	Influencing factors and sources of irritation
Bauer et al. (2014)	**increasing product and process complexities**, **less time-to-market**, highest quality requirements, a wide range of failures, poor standardization levels, **inexperienced workers**, **multidisciplinary collaboration with changing**, unclear responsibilities, complex internal information flows
Bußwolder et al. (2016)	**shorter life cycles**, higher rates of innovation, **increasing number of variants**, persistent globalization, increase of dynamic market trends, competition, **increasing product complexity**
Fjällström et al. (2007)	**late engineering changes**, late or defect deliveries from suppliers, insufficient test and verification of the product and its production system**, limited training for the personnel**
Kremsmayr et al. (2016)	growing requests for specialized products**, shorter product life cycles**, accelerated innovation times, tighter development timelines, **growing production complexity**, demand uncertainty, resource availability, competitive pressure
Surbier et al. (2010)	**technical product changes**, personality differences, cultural differences, language barriers, organizational barriers, physical barriers
Thiebus et al. (2006)	**increasing product diversification**, **decreasing product life cycle times**, permanent need for cost reduction, increasing quality requirements, **increasing complexity in products and processes**, increasing demand for product innovations

Discussion

The purpose of this contribution was to answer the guiding research question that asked about the status quo of supplier communications in ramp-up management. This paper analyzed 86 relevant papers. On this basis, descriptive findings about the development of the literature over time, the distribution on application fields and author origins were made. Content analysis focused on the communication process and its categories. Based on the analysis framework (see Figure 1), the core findings about supplier communication in ramp-up management could be summarized in two steps.

Referring to the ramp-up management, hardly any contributions distinguish separate sub-phases within the ramp-up. Only two papers, namely, Bußwolder et al. (2016) and Kremsmayr et al. (2016), analyze communication in ramp-up management in the three phases of (A) pre-series, (B) pilot series and (C) ramp-up. Until now, ramp-up management was only analyzed in a holistic way, but an in-depth analysis of supplier communications during the three ramp-up management phases is missing.

Referring to the communication process between buyers and suppliers, several findings were derived. The first communication dimension, behavior, is generally characterized through trust and commitment that influence successful relational exchanges (Abdullah and Musa, 2014; Crotts and Aziz, 1998; Large, 2005). Communication behavior is also described as the willingness to share information (Kim and Chai, 2017; Wu et al., 2014). Nevertheless, there is no transfer to the ramp-up management. Only Fjällström et al. (2007) examines human behavior for unpredictable and predictable events during ramp-up. They subdivide behavior into skill-based, rule-based and knowledge-based behaviors.

The second dimension, roles, is underrepresented. Even if there is a role theory described by Andersen et al. (2009) and Dong et al. (2016) that generally define the role between buyers and suppliers through their shared expectations, an explicit analysis of their communications during the ramp-up process could not be found. Additionally, the literature hardly distinguishes institutional communications in the buyer-supplier relationship and individual communications, e.g., between the procurement manager and the product manager. The macro and micro levels of the methodological individualism are hardly connected.

The third dimension of communication, channels, includes addresses, as some examples for different channels are provided by Cai et al. (2010) and Oosterhuis et al. (2013), and is classified by media richness (Prahinski and Benton, 2004; Thomas, 2013). During ramp-up, Surbier et al. (2010) analyzed only face-to-face communication, which is ranked as the richest medium for communication.
Fourth, information type is a relatively explicitly researched communication dimension during ramp-up. Fjällström et al. (2007) classified the information available in the problem information, domain information and problem-solving information. In contrast, Surbier et al. (2010) categorized information in three degrees of information structure as 1) structured information, 2) semi-structured information and 3) non-structured information.
Fifth, a few suggestions about the quality of communication are made by Li and Lin (2006), Marinagi et al. (2015) and Zhou et al. (2014). They well characterized communication quality as, the situation when accurate, reliable and relevant information is received in time. Surprisingly, there is no explicit consideration of communication quality during ramp-up.
Finally, sixth, a list of relevant influencing factors and sources of irritation has been derived from the six key articles. Of these, complexity (in products and processes) and shorter development time (Bauer et al., 2014; Bußwolder et al., 2016; Kremsmayr et al., 2016; Thiebus et al., 2006) are most important influential factors of supplier communications during ramp-up. Late engineering changes (Bauer et al., 2014; Fjällström et al., 2007; Surbier et al., 2014) and inexperienced or limited trained staff (Bauer et al., 2014; Fjällström et al., 2007) are sources of irritation.
Generally, it seems as if the topic has been researched only in a very generic way. Statements about supplier communication refer to ramp-up management, but little is operationalized for this special case. A few isolated starting points exist for the fourth and sixth topics, information type and influencing factors and sources of irritation. Nevertheless, in summation, the discovered knowledge modules build no integrated management model for supplier communications during ramp-up.

Conclusion

The reported literature review indicates that communication is an important component of the success of ramp-up. However, until now, it lacks sufficient theoretical grounding. A total of 86 articles have been identified, but surprisingly only six of them explicitly address the topic. This is also a clear limitation of this research. Even if the topic is addressed, it is discussed without considering a holistic communication approach/ model of production ramp-up. Furthermore, there is no specification or detailing of the communication dimensions for the specific phenomenon of production ramp-up. In sum, there is no full picture of the topic of supplier communications during production ramp-up in the literature. Therefore, this article concludes that there is a wide range of future research gaps.

- There are only isolated starting points of concepts for supplier communication in ramp-up management (see section findings, description Figure 4 and explicit Figure 6).
- Changes in the communication process in the three phases of ramp-up must be individually detailed and described (see section findings in combination with description Figure 5).
- There is a need to research communication during ramp-up within the dyad of buyers and suppliers (see section findings, description Table 3).
- There is no statistical validation of the hypothesis proposed by the conceptual research by Bauer et al. (2014), Kremsmayr et al. (2016) or Thiebus et al. (2006) (see section findings, description Table 3).

The future will bring a change in buyer-supplier communication with respect to the communication channel (modern information and communication systems) and the amount of exchanged data. The future improvements in the communication capabilities could be used to improve ramp-up if managed properly. Communication has a high potential to increase

production quality and reduce production time and costs. Therefore, there is a need for a communication-ramp-up management model to analyze the details of the communication process during ramp-up.

Evaluation of Supplier Innovation

Avoiding the dismissal of "good" supplier innovation due to customers' "bad" evaluation procedure

Abstract

In this paper, a benchmarking analysis is conducted to show best practices for the evaluation and selection of supplier innovations. The results show that the most popular evaluation method is gut feeling and that all of the case companies analyze only the quality of the innovation, neglecting to evaluate the supplier proposing the innovation. To further develop these results, a World Café workshop was held. Consequently, two operationally usable checklists were developed to evaluate the characteristics of the external innovation and the qualities of the innovative supplier. Both checklists can be combined into one evaluation scoring model for supplier innovations.

Key words

Supplier innovation evaluation; innovation assessment

Introduction

Supplier involvement in new product development (NPD) is one of the most common reasons proposed to explain the performance in NPD projects (Dekkers, Chang and Kreutzfeldt, 2013). Roberts' panel study from 2001 shows that in the early 1990s, only 22% of the top R&D-intensive firms surveyed heavily relied on external partners for innovation; however, he also shows this share had grown to 85% by the end of that decade (Roberts, 2001). For example, in the automotive industry, most new patents are registered by suppliers (Schiele, Calvi and Gibbert, 2012). Simultaneously, companies benefit the most (e.g., from a financial perspective) from breakthrough or radical innovations (O'Connor, Ravichandran and Robeson, 2008). Early supplier integration (ESI) in the NPD process is used at buying companies to obtain a competitive advantage (Bidault, Despres and Butler, 1998; Johnsen, 2009; McIvor and Humphreys, 2004). ESI can be defined as the extent to which a buying organization shares

responsibility with a supplying organization to develop and design new products or components (Hoegl and Wagner, 2005). Several studies show that ESI increases the innovative strength of a buying company and the capability of innovation project execution (Fitjar and Rodríguez-Pose, 2013; Koufteros, Cheng and Lai, 2007; Song and Thieme, 2009; Un, Cuervo-Cazurra and Asakawa, 2010). On the other hand, it is also possible that supplier collaboration in the NPD process shows no certain performance improvement (e.g., no reduced time-to-market) (Eisenhardt and Tabrizi, 1995; Hartley, Zirger and Kamath, 1997; Swink, 1999) or even results in a negative impact on the business of the buying company (Littler, Leverick and Wilson, 1993). Furthermore, there are some reports that show deficits on the supplier side or even project obstruction when unsuitable suppliers were selected (Flynn, Flynn, Amundson and Schroeder, 2000; Hartley et al., 1997; Petroni and Panciroli, 2002; Primo and Amundson, 2002; Zsidisin and Smith, 2005). Buying companies are then disappointed by what some authors call supplier obstructionism (Flynn et al., 2000; Hartley et al., 1997; Hibbard, Kumar and Stern, 2001; Petroni and Panciroli, 2002; Primo and Amundson, 2002; Zsidisin and Smith, 2005). Concurrently buying companies seem to have only a limited understanding of how to include suppliers in NPD (Lakemond, Berggren and Weele, 2006).

However, ESI in NPD always implies a high level of dependence on the supplier, which may increase the risks for the buying company. Thus, for organizations, it is important to choose both the "right" innovations (which become in the future commercially successful) from the "right" supplier (which offers proper project execution) to obtain a competitive advantage and ensure the survival of companies.

Although most innovations are provided by suppliers, typical innovation assessment models, both in theory and in practice, tend to focus their analysis on only scoring the quality and the potential of the innovation considered (Cooper and Kleinschmidt, 1987b; Figueroa and Conceição, 2000; García-Álvarez, 2015; Hartschen, Scherer and Brügger, 2009; M. Heesen, 2009; Salerno, Gomes, Silva, Bagno and Freitas, 2015). However, the most promising innovation will not succeed if the supplier proposing it cannot perform proper project execution or cannot further develop the innovation. Based on these facts, the research question of this paper is as follows: How can the selection of the wrong innovations, which may fail due to the deficits of the supplier, be avoided and how can the selection of the promising supplier innovations be enhanced? Since the literature review found no model or process that explicitly focuses on supplier innovations or assesses the innovative supplier, the goal of this study is to develop such a scoring model, which considers both the evaluation of the innovation characteristics and the evaluation of the supplier. By developing such a model the users within a company receive a tool to evaluate supplier innovations and a decision tool to select the most promising ones. Ultimately, this model has the function to raise the number of successfully implemented innovations.

The following theory section presents a short overview and provides a definition of NPD and innovation evaluation as part of the innovation management process and of ESI as well as the role of the supplier in the NPD process. The subsequent section presents the method and analysis used in this study. To assess the best practice for the evaluation of supplier innovations, a benchmarking analysis with 16 leading German companies was conducted. In general, the results show that most companies focus on analyzing innovations but neglect to analyze the suppliers providing the innovations. To discuss the benchmarking results and to develop an innovation evaluation tool that includes the supplier evaluation, a second method was adopted – a World Café workshop. As a first outcome, two operationally usable checklists to evaluate, on the one hand, an external innovation and, on the other hand, an innovative supplier were developed. The second outcome is the combinability of the two checklists into one scoring

model that evaluates a supplier innovation from two sides – the innovation criteria side and the supplier side. Additionally, the results reveal two innovation-supplier constellations, which, to date, have been blind spots. How should "bad" innovations from "good" suppliers or "good" innovations from "bad" suppliers be treated? This paper ends with a discussion and conclusion section showing further considerations and complementary ideas.

Theory

Innovation evaluation as part of the new product development process

Innovations are defined as "new solutions" in products, technology, processes and marketing, representing one way through which organizations gain competitive advantage (O'Reilly and Tushman, 1997). To develop and handle the different kinds of innovations within a company, several NPD and innovation management approaches are known. Typically, sequential, multi-step processes are used to decide on and implement innovations. For instance, Lynn et al. describe a conventional NPD process as occurring through idea generation, idea screening, innovation development, testing, and new product launch (Lynn, Morone and Paulson, 1996; Williams and McGuire, 2010). Effective management of the NPD process from the product idea to launch is crucial to ensure that organizations survive and prosper (Cooper and Kleinschmidt, 1987b). However, for companies, it is not easy to choose and promote promising innovations for several reasons. One reason is the blocking and defensive attitude that can be observed in the individuals of the organization itself. This attitude especially occurs in the face of radical innovations that indicate change or that even cannibalize the current business (Chandy and Tellis, 1998, 2000; O'Connor et al., 2008).

Following Cooper, there are two main challenges in the innovation management process: first, the selection of the strongest innovation ideas and, second, an effective process management (Cooper and Kleinschmidt, 1987b). To ensure the best selection, clustering and evaluating the different innovation ideas is essential. For innovations, the literature describes several clustering approaches. They usually become clustered according to their characteristics, e.g., according to the novelty level (radical/disruptive/incremental), the subject area (product innovation/process innovation/etc.), or the complexity or conflict level (García-Álvarez, 2015; Hartschen et al., 2009; M. Heesen, 2009; Tang, 2006; Tavassoli and Karlsson, 2015). Following Sabisch, evaluation is defined as the detection and assessment of the degree of fulfillment of the given objectives for a particular evaluation object (Sabisch, 1991). The goal of innovation evaluation is to compare different alternatives to prepare the selection decision (Sabisch, 1991; Venter, 2006). It is important to select the innovation project wisely because organizational resources in the form of human resources, capital and time are usually limited and the overall goal is to obtain the maximum innovation success (Granig, 2008). Cooper and Kleinschmidt define three dimensions to measure new product performance: financial, market impact and the so-called opportunity window (if the new product opens a new business field or opportunity) (Cooper and Kleinschmidt, 1987a; García, Sanzo and Trespalacios, 2008). More recent studies distinguish between two basic performance dimensions: internal (or project) and external (or market) success (Alegre, Lapiedra and Chiva, 2006; Blindenbach-Driessen, Van Dalen and Van Den Ende, 2005; García et al., 2008; Tatikonda and Montoya-Weiss, 2001; Valle and Avella, 2003). On the one hand, project success measures the effectiveness of the NPD process (project time, development costs, or the degree of product superiority); on the other hand, market success involves the commercial result of the new product (financial performance, the degree of acceptance and satisfaction perceived by consumers) (Blindenbach-Driessen et al., 2005; García et al., 2008; Valle and Avella, 2003). There are several methods to measure the

abovementioned dimensions, e.g., cost-benefit analysis (which is used to create a ranking between different alternatives) (Gleich, Munck and Tkotz, 2016), the PROMETHEE method (Preference Ranking Organization Method for Enrichment Evaluations, which is an outranking method for a finite set of alternative actions or, in our case, innovations, to be ranked and selected among criteria that are often conflicting) (Behzadian, Kazemzadeh, Albadvi and Aghdasi, 2010; Bin, Azevedo, Duarte, Salles-Filho and Massaguer, 2015) or investment calculation (a procedure for assessing investment projects with regard to quantifiable corporate goals; it may be an assessment of one single innovation object or a comparison of different investment alternatives with the same purpose) (B. Heesen, 2010). The execution of the various evaluation methods prepares a decision by matching and comparing the scores of the innovation project with company goals (Pleschak and Sabisch, 1996). After the evaluation and selection of the innovations, the next process step is project execution and the innovation implementation or innovation launch.

Supplier involvement in the new product development process

Cooper defines effective process management as the second challenge in the innovation management process (after the first challenge, the selection of the strongest innovation ideas) (Cooper and Kleinschmidt, 1987b). Because, at present, buying companies receive most innovations from suppliers (Dekkers et al., 2013), logically, in process management and innovation project execution, cooperation with the supplier is also a crucial aspect (Schiele, 2010). The demand for an ever shorter time-to-market and the enormous technological knowledge that is needed to develop new products force firms to increasingly rely on supplier cooperation (Azadegan, 2011; Hong, Doll, Revilla and Nahm, 2011; Koufteros, Rawski and Rupak, 2010; Thomas, Fugate and Koukova, 2011; Stephan M Wagner, Rau and Lindemann, 2010; Stephan M. Wagner, 2012). With the goal of obtaining a greater competitive advantage through supplier cooperation, many companies are adopting ESI, which is defined as vertical cooperation where companies involve suppliers at an early stage in the NPD process (Bidault et al., 1998; Hoegl and Wagner, 2005). The contribution of a supplier (e.g., through skills, and talents) can constitute a significant advantage in the product development process (He, Keung Lai, Sun and Chen, 2014). Particularly in terms of increasing the innovative strength of a buying company and the capability of innovation project execution, ESI plays a key role (Brem and Tidd, 2012; Fitjar and Rodríguez-Pose, 2013; Koufteros et al., 2007; Song and Thieme, 2009; Un et al., 2010). Several studies show that supplier cooperation in the NPD process may provide enormous benefits, e.g., a shorter time-to-market (Ragatz, Handfield and Petersen, 2002), higher product quality or lower project costs and time (Primo and Amundson, 2002). Conversely, the implication is that buying companies must compete for suppliers with superior innovation power or suppliers with exclusive access to radical innovations. Social exchange theory precisely describes this situation: It posits that actors first evaluate the attractiveness of a potential partner, if possible, compare expectations with the outcomes of the relationship and – importantly – then compare one partner with potential alternatives (Lambe, Wittmann and Spekman, 2001). Additionally, the fact that a large majority of radical innovations come from a minority of firms (O'Connor et al., 2008; Sorescu, Chandy and Prabhu, 2003) leads to an intensification in the competition for the best suppliers and thus to growing supplier dependence. This evolution clearly indicates that if companies want to gain access to the most promising innovations and achieve superior project execution and a privileged relationship (Petersen, Handfield and Ragatz, 2005), then they must compete against other buying companies to receive preferred customer status from the innovative supplier (Schiele, 2012). According to Hüttinger et al., preferred customer status is defined as follows: It influences the behavioral intentions of the supplier to the extent that the supplier awards selected customers with more favorable treatment than others (Hüttinger, Schiele and Veldman, 2012).

This high level of supplier dependence, caused by ESI in the NPD process, carries great risks for buying companies. Some suppliers, for instance, do not always collaborate in the manner expected. Furthermore, some organizations seem to have only a limited understanding of how to include suppliers in NPD (Lakemond et al., 2006). Some studies show the possibility that ESI will lead to no certain performance improvement (Eisenhardt and Tabrizi, 1995; Hartley et al., 1997; Swink, 1999) or that it even results in a negative impact on the business of the buying company (Littler et al., 1993). Additionally, there are many reports that show the incompetence of suppliers in project execution and even project obstruction if unsuitable suppliers were selected (Flynn et al., 2000; Hartley et al., 1997; Petroni and Panciroli, 2002; Primo and Amundson, 2002; Zsidisin and Smith, 2005). The underlying concept in these studies is called "supplier obstructionism", which is defined as the measurement of the damage to NPD projects due to dependence on uncooperative suppliers (Flynn et al., 2000; Hartley et al., 1997; Hibbard et al., 2001; Petroni and Panciroli, 2002; Primo and Amundson, 2002; Zsidisin and Smith, 2005). The worst-case scenario for a buying company would be being dependent on the resources of the supplier for its innovation process while being denied access to these resources (Schiele and Vos, 2015). The description of this phenomenon clearly notes that not only "bad" innovations with bad evaluation scores fail but also a certain number of "good" innovations fail due to the bad performance of the supplier. Since the supplier plays such a key role in the NPD process, it is very surprising that no innovation evaluation tool includes a supplier assessment. Moreover, no innovation evaluation method that explicitly focuses on the characteristics and specialties of supplier innovations was found. The lack of such a method is precisely the research gap that this study aims to close by developing a scoring model that evaluates an innovation from both sides – the innovation characteristics side and the supplier side.

Research Methodology

To evaluate the existing best practices in the innovation evaluation of supplier innovations and to further develop the results, two research methodologies were adopted. Initially, a benchmarking analysis was conducted. Benchmarking is defined as the search for best practices in a certain field or in relation to a specific topic, with the goal of achieving superior performance by implementing the best practice (Camp, 1989). Three types of benchmarking can be distinguished: process benchmarking (which this paper applies), product or service benchmarking and strategic benchmarking (Drew, 1997). The aim of this benchmarking study was to identify the best practice for clustering, evaluating and selecting supplier innovations. Ultimately, 16 companies participated in the benchmarking (73 companies were invited – 22% accepted the invitation). The participants were experts from various leading companies located in Germany (14 were founded in Germany, and 2 were companies with a German branch that were founded abroad). The goal was to devise a participant setup that was as diverse as possible. Therefore, companies with different sizes and from eight business sectors were selected (details are shown in figure 1). Eight of the companies had fewer than 10,000 employees; the other eight firms had more. The individuals representing the companies were either purchasing managers, innovation managers or NPD process managers.

Figure 1: Case companies from the benchmarking and the participants in the World Café

The second method, the World Café, was created by Brown and Isaacs (Brown and Isaacs, 2005) and can be regarded as a specialized form of the conventional focus group approach (Brennan and Ritch, 2010). Following Schieffer et al., the key purpose of a World Café is to work and think within a group and hence innovate collaboratively (Schieffer, Isaacs and Gyllenpalm, 2004). It is a user-friendly method with the following characteristics: The participants divide themselves into small groups that come together at different tables. At each desk, one particular aspect of the research problem is discussed with the help of a moderator who hosts the debate (Hüttinger, Schiele and Schröer, 2014). After a predefined period of time (usually 20-45 minutes), the participants are requested to change tables. They can freely choose the table for the next round but may not return to any table at which they had already participated. Consequently, each discussion round brings together a new group in a new constellation. At the beginning of each round, the moderator shows and summarizes the previous discussion points. This process is repeated until each participant has contributed to every discussion topic (Hüttinger et al., 2014). At the end, each moderator summarizes the results of his table and presents them to the plenum. Frequently, the final step is an evaluation round in which the participants walk around and review the lists of results on each table. They rate the aspects on each table with the help of "stickers". In doing so, a ranking of the aspects emerges on each table. The more "stickers" that one aspect receives, the more important it is in the eyes of the participants.

The superordinate topic of this World Café workshop was the "evaluation and execution of supplier innovations at buying companies". To investigate this subject, four tables were executed; each table addressed one of the following subtopics: "innovation clustering and evaluation, with a focus on the innovation (1)", "innovation clustering and evaluation, with a focus on the supplier (2)", "innovation control, with a focus on the success measurement of the innovation and the process" and "innovation promotors". As the scope of this paper is the innovation evaluation of supplier innovations, only the results of tables 1 and 2 are shown and discussed. Altogether, 15 participants from 12 companies took part (three companies with two experts each participated) – seven of them had already participated on behalf of their companies in the benchmarking, and eight were newly recruited to complete and balance the sample. This combination was chosen to have, on the one hand, participants who were involved in the creation of the base data and, on the other hand, participants who could give new stimuli. Once again, the new participants were selected according to their expertise in the areas of innovation management, NPD and purchasing. Moreover, it was very important to assemble a circle of participants who were as diverse as possible. The participating companies of the World Café are shown in figure 1.

Analysis

All benchmarking participants were interviewed using a detailed questionnaire containing two different subcategories: innovation clustering (1) and innovation evaluation and selection (2). The benchmarking results are summarized in figure 2.

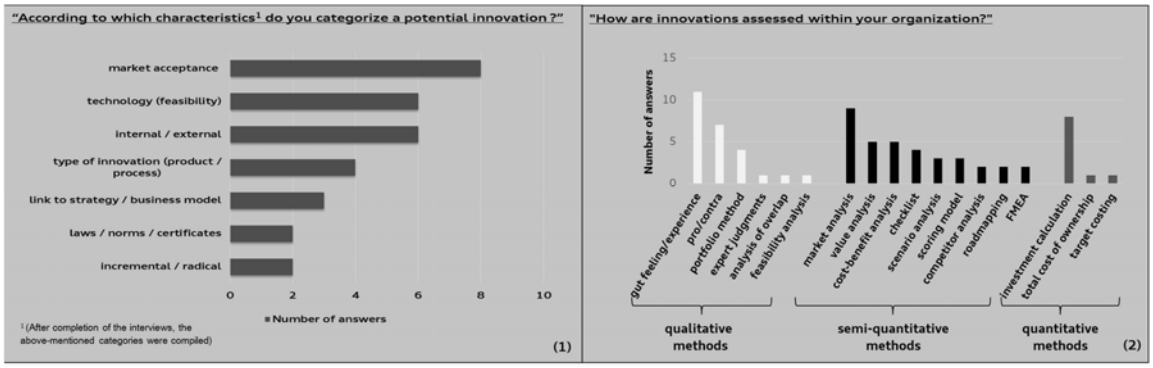

Figure 2: Results of the benchmarking analysis

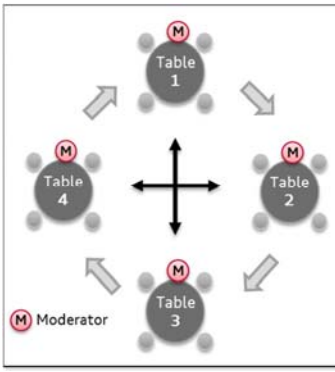
(1) *Innovation clustering:* A total of 58% of the case companies cluster emerging innovation in different categories. The three most commonly used clustering categories are the expected market and customer acceptance, the technology maturity level and the expected feasibility and in internal and external innovations.

(2) *Innovation evaluation and selection:* In the next step, the participants were asked if and how the clustered innovations become evaluated and selected (most companies mentioned several methods). Only 25% of the case companies use different evaluation methods for internal and external innovations. A total of 38% of the used methods are qualitative, 48% of the methods are semi-quantitative, and 14% are quantitative. The most commonly used evaluation method is gut feeling and experience (69% of the case companies apply this method). Market analysis is the second most commonly used evaluation tool (56% of the participants use this method). In addition, the third most popular evaluation method is investment calculation (50% of the case companies apply this method).

Analyzing the results of the benchmarking revealed that most case companies base their innovation evaluations on gut feeling or experience. This finding supports the assumption that there is no easily applicable evaluation tool for innovations available. The results also show that none of the case companies assesses the supplier from which the innovation is distributed. This practice experience also confirms the findings from the literature review. To discuss these insights from the benchmarking analysis and to further develop them and create easy-to-use evaluation checklists and a scoring model for the evaluation of supplier innovation, the World Café method was used as a second technique.



World Café 1

Round	*Time*
1	30 min
2	15 min
3	10 min
4	10 min

Rating: All flipcharts will be shown and presented to the participants. The participants perform the evaluation with the help of stickers (30min). 20 stickers per expert (5 stickers per topic)

World Café 2

Round	*Time*
1	40 min
2	20 min
3	10 min
4	10 min

Summary of results
Each moderator summarizes the results of his table (5 min each = 20 min)

Figure 3: Setup of the World Café workshop

In this study the standard World Café method was changed; two small World Cafés were combined into one workshop. In World Café 1, each moderator at each table showed part of the consolidated results of the benchmarking referring to the topic of his table. In the following four short World Café rounds, the participants discussed the benchmarking findings and had the chance to add new aspects and arguments. At the end of World Café 1, the evaluation round occurred. Each of the 15 participants received 20 stickers (5 for each table) to rate the aspects that were the most important from their perspective. Because, on each table, 75 stickers were used, the highest possible rating for a single aspect was a score of 75 stickers (if one aspect received all stickers). After analyzing the sticker rating, the moderators took the most highly rated aspects to work on in World Café 2. In this World Café, the participants were asked to further detail the main aspects and to create an operational model or tool to use in operational innovation management. The structure of the entire World Café workshop is shown in figure 3.

In World Café 1, initially, all participants received from their table moderators the aggregated result as an input for the following four working rounds. At tables 1 and 2, they received the results of the clustering and evaluation methods used from the benchmarking (figure 2).

(1) At table 1, "innovation clustering and evaluation, with a focus on innovation", 25 criteria and methods were developed in the four discussion rounds in World Café 1. Through the sticker rating procedure, the five criteria with the highest relevance, according to the participants' opinions, were chosen and made eligible for World Café 2. The ranking was calculated according to the number of stickers that an aspect received. The following five criteria received the highest scores: market potential (rank 1: 18% of the 75 stickers at table 1); influence on the existing business model (rank 2: 12%); market/customer acceptance (rank 3: 9%); cost-benefit analysis (rank 4: 9%); and proof of concept (rank 5: 8%). The three criteria "market potential", "market / customer acceptance" and "proof of concept" also ranked in the top 5 in the benchmarking scores.
(2) At table 2, "innovation clustering and evaluation, with a focus on the supplier", 18 possible criteria to rate the innovating supplier were generated. The following five criteria received the highest scores through the "sticker" rating: employees at the supplier (rank 1: 24% of the 75 stickers at table 2); creative potential (rank 2: 19%); endurance (rank 3: 17%); exclusivity (rank 4: 9%); and other customers of the supplier (rank 5: 9%). Neither these nor other criteria were mentioned in the benchmarking to assess the innovating supplier.

The task in World Café 2 was to focus on the top five rated aspects from World Café 1, to further detail them by forming sub-criteria and to create operational models that can be used to evaluate supplier innovations. The participants at table 1 worked on the five main aspects for innovation evaluation, with a focus on innovation characteristics: "market potential", "influence on the existing business model", "market/customer acceptance", "cost-benefit analysis" and "proof of concept". To make a potential evaluation following these criteria more user-friendly, over the four working rounds of World Café 2, the participants created a checklist and formulated and clarified examples for weak or strong scores for each sub-criterion (all results are summarized in figure 4). The criterion "market potential", for example, evaluates the "market situation" (which forecasts whether the innovation only secures the current market share or whether it even creates a new monopoly) and the level of "differentiation" from the competition. The details for the other four criteria of table 1 are shown in figure 4.

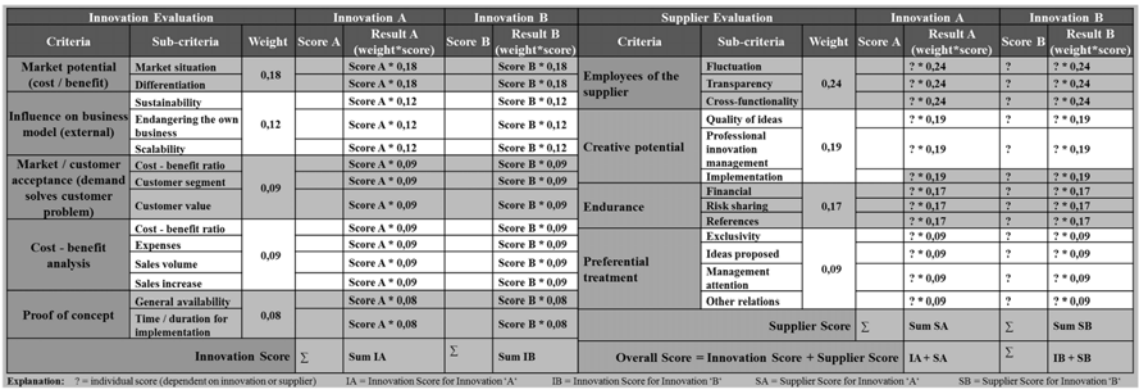
Criteria	Sub-criteria	Example of Weak Score (1)	Example of Strong Score (10)
Market potential (cost / benefit)	Market situation	Secures market position (market share constant)	Creates market monopoly (sole provider)
	Differentiation	No differentiation from competition	Innovation creates USP (unique selling point / proposition)
Influence on business model (external)	Sustainability	Business model not sustainable (short-term)	Business model sustainable (long-term lead)
	Endangering the own business	Innovation has potential to destroy the (current) business	Innovation does not endanger the (current) business
	Scalability	Not scalable	Easily scalable
Market / customer acceptance (demand solves customer problem)	Cost-benefit	Cost-benefit ratio > 2 (customer)	Cost-benefit ratio> 10 (customer)
	Customer segment	Only interesting to existing customers	Opens up new customer groups
	Customer value	Does not add value to the customer	Solves central problem of all customers
Cost-benefit analysis	Cost - benefit ratio	Cost – benefit ratio > 2 (enterprise)	Cost-benefit ratio > 10 (enterprise)
	Expenses	High long-term investment needed	Little investment needed, short payback
	Sales volume	Limited influence on sales	Considerable sales volume (>30% of current)
	Sales increase	No increase	Multiplication of current sales volume over the next years
Proof of concept	General availability	No MVP (minimum viable product) available	Functioning MVP (minimum viable product) + Lessions Learned
	Time / duration for implementation	Long term (2-3 years)	Short term (3 months)

Figure 4: Criteria for innovation evaluation (results from table 1)

At table 2, the participants in World Café 2 also worked on the five aspects that achieved the highest scores in round one: “employees at the supplier”, “creative potential”, “endurance”, “exclusivity” and “other customers of the supplier”. In the four working rounds, they merged two criteria, “exclusivity” and “other customers of the supplier”, into one new aspect called “preferential treatment”. Apart from this action, they also formed sub-criteria and examples for weak and strong scorings, which was precisely the same procedure performed at table 1. The first main criterion, “employees at the supplier”, was sub-divided into “fluctuation” (which assesses the turnover rate of employees), “transparency” (which shows the level of openness regarding the team structure and the qualification of team members) and “cross-functionality” (the level of diversity within the supplier team). The second main criterion, “creative potential”, assesses the overall “quality of ideas” of the supplier, the level of “professionalism within the innovation management” of the supplier and the number of implemented innovations. The main criterion, “endurance”, indicates whether the supplier stands on a solid “financial” basis, performs a fair “risk sharing” and can provide good “references” from other industries or customers. The fourth main criterion, “preferential treatment”, reflects whether the buying company receives “exclusivity”; moreover, it shows whether the supplier proposes ideas to the evaluating company first or not. Furthermore, it assesses the degree of “management attention” on the supplier side and the number of “other relations” between the supplier and the evaluating company. All results for table 2 are shown in figure 5.

Criteria	Sub-criteria	Example of Weak Score (1)	Example of Strong Score (10)
Employees of the supplier	Fluctuation	Constant employee turnover	Less then 2% fluctuation
	Transparency	No visibility of the personnel of the supplier	Entire team with CVs is known and is the “A-team” of the supplier
	Cross-functionality	Only sales personnel visible	On the supplier team multiple functions collaborate well with each other
Creative potential	Quality of ideas	Single idea, narrow view, no understanding of embededdness	Several business model-changing ideas embedded in a global view, understanding the market
	Professionalism within the innovation management	Spontaneous idea management only	Well documented professional innovation management (process, KPI, gates)
	Implementation	Few innovations actually implemented, late cessation of unsuccessful projects	High ratio of ideas presented and implemented, quick abort mechanism
Endurance	Financial	Unstable financial condition	Good solvency - equity ratio available
	Risk sharing	Wants to transfer full risk to customer	Willing to share risks (e.g., carries development costs armortized through future sales)
	References	No references	Many good references in the industry and part of the network
Preferential treatment	Exclusivity	Idea offered to all other customers in the same way	Exclusive access to idea for defined time, offered first to us
	Ideas proposed	Ideas offered elsewhere first	Supplier offers many good ideas to us first
	Management attention	No high-level contact person	We have management attention / are a preferred customer
	Other relations	No business with us	Many other business relationships with us, that the supplier may not want to put at risk

Figure 5: Criteria for the evaluation of the innovating supplier (results from table 2)



Innovation Evaluation			Innovation A		Innovation B		Supplier Evaluation			Innovation A		Innovation B	
Criteria	Sub-criteria	Weight	Score A	Result A (weight*score)	Score B	Result B (weight*score)	Criteria	Sub-criteria	Weight	Score A	Result A (weight*score)	Score B	Result B (weight*score)
Market potential (cost / benefit)	Market situation	0,18		Score A * 0,18		Score B * 0,18	Employees of the supplier	Fluctuation	0,24		? * 0,24	?	? * 0,24
	Differentiation			Score A * 0,18		Score B * 0,18		Transparency			? * 0,24	?	? * 0,24
Influence on business model (external)	Sustainability	0,12		Score A * 0,12		Score B * 0,12		Cross-functionality			? * 0,24	?	? * 0,24
	Endangering the own business			Score A * 0,12		Score B * 0,12	Creative potential	Quality of ideas	0,19		? * 0,19	?	? * 0,19
	Scalability			Score A * 0,12		Score B * 0,12		Professional innovation management			? * 0,19	?	? * 0,19
Market / customer acceptance (demand solves customer problem)	Cost - benefit ratio	0,09		Score A * 0,09		Score B * 0,09		Implementation			? * 0,19	?	? * 0,19
	Customer segment			Score A * 0,09		Score B * 0,09	Endurance	Financial	0,17		? * 0,17	?	? * 0,17
	Customer value			Score A * 0,09		Score B * 0,09		Risk sharing			? * 0,17	?	? * 0,17
Cost - benefit analysis	Cost - benefit ratio	0,09		Score A * 0,09		Score B * 0,09		References			? * 0,17	?	? * 0,17
	Expenses			Score A * 0,09		Score B * 0,09	Preferential treatment	Exclusivity	0,09		? * 0,09	?	? * 0,09
	Sales volume			Score A * 0,09		Score B * 0,09		Ideas proposed			? * 0,09	?	? * 0,09
	Sales increase			Score A * 0,09		Score B * 0,09		Management attention			? * 0,09	?	? * 0,09
Proof of concept	General availability	0,08		Score A * 0,08		Score B * 0,08		Other relations			? * 0,09	?	? * 0,09
	Time / duration for implementation			Score A * 0,08		Score B * 0,08	Supplier Score			∑	Sum SA	∑	Sum SB
Innovation Score			∑	Sum IA	∑	Sum IB	Overall Score = Innovation Score + Supplier Score			IA + SA		∑	IB + SB

Explanation: ? = individual score (dependent on innovation or supplier) IA = Innovation Score for Innovation 'A' IB = Innovation Score for Innovation 'B' SA = Supplier Score for Innovation 'A' SB = Supplier Score for Innovation 'B'

Figure 6: Scoring model for the supplier innovation evaluation

Since the goal of this paper is to create an operational tool to evaluate supplier innovations, the results of tables 1 and 2 were taken and combined into one scoring model. Implemented scoring models normally use either regression or classification methods (Malthouse, 2002). In this research, the scoring model should create a ranking of supplier innovations, and through this classification, it should show which innovation will most likely be successfully implemented. The scoring model consists of two parts: First, it contains the evaluation of the innovation, and second, it comprises the evaluation of the supplier offering the innovation, as well. For both sub-parts, the evaluation variables were defined and clarified by experts who participated in the benchmarking and the World Café workshop. The most important aspects for the evaluation of a supplier innovation are shown in this model (figure 6). The weights for each criterion are derived from the expert ratings according to World Café 1. Consequently, each separate variable is weighted according to its significance. A practitioner using this model can select the innovations with the highest chance of being implemented.

Discussion and Implications

In this section, the key findings of this study will be discussed and an overview of the managerial and research implications shall be provided. This paper presents insights from a benchmarking study and from a World Café workshop. Sixteen German companies participated in the benchmarking and shared their innovation know-how in the innovation clustering (1) and innovation evaluation and selection (2) categories. Notable results from the benchmarking study are that the most popular evaluation method for innovations still seems to be gut feeling and experience. Moreover, all case companies use several clustering, evaluation and selection approaches for innovations, but none of them focuses on evaluating the supplier providing the innovation. To discuss these results and to further develop them, a second method was used – a World Café workshop. In the first part of the World Café, the experts discussed and expanded the identified factors from the benchmarking. After prioritizing the aspects that were selected in the first round, in the second round, two operationally usable checklists were developed to evaluate the characteristics of the external innovation and the qualities of the innovative supplier. Both checklists can be combined into one evaluation scoring model for supplier innovations.

The managerial implications

The results show that it is necessary to innovate the evaluation and selection process for innovations because, presently, supplier evaluation is neglected. Three aspects must be

considered: 1) A focus on potentially specific evaluation criteria for external innovations originating from suppliers (in contrast to internal innovations); 2) an evaluation of the innovative supplier and the inclusion of the result in the innovation evaluation score; and 3) the design of an operationally usable tool, whose purpose is helping innovation managers choosing the most promising innovation more easily.

Since in the automotive sector, for example, more than 75% of the value chain consists of suppliers and several studies show that 85% or more of all innovations are provided by suppliers. It is essential to focus the innovation evaluation and selection process on the specificities of external innovations (Dekkers et al., 2013; Roberts, 2001; Wolff, 2014). The developed innovation evaluation checklist places emphasis on five main criteria: "market potential", "influence on the business model", "market/customer acceptance", "cost-benefit analysis" and "proof of concept". Especially regarding the last two criteria, the kind of innovation plays a crucial role. This assumption can be illustrated as follows: If a buying company evaluates a supplier innovation that then shows for instance, very high potential by creating a unique selling proposition (USP) and solving central problems of all customers, then the following question arises: How is access to this breakthrough innovation gained and at which price? If the innovation was internally generated, this question would not be an issue at all. Viewed from the other side, it would also be possible that a very promising innovation (with a high score rating) will fail because of the bad performance of the supplier (e.g. worse project execution). This possibility shows the importance of the evaluation of the innovative supplier and the inclusion of the result in the innovation evaluation score. The supplier evaluation checklist focuses on four main criteria: "employees at the supplier", "creative potential", "endurance" and "preferential treatment". The first three criteria are only supplier-related, but the score of the fourth criterion, "preferential treatment", depends on the evaluating buying company. The score of this criterion may offer an indication of the probability of whether a company will gain exclusive access to an innovation or not. To receive preferential treatment, the buying company should have considered preferred customer status at the supplier (Hüttinger et al., 2012; Prahalad and Hamel, 2006; Schiele et al., 2012). According to Hüttinger et al., preferred customer status is defined as follows: It influences the behavioral intentions of the supplier to the extent that the supplier awards selected customers with more favorable treatment than others (Hüttinger et al., 2012). The benchmarking results show that the most commonly used evaluation method for innovations is "gut feeling and experience". Moreover, the research literature shows no ready-made evaluation model for supplier innovations. This lack implies that an operational and easy-to-use innovation evaluation tool is missing. Through this study, such an operationally usable tool was suggested. Naturally, this model is a first proposal, and some aspects must be further discussed. One question concerns whether, in the evaluation process, an order has to be followed or whether only one combined score is sufficient? Does it make sense to first evaluate the innovation and to then evaluate the corresponding supplier only for the best innovations? Alternatively, is it more useful to evaluate the supplier first, and only if the supplier receives a good score does it make sense to then evaluate the innovation? After all, if there is a good innovation but bad project execution, then the project will most likely fail.

As visualized in the matrix (figure 7), there are four potential result combinations: a "bad" innovation from a "bad" supplier (1); a "bad" innovation from a "good" supplier (2); a "good" innovation from a "bad" supplier (3); and a "good" innovation from a "good" supplier (4). That the innovations from category (1) are declined and the innovations from category (4) are launched as a project is quite obvious. However, what occurs with the innovations from category (2) and (3)? Perhaps it makes sense to also further develop the "bad" innovations from category (2) because through collaboration with a "good" supplier, it may be possible to enhance them. A common mistake is that the innovations in category (3) are implemented.

Although they are rated “good”, they fail because of the poor project performance of the “bad” supplier. Perhaps it would work better to either further develop the supplier or to buy the intellectual property (IP) of the idea or execute it with another supplier that is rated “good”.

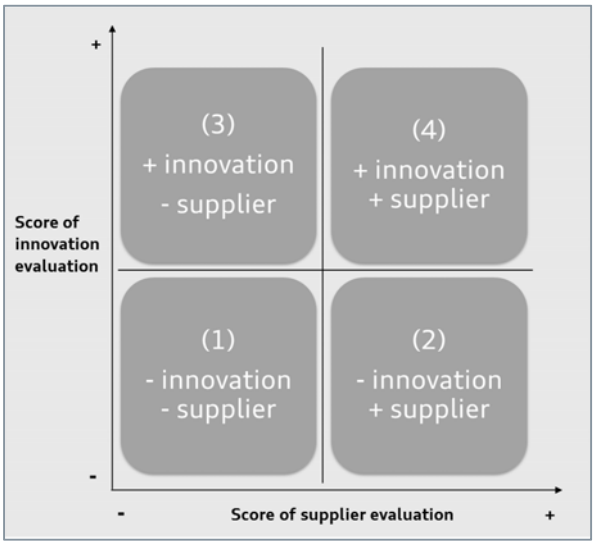


Figure 7: Matrix of the four potential result combinations of evaluating the innovation and the supplier offering the innovation

Another aspect of the developed scoring model that must be discussed is the weighting of the criteria. The weighting that the experts performed in the first round of the World Café workshop was used. As displayed in figure 6, in the current configuration of the scoring model, the criteria from the supplier innovation have a higher total weight (∑ of weights is 0.69) than the criteria from the innovation evaluation (∑ of weights is 0.56). This difference results from the fact that the experts distributed their votes for the most important criteria of the innovation evaluation across more aspects than in the votes for the most important criteria of the supplier evaluation. Therefore, the question is whether this weighting should be leveled to an equal weighting (e.g., such that the sum of the weights for each checklist is 100%) or whether it would perhaps be more useful for every company that uses this model to create its own weighting according to needs.

Research implications

Innovation research should focus more on the evaluation and selection process for innovations because there seems to be a lack of tools to use in operational innovation management. Moreover, the roles of the supplier and of the external character of supplier innovations must be further researched. Presently in many industries, most innovations are provided by suppliers (Dekkers et al., 2013; Schiele et al., 2012); therefore, the evaluation of the supplier and the inclusion of the evaluation results in the overall evaluation of the innovation considered are crucial.

Conclusion and Limitations

By analyzing the operationally used innovation evaluation methods and by developing an evaluation scoring model for supplier innovations, this paper contributes in at least three ways to the existing literature, as follows:

(1) This paper shows that, despite the fact that nowadays the majority of innovations are provided by suppliers, current innovation evaluation models largely neglect supplier-specific aspects. By developing and adding a supplier evaluation dimension, this paper closes an existing research gap left open by previous innovation evaluation models.
(2) Moreover, this study contributes to existing literature by providing two operationally usable checklists, one to evaluate the external innovation itself and another to evaluate the supplier providing the innovation. This checklists are combinable into one scoring model that evaluates a supplier innovation from two sides – the innovation criteria side and the supplier side.
(3) By analyzing the potential result combinations from the scoring model, a matrix with four categories was developed. Two previously not considered categories (matrix fields (2) and (3)) were discovered. The question is, how to proceed with this two categories in the future? If a "bad" innovation from a "good" supplier is spotted (category (2)), it perhaps makes either sense to further develop the "bad" innovation with the "good" supplier, because only the "good" supplier has the capability to enhance it, or to discard the "bad" innovation and maybe to start another project collaboration with the "good" supplier to execute another innovation project. Viewing matrix category (3), it seems to be a common mistake to implement this kind of "good" innovations from "bad" suppliers. Although they are rated "good", they fail because of the poor project performance of the "bad" supplier. So it may would be useful to try to continue this "good" innovation together with another supplier, which has a "good" rating.

In addition to the results discussed above, there are some limitations associated with this study. The benchmarking was performed with only 16 case companies, which is a small sample size. In addition, both the benchmarking and the World Café workshop were conducted with German companies only; thus, the results may not be generalizable to companies from other countries or continents. In future research, other kinds of companies (e.g., from other countries and continents) should be studied. Moreover, it would be useful to apply other research techniques and to employ, for example, a quantitative analysis to check and verify these results (especially the sub-dimensions of the innovation scale) with a larger sample size. Subsequently, a case study in which the scoring model is used would be essential to test its practice. In addition, the research on the evaluation and selection of supplier innovations, the role of the supplier and the "external character" of an innovation through project execution should be developed and further discussed.

An evaluation framework for business services – a design science research approach

Martin Haensel

University of St.Gallen, Chair of Logistics Management, Dufourstrasse 40a, 9000 St. Gallen, Switzerland, martin.haensel@unisg.ch, Tel.: + 41 (0) 71 224 7288, Fax: + 41 (0) 71 224 7315

Abstract

The purchase and evaluation of business services is an important topic for companies. As research in this field is rare, the paper focuses on the acquisition and evaluation of services and aims to develop a framework for the evaluation of services that combines different determining factors. In more detail, the research combines investigations about the integration of the purchaser (as a link between the service providers and the internal customers) in different purchasing phases and the need for collaboration with both parties. These factors are expected to improve the various dimensions of the exchange described by IMP theory. In addition, four service types are included as contingent factors. Conclusively, all research results are merged to an evaluation framework using a design science research approach.

Keywords: service purchasing, business services, service evaluation, design science research

Introduction

Due to the increasing networking of production processes along the supply chain, companies increasingly focus on their core competences and outsource upstream and downstream processes. In light of this development, the external acquisition of business services has become a key success factor for manufacturing companies. Depending on the sector, this is reflected in a service proportion of up to 80% of the total purchasing volume (Hofmann et al., 2016). However, while the procurement of goods has long been subject to highly professionalized procedures, the typical purchasing manager continues to encounter problems and uncertainties in the procurement and evaluation of business services (van der Valk & Rozemeijer, 2009). Normally, these factors refer to different characteristics of business services in comparison to goods: the immateriality, the simultaneity, and the heterogeneity (Grönroos, 2008).

Another factor relates to the information asymmetry that accompanies the purchasing and evaluation (Laffont & Martimort, 2009). With the intention to overcome this information asymmetry, this research focuses on different determining factors on the purchasing and evaluation process. More precisely, the study investigates purchaser integration (PI) and collaboration with internal customer (IC) and service provider (SP) as determining factors. In that context, PI refers to different purchasing phases in which the purchasing department is directly or indirectly integrated (Axelsson & Wynstra, 2002). Collaboration is seen as result of internal or external integration (Schoenherr & Swink, 2012), leading to an enhanced information sharing and improved performance within a firm. The third determining factor on the purchasing and evaluation of business services addresses their heterogeneity. Due to the service-related heterogeneity, current research has led to a demand for different evaluation models for different business services (Haensel & Hofmann, 2017; van der Valk & Rozemeijer, 2009). This is justified by various assigned purposes of business services. While some companies acquire services exclusively for internal reasons (e.g., facility services and accounting services), other services are

directly integrated into value-adding processes (e.g., assembly services and logistics services) (Wynstra et al., 2006).

With a view to service evaluation, Alkin and Christie (2004) describe an anticipatory, an formative, and a summative evaluation phase. While the anticipatory phases empathizes the supplier selection, the formative phases concentrates on the supplier development and the summative phase assesses the service outcome. In all these phases, the collaboration (e.g., communication and the exchange of information) with IC and SP is crucial for a successful purchasing (Chakraborty et al., 2014). Due to different assigned purposes of a business service and different involved parties, the role of purchasers as well as their integration into different purchasing phases varies (Haensel & Hofmann, 2016). As research barely exists on service evaluation, the paper provides an advanced investigation into the aforementioned factors that need to be taken into account while developing an evaluation model for business services. In more detail, the research focuses on the following research questions:

> RQ1: How is PI, collaboration, and different services type (as determining factors) influence the purchasing and evaluation of business services?
>
> RQ2: In which way are these determining factors interconnected with each other and how do they have to be taken into consideration while purchasing and evaluating business services?

With the intention of providing answers to the research questions, the paper starts with an initial literature review of related research streams: the purchasing process and PI, the collaboration with involved parties, and the heterogeneity of services concerning a possible classification. As a theoretical foundation for collaboration, the paper introduces four dimensions of exchange induced by the industrial marketing and purchasing (IMP) theory (Håkansson & Snehota, 2006). In addition, a contingency approach is applied to account for the heterogeneity of acquired business services. As a methodological procedure, a design science research (DSR) approach is applied to combine insights from different and iterative research phases. The DSR approach allows the development of so-called artefacts (e.g., models, methods, and instantiations) (Hevner et al., 2004). Following the recommendations of Hevner et al. (2004), the results section describes the research process starting with an initial formulation of the design objectives, followed by the design and development stage as well as the demonstration and assessment of the designed evaluation framework. The last section discusses the research results and provides insights into their managerial and theoretical contribution.

Literature review

The first section focuses on existing research in the field of service purchasing and evaluation and presents a literature review of the most relevant literature streams. This includes (1) the service purchasing process, (2) the service type as a contingent factor, and (3) the purchaser collaboration with both IC and SP.[1]

Current service purchasing and evaluation as problem statement

Every purchasing activity can be explained as agency dilemma, assuming an information-asymmetry between both SP (agent) and buying firms (principal) (Jensen & Meckling, 1976). Due to the specific characteristics of business services in comparison to goods, the information-asymmetry is more distinctive in two ways. Firstly, it is not possible for a buying firm to test a service beforehand (Järvensivu, 2010). In consequence, the offer from SPs occurs always as a

[1] For the literature review, an approach by vom Brocke et al. (2015) was applied.

performance promise rather than as a guaranteed service outcome (Inklaar et al., 2007). Secondly, an evaluation of intangible services is more complicated in comparison to the assessment of physical goods as measurable criteria barely exists (Mitchell, 1994). Moreover, the intended outcome of a service often relates to external factors (e.g., the economic environment and other involved parties) that cannot be influenced by the SP (Reddy & Czepiel, 1999). With the intention of reducing the information asymmetry, literature provides two major strategies: signaling and screening (Spence, 1973; Stiglitz, 1975). Signaling describes the provision of information by the SP, whereas screening defines the assessment (evaluation) of a SP. Therefore, the evaluation can be seen as an instrument to reduce the information asymmetry induced by the agency theory. With a view to existing literature about evaluation procedures, most of the research focuses on goods purchasing neglecting the different characteristics of business services. However, several authors have investigated that topic as shown in Table 1.

Table 1: Excerpt of existing literature about the evaluation of business services

Author	Evaluated criteria	Service focus
Rottmann et al. (2015)	Utilization rate, amount of conversations, client's satisfaction, budget transgressions, innovative proposals, prevented legal costs	Legal Service
Cater-Steel and Lepmets (2014)	Service quality, system quality, service behaviour, service value, process performance, customer satisfaction	IT-Service
Hsu et al. (2012)	Web site design, security, customer relationships, enjoyment	E-Commerce
Vaidyanathan (2005)	Cost, services, IT, performance metrics, quality, intangibles	Logistics Service
Hsu et al. (2008)	Delivery and service quality, responsiveness, information sharing	Manufacturing
Kaynama and Black (2000)	Content and purpose, accessibility, navigation, design and presentation, responsiveness, background, personalization and customization	Travel Agency
Menon et al. (1998)	On-time shipments and deliveries, meet or exceed promises, availability of top management, superior error rates, responsiveness to unforeseen problems, financial stability, meet performance and quality requirements	Logistics Service

Most of the existing research focus on specific services (e.g., logistics services, consultancy, or legal services). A more generic perspective does not yet exist. While developing an evaluation procedure for business services one must consider several determining factors that influence the evaluation process. These factors are partially described in literature (e.g., the service strategy (Jothi Basu et al., 2015), the contract type (Selviaridis, 2016), and the buyer's qualification (Sharma, 1994)). However, there are still some determining factors in regard to a generic evaluation procedure for business services that have only received limited attention in recent research: the service type as a contingent factor, the purchasing phases and the PI, as well as the collaboration with both IC and SP during different purchasing phases. All three research-streams are discussed in more detail in the following chapters.

Purchasing process and PI as a determining factor for evaluation

Purchasing takes place in nearly every company and is considered to be one of the most important activities. Purchasing, however, does not take place at a single point of time, but rather occurs as a series of follow-up activities (Robinson et al., 1967). These different purchasing steps are also referred to as purchasing phases (Axelsson & Wynstra, 2002), in which the purchaser is directly or indirectly integrated. In that context, Robinson et al. (1967) describe one of the first procurement processes, whereby a distinction is made between numerous procurement steps. The same differentiation applies for the evaluation of business services. Typically,

during different purchasing phases criteria is evaluated with contributions from ICs, SPs, or other involved actors (Ellram et al., 2007; Rottmann et al., 2015). Before companies sign a service contract, IC and the purchaser must define requirements. Subsequently, a first evaluation (anticipatory) is carried out to determine whether a service offer meets the predefined requirements. After the usage of an acquired service, IC evaluates the service again and compares the outcome with the initial service promise (summative). In that context, Van Weele (2009) describes a pre-purchase and an "aftercare" process in which an evaluation takes place. Grönroos (2000) goes a step further and distinguishes between three different phases: the evaluation before, during and after the provision of a service. Following this argumentation, the purchasing department needs to be involved in most of these phases. Haensel and Hofmann (2016) support this position and name PI as an enabler for an informational and social exchange that occurs with SP and IC. In addition, Lejeune and Yakova (2005) also investigate the increased relevance of PI. In their research, they describe it as one of the most relevant success factors for supply chain management.

While looking at the exchange that takes place during the purchasing, IMP theory describes four dimensions of exchange: the informational, the financial, the service, and the social exchange (Håkansson & Snehota, 2006) (Table 2).

Table 2: Comparison of exchange dimensions induced by the IMP theory

Dimension of exchange	Description	Example
Social exchange	The social exchange does not directly relate to the service contract but describes the relationship between the buyer and the SP. With a view to the purchasing process, a social exchange is most relevant during the tendering, the contract closure, the negotiation, and the evaluation (Vargo & Lusch, 2004)	▪ The nature of communication (e.g., friendly, intriguer, fierce) ▪ The cultural or social background of SP
Informational exchange	The informational exchange includes any provision of data and knowledge directly or indirectly related to a service contract. This includes a mutual exchange between two parties, which is necessary for the fulfillment of orders. Since services are based on a performance promise, informational exchange becomes a decisive part of the evaluation (Haensel & Hofmann, 2016).	▪ Experiences or references from previous projects ▪ Information on production plans for the coming year
Exchange of services	In each procurement process, an exchange of services takes place, which describes the actual provision of the service. In contrast to the goods-dominant logic, this exchange is much more complex. This relates to the value co-creation, in which the buying firm is always involved (Vargo & Lusch, 2008).	▪ Provision of an consultancy service ▪ Transportation or warehousing of goods (logistics services)
Financial exchange	The financial exchange describes the payment for the SP. However, since the result of a service is often uncertain (Järvensivu, 2010), the success of a service cannot be completely guaranteed. For this reason, complex payment models often apply for services (e.g., performance-based payments).	▪ Payment of fixed prices or hourly based billings ▪ Differentiation between fixed and variable payment options

If a buying firm assesses the service outcome (and the SP), the evaluation must consider all of these dimensions of exchange. In that context, an evaluation of business services typically considers the service quality, mainly represented by the information, social and service exchange, as well as the service costs, shown by the financial exchange. While qualitative aspects such as the advance in knowledge of the SP is most relevant in the case of the provision of complex services (e.g., in the form of expert knowledge and innovative solutions), more standardized services typically consider the costs of a service. Another aspect of the IMP theory relates to the long-term adaptation and institutionalization. However, for the current research, the focus lies on the short-term exchanges due to its relevance for service evaluation.

The service type as a contingent factor for service evaluation

As previously mentioned, the service characteristics are different in comparison to those of goods. One major aspect in that context describes the heterogeneity of services (Axelsson & Wynstra, 2002). In goods purchasing, firms try to standardize components, gears, or parts of their products to reduce production and process costs. Within the field of business services, SP intend to separate themselves from competitors by providing a unique selling proposition. Due to the personal interaction, which a buying firm experiences while buying business services, every interaction between SP and the purchasing department appears as a unique situation. Therefore, it is difficult to offer a constant service quality. Lindberg and Nordin (2008) argue that the degree of objectification and specification varies depending on the acquired business service. In consequence, a distinction between different service types might be required while developing an evaluation procedure (Haensel & Hofmann, 2017).

With a view to existing service classifications, literature provides several categorizations for business services (Schneider & White, 2004; Smeltzer & Ogden, 2002). Typically, these classifications consider different requirements, different institutions, or viewpoints (Axelsson & Wynstra, 2002). Nevertheless, van der Valk (2008) argues that most of the existing classifications are not derived from a buyer's perspective but rather from a seller's perspective. Following that argumentation, Wynstra et al. (2006), therefore, introduced a classification that includes the usage dimension of business services from a buyer's perspective. They describe a categorization that differentiates between four types of services: consumption, instrumental, manufacturing, and component services. An description of these service types is shown in Table 3.

Table 3: Differentiation of service types (based on Haensel and Hofmann (2017))

Type of service	*Description*	*Example*
Consumption business services	▪ Applied and exclusively used by the buying company (no part of the offer to the end-customers). ▪ The purchaser is responsible for most of the purchasing process (incl. anticipatory, formative, and summative evaluation). ▪ Typically, the service is of lower importance in comparison to instrumental services and semi-manufactured services.	▪ Facility services ▪ Car rental service ▪ Travel services
Instrumental business services	▪ Services occur as a part of a company's own production processes, which increases the value of their own products or services. ▪ Due to the importance of the service type, the essential user typically is involved in the purchasing process. ▪ Moreover, the evaluation of SP includes the essential user, the end-customer, and the purchaser.	▪ Logistics services ▪ Assembly services
Semi-manufactured business services	▪ Services occur as an additional offer to end-customers, but are altered beforehand by the buying firm. ▪ Typically, IC of the services support the purchasing and evaluation process (but less than with instrumental services).	▪ Marketing services ▪ ICT services
Component business service	▪ Externally acquired services become an unaltered part of a firm's final offer to end-customers. ▪ The purchasing department is responsible for the purchase but seeks guidance from other company departments. ▪ Normally, the IC evaluates the service quality after usage.	▪ Maintenance services ▪ After-sale services

Although Table 3 lists various practical services, these are merely examples. Depending on the sector or company context, companies may have different uses for similar services. For example, a logistics service for a post-delivery supplier is likely to be an instrumental service since the service directly affects the core business and decisively influences the value of the company's own products or services. In contrast, equivalent logistics services for a manufacturing company could only be semi-manufactured services since the majority of the added value is

generated during the production processes and not during the transportation to other locations. However, based on the presented classification, it is expected that the service types are a contingent factor while purchasing and evaluating business services. Moreover, Haensel and Hofmann (2017) state that the service type also determines the scope of an evaluation and the collaboration with involved parties (e.g., SP, IC, and end-customers). This also includes a varying need for a social and informational exchange during different purchasing phases.

Collaboration as an enabler for service evaluation

With a focus on purchasing and evaluation, research on purchasing organizations and their buying behaviour represents an important literature stream (Johnston & Lewin, 1996). In this context, the collaboration between SP and the buying firm is most relevant aspect for a successful evaluation (Sheth, 1996). Martinez-Moyano (2006) describes collaboration as a process in which two or more entities work together to achieve common goals. Several authors examine various elements of collaboration in existing literature. Large (2005), for example, states that communication and an informational exchange are the basic elements of collaboration. In contrast to this argumentation, Danese and Romano (2011) focus their research on shared goals, visions, and production plans with SP and describe this as the most relevant exchange for a successful purchase (Chakraborty et al., 2014). In a practical context, purchasing organizations are normally divided into several subsectors (also called departments, ICs, or essential users). Typically, these departments announce a certain demand and, therefore, are the users of acquired services. In contrary, the buyer acts as the representative of each purchasing company, taking the position as a link between the IC (internal collaboration) (Hartley et al., 2014; Williams et al., 2013) and SP (external collaboration) (Chakraborty et al., 2014; Kumar et al., 2005). As mentioned before, Håkansson and Snehota (2006) describe four exchange dimensions between these parties. Morrissey and Pittaway (2006) argue that business services are characterized by a larger social and informational exchange compared to goods purchasing. This fact further increases when quantifiable criteria diminishes and so-called subjective criteria increases. This is again dependent on the service type.

In general, there is no doubt in an asymmetry of available information between SP and buying companies during a purchasing process (Laffont & Martimort, 2009). One focus of the collaboration is therefore to minimize this discrepancy (Haensel & Hofmann, 2018). However, Kopperger (2004) argues that in the area of business services a change of SP is rather unlikely compared to goods purchasing. This could be linked to a lack of information about alternative SP, which causes a difficult comparability. Nevertheless, collaboration during the purchasing is relevant for an evaluation in two different ways. (1) Firstly, collaboration strengthens the informational and the social exchange between the purchasing organisation, SP, and IC. Both types of exchanges allow a comprehensive evaluation of a business service (Vargo & Lusch, 2004). (2) Secondly, the need for collaboration varies in different purchasing phases. This means that in some phases it is more relevant to ensure collaboration with SP or IC. The type of service is expected to have an impact in that context, but this has not yet been investigated in existing research.

Research gap and related research objectives

Existing literature addresses several factors that determine the purchasing and evaluation process. Most of this research, however, focuses on the acquisition of goods and neglects the specific characteristics of business services. Although the effect of different determinants can be applied to both goods and services, various authors' state that a differentiated evaluation approach is required (Hsu et al., 2008). As a summary of the existing literature, the study identifies three research gaps: (1) Most authors agree on the heterogeneity of business services (Axelsson

& Wynstra, 2002). However, the impact on other aspects of purchasing, more precisely on the evaluation of business services, is not adequately addressed in existing literature. This lack of research on service types as a contingent factor also influences the following two research gaps.

(2) Existing research on purchasing describes different phases of purchasing (Grönroos, 2008; Haensel & Hofmann, 2016). In addition, several evaluation steps take place during these phases (Alkin & Christie, 2004). However, existing research does not examine the role of purchasers and their integration into various purchasing phases.

(3) The necessary collaboration of a buyer with SP and ICs, differentiated by the service type, is not examined in the existing research. Nevertheless, existing research assumes that the service type strongly influences the need for collaboration (e.g., social and informational exchange) (Haensel & Hofmann, 2017). Moreover, a service type's impact on the applied evaluation or its scope might vary and therefore needs extended scientific attention.

Design science research as methodical approach

The ultimate goal of the research is the development of a framework for the evaluation of business services that combines all aforementioned determining factors. To develop this framework, the study applies a design science research (DSR) approach. DSR describes a dominant research method that is used in engineering, operations research, and management science to provide innovative solutions for problems within a practical context (Hevner et al., 2004; Peffers et al., 2007; Winter & Albani, 2013). Gregor and Hevner (2013) categorize DSR as prescriptive knowledge aiming to develop new theories, constructs, models, methods, or instantiations. For these so-called artefacts, a further classification concerning their level of contribution is possible. While design theories describe abstract and mature knowledge, instantiations (e.g. specific products) are more specific and limited in nature (Gregor & Hevner, 2013). Even though DSR is different from explanatory research, both influence each other (Winter & Albani, 2013). Therefore, observed behaviour from explanatory research induces new needs and changed requirements for DSR solutions. DSR always focuses on real practical problems. Therefore, solution requirements and objectives are specified and validated. Moreover, the development process of designed artefacts occurs in an iterative process. An advantage of DSR is its ability to be combined with other research methods. Therefore, we followed the argumentation of Winter and Albani (2013) and combined different approaches (of qualitative and quantitate nature) during the design process. Moreover, a staged research process recommended by Seidel et al. (2017) is applied to allow numerous iterations. Figure 1 visualizes the conducted research process.

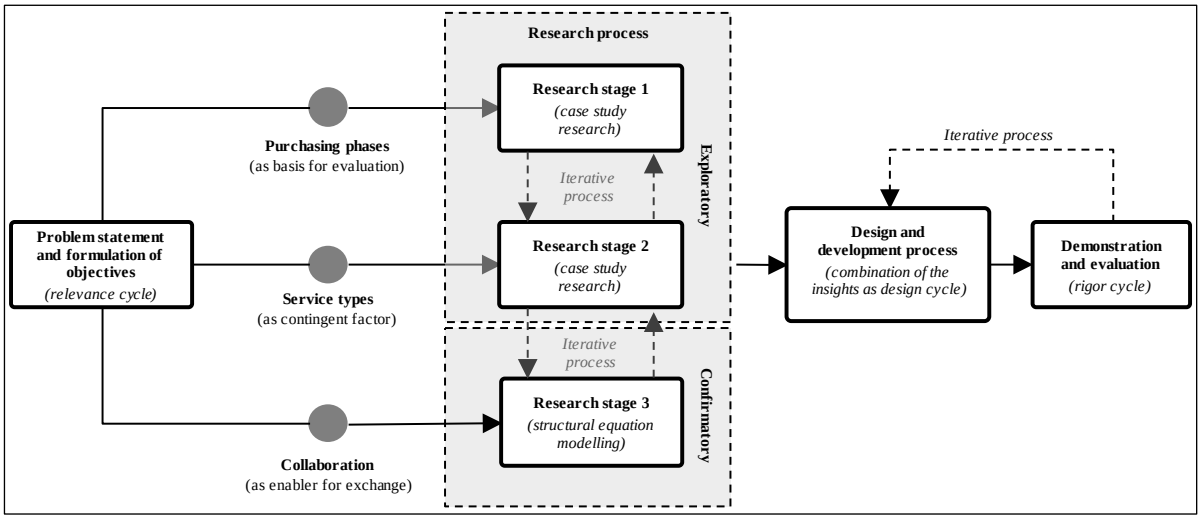

Figure 1: Research process of the design process

As shown on Figure 1, Hevner (2007) defines three cycles in DSR: the relevance cycle, the design cycle and the rigor cycle. While the relevance cycle sets environmental requirements and tries to ensure that the artefact is practically driven, the rigor cycle focuses on existing knowledge and scientific theories. The third cycle, the design cycle, describes the design building and evaluation process. However, both the relevance and the rigor cycle have been considered for the design process.

Problem statement and formulation of objectives

Starting with the problem statement and the formulation of initial research objectives, we identified three major aspects for our research that are fundamentally different from goods purchasing: the PI in different purchasing phases (Haensel & Hofmann, 2016), the service types as a contingent factor (Wynstra et al., 2006), and the collaboration as an enabler for exchange (Cousins et al., 2008). All three aspects are expected to influence the evaluation of business services. Therefore, the goal of our research was the isolated research of each factor followed by a combination of all insights within an evaluation framework.

Insights from the research stages

Within the ***first research stage***, we began examining the topic of the PI and purchasing phases by using an explorative case study research approach. The focus of the research was to allow a deeper understanding of the evaluation of business services and to reveal the impact of PI during different purchasing phases. The choice of case study research seems appropriate as our research was at an early stage and we were trying to investigate little-known phenomena (Eisenhardt, 1989; Miles & Huberman, 1994). The open-ended interviews, each lasting between three to five hours, were conducted with five multinational companies from Switzerland starting in autumn 2015 (Appendix A). All interviews were conducted with purchasing staff, including buyers, raw material managers, and executive purchasing managers (e.g., heads of indirect purchasing). To allow a comparison with the research stages 2 and 3, the focus of the interviews was already on the four different service types proposed by Wynstra et al. (2006).

The ***second research stage*** started in the beginning of 2016 and again applied an exploratory case study research approach focusing on the same case companies (Appendix A). To allow a comparison with the first research stage, the same company representatives were contacted for the interviews. Moreover, the impact of PI was analysed by using two major variables that influence the evaluation of service costs and service quality: collaboration with SP and collaboration with the IC (Danese & Romano, 2011). Based on the IMP theory, the research investigates the social, the informational, the service, and the financial exchange during different purchasing phases with both SPs and ICs.

In the spring of 2016, findings from both qualitative research processes were used to create a questionnaire that was used for the ***third research stage***. The confirmatory study investigated a direct and an indirect impact (e.g., through the buyers qualification) of PI on collaboration for different service types using a structural equation model. We contacted 2,500 companies in Switzerland, Germany and Austria (GAS countries). Due to different cooperation with organizations from Switzerland, Germany, and Austria, the study bases on four different databases that allowed the collection of 208 completed questionnaires. To provide answers for the research hypothesis, we used a partial least square analysis (PLS), a variance-based approach, for our study.

Research results of each stage

Altogether, the research in all three stages reveals that firms place a different assessment focus on different services and the effort involved in the assessment varies from service to service.

Thus, if companies employ, for instance, facility services (a consumption service) that are exclusively used for internal purposes they apply no advanced evaluation procedures for SP. If firms, on the contrary, acquire assembly services (an instrumental service), frequent and extensive evaluation takes place to assess SP. The analysis confirms findings from the qualitative stages and reveals differences depending on the type of service. With a view to IC collaboration, PI shows the most significant impact on value-adding services. When evaluating consumer services, our research shows an indirect effect through a buyer's qualification. This shows that the scope of exchange with SP and IC mediates the effect of PI within different purchasing phases and for different service types. The strongest impact shows up for component services. This might relate to their characteristics. Typically, these services come as an unchanged part and affect directly the offer to the end-customers (van der Valk & Rozemeijer, 2009).

Design and development of an evaluation framework

We presented the results of each research stage at international conferences for purchasing and supply chain management and published all revised papers in different international journals (Haensel & Hofmann, 2016; Haensel & Hofmann, 2017; Haensel & Hofmann, 2018). This procedure allowed us to receive feedback and inputs from the scientific community and resulted in several iterative cycles before concluding our final framework (Figure 2).

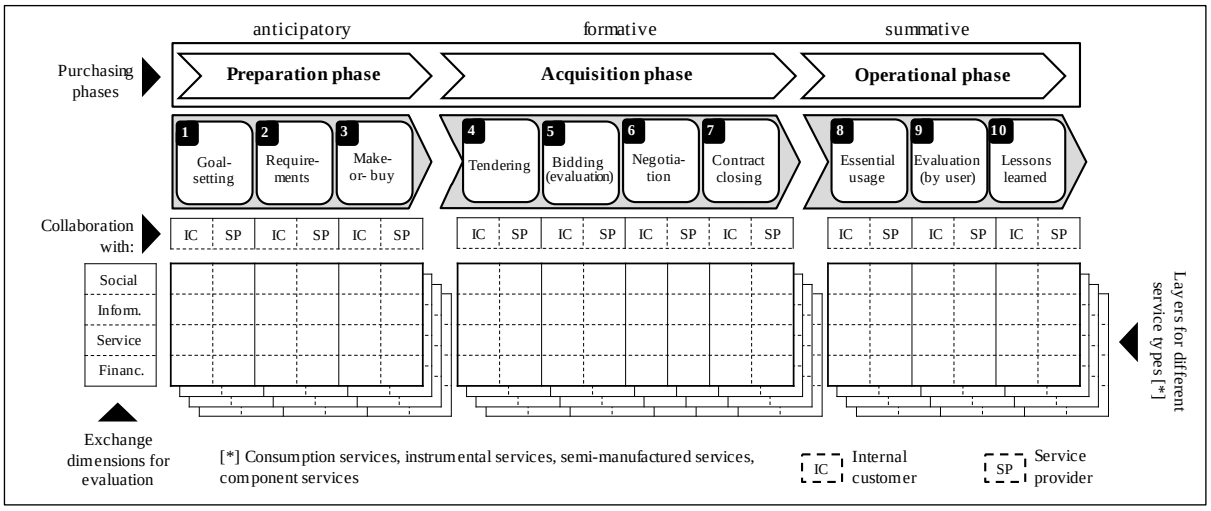

Figure 2: Framework for the purchasing and evaluation of business services

Our designed framework differentiates between three main purchasing phases before, during, and after the purchase (anticipatory, formative, and summative) and divides each main phase in several subsections (purchasing steps). This basis structure was derived from the first research stage and allows a focus on the different phases of a purchase. As the purchasing department is involved in all of these stages, the framework helps to define the necessary resources for different process steps.

In addition, we focused in our framework on the purchaser's collaboration with IC and the SP. For all three parties, the framework includes the exchange dimensions induced by the IMP theory. Consequently, the framework provides a matrix differentiating between the exchange dimensions (on the y-axis) and the involved parties (on the x-axis). While the column for the IC is used to determine a purchaser's exchange that is required for an adequate purchasing and evaluation, the column with the SP indicates the exchange dimensions that are evaluated by the purchaser. These aspects of the framework originate from the third research stage. Conclusively, the described matrices are a set of different layers that stand for different service types. Therefore, a structured differentiation of the exchanges with different involved parties, during

different purchasing steps for different service types is possible. These insights for the framework were derived from the second research stage.

Demonstration and evaluation

One essential step in every DSR approach focuses on the demonstration and evaluation of the designed artefact (Seidel et al., 2017). As our framework for the purchasing and evaluation of business services tries to provide support for purchasing managers, the focus group once again consists of employees responsible for the purchasing within their company, all of whom had been interviewed during the early research stages 1 and 2. The participants were asked to (1) cluster relevant services in accordance with their intended usage and (2) to rate the exchange with IC and SP during different purchasing phases by using Harvey Balls. This structured procedure helps firms to assign a purchasing department's resources in accordance with the relevance (the usage) of a service and to different purchasing phases. Figure 3 shows an excerpt of the completed template used for the demonstration and evaluation stage.

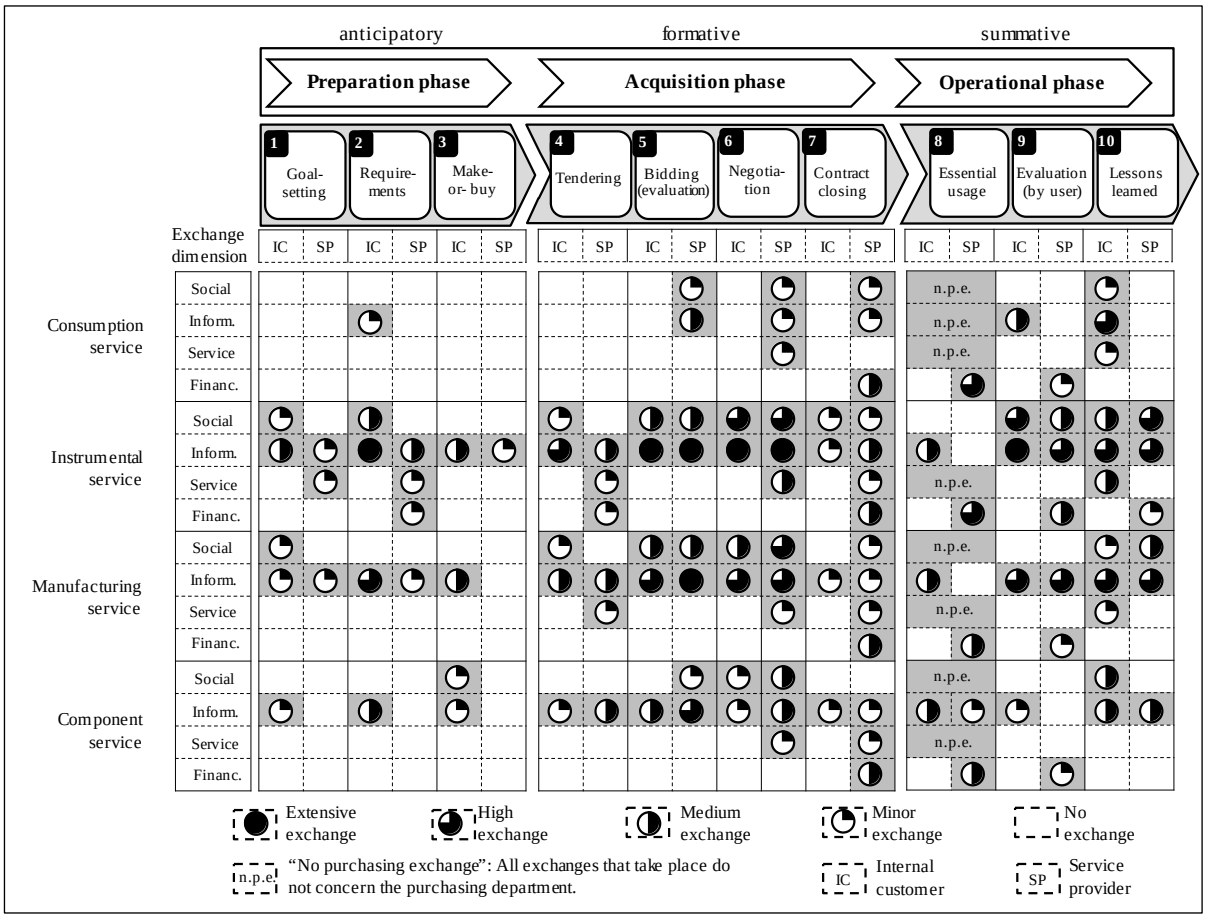

Figure 3: The need for exchange during different purchasing phases for different service types

In this context, it becomes clear that firms assign different resources to different services types described by Wynstra et al. (2006). Because of the fact that firms have to plan with limited resources, the scope of exchanges a company carries out during different purchasing phases varies. However, all insights from the demonstration and evaluation reveal the same picture that was discussed beforehand (Haensel & Hofmann, 2017). The exchange for instrumental services that increase the value of own products or services is always higher than for other services.

Discussion and implications

The aim of the research was to develop an evaluation framework that combines three relevant determining factors: the PI during different purchasing phases, the collaboration with both IC and SP, as well as the consideration of different service types as a contingent factor. The results show differences in the required evaluation effort, but also in the integration of a purchaser and their collaboration during different purchasing phases of a buyer and its integration into adequate evaluation procedures. However, the present scientific work does not specifically investigate the various evaluation procedures available, but instead assumes that they have a different degree of complexity and a clearly distinguishable effort that is required. This means that the investigation cannot predict which evaluation procedure should be used for a specific service. Rather, the work provides evidence that a different effort (e.g., in collaboration, PI, and evaluation) is required for different services.

Managerial implications

Starting with the managerial implications, the research shows that companies should always categorize their purchased business services based on their intended use. The proposed categorization of Wynstra et al. (2006) describes one possible differentiation. However, in the practical context, it may make sense to apply a more detailed classification for each service group. These results confirm early investigations by Haensel and Hofmann (2017), and extend research results from Wynstra et al. (2006) and Holschbach (2011). In addition, companies should collect evaluation methods that are available in their company and sort them according to their degree of complexity. This also means that firms have to determine the expected effort for implementing an evaluation procedure. Following this procedure, an allocation of evaluation procedures to different service types is necessary, whereby a complex evaluation procedure must always be used for the most relevant services.

Furthermore, it is necessary to implement a reasonable PI for each service type. Although the purchasing department is at least partially involved in each phase, it may be useful to reflect whether the available resources are truly being used for the most relevant services. In this context, firms should ensure collaboration with various entities involved in the process (mainly IC and SP). At this point, firms need to provide clear guidelines and strategies for exchanging information in various purchasing phases, taking the different types of services into account. Overall, the designed evaluation framework does not intend to evaluate services but helps firms to structure processes while evaluating service or for the development of an evaluation tool.

Theoretical implications

Following this argumentation, theoretical implications reveal based on the research. The research uses the exchange induced by the IMP theory as a theoretical basis for the investigation (the informational, the social, the service, and the financial exchange) (Håkansson & Snehota, 2006). Moreover, it is assumed that buying firms generally evaluate the dimensions of exchange in order to try to reduce the asymmetry of information that is postulated by the agency theory (Jensen & Meckling, 1976). However, depending on the service type, the observed exchange varies. Thus, the service type functions as a contingent factor for the IMP theory. Consequently, the research provides an extension of the IMP theory providing insights into the purchasing and evaluation of different types of business services. Moreover, literature on purchasing processes and on different service types is combined in our research, revealing a more sophisticated perspective. As a difference between the purchasing of goods and the purchasing of services is expected, the research helps to enhance the knowledge of the research stream of business services. This aspect also relates to suggestions from agency theory that postulates an information

asymmetry between the buying firm and SP. However, the research results focus on an enhancement of collaboration, PI, and evaluation that help to overcome this asymmetry.

An additional complexity driver in the area of service evaluation relates to individually tailored business services for specific purposes (Steiner et al., 2014). These types of services are excluded from the research and provide opportunities for future examinations. In addition, the investigation of the above services bases on a classification by Wynstra et al. (2006), which can be considered as one possible differentiation. Therefore, the impact on the management is applicable to the selected classification, but must be adapted individually to the respective company contexts.

Appendix

Appendix A: Overview about interview partners for research stage 1 and research stage 2

Study perspective		**Case characteristic**			**Number of interviews**	
Case	***Selection criteria***	***Size***	***Origin***	***Industry***	***Interview partner***	***Total***
C1	Large scale, domestic turnover and purchasing	Large	Switzerland	Postal service	Head of global purchasing; head of service purchasing	2
C2	Large scale, worldwide turnover and service purchasing, mass production	Large	Switzerland	Pharmaceuticals	Head of global sourcing; head of global warehousing	2
C3	Large scale, worldwide turnover and purchasing	Large	Switzerland	Engineering	Head of global purchasing; logistic purchasing manager	2
C4	Medium scale, trans-European turnover and service purchasing	Medium	Switzerland	Sanitation technic	Head of global purchasing; head of indirect purchasing	2
C5	Medium scale, trans-European turnover	Medium	Switzerland	Tobacco industry	Head of global operations; director procurement	2

Abstract

Digital supply chain (SC) integration combines the information needed for product and service delivery within the supply chain and supports the management of the product life cycle for the customer. In this study, we show how the improved digital integration capabilities affect to the integration benefits and SC operational performance. Furthermore, the connection to the firm business success will be studied. This study provides a novel framework for structuring different digital integration capabilities with the SC performance. The results show that integration capabilities have a direct linkage to the SC performance which in turn influences on the business success of companies.

Keywords: Supply chain, Integration, Digital strategies

1. Introduction

Supply chain management focuses on optimizing goods and material flows by sharing and analysing the information about these activities (Chen & Paulraj, 2004). This information is delivered in internal and external business transactions. It has been recognized that digital technologies and platforms are needed to facilitate this information flow. Very recently, the use of competitive strategies under digital conditions has raised the question of how the product and supply chain is embedded into digital technologies. Supply chain management is focused on interactions within the supply chain. Previously, the downstream side was emphasised; currently, the upstream side is emphasises as the demand–supply chain digitalization (Schoenherr et al., 2015). As firms and industries become digitalized, they will form strategies by relying on information, communication and connectivity functionality (Bharadwaj, 2013).

Information technology, information gathering, sharing and exchanging among the participants are crucial elements in supporting the process integration and development of supply chain management (Neubert et al., 2004). To enable dynamic action and decision-making, information exchange and information quality are very important issues in coordination within the supply chain (Li & Lin, 2006). Both, firm internal and supply chain wide external integration are needed in effective digital supply chain information management. Internal integration is defined as the integration of information within a firm's boundaries across the firm's business functions (e.g. Richey, 2010). The main motivation for internal integration has been to improve real-time information sharing, manage businesses processes and build better competitiveness. However,

beyond internal integration, there is increasing need to build more effective digital integration across supply chains and networks. External information integration within the supply chain has become a vital element in integrating supply chains, and it has been supported by many standardization units. In the cases when possible it is important that integration of the business processes in a supply chain is based on standards (Aerts et al., 2004). In general the interorganizational coordination is achieved using electronic links between information systems which enable automated and digitalized processing of source-to-pay processes with suppliers and customers in the supply chain (Paulraj et al., 2006; Berente, N. 2009). Furthermore, supply chain information sharing and processing is not just limited to the business process transactional level. For example, product information, sensor data (Internet of Things, IoT) and unstructured social media information are shared via different platforms.

This study provides a novel framework for structuring a business process model that is based on global standards. In particular, it presents the methods used to analyse the data, and it discusses the interesting results. Previous research has highlighted that information integration and service automation are important business value drivers in supply chains (see e.g. Paulraj et al. 2006; Neubert et al., 2004; Hazen and Byrd, 2012; Segars and Grover,1995) In this continue to examine what is the role of digital integration capabilities in the supply chain integration and performance. The paper is structured as follows. We will firstly outline the development of digital strategy and supply chain integration. Then we develop conceptual model and hypotheses for the empirical research. The hypotheses will then be tested by using the collected survey data from the industry. Finally the discussion and conclusions summarize the main contribution and implications of the study.

2. Integration Strategy and Digitalization in Supply Chains

2.1 IT investments and the role of integrations in competitive advantage

The ongoing global digitalization has been predicted to become as a substantial change as industrialization was (Frey and Osborne, 2013). The amount of data available can be expected to grow very fast thanks to digitalization. Brynjolfsson and McAfee (2014) portrayed that “everything that can be digitized will be digitized and everything that can be automated will be automated“. Digitally enabled business may create a range of challenges as well as new opportunities. Digitalization has led to new ways of doing business, as well as threatening traditional ways of doing business with old operating models and legacy processes. Despite the process of digitalization, the goals of most companies and organizations stay traditional, such as achieving improvements in profitability, as well as improving quality, market share, returns on capital and the achieving better profit. The business landscape is changing turbulent and the disruption of many current business models has already begun (Weill & Woerner 2015).

Outdated and legacy systems support weakly integrations and a real-time data sharing and economy. Cost savings are achieved through digitalisation and automation of financial management processes, which significantly reduces manual work. Updating hardware and

software requires ongoing investments in time and money. Legacy systems and their limitations may prevent businesses from gaining a competitive advantage and inhibit business growth and scalability. Also decreased security is a concern when it comes to using legacy system. Many companies are still depend on systems firs developed about 30 years ago. Investments that have previously been seen as strategic decisions have now become costly and part of a complex legacy (Peppard and Ward, 2016)

McKendrick (2015) presents in a globally conducted study that 58% of executives say cloud software enhances their business processes. More and more businesses are investing cloud-based applications to handle their daily business. This software is summarised under the term Software as a Service. Davis (2015) present that almost two thirds of European small and medium-sized enterprises (SMEs) already using cloud-based applications and services. According to this extensive survey, cloud-based services have already been quite broadly accepted and the researchers forecast a strong growth in the near future. This may offers plenty of potential for business processes and IoT integration by software service providers on and integrators (Botta, et al. 2016; Korpela et al. 2016).

Peppard and Ward (2016) have presented that the four main types of the strategic system are the applications that:

1. Share or integrate data (information) via technology-based platform with customers and suppliers and deepen the relationship
2. Produce effective integration of the use of data (information) in the value-adding processes
3. Create opportunities for businesses to develop, produce, sell and deliver a completely new or improved services or product or new information based on a value proposition
4. Increase human cognitive processes insight for information and in knowledge; they provide a good opportunity for the leaders and professionals with information to support the introduction, development and evaluation of strategies

It is important to ensure that information systems investment strategies and plans reflect business strategies and objectives. And also prepare that the personnel has the capability and competences to achieve a great deal of benefits from information system investments.

Stafford (2012) describes important issues regarding the integration: matching data with the most suitable type of connection, ensuring complete error-free communication between systems, maintaining the level of security for data exchange and connections, managing a comprehensive integration scheme to transmit the right data at the right time to the right system avoiding data silos. Businesses do not only need to set up their integration services at the beginning to utilize the connection, but also have to monitor and manage the quality, accuracy and security of software integration (Stafford, 2012). System integration was previously implemented by investing a large-scale effort to manually transferring the information or by performing an individual and expensive integration project. The key objective of integration is to avoid manually transfer information from one system to another and get more real-time information. Similarly, data errors can be reduced and reporting can be automated from data from different systems. With accurate and effective integrations, the company and its ecosystems can achieve a significant competitive advantage.

2.2 Integration and interoperability in Supply chains

Earlier findings of systemic supply chain integration (Korpela et al. 2016), identified transformation requirements for digital supply chain. Business model development: Companies have to develop strategies and business models to most innovatively and effectively leverage digitalization and supply chain integration.

1) Information model development: The proper information models, that includes process and data model are needed to design the systems to collect, store and deliver information in supply chains.
2) Business process standards: ISO/IEC 19845:2015 business process standard for supply chain integration. This defines how the business transactions in the supply chains can be digitally connected.
3) Integration channel: Previously the operator or intermediators have built the services for data transfer between actors and their systems. Their role have been structuring the date between organizations and their systems.
4) Automating transactions: This enables companies to design inter-firm transactions based on commonly agreed business rules and automate digital supply chain.

It has been recognized that deployment of compatible technology, processes and standards improve the information exchange in supply chains. Furthermore, effective information exchange has been widely identified and acknowledged as a significant element of process integration, which has improved cost-effectiveness and overall supply chain performance (Croom, 2005) there are still some barriers for automating activities between the stakeholders in supply chains. High investment costs, incompatibility of software and hardware and the lack of awareness about the benefits of automation are identified to be the main obstacles to deploying advanced technologies ((Evangelista et al. 2012; Murphy and Daley, J.M. 1999).

3. Theoretical background and hypotheses

Integration in supply chain may be investigated in different levels of analysis. In this the supply chain integration is studies mainly in two levels where we firstly focus on the buyer-supplier relationships in supply chain and secondly to the integration of information and communication systems across supply chains. Vijayasarathy (2010) defines supplier integration can be defined as merging of parts into a whole. Supplier integration occurs on the upstream part of the value chain with those suppliers that are considered as most important and valuable for the buyer (Paulraj et al., 2006; Segars and Grover, 1995). In a similar vein, selling companies aspire to integrate downstream part of the value chain with mist important customers. Motives and explanation for supply chain integration comes from resource-based view (RBV) and transaction cost economics theories (TCE). Based on the RBV (Barney) the value of the resources is key for competitive advantage of the firm, and by integration is possible to combine resources of the buyer with those of the suppliers or logistics to generate competitive advantages (Wagner, 2003; Ordanini,and Rubera, 2008; Hazen and Byrd, 2012) TCE theory (Williamsnon 1975), provides rationale for integration based on the assumption that hybrid model of supplier cooperation referring to the closer cooperation reduces transaction costs of operations. Electronic business process management involves end-to-end interoperability within systems, which is explained in the

electronic data integration literature. In brief, the TCE perspective is that the firm economizes on transaction costs through the selection of internal governance costs for handling market transaction costs (Tsang, 2002). It can be assumed that with the digital supply chain platforms, which main purpose is to integrate, automate and streamline the data flow in the supply chain, it is possible to reduce the transaction costs in supply chain. This would possibly allow the realization of several strategic supply chain integration benefits and competitive advantage Competitive Advantage by Use of IT (Kearns and Lederer, 2003).

Figure 1 illustrates the conceptual framework of the study. In the background of the frame there are factors of top management commitment on digitalization, firms' capability for digital integration in supply chains and interoperability of digital solutions. These factors affect to the supply chain integration and supply chain performance which in turn influence on business success of companies. The items used to measure the factors are presented in the Appendix 1.

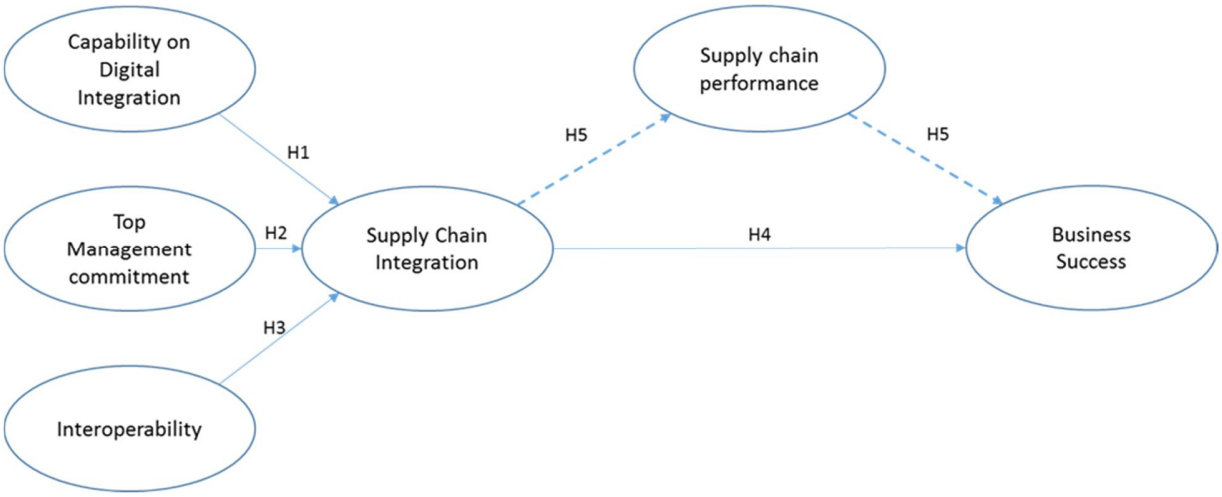

Figure 1 Conceptual framework of the study

3.1 Supply Chain integration benefits

Information technology contribute to better integration by fostering communication-based competencies (Paulraj, A., & Chen, I. J. (2006). According to literature, Inteorganizational system integration capabilities of companies influence on the supply chain integration success (van der Vaart & van Donk, 2008). Companies that invest on technical integration capabilities will get better supply chain integration (Chen & Paulraj, 2004). Thus, they recognize the potential benefits associated to the digital supply chain integration. Because integration capabilities require investments on top management support has an important role in the supply chain integration efforts (Chen and Paulraj, 2004). Top management support may facilitate resources and

investments to the digital integration capabilities which crucial for getting outcomes and benefits of information efforts. Information systems have been identified to foster integration with suppliers by sharing information with suppliers, establishing efficient communications, using common databases and implementing systems that enable linking of the buyer and supplier in real-time (Alfalla-Luque et al., 2013).

Essential capabilities in supply chain information integration include peer-to-peer links with suppliers, extranets that provide access of suppliers to the supply chain platforms of buying firms, and systems that integrate supply chain process transaction between companies transactional electronic data interchange (EDI) systems (see e.g. Shah et al. 2002). The interoperability of these systems requires commonly agreed open supply chain process interfaces as well as platforms that support inter-firm integration. Open supply chain standards (e.g. Edifact, UBL, ISO/IEC 19845:2015, RosettaNet) may provide uniform language for automated communication of transactional information between companies in supply chains. Furthermore, it is necessary that different supply chain systems are easily integrated to assure the interoperability of information. Open Source reference models to external integration are becoming a mainstream, where common standards are implemented to integration solutions. External integration e.g. Saas as a Service, public cloud and distributed platform technologies represents these mainstreams.

The technical interoperability of integration may be based on open interfaces and, for example, Application Programing Interfaces (API) integration solutions and management principles that allow different systems to transfer structured data based on API structure, designed by business processes and communicate automatically between each other. The use and maturity of information technology has linkage to the supply chains integration in the literature (e.g. Flynn et al., 2010). This can be illustrated, for example, by more optimized supply chain flows, increased accuracy of processes, and visibility of processes. The following hypotheses will be presented in order investigate the effect of digital integration capability, top management commitment and technical interoperability to the supply chain integration.

H1: Strategic integration capability of a company influences on supply chain integration?

H2: Commitment of Top management on Digital Integration influences supply chain integration?

H3: Interoperability of purchased information technology solutions influences supply chain integration?

3.2 Relationship between the supply chain Integration and performance

Relationship between information technology, supply chain integration and performance has examined widely but linkage is not self-evident (Daugherty et al. 1992; Gustin et al. 1994). Literature provides evidence for positive effects of information integration technologies influence on supply chain integration, which has a positive impact on performance, indirect at least (Li et al., 2009; Vickery et al, 2003, Wiengarten et al. 2012). Capability to share information among supplier networks has proven to not only increase flexibility but also directly contribute to the

operational performance (Bruque-Cámara et al. 2016). In the other words, the supply chain integration seem promote the supply chain performance and overall business success of companies (Ataseven & Nair 2017; Paulraj et al., 2006). The literature provides consistent support for the positive relationship between supply chain or supplier integration and company performance (Wiengarten et al., 2016;, Paulraj et al., 2006, Alfalla-Luque et al., 2013, van der Vaart & van Donk, 2008). In here, an important aligned concept is systemic value creation, which emphasize the integration benefits of lager networks of organizational systems (Immonen et al. 2015). In general, information technology enhances firm's supply chain logistics efficiency by providing real-time information regarding product availability, inventory level, shipment status and production requirements (Radstaak and Ketelaar 1998). In sum, the degrees of integration seems to lead to better outcomes by which we set the fourth hypothesis as follows.

H4: Supply chain integration has direct influence on the business success.

The supply chain integration seems to influence on the business performance through relatively high costs in implementation and providing advantages with regard both the customer value creation and the supplier engagement (Chang et al. 2016). Especially, the use of information technology in supply chain relationships has provided benefits in operational performance, visibility, faster delivery times, reduced transaction costs and improved inventory turnover (Ataseven & Nair 2017; Frohlich, 2002). For example, information technology has been promoted as an essential tool to ensure the logistics objective of providing timely service (Paulraj and Chen, 2006). However, the associated benefits of integration may not always realise and some studies have indicated even negative relationship between supply integration and performance (Swink et al., 2007). For example, the study by Huo et al., (2016) found no relationship between firm performance and supplier integration. To explain previous, it is necessary to investigate the drivers and outcomes of supply chain more in depth. The overall influences of the supply chain integration seems to depend on the context where appropriate level of product complexity has shown a common denominator for successful outcomes. The complexity refers the product attributes and relational complexity of the markets. In here, the positive performance outcomes have inverted U-shaped relationship to supply complexity, thus, always bounded with specific range of attributes (Ataseven & Nair 2017). Moderate level of complexity has proven to increase likelihood for success of the supply chain integration in general (Wong et al. 2015). In particular, combination of low product complexity and high market complexity are markers for potentially lucrative targets for investments (Wong et al. 2015; Ataseven & Nair 2017) In sum, the performance gains from the supply chain integration are sensitive for complexity of supply networks relationship and likely to have indirect effect on the business success metrics. By the previous, we set the fifth hypothesis as follows.

H5: The supply chain performance mediates the relationship between the supply chain integration and the business success.

4. Empirical Study

In order to map the status of the digital integrations and driver of supply chain performance in companies of different sizes, a survey with special focus on the subject was conducted. The study is based on the survey that was targeted to large and medium-size companies in Finland. The

sample consisted of over 500 companies. These companies were first contacted by phone in order to find the most suitable informant in the field of digitalization and supply chain management. Of those companies, 348 respondents agreed to participate in the survey, and a weblink to the questionnaire was emailed to them. A total of 101 answers were received, resulting in a response rate of 29% (101/348). The survey was presented online questionnaire in the Webropol system. The sample covered companies located all over Finland to ensure good representation of all the types of industrial companies encountered across the country.

Our target respondent group for the survey were the supply chain and IT managers in large and medium sized industrial companies. The respondents presented different industries including manufacturing, process industry, bio, energy and business service sectors. However, the participants were invited to participate to the survey as an individual experts. The developed survey instrument included the firm background information as well as different constructs with the measurement items. Survey instrument was pre-tested with the group of specialists before it was send to the respondents. Survey items were identified from the literature and cooperation with industry practitioners. The applied items and connected references have been illustrated in Appendix 1. The respondents evaluated the questions on a Likert scale from 1 to 5, where 5 indicated total agreement and 1 total disagreement and for a broader understanding the survey also included open questions. The questions were not mandatory, and the respondent was able to bypass individual questions. Due to this, the number of responses on individual questions varied.

4.1 Survey instrument

The measurement model was validated with regard to (1) measurement reliability, (2) validity of the factor structure and (3) discriminant validity of the measurement model (Gefen and Straub 2005; Henseler et al. 2009). The measurement reliability was assessed using construct reliability ('CR') and the variance captured by latent construct by average variance extracted ('AVE') (see e.g. Fornell and Larcker, 1981). The CR coefficient should exceed .50 to indicate acceptable if the model validity otherwise is good (Kline, 2011; Little et al., 1999). The measurement reliabilities are reported in the Table 1 where can be seen that all of the latent variables had good reliability for further analyses.

CRs of the latent constructs were acceptable varying from .773 to very high .926. Factor structure of the measurement model was analyzed by significance and weight of factor loadings, reliability, and validity and for cross-loadings between latent factors. All loadings in outer model (measurement model) were significant ($p<0.001$) and acceptable varying from .784 to .923. The convergent validity of all latent factors by AVE was acceptable higher than .50 for all measured concepts (Fornell and Larcker, 1981).We assessed discriminant validity of the measurement model (1) by cross loadings of the measurement items and (2) by the square root of AVE (i.e. Fornel-Larcker criterion) (Gefen and Straub 2005; Henseler et al.2009). The all measurement items were highly loaded to the defined latent factors and cross loadings did not reach level higher than .589. Furthermore, the square roots of AVE were significantly higher than correlations between any latent factors manifesting good discriminant validity of the measurement model.

Table 1 Measurement reliabilities

	Loading	t-value	p-value	Mean	SD	AVE	CR
Capability on Digital Integration (CDI)						**0,918**	**0,789**
CDI1	0,921	67,000	****	3.280	1.140

BSuccess4	0,856	24,097	****	3.323	0.891		

n) not significant, *) Statistically significant at p<0.1, **) Statistically significant at p<0.05, ***) Statistically significant at p<0.01, ****) Statistically significant at p<0.001

4.2 PLS Path Model

We analyzed main effects in the model which were defined by hypothesis one to seven (Table 2). In the analysis, bootstrap sample was size n=101 which equals to original sample. The resampling of the data was repeated 5000 times ("Basic Bootstrapping") in analysis which is adequate for estimation of parameters in the model (Henseler, Ringle and Sinkovics 2009; Kline 2011). We tested and validated quality of the structural model through the following steps; (1) collinearity issues and overall fit, (3) explanatory power, (4) path significances.

We assess the collinearity and the model fit to the data in order to validate the structural model which provides information on potential misspecification problems. VIF (variance inflation factor) of the latent constructs did not indicate collinearity issues where the values (VIF = from 1.073 to 3.247) remain clearly below critical value of 5. Because of hypothesis testing objective of the article, we need to asses over all fit of the structural model. For that purpose, we use standardized

root mean square residual (SRMR, critical value <.08) and root mean square residual covariance (RMStheta, critical value >.12) to specify estimation error and misspecification of the model (Henseler et al., 2014; Joseph F. Hair et al., 2014). Here, model fit by SRMR = .071 and RMStheta= .199 indicates that serious misspecification of the structural model does not occur. The r-squared for the latent variables in the path model were; "Supply Chain Integration " = .499, "Supply Chain Performance" = 0.464 to "Business Success" = 0.140. Overall, the explanatory power of the model is satisfactory regardless relatively low sample because the true phenomenon in focus is remarkably complex including multiple influences outside the tested model (Abelson, 1985; Prentice and Miller, 1992).

The default model (see Table 2) shows that the "Capability on Digital Integration" (CDI), the "Commitment of Top management on Digital Integration" (CTMan) and the "Interoperability" (Interop) have strong and significant positive influence on the "Supply Chain Integration" (SCI) which confirms the hypotheses H1, H2 and H3. In the tested main model, the Supply Chain Integration (SCI) has significant effect on the Business Success (BSuccess) which confirms hypothesis H4. By results, the supply Chain Performance (SCP) did not have mediator role for the SCI in the model by the found total effect, which lead us to reject H5. By the analysis, the supply chain performance (SCP) seems to depend on the level of the supply chain integration (SCI). However, we did not find significant influence of the SCP to BSuccess. We included several direct effects outside the main model into the PLS-path model as post-hoc purposes. The goal was to validate overall fit of the model to data and to assess role of the supply chain integration as part of the digitalisation strategies. Significant direct effects of the IT-strategy related drivers (CDI, CTMan or Interop) to the Business Success did not found. Following previous, the IT-strategy related drivers did not indicate any significant effects to the supply Chain Performance (SCP). To conclude, the post-hoc analysis shows that the supply chain integration (SCI) has a significant role as a mediator between IT-strategy and business performance.

Table 2 Direct effects in the structural model to test the main hypothesis of the study and post-hoc test for the effects of the ICT to Business performance

Hypothesis	**Path**	***β***	***T Statistics***	***P Values***
H1	CDI → SCI	0,465	6,415	****
H2	CTMan →SCI	0,237	3,190	***
H3	Interop → SCI	0,167	2,281	*
H4	SCI → BSuccess	0,358	2,610	***
H5	SCI →SCP → BSuccess (total effect)	0,063	0,855	0,393
"	*SCI →SCP (direct effect)*	*0,477*	*3,847*	****
"	*SCP → BSuccess (direct effect)*	*0,131*	*0,975*	*n*
Post-hoc test for the direct effects to validate overall model.				
	CDI → BSuccess	-0,084	0,599	n
	CTMan → BSuccess	-0,084	0,598	n
	Interop → BSuccess	0,023	0,203	n
	CDI → SCP	0,166	1,617	n
	CTMan →SCP	0,036	0,427	n
	Interop → SCP	0,135	1,519	n

n) not significant, *) Statistically significant at p<0.1, **) Statistically significant at p<0.05, ***) Statistically significant at p<0.01, ****) Statistically significant at p<0.001

5. Discussion and Conclusions

The study shows that Information technology brings possibilities to the supply chains, however, integration success seem to be the real driver of supply chain performance and further business success. Our findings illustrate that different levels of information integration activities seem to have essential role in leveraging supply chain integration and supply chain performance. The findings mean that information integration is the key enabler of supply chain providing required capabilities for effective integration. Identified facilitating factors include top-management commitment on integration, firm capabilities for integration, and interoperability of information systems. The findings also show that the digital strategies adapted by the firms may not have directly contribute on business success, but the influences are mediated thought the business activity level. In our data, the digitalisation influences on the businesses success through increased integration of the supply chains whereas similar mediation effect did not find with regard operational performance of the supply chains. We assume by the findings that the benefits of adopting the digital strategies are mostly related with fluency of the network wide flows and engagement of the actors into supply chains.

Earlier studies have identified that information integration technologies have a positive impact on company performance, (Li et al., 2009; Vickery et al, 2003, Wiengarten et al. 2012). This study contributes to the existing knowledge by investigating the impact of different levels (strategic, operational and systems) of digital integration on supply chain integration and performance. This study has shown positive relationship between integration and supply chain performance. The motives of supply chain integration has been highlighted in the literature. These studies have been recognized the positive relationship between integration and company performance (Wiengarten et al., 2016; Paulraj et al., 2006). This study has clarified the impact of digital integration and supply chain integration on performance. Furthermore, the positive relationship between supply chain performance and firm business success has been recognized.

Companies with successful histories need to adopt digital strategy if they will thrive in the future. Managers should see information systems and integrations as core to their business and some managers even still see these investments as an administrative costs. Managers should take a key role to manage information systems more strategically. To fully employ the potential of digitalization, the managers should redefine the concept of performance to cover network wide effects and to include indirect gains into accounting models which have traditionally been hidden from evaluators. An essential managerial implication of this study is that essential value potential of information systems in the supply chain is connected to the effective integration of information and communication systems across chains and networks. Effective integration provide systemic value to the supply chains with integrated business processes leading to speeding up supply chains, reducing costs, reducing errors and improving visibility.

The study has some limitations that should be addressed. The study was based on the survey data with rather challenging questionnaire for the respondent companies that show low integration level. This was also validated by feedback from respondents. Therefore, it is assumed that the sample does cover companies with higher integration maturity level. Further research on the digital supply chain integration will be focusing on the API and Blockchain integration. API offers structured data integration end to end digitally and Blockchain by its nature is decentralized

distribution of transactions recorded to common ledgers. Inter-firm contracting and Blockchain Smart Contracting can automate depending transactions in supply chain. These fully digitalized and decentralized integration technologies will re-shape the business models and innovations. We will closely research this technology deployment.

APPENDIX 1 Items used in the survey instrument

Commitment of Top management on Digital Integration
(adapted from Chen and Paulraj, 2004; Boyer and Mc Dermott, 1999)

CTMan1: New investments on digital integration
CTMan2: Top management support for digitalization benefits to our customers
CTMan3: Top management understanding of digitalization benefits to us
CTMan4: Top management support for digitalization resourcing

Capability on Digital Integration
(adapted from Aerts et al., 2004)

CDI1: IT Management has plan for the digital integration
CDI2: Firm has capability and knoweldge of global standards for process integration
CDI3: IT management has clear vision on internal and external integration

Interoperability
(adapted from Peppard, J. & Ward, J., 201; Hallikas et al., 2014)

Interop1: We put a lot of effort into ensuring that purchased services are integrated so that they work smoothly together
Interop2: Purchasing of systems that support open interfaces and standards

Supply Chain Interation by Use of IT
(adapted from Kearns and Lederer, 2003)

SCI1: Influence the buyer's decision to switch to our product
SCI2: Make it more cost-efficient to add new suppliers to our supplier base
SCI3: Establish electronic links with suppliers or customers

Supply Chain Operational Performance
(adapted from McLaren et al., 2002; O'Leary, 2000).

SCP1: Digitalization reduce product or service costs
SCP2: Digitalization reduce errors through improved Information sharing
SCP3: Digitalization reduces supply chain lead time through information sharing

Business Success
(adapted from Germain, R., Droge, C., & Spears, N. 1996; Hendricks and Singhal, 2007).

BSuccess1: Dept Equity Ratio
BSuccess2: Netincome
BSuccess3: Return on Investment
BSuccess4: Profit

Collaborative Public Procurement: a conceptual framework

Summary
Horizonal collaborative public procurement is where two or more public organisations collaborate to perform a procurement activity. A conceptual framework of 4 pillars is provided relating the objectives of collaborative public procurement to different forms and activities of CPP, to examine impact on performance of CPP. Barriers and enablers to CPP are also investigated. The framework is novel; prior work has focused only on specific pillars or the relationship between objectives and organizational form of CPP. The framework is tested empirically to verify the content of each pillar and test linkages between pillars.

Keywords
Collaborative public procurement, collaboration, inter-organizational

Submission category
WP

Introduction

Since the global economic crisis, public services have come under increasing pressure to do more with less, referred to as 'austerity'(Loader, 2011). Consequently, commissioners of government services are forced to cut spending and reduce system inefficiencies. One of the ways in which governments try to become more efficient is to stimulate or enforce more collaborative public procurement (CPP) (Schotanus, 2005; Walker et al. 2008). (Walker, Schotanus, Bakker, & Harland, 2013) endorse this point by noting that collaboration is often no longer an option but is written into policy as part of the political agenda. Whilst many types of collaboration have been identified (Walker et al. 2013) and benefits of collaboration have been acknowledged (Bakker, Walker, Schotanus, & Harland, 2008), there remains little guidance on how to do CPP better.

IRSPP is an international network representing 45 countries whose members are academics, practitioners, policy makers and purchasing professional associations including CIPS, NIGP, PiANO and NEVI (Knight et al., 2012). Bi-annually IRSPP conducts a major piece of research on a topic that the network members perceive as contemporary and important to public procurement practice internationally and CPP was proposed by the members as the topic for IRSPP7.

This paper reports the front end of the IRSPP7 study that sought to provide a conceptual framework for collaborative public procurement that could be used to guide the design and delivery of later empirical case study and survey research. Initially an operations management 'input-process-output' framework is used to review the literature on 'organisational type of CPP-process of CPP-output performance of CPP'. The literature is used to build 'pillars' in the framework containing elements expanding on type, process and output performance and, from the literature, a fourth pillar of 'objectives of CPP is added. Additionally barriers and enablers to each pillar are also elaborated. The developed framework and elements of each pillar are then tested theoretically, focusing on 22 collaborative public procurement papers, and empirically through a survey of 238 public procurement practitioners. The empirical findings show clusters of features of CPP and explain linkages between each of the pillars in the framework. They demonstrate how practitioners prioritise aspects of CPP, some of which are not represented in the literature. They also reveal areas emphasized in the literature that practitioners do not focus on. Both the theoretical and empirical testing support the conceptual framework, with minor additions. These findings are incorporated in the final version of the conceptual framework that contributes to knowledge on inter-organizational collaboration and public procurement.

Literature review

Collaborative public procurement is reviewed, then supplemented by a broader review of collaboration in public management and in inter-organizational networks.

Collaborative public procurement

The term 'collaborative public procurement' (CPP) is used here to describe the phenomenon of public organisations collaborating horizontally with each other to procure goods and services. Terms used to describe this horizontal collaboration include 'cooperative purchasing', 'group procurement', 'joint procurement' and 'shared procurement'. At least 45 different terms have been identified in publications relating to CPP (Essig, 2000) (Essig, 2000). Some of the more frequently used terms are featured in *Table 1*.

Table 1: Terms used comparable with collaborative public procurement

Type	Definition	Author/s
Cooperative purchasing	*The cooperation between two or more organisations in a purchasing group, in one or more steps of the purchasing process by sharing or bundling their purchasing volumes, information or resources in order to improve their performance*	(Schotanus & Telgen, 2007)
Purchasing group	*Two or more organisations that purchase together, either formally or informally, or through a third party*	(Hendrick, 1996)
Joint procurement	*Means combining the procurement actions of two or more contracting authorities. The key defining characteristic is that there should be only one tender published on behalf of all participating authorities*	Tatrai (2015, p.10)
Shared procurement	*Procurement of shared services refers to low value, commonly spent items such as janitorial supplies, administration items*	(Gordon Murray, Rentell, & Geere, 2008)
Purchasing consortium	*Consists of two or more independent organisations that join together, either formally or informally, or through an independent third party, for the purpose of combining their individual requirements for purchased materials, services, and capital goods to leverage more value-added pricing, service, and technology from their external suppliers than could be obtained if each firm purchased goods and services alone*	(Hendrick, 1996)

Consortium sourcing	*the combination of symbiosis and strategy - consortia are organized as symbiotic structural relationships between purchasing companies*	Essig (2000, p.16)

An alternative structure according to Murray, Rentall and Geere (2008) is shared service procurement which enables public bodies to "*maximise the benefits of both the intra-organisational hard core/soft core model and inter-organisational consortia participation*" and should be considered as an important option when public organizations may be smaller and /or lack resource and capabilities in procurement.

Reasons indicated for an increase in collaborative public procurement are the development of E-Procurement (Huber et al., 2004), shifting agendas from a short-term, internal focus to a long-term, external relationship focus (Dobler & Burt, 1996; Essig, 2000), an increased level of competition and cost pressure (Hendrick, 1996; Nollet & Beaulieu, 2005), an increased awareness and importance of purchasing (Walker et al., 2013), and the wish to counterbalance the power of large suppliers (Nollet and Beaulieu, 2005). Efficiencies gained from such collaboration can be termed 'collaborative efficiencies' and can be defined as: "*reforms that recognise and seek to resolve operating-cost interdependencies by creating multi-organisational arrangements to achieve levels of operating efficiency that cannot be achieved, or achieved easily, by single organisations*"(Elston, 2015).

There are many benefits associated with CPP which include economies of scale (Nollet & Beaulieu, 2005; Rozemeijer, 2000), reduction of transaction costs (Johnson, 1999), process cost avoidance (Schotanus, 2005), and improved relationships with suppliers and other organizations who are part of the purchasing group (Hendrick, 1996). Essentially the benefits can be categorized as improved efficiencies and improved effectiveness (Jost et al., 2005, Schotanus and Telgen, 2005, 2007; Walker et al. 2006, 2008). Improved efficiencies can be achieved by reducing transaction costs, bundling purchasing activities together and achieving economies of scale, while improved effectiveness can be reached through a focus on quality enhancement of the goods or services purchased through the collaboration, as well as a more effective execution of process activities, such as learning from other participants in the collaboration (Bakker et al 2008). Enhanced supplier relationship management arising from the collaboration may increase innovation or improve risk management (Patrucco et al., 2017). Reported disadvantages of collaborative procurement include a potential increase of complexity of the purchasing process (Tella & Virolainen, 2005), loss of flexibility and control of procurement activities (Schotanus, 2005), increase in coordination costs (Johnson, 1999), and a need to change and adapt specifications (Schotanus, 2005).

CPP research so far seems to have contributed to collaboration type, collaboration process and collaboration outputs but we find there is no one framework within the CPP literature that integrates these.

Collaboration in public management

One of the main concerns in public management is the complexity of the portfolio of social, economic and environmental problems where responses to form solutions often involve collaboration between public organisations because of shared or similar goals (Gray, 1985; (Agranoff & McGuire, 2004). There are many government policy areas where it is recognised that collaboration across government agencies is required, for example to tackle crime, manage urban areas, provide social services and improve national security. However, following from the global financial crisis, increasingly it is being recognised that collaboration across government bodies is also essential to yield significant savings in operating costs (Bovaird, 2014). Collaboration to integrate back office functions such as HR and IT may yield

efficiencies (Knol et al., 2014; MacCarthaigh, 2014; Elston, 2015). Collaboration across front line government service providers to form 'one-stop-shops' for citizens (Reid, 1995) can also give rise to efficiencies.

Collaborative networks are the most common type of interorganizational network found in public and not-for-profit sectors (Eisingerich, Rubera, & Seifert, 2009), (Kimberley R Isett, Mergel, LeRoux, Mischen, & Rethemeyer, 2011) (Popp, MacKean, Casebeer, Milward, & Lindstrom, 2013). Collaboration in these interorganizational networks is often intersectional, among business, government, non-profit organizations, communities and/or public as a whole (Bryson, Crosby, & Stone, 2006; Rethemeyer & Hatmaker, 2008).

Collaboration across government agencies not only helps to tackle complex problems but also enables the sharing of scarce resources (Keast, Mandell, Brown, & Woolcock, 2004) (Bryson et al., 2006), (Hoberecht, Joseph, Spencer, & Southern, 2011; Weber & Khademian, 2008), Collaboration can help to improve efficiency, legitimacy, power and manage uncertainty (Hoberecht et al., 2011; Kimberley R Isett et al., 2011; Kimberley Roussin Isett & Provan, 2005; Pesämaa, 2007). It has been claimed that they can improve service delivery, advance innovation, support risk distribution and share accountability (Pesämaa 2007, Hoberecht, Joseph et al. 2011) enabling key managers to understand bigger, more sustainable solutions (Hoberecht, Joseph et al. 2011) that individual organizations and managers cannot achieve independently (Provan & Kenis, 2008; Weber & Khademian, 2008). In particular, wicked problems such as poverty and global warming, and reform of complex services such as education and healthcare, cannot be solved by single agencies, organizations and even sectors (Huxham and Vangen 2005, Hoberecht, Joseph et al. 2011). These complex problems facing society provide a "moral imperative" to collaborate across organizations and sectors (Popp et al., 2013).

Interorganisational network collaboration

Much of the focus on collaboration across private sector organisations has been on trying to achieve efficiencies to generate cost savings (Vereecke & Muylle (2006) (Min et al 2005), Essig (2000). Interorganizational networks come in a variety of forms of cooperation including joint ventures, strategic alliances, collaborations and consortia (Podolny and Page 1998), though some view them as informal, social, rather than legally bound constellations of organisations (Barringer & Harrison, 2000).Interaction between organisations in business to business dyadic relationships lead to longer term relationships becoming institutionalised (Ford & Group, 1990; Håkansson & Group, 1982; Håkansson & Laage-Hellman, 1984; Håkansson & Snehota, 1989)..

Supply chain management can be conceptualised as occurring at different levels – within organizations, relationships, supply chains and networks of organizations (Christine M Harland, 1996). Interorganizational supply network activities include partner selection, resource integration, information processing, knowledge capture, social coordination, risk and benefit sharing, decision making, conflict resolution and motivating (C. Harland, Zheng, Johnsen, & Lamming, 2004; Christine M. Harland, Lamming, Zheng, & Johnsen, 2001; Johnsen, Wynstra, Zheng, Harland, & Lamming, 2000). Management of, and in, interorganizational networks is through six network management roles - network structuring agent, coordinator, advisor, information broker, relationship broker and innovation sponsor (Christine M Harland & Knight, 2001; Knight, Harland, Walker, & Sutton, 2005).

All 150 papers reviewed were analysed, coded and mapped onto the initial conceptual framework of type, process and output performance of CPP. In addition to this mapping, it was

observed that many papers also addressed the objectives of collaboration and what was enabling or constraining collaboration from occurring. This led to 5 main 'pillars' in the conceptual framework rather than 3. Within each pillar elements relating to that pillar were recorded. For example, papers examining organisational design discussed organisational form, dynamics among group members (e.g. motivation, decision making, conflict resolution, trust, number of members), and members' roles (e.eg. collaboration coordinator, collaboration leader, technical advisor). These 'elements' provided the content of each 'pillar'

Methodology for testing the conceptual framework

Theoretical testing method

The initial literature review used keywords of "collaboration", "procurement" and "public administration" and combinations of these, yielding 150 papers. To test the initial conceptual framework and the additional content from the broader literature review we focused on a subset from the 150 of 22 papers that focused on public procurement considering both the content (evaluating title, abstract, and the full text) and the journal relevance, as suggested by McGuire (2006), Quintens et al. (2006), Pagano (2009), and (Spina, Caniato, Luzzini, & Ronchi, 2013). Only ABS ranked journal papers were included in the search. As a result 22 papers from 8 operations and supply journals 5 public administration journals remained for in depth analysis to see if they supported the conceptual framework design.

Empirical testing method

A questionnaire survey was designed to collect data on collaborative public procurement projects. It was divided into six sections: the first on general data on the institution, respondent and CPP project, the next five on CPP objectives, type, process, performance, and barriers and enablers. Piloting was conducted to improve item wording, reduce survey length and improve translations. 238 institutions in the IRSPP network contacts agreed to participate, and out of these, 161 useable responses were received, yielding a 10% response rate of the total sample and a 67% response rate of those who agreed to respond. To test the validity of the pillars and of the items included in the conceptual framework, we ran an Exploratory Factor Analysis (EFA. Only items with factor loadings of at least 0.4 were retained. For each of the obtained constructs, we measured reliability.

Findings and discussion

Findings from the theoretical testing

Table 2 below summarises findings of the pillars and elements from the conceptual framework found in the in depth analysis of the collaborative public procurement literature.

Table 2: Support for pillars and elements of conceptual framework

PILLARS AND ELEMENTS OF CONCEPTUAL FRAMEWORK	NUMBER OF PAPERS ADDRESSING THESE
Objectives of collaboration	
Efficiency	6
Quality	2
Competence enhancement	3
Relationship development	4
Broader government objectives	0
Total objectives of collaboration	**15**
Collaboration organisation	
Organisational form	3
Dynamics among group members	6
Members' roles	3

Total collaboration organization	**12**
Collaboration process and tools	
Operational activities	4
Managerial activities	1
Strategy forming activities	3
Policy forming activities	1
Tools	0
Total collaboration process and tools	**9**
Collaboration output performance	
Efficiency savings	12
Effectiveness improvements	7
Strategic performance improvements	4
Total collaboration performance	**23**
Barriers and enablers to collaboration	
Level of partner involvement	**7**
High level support	6
Total barriers and enablers to collaboration	**13**

The theoretical testing supported the general architecture of the framework, but did not confirm all the elements of each pillar or any linkages between pillars

Findings from the empirical testing

Table 3 reports results of the Exploratory Factor Analysis

Table 3: Exploratory Factor Analysis

	Construct	Items	Loading	Cronbach alpha
OBJECTIVES	Efficiency	Optimize supply base	.741	0.785
		Standardize and rationalize needs	.714

		Improve relationship with other institutions	.743	
		Improve relationship with potential suppliers	.667	
	Efficiency	Obtain savings or avoid additional costs	.805	0.804
		Decrease procurement process cost	.786	
		Increase procurement quality	.738	
	Risk management	Outsource management of non – strategic procurement	.803	0.672
		Improve management of procurement risk	.746	
ENABLING FACTORS	Partner involvement	Information brokering/ sharing	,758	0.701
		Knowledge capture	,740	
		Commitment of partners to invest time	,729	
		Risk and benefit sharing	,622	
	Government support	Political support	,933	0.843
		High level support	,924	

The final revised conceptual framework contained the additional findings from the theoretical and empirical testing. Elements not viewed as important by either literature or practice but featuring in the other were retained as they represented potentially interesting areas to explore further.

Revised conceptual framework

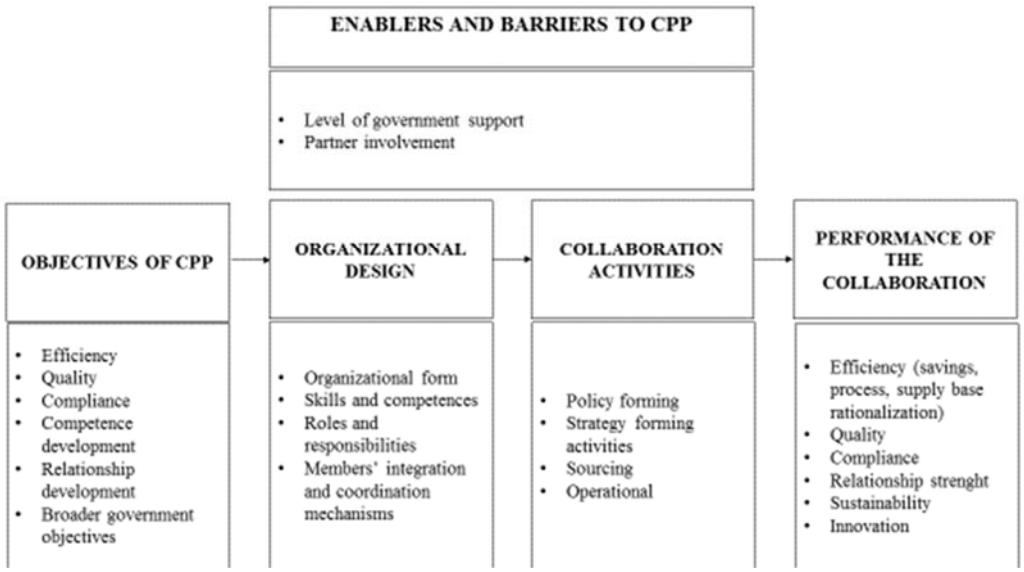

Figure 1:Revised conceptual framework

Conclusions

Whilst there have been contributions to knowledge on Collaborative Public Procurement, to date there has not been evidence of understanding of the objectives, type, process, performance, and barriers and enablers. Most significantly there has not been any empirical testing on how these 'pillar' of CPP are inter-related. This working paper provides a summary of the analysis to date supporting a conceptual framework for Collaborative Public Procurement. This framework is applied in subsequent analysis of the empirical data in the rest of the IRSPP7 study. It can also be used to guide research in Collaborative Public Procurement.

Abstract
The purpose of this paper is to examine how public procurement has been reported on in newspapers over the last two decades. The print media, newspapers in particular, provide an authoritative source of information on the policy and practice of public procurement. However, there has been few attempts to understand their reporting of it. In response, our research investigates Financial Times news coverage of public procurement between 1996 and 2017. Preliminary findings indicate that the tone of reporting has changed in the last two years, with the focus shifting from supranational regulations to specific procurement activities (e.g. school building). In addition, the articles over the entire 1996-2017 period have limited reflection of areas discussed in academic literature, such as sustainability, SMEs and value for money.

Keywords: public procurement, content analysis

Introduction

Public procurement is never far from the news in most countries. At any given time readers are likely to come across stories of public procurements gone wrong, waste and/or corruption by public servants and complaints by suppliers over perceived unfair tendering procedures. For example, one case that featured prominently across media outlets in recent years involved a "flagship" IT system procured by the UK government to manage immigration applications (Barrett, 2014). Despite costing £350 million, the system was not fit for purpose and later mothballed. Admittedly, it is not all bad news. Stories referring to policies and initiatives targeting greater small supplier involvement in public sector supply chains can also be found alongside examples of major cost savings achieved and efficiencies implemented.

News reporting on public procurement is important in two main respects. First, it provides an authoritative insight into what are the key issues and debates in public procurement at a given moment in time. These issues and debates are not trivial. Public procurement accounts for, on average, 13 per cent of GDP and 29 per cent of annual government spending across OECD countries (OECD, 2013). How it is managed and whose interests it is understood to serve has ramifications for the delivery of public services, national finances, economic competitiveness, employment, and much else besides. Second, news reporting shapes our understanding on what role public procurement can and should play in public administration. It legitimises and even helps to institutionalise certain practices and viewpoints.

In spite of its prominence, there has been little academic engagement with news reporting of public procurement. Instead, research has either concentrated at the level of the buying or supplying organisation and the individual buyer or supplier (Flynn and Davis, 2014) or government procurement regulations and policy documents (e.g. Kidalov and Snider, 2011; Thai, 2001). A number of possible explanations exist for this situation, including: the relativeness newness of public procurement as a field of scholarly inquiry and methodological

challenges associated with searching for and then interpreting and coding large volumes of news data on public procurement.

Because of the lack of prior consideration given to media reporting as a data source, public procurement is missing an important perspective - one that has the ability to track changes in its meaning and characterisation over many years. The aim of our research is to address this gap in knowledge. It does so, firstly, by drawing attention to the relevance of media discourse to our understanding of public procurement. It then invokes the literature on institutional fields in order to provide a framework and theoretical ballast for our research. Thereafter, it sets out a research design based on manifest content analysis. In these ways our research endeavours to make empirical, methodological and theoretical contributions to the field.

Institutional Fields

To help make sense of news reporting on public procurement we turn to ideas associated with institutional theory and institutional fields. By institutional field is meant all the actors and organisations that together constitute a marketplace or sector (DiMaggio and Powell, 1983:148). Public procurement as an institutional field comprises public buyers, suppliers, regulators, legislators, industry bodies, professional institutes, communities and the media, among other stakeholders. Institutional fields are more than a network of actors, however. They are "centres of debates in which competing interests negotiate over issue interpretation" (Hoffman, 1999:351) and "arenas of power relations" (Brint and Karabel, 1991:355). It is through debates and shifting power dynamics that institutional norms and beliefs are shaped and reshaped as new players populate the field and the nature of their play changes over time (Davis and Marquis, 2005). These ideas provide the starting point in developing a theoretical framework for our study.

Research Design

The research method involves an analysis of Financial Times newspaper articles on public procurement. Table 1 presents key elements related to the research design. One of the limitations of the research is that only "public procurement" keyword was used. In future, other terms such as "public purchasing" will be included to expand the analysis. Our study uses Text Analytics Toolbox through visualisation of the data using WordClouds. At the start of the process, the data was prepared for text analysis: loaded and extracted, full text was prepared for tokenizing and an array of tokenized documents was created where a list of stop words (e.g. "a", "and" and "the") was removed. The Porter stemmer function was used to group different forms of English words by reducing them to a common stem, the bag-of words model was created and less frequent words removed. The WordClouds were then used to compare articles labelled by year and subject term.

Table 1. Research design.

Dimension	Detail
Analytical method	Manifest content analysis
Data type	Secondary data
Data source	Financial Times digital archives (from ProQuest ABI/INFORM Global)
Time period	1996- Sept 2017 (data was extracted on 19 October 2017)

Keywords/Type/Language	'public procurement' / Document type: News/ English

Preliminary Findings

In total, 472 articles were sourced using "public procurement" keyword search. Table 2 presents selected data attributes obtained from the database and used in the analysis (year, author, title, abstract, full text, subject terms). Other attributes were also available, such as publisher but they were not considered because all articles had the same publisher. As can be seen, only articles between 1997 and 2011 have abstracts and only a small number of the sample has one or more subject term present (main concentration is 1996-2005).

An initial assessment was done on the abstracts in the small data set for specific time period. However, due to limited number of articles having an abstract the full text was examined using text analytics. It can be seen that the maximum number of words in articles has been increasing over the years, with longest published in 2017 (4062 words). The average is 616 words over the whole time period. The number of articles published reached the highest in 2006 with noticeable decreasing trend after that year. Table 3 presents the number of news articles that has a specific subject term. It is important to note that an article can have more than one subject term and the number of articles in Table 3 does not represent a unique number of papers. For example, article A is counted in "Government News" and "Government – Central" and "United Kingdom" because it has all these subject terms.

Table 2. Summary of FT news articles.

Year	Num. of Titles	Num. of Abstracts	Num. of Full Text	Count of at least one 'subject terms' present	Max num. of words (title)	Max num. of words (full text)
1996	14		14	14	29	827
1997	24	10	24	24	24	1324
1998	18	18	18	18	42	1774
1999	11	11	11	11	35	1101
2000	20	20	20	20	47	895
2001	24	24	24	24	37	1703
2002	17	17	17	17	38	769
2003	30	30	30	4	43	1366
2004	29	29	29	1	42	2373
2005	31	31	31	1	30	1408
2006	44	44	44		41	2905
2007	18	18	18		22	1808
2008	24	24	24	1	11	2309
2009	15	15	15		9	1005
2010	28	28	28	1	11	1768
2011	23	12	23	3	10	2424
2012	20		20		11	1993
2013	16		16		9	2070
2014	17		17		11	2026
2015	18		18		12	1491
2016	10		10		11	2025

2017	21		21	21	12	4062
Total	472	331	472	160		

Table 3. Top subject terms.

Top Subject Terms (Classification)	Num. of articles	Top Subject Terms (Country)	Num. of articles
Government News	48	United Kingdom	62
Government - Central	38	Europe	55
Company News	30	European Economic Community/ EC	49
Foreign trade	28	European Union	46
Economic News	24	Western Europe	44

International relations	13	Mediterranean	17
Markets & market information	13	Asia	12
European Union Government	12	Japan	11
Contracts	11	East Europe	9

As can be seen in Figure 1 in combination with Table 3, the news coverage prior to 2014 mainly focused on government and European matters, with some articles linked to PFI, contracts, technology, corruption. It is linked to the scope of Financial Times that has a special emphasis on business and economic news.

In it notable that after 2015, the matters related to specific provisions, for example in local communities (e.g. schools, teachers, education) become more prominent in publications. It is also important to note that some academic discussions in relation to the public procurement over the last decade have limited visibility in news articles. For example, after further examination, words such as “sustainability” have only been mentioned in six articles; “SME/SMEs” in eight and “value for money” in twenty-seven. This exploratory study emphasises the importance of academia to engage further with periodic publications to bring these important discussions to the public.

The next step of the research is to finalise the theoretical framework related to public procurement academic literature and to link prominent academic topics to newspaper sources expanding on potential reasons and limitations when trying to link two diverse sources: academic papers and international daily newspaper. One potential reason for ‘mismatch’ can be linked to different type of language used in each domain, nevertheless some similarity we would expect to emerge during the analysis.

Figure 1. Visualisation (WordClouds) for different time periods.

Abstract

Early supplier involvement in product development gained importance in the last decades due to higher technological complexity and increased outsourcing activities. This paper analyzes economic and ecological aspects of product development partnerships in the German foundry industry. The analysis is based on comprehensive surveys conducted in 2013 and 2017 covering supplier and customer integration issues and potentials at the interfaces of German casting houses and their customers. In general, the arrangement of cross-company product development collaborations seems rather stable. In a time of increasing environmental requirements, this lack of significant change opens a new field of analysis for increased sustainability.

Keywords: Product Development Partnership, Foundry Industry, Trend Study, Supplier Integration

Introduction

During the last decades, industrial companies were confronted with various challenges due to shorter technology and product lifecycles, increasing customer demands and higher environmental requirements (Cooper, 2011; Smith and Reinertsen, 1998; Ulrich and Eppinger, 2016). This is in particular valid for small and medium-sized companies (Clarke and Gershenson, 2007; Fiksel, 2009; Schewe and Becker, 2009). Especially, sustainability aspects are gaining more and more importance in this context (Bras, 2009; Brandenburg, Hahn and Rebs, 2018; Matsumoto et al., 2017; de Oliveira et al., 2016). Against the background of increasing worldwide demand for raw materials and energy, a sustainable use of resources in production processes is highly important. This requirements is particularly relevant for the energy-intensive casting industry (Institut für Gießereitechnik, 2013; Vieweg and Reinhard, 2009; Vieweg and Wanninger, 2010). As a result, it seems important to extend the research on how suppliers can be integrated by their customers during product (e.g. casting) development in a sustainable way (Eisto et al., 2010; Fandl and Held, 2018; Gualandris and Kalchschmidt, 2016). Environmental effects have not yet been a focus of research on early supplier integration for product development. Less than 3% of publications (17 out of 596) between 1985 and 2014 have considered sustainability aspects (Held, 2015b).

In addition to that, there have been calls to tackle the problems of one-off data collections by including more longitudinal data collection aspects in the field of early supplier integration (Wynstra, Corswant and Wetzels, 2003; Song and Parry, 1997; Petersen at al., 2008; Lawson and Potter, 2012; Hartley et al., 1997). Combining these considerations, this paper deepens the knowledge in this field by presenting a survey-based, longitudinal trend study on the impacts of ecological product development partnerships in the German foundry value chain.
This paper is structured as follows: after this introduction, the scope of this paper is grounded in existing academic literature. This is followed by an overview of the sample structure and the survey design of the trend study. Afterwards, the trend study results about the development of ecological product development partnerships in the German foundry value chain are presented. The paper finishes with a conclusion and outlook.

Literature overview

Several studies and surveys covering diverse industries confirm that many enterprises increasingly recognize the economic benefits of sustainable products and processes (cp. e.g. Abele, Anderl and Birkhofer, 2005; Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety, 2002; Hundal 2002). Integration of suppliers in product development initiatives has long been established as being a strategically critical issue with significant impacts on performance improvements such as cycle time reductions, quality improvements and cost reductions (Birou and Fawcett, 1994; Ragatz, Handfield and Scannell, 1997). The positive relation between supplier relationship and environmental impact has been studied in both directions. Maxwell and van der Vorst (2003) found that reducing the environmental impact of product development can lead to improved supplier relationships through the ability to provide more sustainable offerings. On the other hand, environmental benefits can be achieved through a strengthened supplier relationship, which can for example lead to more efficient recycling and/or refurbishment processes (Tukker and Tischner, 2017). However, in order to drive sustainable competitive advantage, supplier integration cannot be static, but has to be interpreted on the basis of dynamic re-configurability (Vanpoucke, Vereecke and Wetzels, 2014). In order to achieve this, the alignment of strategic supplier portfolio selection and corporate sustainability targets can be the basis for development of an optimal strategic supplier portfolio (Neumueller, Lasch and Kellner, 2016). This has been studied and confirmed in cases such as for the fashion industry, where supplier integration and green sustainability programs were crucial performance factors (Li et al., 2016) and for the car industry, where sustainability in early product development stimulates supplier collaboration (Schoeggl, Baumgartner and Hofer, 2017).

Trend study overview – sample structure and survey design

Data collection generally followed the methods proposed by Dillman (2009). From the end of 2012 to the beginning of 2013, a first survey was conducted that covered supplier and customer integration issues at the interfaces of casting houses and their customers (Fandl, Held and Kersten, 2013; Held, 2015a). Sales, product development and management experts from all German iron and non-ferrous metal foundries were contacted for this comprehensive survey. In the middle of 2017, the survey was replicated using the same target group and

identical questions, with one exception - a question covering the advantages of involving suppliers in product development was slightly reformulated and used a different scale. Survey questions and scales have been inspired by and based on previous study designs in a similar context (Monczka et al., 2000; Primo and Amundson, 2002; Ragatz, Handfield and Scannell, 1997; McGinnis and Vallopra, 1999; McIvor and Humphreys, 2004). Survey responses have been checked for consistency and erroneous responses have been excluded from the analysis.

In the first and second survey periods, a total of 1,589 and 1,738 e-mail addresses were compiled respectively (cp. Gießerei Erfahrungsaustausch, 2015). Due to failed e-mail deliveries and companies no longer in existence, 1,156 and 1,467 potential participants were actually reached. From this pool of potential participants, 215 and then 122 completed and submitted the survey successfully after two follow-ups each time. This represents a response rate of 18.6% and 8.6% respectively. Non-response bias was checked (Armstrong and Overton, 1977; Lambert and Harrington, 1990) and is not a serious problem for this study. All participants of the first round were contacted again for the second round. However, due to anonymity requirements, the exact percentual overlap of identical respondents between the two studies could not be identified. Even though the response rate was substantially smaller in the follow-up survey, the coverage allows generalizations and a differentiated analysis. The lower percentage of participants might potentially be due to the fact that the German Casting association was not mentioned in the covering e-mail of the second survey. Also, filling out the same questions a second time might explain the unwillingness to take part. The lower attendance rate could also be an indication that environmental issues might be of lower importance to casting companies in 2017.

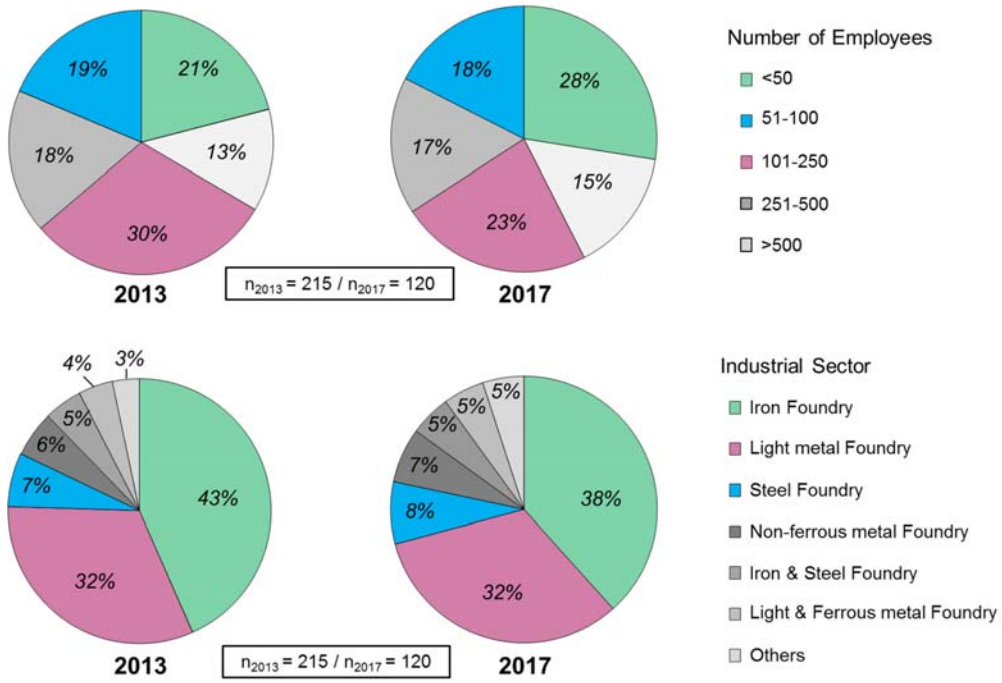

Figure 1: Distribution of the participants of the survey split by companies sizes (top) and casting materials (bottom)

Figure 1 provides the distribution of the participants according to the size of their companies (measured by the number of full-time employees) and according to the industrial sector they are in (based on the type of casting material they work with). On average, the company sizes of the participants of the second survey round tend to be slightly smaller. Iron foundries represent the largest category with approx. 40%, followed by the light metal foundries with a share of 32% and steel foundries with a share of 8%. However, several foundries use two or more casting materials. The samples can be regarded as representative of the German casting industry (Fandl, 2017; Statistica, 2017).

Figure 2 shows relevant certificates that were employed by the companies of the survey participants. More than 85% of the German casting companies are and have been certified by the DIN EN ISO 9001 standard. This standard is the foundation of further certification efforts of many companies in the foundry supply chain. This was followed by the environmental management standard DIN EN ISO 14001 with a share of 41% in 2013; there is a slight increase in the percentage of casting companies being certified by these two standards in the last years. Only 23% of the companies of the 2013 survey attained the DIN EN ISO 50001/DIN EN 16001 energy management certification. This percentage increased by more than 100%, so that more than four out of ten companies in the survey now achieved an energy management certification.

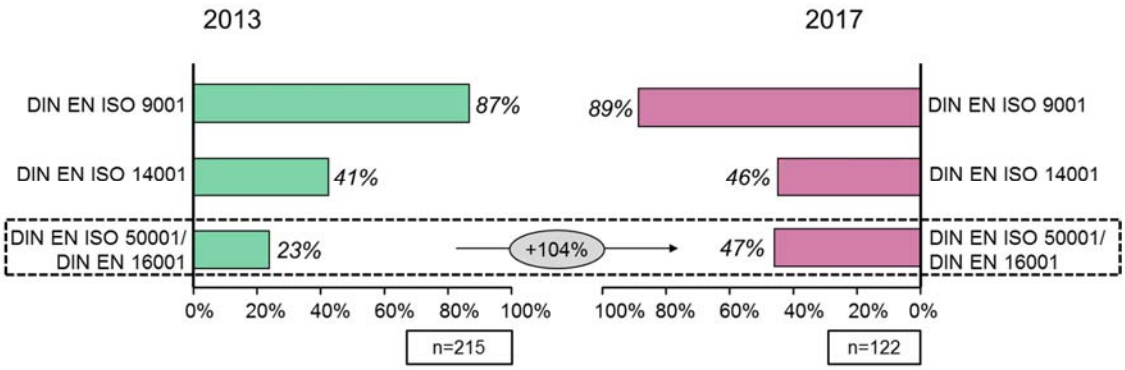

Figure 2: Certificates of German foundries (selection)

A more in-depth analysis reveals there is a strong correlation between the DIN EN ISO 50001/DIN EN 16001 certification and the size of a casting company. The percentage of companies that own this certificate decreases strongly with the size of the company: in 2013, DIN EN ISO 50001/DIN EN 16001 certifications were not present at all at any very small company (<50 employees). In 2017, about 20% of the companies with less than 50 full-time employees were already able to achieve an energy management certification. This increase in the percentage of ISO 50001 certified foundries is most likely based on the possibility of reimbursements of concession taxes by the German Renewable Energies Act, which has provided incentives to implement energy management certifications since 2013 (Reimann, 2017).

The previously described sample is used to gain an understanding of the need for collaborations and supplier integration for sustainable product development. The developed survey questionnaire is based on three core hypotheses that have been designed to cover the

key aspects of this research (potentials, level of integration and importance of environmental aspects) and that are supported by several sub-hypotheses (see Figure 3).

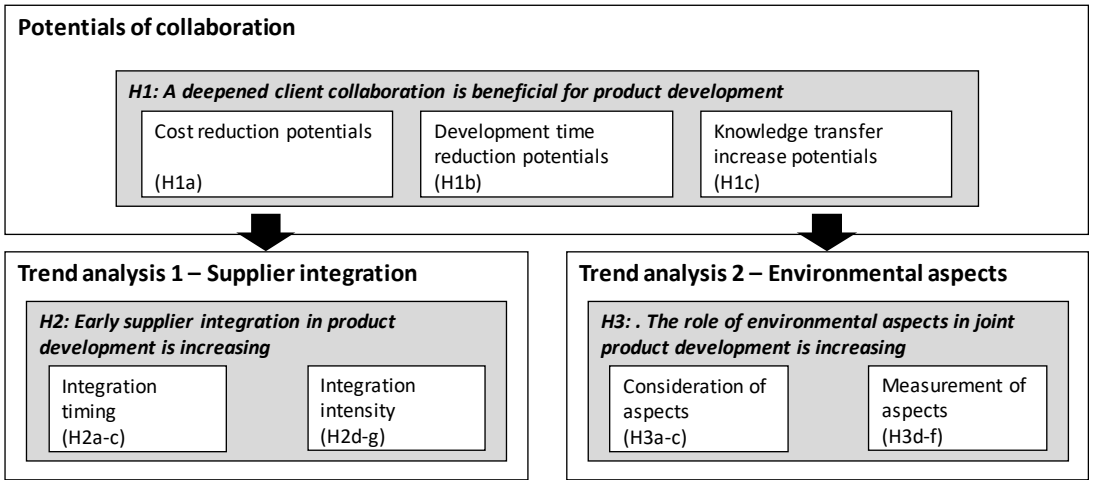

Figure 3: Structure of hypotheses

The sub-hypotheses directly relate to the survey questions:

1. Potentials of collaboration
   The first part investigates if there is a general understanding that client collaborations are beneficial for the development of new castings. Hypothesis 1: **A deepened client collaboration is perceived to be beneficial for casting development** (Monczka et al., 2000; Primo and Amundson, 2002; Ragatz, Handfield and Scannell, 1997). The hypothesis will be tested by looking at three potential collaboration benefits – cost reduction potentials, development time reduction potentials and the potential to increase knowledge transfers between collaboration partners. These three sub-hypotheses to test collaboration benefits have been linked to provide a comprehensive measure for collaboration potentials loosely following the triple constraint ("time", "cost", "performance") as a measure for success (Kerzner, 2010).

2. Trend analysis 1: Supplier integration
   The first part of the trend analysis looks at how the integration of suppliers has changed between 2013 and 2017. Hypothesis 2: **Early supplier integration/involvement of casting companies in product development is increasing.** This hypothesis has been frequently devised for many years for numerous industries (cp. e.g. Dombrowski and Karl, 2016; Handfield et al., 1999; Held, 2010, 2015b; Hoegl and Wagner, 2005; Johnsen, 2009; Petersen, Handfield and Ragatz, 2003; van Echtelt, 2004, Wagner, 2010). It will be tested by looking at the intensity and point in time of supplier integration (McGinnis and Vallopra, 1999; McIvor and Humphreys, 2004; Petersen, Handfield and Ragatz, 2005).

3. Trend analysis 2: Environmental aspects
   The second part of the trend analysis looks at how the role of environmental aspects has changed between 2013 and 2017. Hypothesis 3: **The role of environmental aspects in joint product development is increasing.** This hypothesis is also stated many times
